	AddItem (see page 2209)	Adds an item to the drop-down list of items.
	Clear (see page 2212)	Deletes all text from the edit box and all items from the Items (see page 2227) list.
	ClearSelection (see page 2212)	Deselects any selected items in the drop-down list.
	CopySelection (see page 2213)	Copies the selected item in the drop-down list to another list control.
	DeleteSelected (see page 2214)	Deletes the selected item from the drop-down list.
	Focused (see page 2215)	Indicates whether the combo box has input focus.
	GetCount (see page 2216)	Returns the value of the ItemCount (see page 2226) property.
	SelectAll (see page 2220)	Selects the entire block of text in the edit box.

29.1.8.5.1 TCustomCombo.AddItem Method

Adds an item to the drop-down list of items.

Pascal

```
procedure AddItem(Item: String; AObject: TObject); override;
```

C++

```
virtual __fastcall AddItem(UnicodeString Item, TObject * AObject);
```

Description

Call AddItem to add a string, with an associated object, to the drop-down list.

Item is the string to add to the drop-down list.

AObject is an object associated with that string. It can be accessed using the Objects property of the TStrings object that implements the Items (see page 2227) property.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;
```

```
    //adding items to the combo box
    comb.AddItem('firstChoice', nil);
    comb.AddItem('secondChoice', nil);
    comb.AddItem('thirdChoice', nil);

    //setting the default value
    comb.ItemIndex := 1;
  end;
```

See Also

Items (see page 2227)

Objects

29.1.8.5.2 TCustomCombo.AdjustDropDown Method

Adjusts the size and position of the drop down list.

Pascal

```
procedure AdjustDropDown; virtual;
```

C++

```
virtual __fastcall AdjustDropDown();
```

Description

TCustomCombo (see page 2203) calls AdjustDropDown when it drops down the drop-down list. This method adjusts the size and position of the drop-down list to reflect the values of the ItemHeight (see page 2226) and DropDownCount (see page 2225) properties.

See Also

ItemHeight (see page 2226)

DroppedDown (see page 2225)

DropDownCount (see page 2225)

29.1.8.5.3 TCustomCombo.Change Method

Generates an OnChange (see page 2237) event.

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

Change is called automatically in response to notifications that the text has changed. It responds by generating an OnChange (see page 2237) event. Override this method to add additional processing when the text changes, or to block the OnChange (see page 2237) event.

See Also

OnChange (see page 2237)

Changed

29.1.8.5.4 TCustomCombo.Clear Method

Deletes all text from the edit box and all items from the Items (see page 2227) list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call Clear to empty the combo box at runtime.

See Also

Items (see page 2227)

Text

29.1.8.5.5 TCustomCombo.ClearSelection Method

Deselects any selected items in the drop-down list.

Pascal

```
procedure ClearSelection; override;
```

C++

```
virtual __fastcall ClearSelection();
```

Description

ClearSelection checks whether an item in the drop-down list is currently selected. If so, it deselects the item (sets ItemIndex to –1), and changes the Text property to an empty string.

See Also

ItemIndex

Text

29.1.8.5.6 TCustomCombo.CloseUp Method

Generates an OnCloseUp (see page 2239) event.

Pascal

```
procedure CloseUp; dynamic;
```

C++

```
__fastcall CloseUp();
```

Description

CloseUp is called automatically when the DroppedDown (see page 2225) property changes to false. It generates an OnCloseUp (see page 2239) event.

Override CloseUp to implement additional class-specific responses when the drop-down list closes up or to suppress the event.

See Also

DroppedDown (see page 2225)

OnCloseUp (see page 2239)

29.1.8.5.7 TCustomCombo.ComboWndProc Method

Responds to Windows messages sent to the edit control or drop-down list.

Pascal

```
procedure ComboWndProc(var Message: TMessage; ComboWnd: HWnd; ComboProc: TWindowProcPtr);
virtual;
```

C++

```
virtual __fastcall ComboWndProc(TMessage Message, HWnd ComboWnd, TWindowProcPtr ComboProc);
```

Description

ComboWndProc handles the common processing of Windows messages sent to the edit region or list portion of the combo box. It is called by the EditWndProc (see page 2215) and ListWndProc (see page 2218) methods to take care of all processing that is not specific to the edit region or drop-down list.

The Message parameter describes the Windows message. The ComboWnd parameter is the windows handle for the edit region or list. The ComboProc parameter is a pointer to the default window procedure for the window that received the message. ComboWndProc provides default responses to focus events, mouse events, and key strokes.

Override ComboWndProc to change the way the combo box responds to Windows messages. When overriding ComboWndProc, be sure to call the parent class's method to process all unhandled messages.

Note: Do not confuse ComboWndProc with the WndProc (see page 2223) method. ComboWndProc responds to messages that are sent to the edit region or drop-down list. WndProc (see page 2223) responds to messages sent to the combo box itself.

See Also

WndProc (see page 2223)

EditWndProc (see page 2215)

ListWndProc (see page 2218)

29.1.8.5.8 TCustomCombo.CopySelection Method

Copies the selected item in the drop-down list to another list control.

Pascal

```
procedure CopySelection(Destination: TCustomListControl); override;
```

C++

```
virtual __fastcall CopySelection(TCustomListControl Destination);
```

Description

CopySelection checks whether an item is selected in the drop-down list, and if so, adds it to the control specified by Destination, along with its associated object.

See Also

Items (see page 2227)

ItemIndex

29.1.8.5.9 TCustomCombo.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo (see page 2203) overrides the inherited method to ensure that the newly-created window and the TCustomCombo (see page 2203) properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo (see page 2203) instance.

See Also

CreateHandle

29.1.8.5.10 TCustomCombo.DeleteSelected Method

Deletes the selected item from the drop-down list.

Pascal

```
procedure DeleteSelected; override;
```

C++

```
virtual __fastcall DeleteSelected();
```

Description

DeleteSelected deletes the item specified by the ItemIndex property from the drop-down list.

See Also

ItemIndex

Items (see page 2227)

29.1.8.5.11 TCustomCombo.DestroyWindowHandle Method

Destroys all of the windows controls that implement the combo box.

Pascal

```
procedure DestroyWindowHandle; override;
```

C++

```
virtual __fastcall DestroyWindowHandle();
```

Description

The DestroyWnd method calls DestroyWindowHandle to release the underlying Windows control. TCustomCombo (see page 2203) overrides the inherited method to reset the EditHandle (see page 2225) and ListHandle (see page 2229) properties once the underlying Windows controls are gone.

See Also

DestroyWnd

EditHandle (see page 2225)

ListHandle (see page 2229)

29.1.8.5.12 TCustomCombo.DropDown Method

Generates an OnDropDown (see page 2239) event.

Pascal

```
procedure DropDown; dynamic;
```

C++

```
__fastcall DropDown();
```

Description

DropDown is called automatically when the DroppedDown (see page 2225) property changes to true. It responds by generating an OnDropDown (see page 2239) event. To perform additional processing or block the OnDropDown (see page 2239) event, override DropDown.

See Also

OnDropDown (see page 2239)

DroppedDown (see page 2225)

29.1.8.5.13 TCustomCombo.EditWndProc Method

Responds to Windows messages that are sent to the edit control portion of the combo box.

Pascal

```
procedure EditWndProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall EditWndProc(TMessage Message);
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. EditWndProc is the window procedure for the edit control portion of the combo box.

See Also

EditHandle (see page 2225)

WndProc (see page 2223)

ListWndProc (see page 2218)

ComboWndProc (see page 2213)

29.1.8.5.14 TCustomCombo.Focused Method

Indicates whether the combo box has input focus.

Pascal

```
function Focused: Boolean; override;
```

C++

```
virtual __fastcall Boolean Focused();
```

Description

Call Focused to determine whether the combo box is currently the recipient of keyboard input. When Focused returns true, the combo box is the active control and keystroke messages are sent to it. When Focused is false, the combo box is not active (although it may be selected).

See Also

ActiveControl

29.1.8.5.15 TCustomCombo.GetCount Method

Returns the value of the ItemCount (see page 2226) property.

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount returns the number of items in the drop-down list.

See Also

ItemCount (see page 2226)

29.1.8.5.16 TCustomCombo.GetDroppedDown Method

Returns the value of the DroppedDown (see page 2225) property.

Pascal

```
function GetDroppedDown: Boolean;
```

C++

```
__fastcall Boolean GetDroppedDown();
```

Description

GetDroppedDown is the read implementation of the DroppedDown (see page 2225) property. It returns true if the drop-down list is showing.

See Also

DroppedDown (see page 2225)

29.1.8.5.17 TCustomCombo.GetItemCount Method

Returns the value of the ItemCount (see page 2226) property.

Pascal

```
function GetItemCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemCount() = 0;
```

Description

GetItemCount is the protected read access method for the ItemCount (see page 2226) property. In TCustomCombo (see page 2203), this method is abstract (pure virtual), meaning it has no implementation. Descendant classes override this method to return the number of items in the drop-down list.

See Also

ItemCount (see page 2226)

29.1.8.5.18 TCustomCombo.GetItemHt Method

Returns the value of the ItemHeight (see page 2226) property.

Pascal

```
function GetItemHt: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemHt() = 0;
```

Description

GetItemHt is the protected read access method for the ItemHeight (see page 2226) property. In TCustomCombo (see page 2203), this method is abstract (pure virtual), meaning it has no implementation. Descendant classes override this method to return the height of items in the drop-down list.

See Also

ItemHeight (see page 2226)

29.1.8.5.19 TCustomCombo.GetItemIndex Method

Returns the value of the ItemIndex property.

Pascal

```
function GetItemIndex: Integer; override;
```

C++

```
virtual __fastcall int GetItemIndex();
```

Description

GetItemIndex is the read implementation of the ItemIndex property. It returns the index of the selected item in the drop-down list. The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1.

See Also

ItemIndex

29.1.8.5.20 TCustomCombo.GetItemsClass Method

Indicates the class that implements the Items (see page 2227) property.

Pascal

```
function GetItemsClass: TCustomComboBoxStringsClass; virtual; abstract;
```

C++

```
virtual __fastcall TCustomComboBoxStringsClass GetItemsClass() = 0;
```

Description

TCustomCombo (see page 2203) uses GetItemsClass internally to determine what class to instantiate when it implements the Items (see page 2227) property.

In TCustomCombo (see page 2203), GetItemsClass is abstract pure virtual, meaning it has no implementation. TCustomCombo (see page 2203) descendants override this method to indicate a TCustomComboBoxStrings (see page 2257) descendant that implements the Items (see page 2227) property.

See Also

Items (see page 2227)

29.1.8.5.21 TCustomCombo.GetSelLength Method

Returns the value of the SelLength (see page 2230) property.

Pascal

```
function GetSelLength: Integer;
```

C++

```
__fastcall int GetSelLength();
```

Description

GetSelLength is the read implementation of the SelLength (see page 2230) property. It returns the number of selected characters.

See Also

SelLength (see page 2230)

29.1.8.5.22 TCustomCombo.GetSelStart Method

Returns the value of the SelStart (see page 2233) property.

Pascal

```
function GetSelStart: Integer;
```

C++

```
__fastcall int GetSelStart();
```

Description

GetSelStart is the read implementation of the SelStart (see page 2233) property. It returns the position of the first selected character, or the position of the cursor if no characters are selected.

See Also

SelStart (see page 2233)

29.1.8.5.23 TCustomCombo.ListWndProc Method

Responds to Windows messages that are sent to the drop-down list portion of the combo box.

Pascal

```
procedure ListWndProc(var Message: TMessage);
```

C++

```
__fastcall ListWndProc(TMessage Message);
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. ListWndProc is the window procedure for the drop-down list.

See Also

ListHandle (see page 2229)

WndProc (see page 2223)

EditWndProc (see page 2215)

ComboWndProc (see page 2213)

29.1.8.5.24 TCustomCombo.Loaded Method

Initializes the combo box after its form is loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The component streaming system calls this method after it loads the combo box's form from a stream.

TCustomCombo (see page 2203) overrides the inherited method to select the item specified by the ItemIndex property once the form is fully loaded.

See Also

Loaded

ItemIndex

29.1.8.5.25 TCustomCombo.Select Method

Generates an OnSelect (see page 2241) event.

Pascal

```
procedure Select; dynamic;
```

C++

```
__fastcall Select();
```

Description

Select is called automatically when the selected item in the drop-down list changes. It responds by generating an OnSelect (see page 2241) event. To perform additional processing or block the OnSelect (see page 2241) event, override Select.

See Also

OnSelect (see page 2241)

ItemIndex

29.1.8.5.26 TCustomCombo.SelectAll Method

Selects the entire block of text in the edit box.

Pascal

```
procedure SelectAll; override;
```

C++

```
virtual __fastcall SelectAll();
```

Description

Use SelectAll to select the entire block of text in the edit box. To select only part of the text, use the SelStart (see page 2233) and SelLength (see page 2230) properties.

See Also

SelStart (see page 2233)

SelLength (see page 2230)

29.1.8.5.27 TCustomCombo.SetDropDownCount Method

Sets the value of the DropDownCount (see page 2225) property.

Pascal

```
procedure SetDropDownCount(const Value: Integer); virtual;
```

C++

```
virtual __fastcall SetDropDownCount(const int Value);
```

Description

SetDropDownCount is the protected write implementation of the DropDownCount (see page 2225) property.

See Also

DropDownCount (see page 2225)

29.1.8.5.28 TCustomCombo.SetDroppedDown Method

Sets the value of the DroppedDown (see page 2225) property.

Pascal

```
procedure SetDroppedDown(Value: Boolean);
```

C++

```
__fastcall SetDroppedDown(Boolean Value);
```

Description

SetDroppedDown is the protected write implementation of the DroppedDown (see page 2225) property.

See Also

DroppedDown (see page 2225)

29.1.8.5.29 TCustomCombo.SetItemHeight Method

Sets the value of the ItemHeight (see page 2226) property.

Pascal

```
procedure SetItemHeight(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetItemHeight(int Value);
```

Description

SetItemHeight is the protected write implementation of the ItemHeight (see page 2226) property. Although SetItemHeight never raises an exception, in some cases it does not change the value of the ItemHeight (see page 2226) property. ItemHeight (see page 2226) can only be changed for some TCustomCombo (see page 2203) descendants, and then only under specific circumstances.

For example, TComboBoxEx never allows the ItemHeight (see page 2226) property to change.

See Also

ItemHeight (see page 2226)

29.1.8.5.30 TCustomCombo.SetItemIndex Method

Sets the value of the ItemIndex property.

Pascal

```
procedure SetItemIndex(const Value: Integer); override;
```

C++

```
virtual __fastcall SetItemIndex(const int Value);
```

Description

SetItemIndex is the protected write implementation of the ItemIndex property. It selects an item in the drop-down list.

Value is the item to select, where 0 indicates the first item, 1 indicates the second item, and so on. A negative Value causes all items to be unselected.

See Also

ItemIndex

29.1.8.5.31 TCustomCombo.SetItems Method

Sets the value of the Items (see page 2227) property.

Pascal

```
procedure SetItems(const Value: TStrings); virtual;
```

C++

```
virtual __fastcall SetItems(const TStrings Value);
```

Description

SetItems is the protected write implementation for the Items (see page 2227) property. It copies the strings (and possibly their associated objects) from Value to the Items (see page 2227) property.

See Also

Items (see page 2227)

Assign

29.1.8.5.32 TCustomCombo.SetMaxLength Method

Sets the value of the MaxLength (see page 2229) property.

Pascal

```
procedure SetMaxLength(Value: Integer);
```

C++

```
__fastcall SetMaxLength(int Value);
```

Description

SetMaxLength is the protected write implementation of the MaxLength (see page 2229) property.

See Also

MaxLength (see page 2229)

29.1.8.5.33 TCustomCombo.SetSelLength Method

Sets the value of the SelLength (see page 2230) property.

Pascal

```
procedure SetSelLength(Value: Integer);
```

C++

```
__fastcall SetSelLength(int Value);
```

Description

SetSelLength is the protected write implementation of the SelLength (see page 2230) property.

See Also

SelLength (see page 2230)

29.1.8.5.34 TCustomCombo.SetSelStart Method

Sets the value of the SelStart (see page 2233) property.

Pascal

```
procedure SetSelStart(Value: Integer);
```

C++

```
__fastcall SetSelStart(int Value);
```

Description

SetSelStart is the protected write implementation of the SelStart (see page 2233) property.

See Also

SelStart (see page 2233)

29.1.8.5.35 TCustomCombo.WndProc Method

Processes messages received by the combo box.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method to received Windows messages that are sent to the combo box. Messages sent to the child windows of the combo box (for the edit region and the list portion) go to the EditWndProc (see page 2215) or ListWndProc (see page 2218) method instead. WndProc handles messages about changes to the system colors defined in the Windows control panel, and closes up the drop-down list when the Enter key or the Escape key is pressed. All other messages are passed to Dispatch for default processing.

See Also

ComboWndProc (see page 2213)

EditWndProc (see page 2215)

ListWndProc (see page 2218)

29.1.8.6 TCustomCombo Properties

The properties of the TCustomCombo class are listed here.

Protected Properties

	Name	Description
	DropDownCount (see page 2225)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 2225)	Returns the window handle for the edit portion of the combo box.
R	ItemCount (see page 2226)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 2226)	Specifies the height, in pixels, of the items in the drop-down list.
R	ListHandle (see page 2229)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 2229)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentColor (see page 2230)	Determines where a control looks for its color information.

Public Properties

	Name	Description
R	Canvas (see page 2224)	Provides access to the drawing surface of the combo box.
	DroppedDown (see page 2225)	Indicates whether the drop-down list is currently displayed.
	Items (see page 2227)	Provides access to the list of items (strings) in the list portion of the combo box.
	SelLength (see page 2230)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2233)	Specifies the position of the first selected character in the edit portion of the combo box.
	TabStop (see page 2236)	Determines if the user can tab to a control.

29.1.8.6.1 TCustomCombo.Canvas Property

Provides access to the drawing surface of the combo box.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use Canvas as the drawing surface when customizing the way the combo box paints itself. For example, when using a TCustomCombo (see page 2203) descendant that allows applications to draw combo box items in an OnDrawItem even, the OnDrawItem event handler uses Canvas for painting the customized items.

C++ Examples:

```
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TComboBox *myComboBox;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TComboBox")
  {
    myComboBox = dynamic_cast<TComboBox *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myComboBox->Canvas->MoveTo(myComboBox->ClientRect.Left, myComboBox->ClientRect.Top);
    myComboBox->Canvas->LineTo(myComboBox->ClientRect.Right, myComboBox->ClientRect.Bottom);
    myComboBox = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TComboBox) then
  begin
    myComboBox:= (ListBox1.Items.Objects[Index] as TComboBox);
    with myComboBox.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myComboBox.Canvas.MoveTo(Left, Top);
      myComboBox.Canvas.LineTo(Right, Bottom);
    end;
  myComboBox:= nil;
  end;
```

See Also

OnDrawItem (see page 2256)

29.1.8.6.2 TCustomCombo.DropDownCount Property

Specifies the maximum number of items displayed in the drop-down list.

Pascal

```
property DropDownCount: Integer;
```

C++

```
__property int DropDownCount;
```

Description

By default, the drop-down list is long enough to contain eight items without requiring the user to scroll to see them all. To make the drop-down list smaller or larger, specify a number larger or smaller than eight as the DropDownCount value.

If the DropDownCount value is larger than the number of items in the Items (see page 2227) property, the drop-down list will be just large enough to hold all the possible choices and no more. If the DropDownCount value is smaller then the number of item in the Items (see page 2227) property, the drop down list will display a scroll bar.

See Also

Items (see page 2227)

ItemCount (see page 2226)

29.1.8.6.3 TCustomCombo.DroppedDown Property

Indicates whether the drop-down list is currently displayed.

Pascal

```
property DroppedDown: Boolean;
```

C++

```
__property Boolean DroppedDown;
```

Description

Read (see page 3727) DroppedDown to determine whether the drop-down list is visible. Set DropDown (see page 2215) to drop the list down or close it up. DroppedDown is true when the drop-down list is open, and false when it is closed.

See Also

OnDropDown (see page 2239)

29.1.8.6.4 TCustomCombo.EditHandle Property

Returns the window handle for the edit portion of the combo box.

Pascal

```
property EditHandle: HWnd;
```

C++

```
__property HWnd EditHandle;
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. EditHandle is the

window handle of the edit control portion. (The Handle property and the ListHandle (see page 2229) property give the handles for the combo box itself and the drop-down list, respectively.)

Use EditHandle when making Windows API calls addressed to the edit portion of the combo box.

See Also

Handle

ListHandle (see page 2229)

29.1.8.6.5 TCustomCombo.ItemCount Property

Specifies the number of items in the drop-down list.

Pascal

```
property ItemCount: Integer;
```

C++

```
__property int ItemCount;
```

Description

Read (see page 3727) ItemCount to get the number of items in the drop-down list. ItemCount is the number of all items, not just those that are visible at one time.

See Also

Items (see page 2227)

DropDownCount (see page 2225)

29.1.8.6.6 TCustomCombo.ItemHeight Property

Specifies the height, in pixels, of the items in the drop-down list.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Read (see page 3727) ItemHeight to determine the height of the items in the drop-down list.

The effect of setting ItemHeight varies, depending on the type of combo box and the style. For example, TComboBox (see page 2106) lets you set the item height only when Style is set to csOwnerDrawFixed or csOwnerDrawVariable. If Style is csOwnerDrawVariable, ItemHeight is the default height for drawing list items, but this value can be overridden by an OnMeasureItem event handler.

TComboBoxEx does not let you change the value of ItemHeight.

Note: Combo boxes that do not support changes to ItemHeight do not raise an exception when you attempt to change ItemHeight; they simply ignore the attempt.

See Also

Items (see page 2227)

OnMeasureItem (see page 2257)

Style (see page 2255)

29.1.8.6.7 TCustomCombo.Items Property

Provides access to the list of items (strings) in the list portion of the combo box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Read (see page 3727) Items to access the list of items that appears in the combo box. Use the methods of Items to add, insert, delete and move items. Set the value of Items to copy the items from another string list.

C++ Examples:

```
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
  ComboBox1->Items->AddObject("vsIcon", reinterpret_cast<TObject *>(vsIcon));
  ComboBox1->Items->AddObject("vsList", reinterpret_cast<TObject *>(vsList));
  ComboBox1->Items->AddObject("vsReport", reinterpret_cast<TObject *>(vsReport));
  ComboBox1->Items->AddObject("vsSmallIcon", reinterpret_cast<TObject *>(vsSmallIcon));
  // Display first item in the Combo Box
```

```
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
}
```

Delphi Examples:

```
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
    for I := 0 to ImageList1.Count - 1 do
    begin
      ListItem := Items.Add;
      Listitem.Caption := 'Image' + IntToStr(I);
      ListItem.ImageIndex := I;
      Listitem.SubItems.Add(Col2Array[I]);
    end;
    // Create two columns to show during viewing as vsReport
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 1';
    NewColumn.Width := 200;
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 2';
    NewColumn.Width := 200;
    // Add View styles and constants to the Combo Box
    ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
    ComboBox1.Items.AddObject('vsList', TObject(vsList));
    ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
    ComboBox1.Items.AddObject(
      'vsSmallIcon', TObject(vsSmallIcon));
    // Display first item in the Combo Box
    ComboBox1.ItemIndex := 0;
  end;
end;

Assign

29.1.8.6.8 TCustomCombo.ListHandle Property

Provides access to the window handle of the list of items in the combo box.

Pascal

```
property ListHandle: HWnd;
```

C++

```
__property HWnd ListHandle;
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. ListHandle is the window handle of the drop-down list. (The Handle property and the EditHandle (see page 2225) property give the handles for the combo box itself and the edit portion, respectively.)

Use ListHandle when making Windows API calls addressed to the list portion of the combo box.

Note: ListHandle is only available when the combo box has a "simple" style (an edit box with a fixed list below rather than a drop-down list).

See Also

Handle

EditHandle (see page 2225)

29.1.8.6.9 TCustomCombo.MaxLength Property

Specifies the maximum number of characters the user can type into the edit portion of the combo box.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that the user can enter into the edit portion of the combo box. A value of 0 indicates that there is no application-defined limit on the length.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that

may be entered into an edit control.

Text

29.1.8.6.10 TCustomCombo.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.8.6.11 TCustomCombo.SelLength Property

Specifies the length, in characters, of the selected text in the edit portion of the combo box.

Pascal

```
property SelLength: Integer;
```

C++

```
__property int SelLength;
```

Description

The selected portion of the text in the edit region of the combo box is the string of SelLength characters that starts at the character specified by the SelStart (see page 2233) property. The selected text appears highlighted in the edit region of the combo box.

To select a section of text in the edit region, first set the SelStart (see page 2233) property to position the cursor, and then set SelLength to the number of characters that should be selected. The SelText property is the substring that is selected.

Note: The SelLength property is only valid when the combo box has focus. When the combo box does not have focus, reading SelLength always yields a value of 0, and setting it has no effect.

C++ Examples:

```
/*
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
*/
void __fastcall TForm1::ComboBox1KeyPress(TObject *Sender, char &Key)
{
  // first, process the keystroke to obtain the current string
  // This code requires all items in list to be uppercase
  if (Key >= 'a' && Key <= 'z')

Text

29.1.8.6.12 TCustomCombo.SelStart Property

Specifies the position of the first selected character in the edit portion of the combo box.

Pascal

```
property SelStart: Integer;
```

C++

```
__property int SelStart;
```

Description

Read (see page 3727) SelStart to determine where the selection starts in the Text property. The first character is designated with 0, the second with 1, and so on. When SelLength (see page 2230) is 0, SelStart is the position of the cursor.

Set SelStart to position the cursor in the edit region of the combo box. Setting SelStart to 0 positions the cursor before the first character, setting SelStart to 1 positions the cursor before the second character, and so on.

Note: Setting SelStart changes the SelLength (see page 2230) property to 0. When using SelStart and SelLength (see page 2230) to programmatically select a portion of the text in the edit region, set SelStart before setting SelLength (see page 2230).

Note: The SelStart property is only valid when the combo box has focus. When the combo box does not have focus, reading SelStart always yields a value of 0, and setting it has no effect.

C++ Examples:

```
/*
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.

Text

29.1.8.6.13 TCustomCombo.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.8.7 TCustomCombo Events

The events of the TCustomCombo class are listed here.

Protected Events

	Name	Description
	OnChange (see page 2237)	Occurs when the user changes the text displayed in the edit region.

	OnCloseUp (see page 2239)	Occurs when the drop-down list closes up due to some user action.
	OnDropDown (see page 2239)	Occurs when the user opens the drop-down list.
	OnSelect (see page 2241)	Occurs when the user selects a string in the drop-down list.

29.1.8.7.1 TCustomCombo.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3789) an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
  if (pCB)
    PageControl1->ActivePage = dynamic_cast<TTabSheet *>(pCB->Items->Objects[pCB->ItemIndex]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
    ComboBox1->Items->AddObject(PageControl1->Pages[i]->Name, PageControl1->Pages[i]);
  }
  ComboBox1->ItemIndex = 0;
  PageControl1->ActivePage = dynamic_cast<TTabSheet
*>(ComboBox1->Items->Objects[ComboBox1->ItemIndex]);
}
/*
The following example assumes that a drive combo box, a file
```

```
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
const
  colorarray : Array[0..4] of TColor = (
    clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
  for i := 0 to PageControl1.PageCount - 1 do
    begin
    PageControl1.Pages[i].Brush.Color := colorarray[i];
    ComboBox1.Items.AddObject(PageControl1.Pages[i].Name,
      PageControl1.Pages[i]);
    end;
  ComboBox1.ItemIndex := 0;
  PageControl1.ActivePage := TTabSheet(ComboBox1.Items.Objects[ComboBox1.ItemIndex]);
end;

procedure TForm1.ComboBox1Change(Sender: TObject);
begin
  if (Sender is TComboBox) then
    with (Sender as TComboBox) do
      PageControl1.ActivePage := TTabSheet(Items.Objects[ItemIndex]);
end;
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
```

```
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

OnCloseUp (see page 2239)

29.1.8.7.2 TCustomCombo.OnCloseUp Event

Occurs when the drop-down list closes up due to some user action.

Pascal

```
property OnCloseUp: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCloseUp;
```

Description

Write (see page 3789) an OnCloseUp event handler to implement special processing that needs to occur when the drop-down list closes up. For example, an OnCloseUp event handler can check whether the user changed the selected item while the list was dropped down and respond accordingly.

See Also

OnDropDown (see page 2239)

DroppedDown (see page 2225)

29.1.8.7.3 TCustomCombo.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDown;
```

Description

Write (see page 3789) an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
```

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
```

```
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

29.1.8.7.4 TCustomCombo.OnSelect Event

Occurs when the user selects a string in the drop-down list.

Pascal

```
property OnSelect: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnSelect;
```

Description

Write (see page 3789) an OnSelect event handler to respond when the user changes the selected item in the drop-down list. OnSelect occurs after the selection has changed and the Text property reflects the new item.

29.1.9 TCustomComboBox Class

TCustomComboBox is the base class for combobox components.

Class Hierarchy

Pascal

```
TCustomComboBox = class(TCustomCombo);
```

C++

```
class TCustomComboBox : public TCustomCombo;
```

File

StdCtrls

Description

Use TCustomComboBox as a base class when defining a control that represents a specialized Windows combo box. A combo box is an edit box with a scrollable list attached to it; users can select an item from the list or type directly into the edit box. Combo boxes can present the list as a drop-down list or as a list box that is always visible.

Note: To create a combo box class that uses the extended combo box features such as images associated with entries, do not use TCustomComboBox. Instead, use the TCustomComboBoxEx class instead.

Do not create instances of TCustomComboBox. To put a combo box in a form, use a descendant of TCustomComboBox, such as TComboBox (see page 2106).

29.1.9.1 TCustomComboBox Members

The following tables list the members exposed by TCustomComboBox.

Protected Events

	Name	Description
	OnChange (see page 2237)	Occurs when the user changes the text displayed in the edit region.
	OnCloseUp (see page 2239)	Occurs when the drop-down list closes up due to some user action.
	OnDrawItem (see page 2256)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnDropDown (see page 2239)	Occurs when the user opens the drop-down list.
	OnMeasureItem (see page 2257)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnSelect (see page 2241)	Occurs when the user selects a string in the drop-down list.

Protected Fields

	Name	Description
	FDefEditProc (see page 2206)	This is FDefEditProc, a member of class TCustomCombo.
	FDefListProc (see page 2206)	This is FDefListProc, a member of class TCustomCombo.
	FDropHandle (see page 2207)	This is FDropHandle, a member of class TCustomCombo.
	FDroppingDown (see page 2207)	This is FDroppingDown, a member of class TCustomCombo.
	FEditHandle (see page 2207)	This is FEditHandle, a member of class TCustomCombo.
	FEditInstance (see page 2207)	This is FEditInstance, a member of class TCustomCombo.
	FFocusChanged (see page 2207)	This is FFocusChanged, a member of class TCustomCombo.
	FIsFocused (see page 2208)	This is FIsFocused, a member of class TCustomCombo.
	FListHandle (see page 2208)	This is FListHandle, a member of class TCustomCombo.
	FListInstance (see page 2208)	This is FListInstance, a member of class TCustomCombo.
	FSaveIndex (see page 2208)	This is FSaveIndex, a member of class TCustomCombo.

Protected Methods

	Name	Description
	AdjustDropDown (see page 2211)	Adjusts the size and position of the drop down list.
	Change (see page 2211)	Generates an OnChange (see page 2237) event.
	CloseUp (see page 2212)	Generates an OnCloseUp (see page 2239) event.
	ComboWndProc (see page 2213)	Responds to Windows messages sent to the edit control or drop-down list.

	CreateParams (see page 2245)	Initializes the window-creation parameter record.
	CreateWnd (see page 2245)	Creates the Windows control that represents the combo box.
	DestroyWindowHandle (see page 2214)	Destroys all of the windows controls that implement the combo box.
	DestroyWnd (see page 2246)	Destroys the Windows control that represents the combo box.
	DoSetTextHint (see page 2246)	This is DoSetTextHint, a member of class TCustomComboBox.
	DrawItem (see page 2246)	Generates an OnDrawItem (see page 2256) event.
	DropDown (see page 2215)	Generates an OnDropDown (see page 2239) event.
	EditWndProc (see page 2215)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	GetDroppedDown (see page 2216)	Returns the value of the DroppedDown (see page 2225) property.
	GetItemCount (see page 2247)	Returns the number of items in the Items (see page 2227) property list.
	GetItemHt (see page 2247)	Returns the value of the ItemHeight (see page 2226) property.
	GetItemIndex (see page 2217)	Returns the value of the ItemIndex property.
	GetItemsClass (see page 2247)	Returns the class used to implement the Items (see page 2227) property.
	GetSelLength (see page 2218)	Returns the value of the SelLength (see page 2230) property.
	GetSelStart (see page 2218)	Returns the value of the SelStart (see page 2233) property.
	GetSelText (see page 2248)	Returns the value of the SelText (see page 2253) property.
	KeyPress (see page 2248)	Responds to WM_CHAR messages sent to the combo box.
	ListWndProc (see page 2218)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
	Loaded (see page 2219)	Initializes the combo box after its form is loaded into memory.
	MeasureItem (see page 2249)	Generates an OnMeasureItem (see page 2257) event.
	Select (see page 2219)	Generates an OnSelect (see page 2241) event.
	SelectItem (see page 2249)	Selects a specified item from the drop-down list.
	SetDropDownCount (see page 2220)	Sets the value of the DropDownCount (see page 2225) property.
	SetDroppedDown (see page 2220)	Sets the value of the DroppedDown (see page 2225) property.
	SetItemHeight (see page 2221)	Sets the value of the ItemHeight (see page 2226) property.
	SetItemIndex (see page 2221)	Sets the value of the ItemIndex property.
	SetItems (see page 2221)	Sets the value of the Items (see page 2227) property.
	SetMaxLength (see page 2222)	Sets the value of the MaxLength (see page 2229) property.
	SetSelLength (see page 2222)	Sets the value of the SelLength (see page 2230) property.
	SetSelStart (see page 2222)	Sets the value of the SelStart (see page 2233) property.
	SetStyle (see page 2249)	Sets the Style (see page 2255) property.
	WndProc (see page 2250)	Processes messages received by the combo box.

Protected Properties

	Name	Description
	DropDownCount (see page 2225)	Specifies the maximum number of items displayed in the drop-down list.
	EditHandle (see page 2225)	Returns the window handle for the edit portion of the combo box.
	ItemCount (see page 2226)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 2226)	Specifies the height, in pixels, of the items in the drop-down list.
	ListHandle (see page 2229)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 2229)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentColor (see page 2230)	Determines where a control looks for its color information.
	Sorted (see page 2254)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 2255)	Determines the display style of the combo box.

Public Methods

	Name	Description
	AddItem (see page 2209)	Adds an item to the drop-down list of items.
	Clear (see page 2212)	Deletes all text from the edit box and all items from the Items (see page 2227) list.
	ClearSelection (see page 2212)	Deselects any selected items in the drop-down list.
	CopySelection (see page 2213)	Copies the selected item in the drop-down list to another list control.
	Create (see page 2244)	Creates and initializes a TCustomComboBox (see page 2241) instance.

	DeleteSelected (see page 2214)	Deletes the selected item from the drop-down list.
	Destroy (see page 2244)	Destroys the combo box and frees its memory.
	Focused (see page 2215)	Indicates whether the combo box has input focus.
	GetCount (see page 2216)	Returns the value of the ItemCount (see page 2226) property.
	SelectAll (see page 2220)	Selects the entire block of text in the edit box.

Public Properties

	Name	Description
	AutoCloseUp (see page 2250)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2251)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2252)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2253)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	Canvas (see page 2224)	Provides access to the drawing surface of the combo box.
	CharCase (see page 2253)	Determines the case of the text in the combo box.
	DroppedDown (see page 2225)	Indicates whether the drop-down list is currently displayed.
	Items (see page 2227)	Provides access to the list of items (strings) in the list portion of the combo box.
	SelLength (see page 2230)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2233)	Specifies the position of the first selected character in the edit portion of the combo box.
	SelText (see page 2253)	Represents the selected text in the edit region.
	TabStop (see page 2236)	Determines if the user can tab to a control.
	TextHint (see page 2256)	This is TextHint, a member of class TCustomComboBox.

29.1.9.2 TCustomComboBox.Create Constructor

Creates and initializes a TCustomComboBox (see page 2241) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomComboBox(TComponent * AOwner);
```

Description

Call Create to generate a combo box at runtime. Combo boxes placed on forms at design time are created automatically.

AOwner is a component, typically the form, that is responsible for freeing the combo box instance.

See Also

Owner

29.1.9.3 TCustomComboBox.Destroy Destructor

Destroys the combo box and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomComboBox();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the combo box is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3382)

29.1.9.4 TCustomComboBox Methods

The methods of the TCustomComboBox class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2245)	Initializes the window-creation parameter record.
	CreateWnd (see page 2245)	Creates the Windows control that represents the combo box.
	DestroyWnd (see page 2246)	Destroys the Windows control that represents the combo box.
	DoSetTextHint (see page 2246)	This is DoSetTextHint, a member of class TCustomComboBox.
	DrawItem (see page 2246)	Generates an OnDrawItem (see page 2256) event.
	GetItemCount (see page 2247)	Returns the number of items in the Items (see page 2227) property list.
	GetItemHt (see page 2247)	Returns the value of the ItemHeight (see page 2226) property.
	GetItemsClass (see page 2247)	Returns the class used to implement the Items (see page 2227) property.
	GetSelText (see page 2248)	Returns the value of the SelText (see page 2253) property.
	KeyPress (see page 2248)	Responds to WM_CHAR messages sent to the combo box.
	MeasureItem (see page 2249)	Generates an OnMeasureItem (see page 2257) event.
	SelectItem (see page 2249)	Selects a specified item from the drop-down list.
	SetStyle (see page 2249)	Sets the Style (see page 2255) property.
	WndProc (see page 2250)	Processes messages received by the combo box.

29.1.9.4.1 TCustomComboBox.CreateParams Method

Initializes the window-creation parameter record.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2245) method calls CreateParams to initialize the parameters it uses to create the window for the combo box. CreateParams overrides the inherited method to implement the Style (see page 2255) property.

See Also

CreateWnd (see page 2245)

Style (see page 2255)

29.1.9.4.2 TCustomComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle

29.1.9.4.3 TCustomComboBox.DestroyWnd Method

Destroys the Windows control that represents the combo box.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. TCustomComboBox (see page 2241) calls DestroyWnd to destroy this Windows control when necessary.

DestroyWnd saves the contents of Items (see page 2227) list before calling the inherited DestroyWnd method. The saved list is used if the window is recreated.

See Also

CreateWnd (see page 2245)

29.1.9.4.4 TCustomComboBox.DoSetTextHint Method

Pascal

```
procedure DoSetTextHint; virtual;
```

C++

```
virtual __fastcall DoSetTextHint();
```

Description

This is DoSetTextHint, a member of class TCustomComboBox.

29.1.9.4.5 TCustomComboBox.DrawItem Method

Generates an OnDrawItem (see page 2256) event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); virtual;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

When Style (see page 2255) is csOwnerDrawFixed or csOwnerDrawVariable, DrawItem is called whenever an item in the list needs to be drawn. If an OnDrawItem (see page 2256) event handler is assigned, DrawItem generates an OnDrawItem (see page 2256) event, passing the Index, Rect, and State parameters to the event handler. Otherwise, OnDrawItem (see page 2256) fills the rectangle passed in Rect and draws any text associated with the indexed item, ignoring the State parameter.

Override DrawItem to provide class-specific drawing code for the items in the list.

See Also

OnDrawItem (see page 2256)

Style (see page 2255)

29.1.9.4.6 TCustomComboBox.GetItemCount Method

Returns the number of items in the Items (see page 2227) property list.

Pascal

```
function GetItemCount: Integer; override;
```

C++

```
virtual __fastcall int GetItemCount();
```

Description

GetItemCount is used internally to quickly determine the number of items in the drop-down list of the combo box.

See Also

Items (see page 2227)

29.1.9.4.7 TCustomComboBox.GetItemHt Method

Returns the value of the ItemHeight (see page 2226) property.

Pascal

```
function GetItemHt: Integer; override;
```

C++

```
virtual __fastcall int GetItemHt();
```

Description

GetItemHt is the protected read implementation of the ItemHeight (see page 2226) property.

See Also

ItemHeight

29.1.9.4.8 TCustomComboBox.GetItemsClass Method

Returns the class used to implement the Items (see page 2227) property.

Pascal

```
function GetItemsClass: TCustomComboBoxStringsClass; override;
```

C++

```
virtual __fastcall TCustomComboBoxStringsClass GetItemsClass();
```

Description

Combo box controls use GetItemsClass internally to determine what class to use when implementing the Items (see page 2227) property. This allows the TCustomCombo (see page 2203) base class to implement the Items (see page 2227) property for both TCustomComboBox (see page 2241) descendants and TCustomComboBoxEx descendants.

See Also

Items (see page 2227)

29.1.9.4.9 TCustomComboBox.GetSelText Method

Returns the value of the SelText (see page 2253) property.

Pascal

```
function GetSelText: string;
```

C++

```
__fastcall UnicodeString GetSelText();
```

Description

GetSelText is the protected read implementation of the SelText (see page 2253) property.

See Also

SelText (see page 2253)

29.1.9.4.10 TCustomComboBox.KeyPress Method

Responds to WM_CHAR messages sent to the combo box.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress processes standard keystroke messages for the combo box control. If the KeyPress method does not handle the keystroke, it calls the inherited method, which generates an OnKeyPress event.

Key is the character represented by the key that was pressed. If the KeyPress method changes Key to 0, no further processing occurs for the keystroke.

See Also

KeyDown

KeyUp

OnKeyPress

29.1.9.4.11 TCustomComboBox.MeasureItem Method

Generates an OnMeasureItem (see page 2257) event.

Pascal

```
procedure MeasureItem(Index: Integer; var Height: Integer); virtual;
```

C++

```
virtual __fastcall MeasureItem(int Index, int Height);
```

Description

MeasureItem is the protected implementation method for the OnMeasureItem (see page 2257) event. Override MeasureItem to provide class-specific code to specify the size of list items when Style (see page 2255) is csOwnerDrawVariable.

See Also

OnMeasureItem (see page 2257)

Style (see page 2255)

29.1.9.4.12 TCustomComboBox.SelectItem Method

Selects a specified item from the drop-down list.

Pascal

```
function SelectItem(const AnItem: string): Boolean;
```

C++

```
__fastcall Boolean SelectItem(const UnicodeString AnItem);
```

Description

SelectItem selects the first item in the drop-down list that matches the string specified by AnItem. If the list does not contain a string that matches AnItem, SelectItem does nothing.

See Also

Items (see page 2227)

ItemIndex

29.1.9.4.13 TCustomComboBox.SetStyle Method

Sets the Style (see page 2255) property.

Pascal

```
procedure SetStyle(Value: TComboBoxStyle); virtual;
```

C++

```
virtual __fastcall SetStyle(TComboBoxStyle Value);
```

Description

SetStyle is the protected implementation method for the Style (see page 2255) property. Override SetStyle to change the implementation of the Style (see page 2255) property.

See Also

Style (see page 2255)

29.1.9.4.14 TCustomComboBox.WndProc Method

Processes messages received by the combo box.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method to received Windows messages that are sent to the combo box. Messages sent to the child windows of the combo box (for the edit region and the list portion) go to the EditWndProc (see page 2215) or ListWndProc (see page 2218) method instead. WndProc handles messages about changes to the system colors defined in the Windows control panel, and closes up the drop-down list when the Enter key or the Escape key is pressed. All other messages are passed to Dispatch for default processing.

See Also

ComboWndProc (see page 2213)

System::TObject::Dispatch (see page 3379)

WndProc

EditWndProc (see page 2215)

ListWndProc (see page 2218)

29.1.9.5 TCustomComboBox Properties

The properties of the TCustomComboBox class are listed here.

Protected Properties

	Name	Description
	Sorted (see page 2254)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 2255)	Determines the display style of the combo box.

Public Properties

	Name	Description
	AutoCloseUp (see page 2250)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2251)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2252)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2253)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	CharCase (see page 2253)	Determines the case of the text in the combo box.
	SelText (see page 2253)	Represents the selected text in the edit region.
	TextHint (see page 2256)	This is TextHint, a member of class TCustomComboBox.

29.1.9.5.1 TCustomComboBox.AutoCloseUp Property

Specifies whether the drop-down closes up automatically when the user selects an item.

Pascal

```
property AutoCloseUp: Boolean;
```

C++

```
__property Boolean AutoCloseUp;
```

Description

When AutoCloseUp is true, the drop-down closes up automatically when the user selects an item.

See Also

AutoDropDown (see page 2253)

29.1.9.5.2 TCustomComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay (see page 2252) milliseconds between the characters typed and the autocomplete operation.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

See Also

AutoCompleteDelay (see page 2252)

29.1.9.5.3 TCustomComboBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2251) is true.

See Also

AutoComplete (see page 2251)

29.1.9.5.4 TCustomComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown: Boolean;
```

C++

```
__property Boolean AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

autocomplete (see page 2251)

OnDropDown (see page 2239)

DroppedDown (see page 2225)

29.1.9.5.5 TCustomComboBox.CharCase Property

Determines the case of the text in the combo box.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the combo box into upper or lower case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types into the combo box. Changing the CharCase property changes the actual text, not just its appearance; case information is lost and cannot be recaptured by changing CharCase back to ecNormal.

See Also

Text

29.1.9.5.6 TCustomComboBox.SelText Property

Represents the selected text in the edit region.

Pascal

```
property SelText: string;
```

C++

```
__property UnicodeString SelText;
```

Description

Read (see page 3727) SelText to obtain the text that is selected in the edit region of the combo box. When the combo box is

the active control, SelText appears highlighted. Set SelText to replace the current selection with a different substring. If no text is selected when a value is assigned to SelText, the SelText string is inserted in the text at the cursor.

Note: The SelText property is only valid when the combo box has focus. When the combo box does not have focus, reading SelText always yields an empty string and setting it inserts the text at the cursor rather than replacing the selected text.

See Also

SelLength (see page 2230)

SelStart (see page 2233)

29.1.9.5.7 TCustomComboBox.Sorted Property

Determines whether the list portion of the combo box is alphabetized.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Set Sorted to true to sort the items in the Items (see page 2227) list alphabetically. New (see page 3712) items added to the list while Sorted is true are inserted in the correct alphabetical position.

When Sorted is changed from false to true, the original order of the items is lost. Setting Sorted back to false does not restore the original order.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
```

```
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

See Also

Items

Using TDBListBox and TDBComboBox

29.1.9.5.8 TCustomComboBox.Style Property

Determines the display style of the combo box.

Pascal

```
property Style: TComboBoxStyle;
```

C++

```
__property TComboBoxStyle Style;
```

Description

Set Style to specify how the list and edit region of the combo box should appear.

When Style is csOwnerDrawFixed or csOwnerDrawVariable, the OnDrawItem (see page 2256) event occurs when the list

items need to be drawn. If Style is csOwnerDrawVariable, an OnMeasureItem (see page 2257) event occurs as well.

See Also

Height

ItemHeight

OnDrawItem (see page 2256)

OnMeasureItem (see page 2257)

29.1.9.5.9 TCustomComboBox.TextHint Property

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

This is TextHint, a member of class TCustomComboBox.

29.1.9.6 TCustomComboBox Events

The events of the TCustomComboBox class are listed here.

Protected Events

	Name	Description
	OnDrawItem (see page 2256)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnMeasureItem (see page 2257)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.

29.1.9.6.1 TCustomComboBox.OnDrawItem Event

Occurs when an item in an owner-draw combo box needs to be displayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Write (see page 3789) an OnDrawItem event handler to draw the items in the drop-down list of an owner-draw combo box. An OnDrawItem event handler can add graphic elements to the list items, or replace the list item text by graphics.

Draw the items on the Canvas (see page 2224) using the coordinates provided by the Rect parameter. OnDrawItem occurs only if Style (see page 2255) is set to csOwnerDrawFixed or csOwnerDrawVariable.

If an OnDrawItem event handler is not provided, the combo box fills the Rect parameter with the current brush and writes the text value of the item specified by the Index parameter.

See Also

Canvas

Items

OnMeasureItem (see page 2257)

Style (see page 2255)

29.1.9.6.2 TCustomComboBox.OnMeasureItem Event

Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

When Style (see page 2255) is set to csOwnerDrawVariable, the OnMeasureItem event precedes OnDrawItem (see page 2256). Write (see page 3789) an OnMeasureItem event handler to specify the height, in pixels, needed to draw an item in the drop-down list.

See Also

ItemHeight

Items

OnDrawItem (see page 2256)

Style (see page 2255)

29.1.10 TCustomComboBoxStrings Class

TCustomComboBoxStrings represents the strings in the drop-down list of a combo box.

Class Hierarchy

Pascal

```
TCustomComboBoxStrings = class(TStrings);
```

C++

```
class TCustomComboBoxStrings : public TStrings;
```

File

StdCtrls

Description

TCustomComboBoxStrings is the base class for objects that represent the items in the drop-down list of a combo box. Each type of combo box (TComboBox (see page 2106) or TComboBoxEx) uses its own TCustomComboBoxStrings descendant to manage the list of items.

Do not create instances of TCustomComboBoxStrings. This class is designed to work only with a combo box. TCustomCombo (see page 2203) creates the TCustomComboBoxStrings descendant it uses to implement its Items property.

See Also

TCustomCombo (see page 2203)

TComboBox (see page 2106)

TComboBoxEx

29.1.10.1 TCustomComboBoxStrings Members

The following tables list the members exposed by TCustomComboBoxStrings.

Protected Methods

	Name	Description
	Get (see page 2260)	Returns a string given its index.
	GetCount (see page 2261)	Returns the number of strings in the list
	GetObject (see page 2261)	Returns the object associated with the item at a specified index.
	PutObject (see page 2262)	Changes the object associated with the string at a specified index.
	SetUpdateState (see page 2262)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
	ComboBox (see page 2263)	Identifies the combo box whose items this object represents.

Public Methods

	Name	Description
	Clear (see page 2259)	Deletes all the strings from the list.
	Create (see page 2258)	Constructs an object and initializes its data before the object is first used.
	Delete (see page 2260)	Removes the item specified by the Index parameter.
	Destroy (see page 2259)	Destroys the TPersistent instance and frees its memory.
	IndexOf (see page 2261)	Returns the position of a string in the list.

29.1.10.2 TCustomComboBoxStrings.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TCustomComboBoxStrings();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3366)

System::TObject::Free (see page 3382)

29.1.10.3 TCustomComboBoxStrings.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomComboBoxStrings();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3382)

System::TObject::Destroy (see page 3366)

29.1.10.4 TCustomComboBoxStrings Methods

The methods of the TCustomComboBoxStrings class are listed here.

Protected Methods

	Name	Description
	Get (see page 2260)	Returns a string given its index.
	GetCount (see page 2261)	Returns the number of strings in the list
	GetObject (see page 2261)	Returns the object associated with the item at a specified index.
	PutObject (see page 2262)	Changes the object associated with the string at a specified index.
	SetUpdateState (see page 2262)	Performs internal adjustments before or after a series of updates.

Public Methods

	Name	Description
	Clear (see page 2259)	Deletes all the strings from the list.
	Delete (see page 2260)	Removes the item specified by the Index parameter.
	IndexOf (see page 2261)	Returns the position of a string in the list.

29.1.10.4.1 TCustomComboBoxStrings.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the drop-down list of the combo box. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 2260)

Objects

Strings

29.1.10.4.2 TCustomComboBoxStrings.Delete Method

Removes the item specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single item from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string in the drop-down list, where 0 is the first string, 1 is the second string, and so on.

See Also

Add

AddObject

Clear (see page 2259)

IndexOf (see page 2261)

InsertObject

Objects

Strings

29.1.10.4.3 TCustomComboBoxStrings.Get Method

Returns a string given its index.

Pascal

```
function Get(Index: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString Get(int Index);
```

Description

Get is the protected read implementation of the Strings property. It fetches the specified string from the combo box identified by the ComboBox (see page 2263) property.

Index identifies the string to return, where 0 is the index of the first string, 1 is the index of the second string, and so on.

See Also

Strings

IndexOf (see page 2261)

ComboBox (see page 2263)

29.1.10.4.4 TCustomComboBoxStrings.GetCount Method

Returns the number of strings in the list

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count property. It fetches the number of items from the combo box identified by the ComboBox (see page 2263) property.

See Also

Count

ComboBox (see page 2263)

29.1.10.4.5 TCustomComboBoxStrings.GetObject Method

Returns the object associated with the item at a specified index.

Pascal

```
function GetObject(Index: Integer): TObject; override;
```

C++

```
virtual __fastcall TObject * GetObject(int Index);
```

Description

GetObject is the protected read implementation of the Objects property. It fetches the associated object for the identified item from the combo box identified by the ComboBox (see page 2263) property.

Index is the index of the item with which the object is associated.

See Also

Objects

ComboBox (see page 2263)

29.1.10.4.6 TCustomComboBoxStrings.IndexOf Method

Returns the position of a string in the list.

Pascal

```
function IndexOf(const S: string): Integer; override;
```

C++

```
virtual __fastcall int IndexOf(const UnicodeString S);
```

Description

Call IndexOf to obtain the position of the first occurrence of a string that matches S. The string must be an exact match (S can't be the prefix of a string in the combo box).

IndexOf returns the 0-based index of the string. Thus, if S matches the first string in the list, IndexOf returns 0, if S is the second

string, IndexOf returns 1, and so on. If the string does not have a match in the string list, IndexOf returns -1.

See Also

IndexOfName

IndexOfObject

Strings

29.1.10.4.7 TCustomComboBoxStrings.PutObject Method

Changes the object associated with the string at a specified index.

Pascal

```
procedure PutObject(Index: Integer; AObject: TObject); override;
```

C++

```
virtual __fastcall PutObject(int Index, TObject * AObject);
```

Description

PutObject is the protected write implementation of the Objects property. It associates the object specified by AObject with the item identified by Index.

Index identifies an item in the drop-down list of the combo box, where 0 is the index of the first item, 1 is the index of the second item, and so on.

AObject is the object to associated with the specified item.

See Also

Objects

29.1.10.4.8 TCustomComboBoxStrings.SetUpdateState Method

Performs internal adjustments before or after a series of updates.

Pascal

```
procedure SetUpdateState(Updating: Boolean); override;
```

C++

```
virtual __fastcall SetUpdateState(Boolean Updating);
```

Description

SetUpdateState is called at the beginning or end of a series of updates. When the BeginUpdate method is first called and the TCustomComboBoxStrings (see page 2257) object is not already in the middle of an update, SetUpdateState is called with Updating set to true. When the EndUpdate method is called and it cancels out the last unmatched call to BeginUpdate, SetUpdateState is called with Updating set to false.

SetUpdateState refreshes the combo box when Updating is false, so that the combo box reflects the new set of strings.

See Also

BeginUpdate

EndUpdate

29.1.10.5 TCustomComboBoxStrings Properties

The properties of the TCustomComboBoxStrings class are listed here.

Protected Properties

	Name	Description
	ComboBox (see page 2263)	Identifies the combo box whose items this object represents.

29.1.10.5.1 TCustomComboBoxStrings.ComboBox Property

Identifies the combo box whose items this object represents.

Pascal

```
property ComboBox: TCustomCombo;
```

C++

```
__property TCustomCombo ComboBox;
```

Description

TCustomComboBoxStrings (see page 2257) uses ComboBox internally so that the strings in the list and the items in the drop-down list of the combo box remain synchronized.

See Also

Items (see page 2227)

29.1.11 TCustomEdit Class

TCustomEdit is the base class from which all edit-box and memo controls are derived.

Class Hierarchy

Pascal

```
TCustomEdit = class(TWinControl);
```

C++

```
class TCustomEdit : public TWinControl;
```

File

StdCtrls

Description

TCustomEdit encapsulates the behavior common to all components for editing text by introducing methods and properties that provide:

Basic text editing functions such as selecting text, modifying selected text, and case conversions.

Ability to respond to changes in the contents of the text.

Access control of the text for making it read-only or introducing a password character to hide the actual value.

Do not create instances of TCustomEdit. Use TCustomEdit as a base class when declaring control objects that permit the user to

enter or modify text. Properties and methods of TCustomEdit provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TCustomMaskEdit

TCustomMemo (see page 2361)

TEdit (see page 2380)

29.1.11.1 TCustomEdit Members

The following tables list the members exposed by TCustomEdit.

Protected Events

	Name	Description
	OnChange (see page 2299)	Occurs when the text for the edit control may have changed.

Protected Methods

	Name	Description
	Change (see page 2266)	Generates an OnChange (see page 2299) event.
V	CreateParams (see page 2269)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2270)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2270)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2273)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2273)	Sets the MaxLength (see page 2286) property.
V	DoSetTextHint (see page 2273)	This is DoSetTextHint, a member of class TCustomEdit.
V	GetSelLength (see page 2274)	Returns the SelLength (see page 2289) property.
V	GetSelStart (see page 2274)	Returns the SelStart (see page 2293) property.
V	GetSelText (see page 2275)	Returns the SelText (see page 2296) property.
	SetAlignment (see page 2279)	Sets the Alignment (see page 2283) property.
V	SetAutoSize (see page 2279)	Sets the AutoSize (see page 2284) property.
V	SetSelLength (see page 2280)	Sets the SelLength (see page 2289) property.
V	SetSelStart (see page 2280)	Sets the SelStart (see page 2293) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2284)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2284)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2285)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2286)	Determines the case of the text within the edit control.
	HideSelection (see page 2286)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2286)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2287)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2288)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2288)	Determines where a control looks for its color information.
	PasswordChar (see page 2289)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Methods

	Name	Description
	Clear (see page 2267)	Deletes all text from the edit control.
	ClearSelection (see page 2267)	Removes the selected text from the edit control.
	ClearUndo (see page 2268)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2268)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2265)	Creates an instance of TCustomEdit (see page 2263).
	CutToClipboard (see page 2271)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2272)	Provides message handling for all messages that the control does not fully process itself.
	GetControlsAlignment (see page 2274)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2275)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2276)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2278)	Selects all text in the edit control.
	SetSelText (see page 2281)	Sets the SelText (see page 2296) property.
	SetSelTextBuf (see page 2281)	Replaces the selected text with a null-terminated string.
	Undo (see page 2282)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	Alignment (see page 2283)	Determines how the text is aligned within the text edit control.
	CanUndo (see page 2285)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2287)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2289)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2289)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2293)	Specifies the position of the first selected character in the text.
	SelText (see page 2296)	Specifies the selected portion of the edit control's text.
	Text (see page 2297)	Contains a text string associated with the control.
	TextHint (see page 2299)	A hint or message to be displayed when the Text (see page 2297) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2297)	Determines if the user can tab to a control.

29.1.11.2 TCustomEdit.Create Constructor

Creates an instance of TCustomEdit (see page 2263).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomEdit(TComponent * AOwner);
```

Description

Call Create to create and initialize an instance of TCustomEdit (see page 2263).

AOwner is another component, typically the form, that is responsible for freeing the edit control. It becomes the value of the Owner property.

Derived objects that override the Create method should call the inherited Create before performing any additional initialization.

See Also

Owner

29.1.11.3 TCustomEdit Methods

The methods of the TCustomEdit class are listed here.

Protected Methods

	Name	Description
	Change (see page 2266)	Generates an OnChange (see page 2299) event.
V	CreateParams (see page 2269)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2270)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2270)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2273)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2273)	Sets the MaxLength (see page 2286) property.
V	DoSetTextHint (see page 2273)	This is DoSetTextHint, a member of class TCustomEdit.
V	GetSelLength (see page 2274)	Returns the SelLength (see page 2289) property.
V	GetSelStart (see page 2274)	Returns the SelStart (see page 2293) property.
V	GetSelText (see page 2275)	Returns the SelText (see page 2296) property.
	SetAlignment (see page 2279)	Sets the Alignment (see page 2283) property.
V	SetAutoSize (see page 2279)	Sets the AutoSize (see page 2284) property.
V	SetSelLength (see page 2280)	Sets the SelLength (see page 2289) property.
V	SetSelStart (see page 2280)	Sets the SelStart (see page 2293) property.

Public Methods

	Name	Description
V	Clear (see page 2267)	Deletes all text from the edit control.
	ClearSelection (see page 2267)	Removes the selected text from the edit control.
	ClearUndo (see page 2268)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2268)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	CutToClipboard (see page 2271)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 2272)	Provides message handling for all messages that the control does not fully process itself.
V	GetControlsAlignment (see page 2274)	Indicates how text is aligned within the control.
V	GetSelTextBuf (see page 2275)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2276)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2278)	Selects all text in the edit control.
	SetSelText (see page 2281)	Sets the SelText (see page 2296) property.
	SetSelTextBuf (see page 2281)	Replaces the selected text with a null-terminated string.
	Undo (see page 2282)	Backs out all changes in the undo buffer.

29.1.11.3.1 TCustomEdit.Change Method

Generates an OnChange (see page 2299) event.

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

Applications do not call the Change method directly. It is triggered automatically by Windows events. Change is exposed as a protected method so that derived classes can make additional responses when the text changes beyond invoking the OnChange (see page 2299) event handler. If Derived classes that override the Change method do not call the inherited method, the OnChange (see page 2299) event handler will not be called.

See Also

Handle

OnChange (see page 2299)

Text

29.1.11.3.2 TCustomEdit.Clear Method

Deletes all text from the edit control.

Pascal

```
procedure Clear; virtual;
```

C++

```
virtual __fastcall Clear();
```

Description

Use Clear to replace the Text (see page 2297) property with an empty string. Clear removes all text, not just the selected text. To remove just the selected text, use ClearSelection (see page 2267).

See Also

ClearSelection (see page 2267)

Text

29.1.11.3.3 TCustomEdit.ClearSelection Method

Removes the selected text from the edit control.

Pascal

```
procedure ClearSelection;
```

C++

```
__fastcall ClearSelection();
```

Description

Use ClearSelection to delete the selected text from the edit control. If no text is selected, ClearSelection does nothing. If all of the text is selected, ClearSelection clears all text, like the Clear (see page 2267) method.

Note: Calling ClearSelection does the same thing as sending the edit control a WM_CLEAR message.

See Also

Clear (see page 2267)

CutToClipboard (see page 2271)

SelText (see page 2296)

SetSelTextBuf (see page 2281)

29.1.11.3.4 TCustomEdit.ClearUndo Method

Clears the undo buffer so that no changes to the text can be backed out.

Pascal

```
procedure ClearUndo;
```

C++

```
__fastcall ClearUndo();
```

Description

Use ClearUndo to commit changes to the Text (see page 2297) property. After calling ClearUndo, the CanUndo (see page 2285) property is false and the Undo (see page 2282) method does nothing.

See Also

Undo (see page 2282)

CanUndo (see page 2285)

Text

29.1.11.3.5 TCustomEdit.CopyToClipboard Method

Copies the selected text in the edit control to the Clipboard in CF_TEXT format.

Pascal

```
procedure CopyToClipboard;
```

C++

```
__fastcall CopyToClipboard();
```

Description

Use CopyToClipboard to replace the contents of the Clipboard with the selected text. CopyToClipboard does not clear the Clipboard if no text is selected. If no text is selected, CopyToClipboard does nothing.

Note: Calling CopyToClipboard does the same thing as sending the edit control a WM_COPY message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->SelectAll();
  RichEdit1->CopyToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("..\\overview.rtf");
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;
  RichEdit1.CopyToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  // you may need to change this path to suit your environment
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
end;
```

Displaying and Editing Text in a Memo Control

29.1.11.3.6 TCustomEdit.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2270) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 2270). TCustomEdit (see page 2263) overrides the inherited method to specify a scrollable single-line edit control

that reflects the current values of the BorderStyle (see page 2285), HideSelection (see page 2286), PasswordChar (see page 2289), and ReadOnly (see page 2289) properties.

See Also

BorderStyle (see page 2285)

CreateWindowHandle (see page 2270)

CreateWnd (see page 2270)

HideSelection (see page 2286)

PasswordChar (see page 2289)

ReadOnly (see page 2289)

29.1.11.3.7 TCustomEdit.CreateWindowHandle Method

Creates a Windows control to represent the control.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

CreateWindowHandle calls the inherited CreateWindowHandle method after working around a Win95 bug involving setting the read-only style on machines with Far East locales.

See Also

CreateParams (see page 2269)

CreateWnd (see page 2270)

DestroyWnd (see page 2273)

CreateWindowHandle

29.1.11.3.8 TCustomEdit.CreateWnd Method

Creates a Windows control corresponding to the edit control.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called when the edit control is created, and whenever a change to the edit control requires the window to be recreated. After calling the inherited method, CreateWnd sends the newly created window messages to enforce the MaxLength (see page 2286) and PasswordChar (see page 2289) properties.

See Also

CreateParams (see page 2269)

CreateWindowHandle

DestroyWnd (see page 2273)

MaxLength (see page 2286)

PasswordChar (see page 2289)

CreateWnd

29.1.11.3.9 TCustomEdit.CutToClipboard Method

Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.

Pascal

```
procedure CutToClipboard;
```

C++

```
__fastcall CutToClipboard();
```

Description

Use CutToClipboard to replace the contents of the Clipboard with the selected text while clearing the selected text. If no text is selected, CutToClipboard does nothing.

Note: Calling CopyToClipboard (see page 2268) does the same thing as sending the edit control a WM_CUT message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // ensure that all the text is cut, not just the current selection
  RichEdit1->SelectAll();
  RichEdit1->CutToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
```

```
  control, the formatting information would be copied as well.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    RichEdit1.SelectAll;  { ensure that all the text is cut, not just the current selection }
    RichEdit1.CutToClipboard;
    Edit1.Clear;
    Edit1.PasteFromClipboard;
    RichEdit1.SetFocus;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const
    Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
```

See Also

ClearSelection (see page 2267)

CopyToClipboard (see page 2268)

GetSelTextBuf (see page 2275)

PasteFromClipboard (see page 2276)

SelText (see page 2296)

Displaying and Editing Text in a Memo Control

29.1.11.3.10 TCustomEdit.DefaultHandler Method

Provides message handling for all messages that the control does not fully process itself.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to change the default message handling for the edit control. The Message parameter can be cast to a TMessage type, to obtain the WParam, LParam, and Result of the message. If the Result of the message is non-zero, the message has already been handled. Set the Result field to a non-zero value to prevent further processing of the message by the inherited method.

Note: In Delphi, calling inherited in a message-handling method results in a call to the ancestor's DefaultHandler method if that ancestor does not specify a handler for the message being handled.

See Also

WindowProc

DefWndProc

TMessage

29.1.11.3.11 TCustomEdit.DestroyWnd Method

Destroys the Windows control that corresponds to the edit control.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

The Windows control for the edit box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. When this happens, DestroyWnd is called.

Before the window is destroyed, DestroyWnd saves a copy of any properties that are needed to recreate the window after it is destroyed.

See Also

CreateWnd (see page 2270)

29.1.11.3.12 TCustomEdit.DoSetMaxLength Method

Sets the MaxLength (see page 2286) property.

Pascal

```
procedure DoSetMaxLength(Value: Integer); virtual;
```

C++

```
virtual __fastcall DoSetMaxLength(int Value);
```

Description

DoSetMaxLength is the property access function for the MaxLength (see page 2286) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the MaxLength (see page 2286) property.

DoSetMaxLength sends an EM_LIMITTEXT message to the window of the edit control.

See Also

MaxLength (see page 2286)

29.1.11.3.13 TCustomEdit.DoSetTextHint Method

Pascal

```
procedure DoSetTextHint(const Value: string); virtual;
```

C++

```
virtual __fastcall DoSetTextHint(const UnicodeString Value);
```

Description

This is DoSetTextHint, a member of class TCustomEdit.

29.1.11.3.14 TCustomEdit.GetControlsAlignment Method

Indicates how text is aligned within the control.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the alignment of the control. For controls that do not have an Alignment property, GetControlsAlignment returns taLeftJustify.

Note: GetControlsAlignment returns the alignment of text before it is altered by the BiDiMode property. To check if the alignment should be reversed to reflect the BiDiMode property, call UseRightToLeftAlignment.

See Also

BiDiMode

Text

Caption

UseRightToLeftAlignment

29.1.11.3.15 TCustomEdit.GetSelLength Method

Returns the SelLength (see page 2289) property.

Pascal

```
function GetSelLength: Integer; virtual;
```

C++

```
virtual __fastcall int GetSelLength();
```

Description

GetSelLength is the property access function for the SelLength (see page 2289) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the SelLength (see page 2289) property.

GetSelLength sends an EM_GETSEL message to the window of the edit control and returns the difference between the starting position and the ending position.

See Also

SelLength (see page 2289)

SetSelLength (see page 2280)

29.1.11.3.16 TCustomEdit.GetSelStart Method

Returns the SelStart (see page 2293) property.

Pascal

```
function GetSelStart: Integer; virtual;
```

C++

```
virtual __fastcall int GetSelStart();
```

Description

GetSelStart is the property access method for the SelStart (see page 2293) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the SelStart (see page 2293) property.

GetSelStart sends an EM_GETSEL message to the window of the edit control and returns the starting position.

See Also

SelStart (see page 2293)

SetSelStart (see page 2280)

29.1.11.3.17 TCustomEdit.GetSelText Method

Returns the SelText (see page 2296) property.

Pascal

```
function GetSelText: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetSelText();
```

Description

GetSelText is the property access method for the SelText (see page 2296) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the SelText (see page 2296) property.

See Also

SelText (see page 2296)

29.1.11.3.18 TCustomEdit.GetSelTextBuf Method

Copies the selected text into a buffer and returns the number of characters copied.

Pascal

```
function GetSelTextBuf(Buffer: PChar; BufSize: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int GetSelTextBuf(const char * Buffer, int BufSize);
```

Description

Use GetSelTextBuf to copy the selected text into a character buffer. If there is no selection, the buffer receives an empty string. If the selection contains more than (BufSize - 1) characters, only the first (BufSize - 1) characters are copied. GetSelTextBuf returns the number of characters that were actually copied into the buffer.

C++ Examples:

```
/*
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
*/
Char *Buffer;
```

```
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->SelLength; //Get length of selected text in Edit1
  Size++;                      //Add room for null character
  static std::auto_ptr<Char> _BufferCleaner(Buffer = new Char[Size]);
  Edit1->GetSelTextBuf(Buffer, Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
}
//---------------------------------------------------------------------------
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->SelText;
}
```

Delphi Examples:

```
{
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Integer;
begin
  Size := Edit1.SelLength; {Get length of selected text in Edit1}
  Inc(Size); {Add room for null character}
  GetMem(Buffer, Size); {Creates Buffer dynamic variable}
  Edit1.GetSelTextBuf(Buffer,Size); {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);{Converts Buffer into Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.SelText;
end;
```

See Also

CopyToClipboard (see page 2268)

SetSelTextBuf (see page 2281)

29.1.11.3.19 TCustomEdit.PasteFromClipboard Method

Pastes the contents of the Clipboard into edit control, replacing the current selection.

Pascal

```
procedure PasteFromClipboard;
```

C++

```
__fastcall PasteFromClipboard();
```

Description

Use PasteFromClipboard to replace the selected text with the contents of the Clipboard, or, if no text is selected, to insert the contents of the Clipboard at the cursor. If the Clipboard is empty, or if it does not contain anything in CF_TEXT format, PasteFromClipboard does nothing.

Note: Calling PasteFromClipboard does the same thing as sending the edit control a WM_PASTE message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->SelectAll();
  RichEdit1->CopyToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("..\\overview.rtf");
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;
  RichEdit1.CopyToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  // you may need to change this path to suit your environment
  Path = 'OverView.RTF';
```

```
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
end;
```

Displaying and Editing Text in a Memo Control

29.1.11.3.20 TCustomEdit.SelectAll Method

Selects all text in the edit control.

Pascal

```
procedure SelectAll;
```

C++

```
__fastcall SelectAll();
```

Description

Use SelectAll to select all text in the edit control. To select only part of the text, use the SelStart (see page 2293) and SelLength (see page 2289) properties.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // ensure that all the text is cut, not just the current selection
  RichEdit1->SelectAll();
  RichEdit1->CutToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
```

```
  button on a form. When the user clicks the button, text is
  cut from the rich edit control and pasted into the edit box.
  Note that only the text is pasted. If the rich edit control
  includes any formatting information that is not pasted into
  the edit control.  If the destination where a rich edit
  control, the formatting information would be copied as well.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    RichEdit1.SelectAll;  { ensure that all the text is cut, not just the current selection }
    RichEdit1.CutToClipboard;
    Edit1.Clear;
    Edit1.PasteFromClipboard;
    RichEdit1.SetFocus;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const
    Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
```

29.1.11.3.21 TCustomEdit.SetAlignment Method

Sets the Alignment (see page 2283) property.

Pascal

```
procedure SetAlignment(Value: TAlignment);
```

C++

```
__fastcall SetAlignment(TAlignment Value);
```

Description

SetAlignment is exposed as a protected method so derived classes can customize their implementation of the Alignment (see page 2283) property.

See Also

Alignment (see page 2283)

29.1.11.3.22 TCustomEdit.SetAutoSize Method

Sets the AutoSize (see page 2284) property.

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

SetAutoSize is the protected write implementation of the AutoSize (see page 2284) property.

TCustomEdit (see page 2263) overrides the inherited method to update the height of the edit control to reflect the current font when the value of AutoSize (see page 2284) changes to true.

See Also

AutoSize (see page 2284)

29.1.11.3.23 TCustomEdit.SetSelLength Method

Sets the SelLength (see page 2289) property.

Pascal

```
procedure SetSelLength(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetSelLength(int Value);
```

Description

SetSelLength is the property access method for the SelLength (see page 2289) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the SelLength (see page 2289) property.

SetSelLength sends an EM_SETSEL message to the window of the edit control, specifying a selection that begins at SelStart (see page 2293) and ends at SelStart (see page 2293) + Value.

See Also

GetSelLength (see page 2274)

SelLength (see page 2289)

SelStart (see page 2293)

29.1.11.3.24 TCustomEdit.SetSelStart Method

Sets the SelStart (see page 2293) property.

Pascal

```
procedure SetSelStart(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetSelStart(int Value);
```

Description

SetSelStart is the property access method for the SelStart (see page 2293) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2263) can customize the implementation of the SelStart (see page 2293) property.

SetSelLength (see page 2280) sends an EM_SETSEL message to the window of the edit control to position the cursor on the position indicated by Value.

See Also

GetSelStart (see page 2274)

SelStart (see page 2293)

29.1.11.3.25 TCustomEdit.SetSelText Method

Sets the SelText (see page 2296) property.

Pascal

```
procedure SetSelText(const Value: string);
```

C++

```
__fastcall SetSelText(const UnicodeString Value);
```

Description

SetSelText is the property access method for the SelText (see page 2296) property.

See Also

GetSelTextBuf (see page 2275)

SelText (see page 2296)

29.1.11.3.26 TCustomEdit.SetSelTextBuf Method

Replaces the selected text with a null-terminated string.

Pascal

```
procedure SetSelTextBuf(Buffer: PChar);
```

C++

```
__fastcall SetSelTextBuf(const char * Buffer);
```

Description

Use SetSelTextBuf to replace the current selection by the contents of the null-terminated string pointed to by Buffer. If no text is selected, the contents of Buffer are inserted at the cursor. SetSelTextBuf does the same thing as setting the SelText (see page 2296) property, except that it takes a pointer to a char type rather than a string.

C++ Examples:

```
/*
This example inserts the contents of temp_string at the
current location of the cursor.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
   const AnsiString Path = "../readme.txt";
   Memo1->Lines->LoadFromFile(Path);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  WideChar *temp_string = L"I am now here";
  Memo1->SetSelTextBuf(temp_string);
}
```

Delphi Examples:

```
{
This example inserts the contents of temp_string at the
current location of the cursor.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  temp_string: array[0..15] of Char;
begin
  temp_string := 'I am now here';
  Memo1.SetSelTextBuf(temp_string);
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'readme.txt';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
```

PasteFromClipboard (see page 2276)

SelText (see page 2296)

SetTextBuf

29.1.11.3.27 TCustomEdit.Undo Method

Backs out all changes in the undo buffer.

Pascal

```
procedure Undo;
```

C++

```
__fastcall Undo();
```

Description

Call Undo to cancel all changes made to the Text (see page 2297) property since the last call to the ClearUndo (see page 2268) method. If ClearUndo (see page 2268) was never called, Undo rolls back all changes.

To determine whether there are any changes in the undo buffer, check the CanUndo (see page 2285) property.

See Also

ClearUndo (see page 2268)

CanUndo (see page 2285)

Text

29.1.11.4 TCustomEdit Properties

The properties of the TCustomEdit class are listed here.

Protected Properties

	Name	Description
	AutoSelect (see page 2284)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2284)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2285)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2286)	Determines the case of the text within the edit control.

	HideSelection (see page 2286)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2286)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2287)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2288)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2288)	Determines where a control looks for its color information.
	PasswordChar (see page 2289)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Properties

	Name	Description
	Alignment (see page 2283)	Determines how the text is aligned within the text edit control.
R	CanUndo (see page 2285)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2287)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2289)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2289)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2293)	Specifies the position of the first selected character in the text.
	SelText (see page 2296)	Specifies the selected portion of the edit control's text.
	Text (see page 2297)	Contains a text string associated with the control.
	TextHint (see page 2299)	A hint or message to be displayed when the Text (see page 2297) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2297)	Determines if the user can tab to a control.

29.1.11.4.1 TCustomEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

See Also

SetAlignment (see page 2279)

Text

Displaying and Editing Fields in an Edit Box

29.1.11.4.2 TCustomEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect: Boolean;
```

C++

```
__property Boolean AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

See Also

SelectAll (see page 2278)

SelLength (see page 2289)

SelStart (see page 2293)

SelText (see page 2296)

SetSelTextBuf (see page 2281)

29.1.11.4.3 TCustomEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
```

```
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

See Also

BorderStyle (see page 2285)

ClientHeight

ControlStyle

Height

29.1.11.4.4 TCustomEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

29.1.11.4.5 TCustomEdit.CanUndo Property

Indicates whether the edit control contains changes that can be backed out.

Pascal

```
property CanUndo: Boolean;
```

C++

```
__property Boolean CanUndo;
```

Description

Read (see page 3727) CanUndo to determine whether the user has made any changes to the text that can be undone by calling the Undo (see page 2282) method. This is useful when enabling or disabling menu items that correspond to these commands.

See Also

Undo (see page 2282)

ClearUndo (see page 2268)

Text

29.1.11.4.6 TCustomEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

See Also

Text

29.1.11.4.7 TCustomEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

See Also

SelLength (see page 2289)

SelStart (see page 2293)

SelText (see page 2296)

SetSelTextBuf (see page 2281)

29.1.11.4.8 TCustomEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

See Also

Text

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

29.1.11.4.9 TCustomEdit.Modified Property

Indicates whether the user edited the text of the edit control.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Use Modified to determine whether the user changed the Text (see page 2297) property of the edit control. Modified is only reset to **False** when you assign a value to the Text (see page 2297) property. In particular, it is not reset when the control receives focus.

See Also

Change (see page 2266)

OnChange (see page 2299)

SetTextBuf

Text

29.1.11.4.10 TCustomEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly: Boolean;
```

C++

```
__property Boolean NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

29.1.11.4.11 TCustomEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

See Also

Text

29.1.11.4.12 TCustomEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color

Parent

ParentFont

ParentShowHint

29.1.11.4.13 TCustomEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar: Char;
```

C++

```
__property Char PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text (see page 2297) property reflects the actual characters that are typed.

See Also

Text

29.1.11.4.14 TCustomEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

See Also

CopyToClipboard (see page 2268)

GetSelTextBuf (see page 2275)

29.1.11.4.15 TCustomEdit.SelLength Property

Specifies the number of characters (bytes) that are selected.

Pascal

```
property SelLength: Integer;
```

C++

```
__property int SelLength;
```

Description

Read (see page 3727) SelLength to determine the length, in bytes, of the selected text. This is the same as the number of

characters, unless you are using a multi-byte character set. Set SelLength to change the selection to consist of the first SelLength bytes starting at SelStart (see page 2293).

Note: Setting SelLength to a value greater than the number of characters from SelStart (see page 2293) to the end of the text results in the selection of all characters from SelStart (see page 2293) to the end of the text. Reading SelLength immediately after setting it to a value greater than the number of available characters returns the number of characters actually selected, not the value that was just set.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection. Notice that the
"Match whole word only" and "Match case" work.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FindDialog1->Position = Point(RichEdit1->Left + RichEdit1->Width, RichEdit1->Top);
  FindDialog1->Execute();
}

void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  int FoundAt, StartPos, ToEnd;
  TSearchTypes mySearchTypes = TSearchTypes();
  // begin the search after the current selection
  // if there is one
  // otherwise, begin at the start of the text
  if (FindDialog1->Options.Contains(frMatchCase))
    mySearchTypes << stMatchCase;
  if (FindDialog1->Options.Contains(frWholeWord))
    mySearchTypes << stWholeWord;
  if (RichEdit1->SelLength)
    StartPos = RichEdit1->SelStart + RichEdit1->SelLength;
  else
    StartPos = 0;
  // ToEnd is the length from StartPos
  // to the end of the text in the rich edit control
  ToEnd = RichEdit1->Text.Length() - StartPos;
  FoundAt = RichEdit1->FindText(FindDialog1->FindText, StartPos, ToEnd, mySearchTypes);
  if (FoundAt != -1)
  {
    RichEdit1->SetFocus();
    RichEdit1->SelStart = FoundAt;
    RichEdit1->SelLength = FindDialog1->FindText.Length();
  }
  else Beep();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("../Overview.RTF");  // starts in Debug
  RichEdit1->ScrollBars = ssVertical;
}
/*
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
```

```
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
*/
void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  for (int I = 0; I < Memo1->Lines->Count; I++)

      if PosReturn <> 0 then {found!}
      begin
        SkipChars := 0;
        for J := 0 to I - 1 do
          SkipChars := SkipChars + Length(Memo1.Lines[J]);
        SkipChars := SkipChars + (I*2);
        SkipChars := SkipChars + PosReturn - 1;
        Memo1.SetFocus;
        Memo1.SelStart := SkipChars;
        Memo1.SelLength := Length(FindDialog1.FindText);
        Break;
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const Path = 'country.list';
  begin
    Memo1.Lines.LoadFromFile(Path);
  end;
```

See Also

SelStart (see page 2293)

SelText (see page 2296)

29.1.11.4.16 TCustomEdit.SelStart Property

Specifies the position of the first selected character in the text.

Pascal

```
property SelStart: Integer;
```

C++

```
__property int SelStart;
```

Description

Read (see page 3727) SelStart to determine the position of the first selected character, where 0 indicates the first character. If there is no selected text, SelStart indicates the position of the cursor. Set SelStart to remove the current selection and position the cursor just before the indicated character.

To select a particular range of the text, first set SelStart to position the cursor, and then set SelLength (see page 2289) to extend the selection.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection. Notice that the
"Match whole word only" and "Match case" work.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{

SelLength (see page 2289)

SelText (see page 2296)

29.1.11.4.17 TCustomEdit.SelText Property

Specifies the selected portion of the edit control's text.

Pascal

```
property SelText: string;
```

C++

```
__property UnicodeString SelText;
```

Description

Read (see page 3727) SelText to determine the value of the selected text. Set SelText to replace the selected text with a new string. If there is no selection, but the edit control has focus, set SelText to insert a new string into the text at the cursor.

C++ Examples:

```
/*
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
*/
Char *Buffer;

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->SelLength; //Get length of selected text in Edit1
  Size++;                      //Add room for null character
  static std::auto_ptr<Char> _BufferCleaner(Buffer = new Char[Size]);
  Edit1->GetSelTextBuf(Buffer, Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
}
//---------------------------------------------------------------------------
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->SelText;
}
```

Delphi Examples:

```
{
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Integer;
begin
  Size := Edit1.SelLength; {Get length of selected text in Edit1}
```

```
    Inc(Size); {Add room for null character}
    GetMem(Buffer, Size); {Creates Buffer dynamic variable}
    Edit1.GetSelTextBuf(Buffer,Size); {Puts Edit1.Text into Buffer}
    Edit2.Text := StrPas(Buffer);{Converts Buffer into Pascal-style string}
    FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
  end;

  {
  Note: the same thing could be accomplished more simply as follows:
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    Edit2.Text := Edit1.SelText;
  end;
```

29.1.11.4.18 TCustomEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.11.4.19 TCustomEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                         //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

Caption

Lines (see page 2368)

29.1.11.4.20 TCustomEdit.TextHint Property

A hint or message to be displayed when the Text (see page 2297) property is empty.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

29.1.11.5 TCustomEdit Events

The events of the TCustomEdit class are listed here.

Protected Events

	Name	Description
	OnChange (see page 2299)	Occurs when the text for the edit control may have changed.

29.1.11.5.1 TCustomEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3789) an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified (see page 2287) property to see if a change actually occurred. The Text (see page 2297) property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 2266)

Text

29.1.12 TCustomGroupBox Class

TCustomGroupBox is the base class for all group-box components.

Class Hierarchy

Pascal

```
TCustomGroupBox = class(TCustomControl);
```

C++

```
class TCustomGroupBox : public TCustomControl;
```

File

StdCtrls

Description

Group boxes are visual components that act as containers for sets of related controls, such as radio buttons. Group boxes may also contain other group boxes. TCustomGroupBox is the class from which all group-box components—including TGroupBox (see page 2451), TRadioGroup, and TDBRadioGroup—descend.

See Also

TCustomGroupBox

TDBRadioGroup

TRadioGroup

TGroupBox (see page 2451)

TCustomControl

TWidgetControl

29.1.12.1 TCustomGroupBox Members

The following tables list the members exposed by TCustomGroupBox.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2301)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2301)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2302)	Renders the onscreen image of the group box.

Public Methods

	Name	Description
	Create (see page 2300)	Creates and initializes a TCustomGroupBox (see page 2299) instance.

29.1.12.2 TCustomGroupBox.Create Constructor

Creates and initializes a TCustomGroupBox (see page 2299) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomGroupBox(TComponent * AOwner);
```

Description

Call Create to instantiate a group box at runtime. Group boxes placed on forms at design time are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the group box. It becomes the value of the Owner property.

See Also

Owner

29.1.12.3 TCustomGroupBox Methods

The methods of the TCustomGroupBox class are listed here.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2301)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2301)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2302)	Renders the onscreen image of the group box.

29.1.12.3.1 TCustomGroupBox.AdjustClientRect Method

Adjusts the ClientRect property for idiosyncrasies of the window.

Pascal

```
procedure AdjustClientRect(var Rect: TRect); override;
```

C++

```
virtual __fastcall AdjustClientRect(TRect Rect);
```

Description

AdjustClientRect is called internally when the group box needs accurate information on where to place child controls within the client area. It indents the client rectangle slightly so that child controls are not placed on the frame (or caption) of the group box.

See Also

ClientRect

Caption

29.1.12.3.2 TCustomGroupBox.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a group box creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

Specify the parameter record as the value of the Params parameter. The TCreateParams type is a data structure holding information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TCustomGroupBox (see page 2299) adjusts the window style by turning off the CS_HREDRAW and CS_VREDRAW flags.

See Also

CreateWnd

CreateWindowHandle

29.1.12.3.3 TCustomGroupBox.Paint Method

Renders the onscreen image of the group box.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint draws a border around the group box and fills in the caption.

29.1.13 TCustomLabel Class

TCustomLabel is the base class for non-windowed controls that display text on a form.

Class Hierarchy

Pascal

```
TCustomLabel = class(TGraphicControl);
```

C++

```
class TCustomLabel : public TGraphicControl;
```

File

StdCtrls

Description

Use TCustomLabel as a base class when defining objects that display text that users can't edit. TCustomLabel introduces several new properties and methods to control the appearance of the text.

TCustomLabel is not a descendant of TWinControl, so it does not have its own window and can't receive direct input from the keyboard. To define an object that responds to direct keyboard input in addition to displaying text, use TCustomStaticText (see page 2375) as a base class.

Do not create instances of TCustomLabel. To put a label on a form, use a TLabel (see page 2522) object.

See Also

TCustomStaticText (see page 2375)

TLabel (see page 2522)

29.1.13.1 TCustomLabel Members

The following tables list the members exposed by TCustomLabel.

Protected Methods

	Name	Description
	AdjustBounds (see page 2304)	Resizes the label when the text changes.
	DoDrawText (see page 2304)	Renders the text in the client area.
	GetLabelText (see page 2305)	Returns the value of the Caption (see page 2310) property.
	Loaded (see page 2305)	Adjusts the size of the label when it is first loaded. .
	Notification (see page 2305)	Responds to notifications when objects are about to be created or destroyed.
	Paint (see page 2306)	Draws the image of the label.
	SetAutoSize (see page 2306)	Sets the AutoSize (see page 2307) property.

Protected Properties

	Name	Description
	Alignment (see page 2307)	Controls the horizontal placement of the text within the label.
	AutoSize (see page 2307)	Determines whether the size of the label automatically resizes to accommodate the text.
	EllipsisPosition (see page 2313)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	FocusControl (see page 2313)	Designates a windowed control associated with the label.
	Layout (see page 2314)	Specifies the vertical placement of the text within the label.
	ShowAccelChar (see page 2314)	Determines how an ampersand in the label text is displayed.
	Transparent (see page 2315)	Specifies whether controls that sit below the label on a form can be seen through the label.
	WordWrap (see page 2316)	Specifies whether the label text wraps when it is too long for the width of the label.

Public Methods

	Name	Description
	Create (see page 2303)	Creates and initializes an instance of TCustomLabel (see page 2302).

Public Properties

	Name	Description
	Canvas (see page 2308)	Provides the drawing surface used by the graphic control.
	Caption (see page 2310)	Specifies a text string that identifies the control to the user.
	GlowSize (see page 2314)	This is GlowSize, a member of class TCustomLabel.

29.1.13.2 TCustomLabel.Create Constructor

Creates and initializes an instance of TCustomLabel (see page 2302).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomLabel(TComponent * AOwner);
```

Description

Call Create to create an instance of TCustomLabel (see page 2302) at runtime. Labels placed on forms at design time are created automatically.

AOwner is a component, typically the form, that is responsible for freeing the label.

See Also

Owner

29.1.13.3 TCustomLabel Methods

The methods of the TCustomLabel class are listed here.

Protected Methods

	Name	Description
	AdjustBounds (see page 2304)	Resizes the label when the text changes.
	DoDrawText (see page 2304)	Renders the text in the client area.
V	GetLabelText (see page 2305)	Returns the value of the Caption (see page 2310) property.
V	Loaded (see page 2305)	Adjusts the size of the label when it is first loaded. .
V	Notification (see page 2305)	Responds to notifications when objects are about to be created or destroyed.
V	Paint (see page 2306)	Draws the image of the label.
V	SetAutoSize (see page 2306)	Sets the AutoSize (see page 2307) property.

29.1.13.3.1 TCustomLabel.AdjustBounds Method

Resizes the label when the text changes.

Pascal

```
procedure AdjustBounds; dynamic;
```

C++

```
__fastcall AdjustBounds();
```

Description

When the text in the label or the font changes, AdjustBounds is implicitly called. It redraws the text in the client area, and then resizes the label if the AutoSize (see page 2307) property is true.

When WordWrap (see page 2316) is true, the width of the label is fixed. If AutoSize (see page 2307) is also true, changes to the text cause the label to change in height. When AutoSize (see page 2307) is true and WordWrap (see page 2316) is false, the height of the label is determined by the font, and changes to the text cause the label to change in width.

Override AdjustBounds to make additional adjustments when the text changes.

See Also

DoDrawText (see page 2304)

AutoSize (see page 2307)

29.1.13.3.2 TCustomLabel.DoDrawText Method

Renders the text in the client area.

Pascal

```
procedure DoDrawText(var Rect: TRect; Flags: Longint); dynamic;
```

C++

```
__fastcall DoDrawText(TRect Rect, Longint Flags);
```

Description

When the label needs to draw itself, DoDrawText is implicitly called. DoDrawText uses the Windows API function, DrawText, to render the caption in the client area.

The first parameter, Rect, specifies the boundaries of the text within the client area. The second parameter, Flags, specifies how the text is aligned within those boundaries, how tab characters are handled, etc. See the Microsoft Windows API DrawText function for all the possible values of Flags.

Override DoDrawText to render text differently.

See Also

Caption

AdjustBounds (see page 2304)

29.1.13.3.3 TCustomLabel.GetLabelText Method

Returns the value of the Caption (see page 2310) property.

Pascal

```
function GetLabelText: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetLabelText();
```

Description

Call GetLabelText to obtain the string that appears as the text of the label.

See Also

Caption

29.1.13.3.4 TCustomLabel.Loaded Method

Adjusts the size of the label when it is first loaded. .

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The protected Loaded method is called immediately after a saved version of the form that contains the label is loaded into memory. TCustomLabel (see page 2302) uses this method to adjust the size of the label to the text it contains if the AutoSize (see page 2307) property is true.

See Also

AutoSize (see page 2307)

29.1.13.3.5 TCustomLabel.Notification Method

Responds to notifications when objects are about to be created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification is called automatically when components are created or destroyed. After calling the inherited method, Notification checks whether the windowed control specified by the FocusControl (see page 2313) property is about to be destroyed. If the windowed control is going away, Notification sets the FocusControl (see page 2313) property to nil (Delphi) or NULL (C++).

See Also

FocusControl (see page 2313)

29.1.13.3.6 TCustomLabel.Paint Method

Draws the image of the label.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called automatically when the label receives a WM_PAINT message from its Parent. Paint writes the text returned by the GetLabelText (see page 2305) method.

See Also

GetLabelText (see page 2305)

29.1.13.3.7 TCustomLabel.SetAutoSize Method

Sets the AutoSize (see page 2307) property.

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

SetAutoSize is the protected access method for the AutoSize (see page 2307) property. It is exposed as a protected method so descendants can override it to change the implementation of the AutoSize (see page 2307) property.

See Also

AutoSize (see page 2307)

29.1.13.4 TCustomLabel Properties

The properties of the TCustomLabel class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 2307)	Controls the horizontal placement of the text within the label.
	AutoSize (see page 2307)	Determines whether the size of the label automatically resizes to accommodate the text.
	EllipsisPosition (see page 2313)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	FocusControl (see page 2313)	Designates a windowed control associated with the label.
	Layout (see page 2314)	Specifies the vertical placement of the text within the label.
	ShowAccelChar (see page 2314)	Determines how an ampersand in the label text is displayed.
	Transparent (see page 2315)	Specifies whether controls that sit below the label on a form can be seen through the label.
	WordWrap (see page 2316)	Specifies whether the label text wraps when it is too long for the width of the label.

Public Properties

	Name	Description
	Canvas (see page 2308)	Provides the drawing surface used by the graphic control.
	Caption (see page 2310)	Specifies a text string that identifies the control to the user.
	GlowSize (see page 2314)	This is GlowSize, a member of class TCustomLabel.

29.1.13.4.1 TCustomLabel.Alignment Property

Controls the horizontal placement of the text within the label.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Set Alignment to specify how the text of the label is justified within the ClientRect of the label control.

The effect of the Alignment property is more obvious if the WordWrap (see page 2316) property is true and the label includes more than one line of text.

See Also

ClientRect

GetLabelText (see page 2305)

Layout (see page 2314)

WordWrap (see page 2316)

29.1.13.4.2 TCustomLabel.AutoSize Property

Determines whether the size of the label automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the label adjust its size automatically so the client area accommodates the height and width of the text.

When AutoSize is false, the label is fixed in size. When AutoSize is true, the size of the label readjusts whenever the text changes. The size of the label is also readjusts when the Font property changes.

When WordWrap (see page 2316) is true, the width of the label is fixed. If AutoSize is also true, changes to the text cause the label to change in height. When AutoSize is true and WordWrap (see page 2316) is false, the font determines the height of the label, and changes to the text cause the label to change in width.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
```

BoundsRect

GetLabelText (see page 2305)

Font

WordWrap (see page 2316)

Layout (see page 2314)

29.1.13.4.3 TCustomLabel.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl instance does not have its own Windows screen object, it obtains its device context from its parent

control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = dynamic_cast<TLabel *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

29.1.13.4.4 TCustomLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}
```

```
TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
```

```
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
    ToolBar1.Free;
  end;
```

29.1.13.4.5 TCustomLabel.EllipsisPosition Property

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
property EllipsisPosition: TEllipsisPosition;
```

C++

```
__property TEllipsisPosition EllipsisPosition;
```

Description

Set EllipsisPosition to determine how an ellipsis is placed in text that does not fit in its allocated rectangle. This is a TEllipsisPosition (see page 2908) constant and its value corresponds to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

See Also

WordWrap (see page 2316)

TypeName

29.1.13.4.6 TCustomLabel.FocusControl Property

Designates a windowed control associated with the label.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Set FocusControl to the windowed control that should receive focus when the user presses the accelerator key specified by the

label. Specify an accelerator key by preceding a character in the label text with an ampersand (&) and setting the ShowAccelChar (see page 2314) property to true.

See Also

ShowAccelChar (see page 2314)

GetLabelText (see page 2305)

29.1.13.4.7 TCustomLabel.GlowSize Property

Pascal

```
property GlowSize: Integer;
```

C++

```
__property int GlowSize;
```

Description

This is GlowSize, a member of class TCustomLabel.

29.1.13.4.8 TCustomLabel.Layout Property

Specifies the vertical placement of the text within the label.

Pascal

```
property Layout: TTextLayout;
```

C++

```
__property TTextLayout Layout;
```

Description

Set Layout to specify how the text of the label is placed within the ClientRect of the label control. Layout is the vertical analog to the Alignment (see page 2307) property.

See Also

Alignment (see page 2307)

ClientRect

29.1.13.4.9 TCustomLabel.ShowAccelChar Property

Determines how an ampersand in the label text is displayed.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

Set ShowAccelChar to true to allow the label to display an underlined accelerator key value. When ShowAccelChar is true, any character preceded by an ampersand (&) appears underlined. If the FocusControl (see page 2313) property is set, the windowed control specified by the FocusControl (see page 2313) property receives input focus when the user types that underlined character. To display an ampersand when ShowAccelChar is true, use two ampersands (&&) to stand for the single ampersand that is displayed.

Set ShowAccelChar to false to display the label text with all ampersands appearing as ampersands. When ShowAccelChar is false, the value of the FocusControl (see page 2313) property is not used.

C++ Examples:

```
/*
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label1->ShowAccelChar = true;
  Label1->Caption = "An &Underlined character appears here";
  Label2->ShowAccelChar = false;
  Label2->Caption = "An ampersand (&) appears here";
}
```

Delphi Examples:

```
{
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label1.ShowAccelChar := True;
  Label1.Caption := 'An &Underlined character appears here';
  Label2.ShowAccelChar := False;
  Label2.Caption := 'An ampersand (&) appears here';
end;
```

See Also

FocusControl (see page 2313)

GetLabelText (see page 2305)

29.1.13.4.10 TCustomLabel.Transparent Property

Specifies whether controls that sit below the label on a form can be seen through the label.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to prevent the label from obscuring other controls on the form. For example, if the label is used to add text to a graphic, set Transparent to true so that the label does not stand out as a separate object.

Writing text so that the background is transparent is slower than writing text when Transparent is false. If the label is not obscuring a complicated image, performance can be improved by setting the background color of the label to match the object beneath it and setting Transparent to false.

See Also

Color

ParentColor

29.1.13.4.11 TCustomLabel.WordWrap Property

Specifies whether the label text wraps when it is too long for the width of the label.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the label to display multiple line of text. When WordWrap is true, text that is too wide for the label control wraps at the right margin and continues in additional lines.

Set WordWrap to false to limit the label to a single line. When WordWrap is false, text that is too wide for the label appears truncated.

ClientWidth

GetLabelText (see page 2305)

29.1.14 TCustomListBox Class

TCustomListBox is the base class for listbox objects that are wrappers for list box controls.

Class Hierarchy

Pascal

```
TCustomListBox = class(TCustomMultiSelectListControl);
```

C++

```
class TCustomListBox : public TCustomMultiSelectListControl;
```

File

StdCtrls

Description

TCustomListBox encapsulates behavior common to all list box controls. List box objects are used to display a scrollable list from which users can select one or more items. Use a list box control to limit the user to selecting from a list of items. Items (see page 2346) can be added at design time or at runtime.

As a wrapper for a list box TCustomListBox introduces methods for:

Displaying, sorting, selecting, manipulating, and querying items in the list.

Creating owner-draw style list boxes that can display graphical images such as icons and bitmaps.

Creating multiple-column and multiple-selection lists.

By default, TCustomListBox is a standard list box that displays items as text strings. These items are contained in a TStrings object, and the methods of the TStrings object are used to add, insert or delete a string. The following code demonstrates adding a new string to the list box:

MyListBox.Items.Add('New (see page 3712) item'); //Delphi

MyListBox->Items (see page 2346)->Add("New (see page 3712) item"); // C++

Descendants of TCustomListBox inherit the basic functionality of TCustomListBox. Some descendants also have specialized behavior and can be linked to file, directory, drive, or database information. Use these list boxes to easily access and list this type of information.

A combo box is a list box with an edit control and an optional drop down style for the list. Use a combo box to allow users to type their selection into an edit box or to save space on a form by having the list drop down.

For lists of items that require a matrix or expandable tree-like structure, use list views or tree views. These controls allow the grouping of items under column headings or in expandable and contractible rows.

TStrings

29.1.14.1 TCustomListBox Members

The following tables list the members exposed by TCustomListBox.

Protected Events

	Name	Description
	OnData (see page 2356)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2356)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2357)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDrawItem (see page 2357)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnMeasureItem (see page 2359)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Protected Fields

	Name	Description
	FMoving (see page 2319)	This is FMoving, a member of class TCustomListBox.

Protected Methods

	Name	Description
V	CreateParams (see page 2322)	Initializes the window-creation parameter record passed in the Params parameter.
V	CreateWnd (see page 2323)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2324)	Deletes a string from the list box.
V	DestroyWnd (see page 2324)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2325)	Returns the index of a string in the list box.
	DoGetData (see page 2325)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2326)	Returns the object associated with an item in a virtual list box.
V	DragCanceled (see page 2326)	Sends a mouse message canceling the drag-and-drop operation.
V	DrawItem (see page 2326)	Generates an OnDrawItem (see page 2357) event.
	GetItemData (see page 2327)	Returns a 32-bit value associated with the specified item in a list box.
V	GetItemIndex (see page 2328)	Returns the value of the ItemIndex property.
V	GetSelCount (see page 2328)	Returns the number of selected items.
	GetSelected (see page 2328)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2328)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2329)	Associates an integer with a specified item in the list box.
V	KeyPress (see page 2332)	Responds when the user presses a key.
V	LoadRecreateItems (see page 2333)	This is LoadRecreateItems, a member of class TCustomListBox.
V	MeasureItem (see page 2333)	Generates an OnMeasureItem (see page 2359) event.

	ResetContent (see page 2334)	Removes all of the items from a list box.
V	SaveRecreateItems (see page 2334)	This is SaveRecreateItems, a member of class TCustomListBox.
	SetItemData (see page 2334)	Sets the 32-bit value associated with the specified item in a list box.
V	SetItemIndex (see page 2335)	Gives focus to the item with a specified index.
V	SetMultiSelect (see page 2335)	Sets the MultiSelect property.
V	WndProc (see page 2335)	Handles Windows messages.

Protected Properties

	Name	Description
	BorderStyle (see page 2341)	Determines whether the list box has a border.
	Columns (see page 2344)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	ExtendedSelect (see page 2345)	Determines if the user can select a sequential range of items in the list box.
	IntegralHeight (see page 2345)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2346)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 2349)	Determines where a control looks for its color information.
	Sorted (see page 2352)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2353)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 2354)	Specifies the size of the tabs in the list box.

Public Methods

	Name	Description
V	AddItem (see page 2320)	Adds an item to the list box
V	Clear (see page 2321)	Deletes all items from the list box.
V	ClearSelection (see page 2321)	Deselects all selected items in the list box, if possible.
V	CopySelection (see page 2322)	Copies the selected items to another list-type control
V	Create (see page 2318)	Instantiates a list box control.
V	DeleteSelected (see page 2324)	Deletes the selected items from the list box
V	Destroy (see page 2319)	Destroys the instance of a list box control.
V	GetCount (see page 2327)	Returns the value of the Count (see page 2344) property.
	ItemAtPos (see page 2329)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2331)	Returns the rectangle that surrounds the item specified in the Item parameter.
V	SelectAll (see page 2334)	Selects the entire block of text in the list box.

Public Properties

	Name	Description
	AutoComplete (see page 2340)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2341)	Specifies the delay between a key press and an attempt to autocomplete the field.
R	Canvas (see page 2341)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2357) event of an owner-draw list box.
	Count (see page 2344)	Indicates the number of items in the list box.
	Items (see page 2346)	Contains the strings that appear in the list box.
	ScrollWidth (see page 2349)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	Selected (see page 2350)	Indicates whether a particular item is selected.
	TopIndex (see page 2354)	Specifies the index number of the item that appears at the top of the list box.

Published Properties

	Name	Description
	TabStop (see page 2354)	Determines if the user can tab to a control.

29.1.14.2 TCustomListBox.Create Constructor

Instantiates a list box control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a list box control at runtime. For list boxes created at design time, Create is called automatically.AOwner is the component that is responsible for freeing the list box. It becomes the value of the Owner property. If AOwner is nil, the caller is responsible for explicitly freeing the control.

See Also

Owner

29.1.14.3 TCustomListBox.Destroy Destructor

Destroys the instance of a list box control.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomListBox();
```

Description

Do not call Destroy directly in an application. Instead, an application should call Free. Free checks that the list box reference is not nil before it calls Destroy.

Destroy frees the memory associated with the objects for the Canvas (see page 2341) and Items (see page 2346) properties. Then it calls the inherited destructor to destroy the list box object.

See Also

System::TObject::Free (see page 3382)

29.1.14.4 TCustomListBox Fields

The fields of the TCustomListBox class are listed here.

Protected Fields

	Name	Description
	FMoving (see page 2319)	This is FMoving, a member of class TCustomListBox.

29.1.14.4.1 TCustomListBox.FMoving Field

Pascal

```
FMoving: Boolean;
```

C++

```
Boolean FMoving;
```

Description

This is FMoving, a member of class TCustomListBox.

29.1.14.5 TCustomListBox Methods

The methods of the TCustomListBox class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2322)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateWnd (see page 2323)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2324)	Deletes a string from the list box.
	DestroyWnd (see page 2324)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2325)	Returns the index of a string in the list box.
	DoGetData (see page 2325)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2326)	Returns the object associated with an item in a virtual list box.
	DragCanceled (see page 2326)	Sends a mouse message canceling the drag-and-drop operation.
	DrawItem (see page 2326)	Generates an OnDrawItem (see page 2357) event.
	GetItemData (see page 2327)	Returns a 32-bit value associated with the specified item in a list box.
	GetItemIndex (see page 2328)	Returns the value of the ItemIndex property.
	GetSelCount (see page 2328)	Returns the number of selected items.
	GetSelected (see page 2328)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2328)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2329)	Associates an integer with a specified item in the list box.
	KeyPress (see page 2332)	Responds when the user presses a key.
	LoadRecreateItems (see page 2333)	This is LoadRecreateItems, a member of class TCustomListBox.
	MeasureItem (see page 2333)	Generates an OnMeasureItem (see page 2359) event.
	ResetContent (see page 2334)	Removes all of the items from a list box.
	SaveRecreateItems (see page 2334)	This is SaveRecreateItems, a member of class TCustomListBox.
	SetItemData (see page 2334)	Sets the 32-bit value associated with the specified item in a list box.
	SetItemIndex (see page 2335)	Gives focus to the item with a specified index.
	SetMultiSelect (see page 2335)	Sets the MultiSelect property.
	WndProc (see page 2335)	Handles Windows messages.

Public Methods

	Name	Description
	AddItem (see page 2320)	Adds an item to the list box
	Clear (see page 2321)	Deletes all items from the list box.
	ClearSelection (see page 2321)	Deselects all selected items in the list box, if possible.
	CopySelection (see page 2322)	Copies the selected items to another list-type control
	DeleteSelected (see page 2324)	Deletes the selected items from the list box
	GetCount (see page 2327)	Returns the value of the Count (see page 2344) property.
	ItemAtPos (see page 2329)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2331)	Returns the rectangle that surrounds the item specified in the Item parameter.
	SelectAll (see page 2334)	Selects the entire block of text in the list box.

29.1.14.5.1 TCustomListBox.AddItem Method

Adds an item to the list box

Pascal

```
procedure AddItem(Item: String; AObject: TObject); override;
```

C++

```
virtual __fastcall AddItem(UnicodeString Item, TObject * AObject);
```

Description

Call AddItem to add a new item to the end of the list.

Item is the text of the item to add.

AObject is the object associated with the new item.

See Also

AddObject

Items (see page 2346)

29.1.14.5.2 TCustomListBox.Clear Method

Deletes all items from the list box.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Use Clear to delete all of the items in the list box at once. Although the items in a standard list box are of type TStrings, use the Clear method of the list box rather than calling the Clear method of the Items (see page 2346) property. This allows descendants of TCustomListBox (see page 2316) to perform any other necessary clean-up in the Clear method, in addition to deleting the items from the Items (see page 2346) property. Thus, applications should use

```
ListBox1.Clear;
ListBox1->Clear();
```

rather than

```
ListBox1.Items.Clear;
ListBox1->Items->Clear();
```

See Also

Clear

Items (see page 2346)

29.1.14.5.3 TCustomListBox.ClearSelection Method

Deselects all selected items in the list box, if possible.

Pascal

```
procedure ClearSelection; override;
```

C++

```
virtual __fastcall ClearSelection();
```

Description

Use ClearSelection to deselect all the currently selected items in the list box. When the list box receives focus, after ClearSelection is called, the last item that was selected is the item that receives the current focus in the list box. Although this

item receives focus, the item itself is not selected.

DeleteSelected (see page 2324)

extendedselect (see page 2345)

MultiSelect

SelCount

Selected (see page 2350)

ItemIndex

29.1.14.5.4 TCustomListBox.CopySelection Method

Copies the selected items to another list-type control

Pascal

```
procedure CopySelection(Destination: TCustomListControl); override;
```

C++

```
virtual __fastcall CopySelection(TCustomListControl Destination);
```

Description

Call CopySelection to copy all the items selected in the list box to a combo box, list view, or another list box. If the destination control is not sorted, the selected items are added to the end of its list.

Destination is the list box, combo box, or list view to which the selected items are copied.

MoveSelection

extendedselect (see page 2345)

MultiSelect

SelCount

Selected (see page 2350)

ItemIndex

29.1.14.5.5 TCustomListBox.CreateParams Method

Initializes the window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams is used to pass information, in its Params parameter, to CreateWindowHandle when the list box control is created.

TCustomListBox (see page 2316) overrides CreateParams to customize the representation of the window. It uses information from the list box Columns (see page 2344), ExtendedSelect (see page 2345), IntegralHeight (see page 2345),

MultiSelect, Sorted (see page 2352) and Style (see page 2353) properties and sets WS_HSCROLL, WS_VSCROLL, LBS_HASSTRINGS and LBS_NOTIFY Windows styles for creation of the list box.

When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

Columns (see page 2344)

CreateWindowHandle

CreateWnd

extendedselect (see page 2345)

IntegralHeight (see page 2345)

MultiSelect

Sorted (see page 2352)

Style (see page 2353)

29.1.14.5.6 TCustomListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams (see page 2322) to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns (see page 2344)

CreateParams (see page 2322)

CreateWindowHandle

CreateWnd

ItemIndex

Items (see page 2346)

TabWidth (see page 2354)

TopIndex (see page 2354)

29.1.14.5.7 TCustomListBox.DeleteSelected Method

Deletes the selected items from the list box

Pascal

```
procedure DeleteSelected; override;
```

C++

```
virtual __fastcall DeleteSelected();
```

Description

Call DeleteSelected to delete the selected items from the list box.

See Also

ClearSelection

MoveSelection

CopySelection (see page 2322)

extendedselect (see page 2345)

MultiSelect

SelCount

Selected (see page 2350)

ItemIndex

29.1.14.5.8 TCustomListBox.DeleteString Method

Deletes a string from the list box.

Pascal

```
procedure DeleteString(Index: Integer); dynamic;
```

C++

```
__fastcall DeleteString(int Index);
```

Description

DeleteString deletes the string, specified by the Index parameter, from the list box control.

29.1.14.5.9 TCustomListBox.DestroyWnd Method

Saves the list box items in a string list before freeing the underlying Windows control.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

DestroyWnd saves the list box text string items in the Items (see page 2346) property to internal storage in a TStringList object that it creates. It then calls the inherited DestroyWnd method to destroy the windowed control's window handle and free

associated device contexts.

See Also

DestroyWnd

Items (see page 2346)

TStringList

29.1.14.5.10 TCustomListBox.DoFindData Method

Returns the index of a string in the list box.

Pascal

```
function DoFindData(const Data: String): Integer;
```

C++

```
__fastcall int DoFindData(const UnicodeString Data);
```

Description

This protected method is called automatically when the list box needs to indicate the index for an item.

If the list box is virtual (that is, if the value of the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw), DoFindData generates an OnDataFind (see page 2356) event so that the index can be provided dynamically. If the list box is not virtual (any other Style (see page 2353)), DoFindData locates the specified string from the Items (see page 2346) property and returns its index.

Data is the text of the item to locate.

See Also

OnDataFind (see page 2356)

Style (see page 2353)

Items (see page 2346)

29.1.14.5.11 TCustomListBox.DoGetData Method

Returns a string in the list box given its index.

Pascal

```
function DoGetData(const Index: Integer): String;
```

C++

```
__fastcall UnicodeString DoGetData(const int Index);
```

Description

This protected method is called automatically when a virtual list box needs to supply the text of an item. DoGetData is never called unless the list box is virtual (that is, unless the value of the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw).

DoGetData generates an OnData (see page 2356) event and returns the string that is supplied dynamically by the event handler.

See Also

OnData (see page 2356)

Style (see page 2353)

Items (see page 2346)

29.1.14.5.12 TCustomListBox.DoGetDataObject Method

Returns the object associated with an item in a virtual list box.

Pascal

```
function DoGetDataObject(const Index: Integer): TObject;
```

C++

```
__fastcall TObject * DoGetDataObject(const int Index);
```

Description

This protected method is called automatically when a virtual list box needs to supply the object associated with an item. DoGetDataObject is never called unless the list box is virtual (that is, unless the value of the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw).

DoGetDataObject generates an OnDataObject (see page 2357) event and returns the object that is supplied dynamically by the event handler.

See Also

OnDataObject (see page 2357)

Style (see page 2353)

Items (see page 2346)

29.1.14.5.13 TCustomListBox.DragCanceled Method

Sends a mouse message canceling the drag-and-drop operation.

Pascal

```
procedure DragCanceled; override;
```

C++

```
virtual __fastcall DragCanceled();
```

Description

DragCanceled is called in response to the cancellation of a drag-and-drop operation that had started. Users can cancel the operation by dropping the item over a component that does not accept the item, or by pressing Esc while dragging.

The OnEndDrag event occurs after the call to DragCanceled.

See Also

OnEndDrag

29.1.14.5.14 TCustomListBox.DrawItem Method

Generates an OnDrawItem (see page 2357) event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); virtual;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem (see page 2357) event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight (see page 2346)

MeasureItem (see page 2333)

OnDrawItem (see page 2357)

OnMeasureItem (see page 2359)

Style (see page 2353)

29.1.14.5.15 TCustomListBox.GetCount Method

Returns the value of the Count (see page 2344) property.

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count (see page 2344) property.

See Also

Count (see page 2344)

29.1.14.5.16 TCustomListBox.GetItemData Method

Returns a 32-bit value associated with the specified item in a list box.

Pascal

```
function GetItemData(Index: Integer): TCustomLongData; dynamic;
```

C++

```
__fastcall TCustomLongData GetItemData(int Index);
```

Description

GetItemData retrieves the data associated with a particular item in the list box. This value can be displayed as that list box item, or can be a value (such as a pointer) associated with the list box item.

See Also

SetItemData (see page 2334)

29.1.14.5.17 TCustomListBox.GetItemIndex Method

Returns the value of the ItemIndex property.

Pascal

```
function GetItemIndex: Integer; override;
```

C++

```
virtual __fastcall int GetItemIndex();
```

Description

GetItemIndex is the protected read implementation of the ItemIndex property. It returns the index of the first selected item in the list box.

The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1.

See Also

ItemIndex

29.1.14.5.18 TCustomListBox.GetSelCount Method

Returns the number of selected items.

Pascal

```
function GetSelCount: Integer; override;
```

C++

```
virtual __fastcall int GetSelCount();
```

Description

GetSelCount is the protected read implementation of the SelCount property.

See Also

SelCount

29.1.14.5.19 TCustomListBox.GetSelected Method

Indicates whether a particular item is selected.

Pascal

```
function GetSelected(Index: Integer): Boolean;
```

C++

```
__fastcall Boolean GetSelected(int Index);
```

Description

GetSelected is the protected read implementation of the Selected (see page 2350) property. It returns true if the item specified by Index is selected, false if it is not.

29.1.14.5.20 TCustomListBox.InternalGetItemData Method

Retrieves the data associated with an item in the list box.

Pascal

```
function InternalGetItemData(Index: Integer): TCustomLongData; dynamic;
```

C++

```
__fastcall TCustomLongData InternalGetItemData(int Index);
```

Description

InternalGetItemData is the low-level protected method for fetching the data associated with an item in the list box. It retrieves a reference pointer to the object associated with the specified item, as an integer.

Index is the index of the item whose data is to be fetched.

See Also

GetItemData (see page 2327)

29.1.14.5.21 TCustomListBox.InternalSetItemData Method

Associates an integer with a specified item in the list box.

Pascal

```
procedure InternalSetItemData(Index: Integer; AData: TCustomLongData); dynamic;
```

C++

```
__fastcall InternalSetItemData(int Index, TCustomLongData AData);
```

Description

InternalSetItemData is the low-level protected method for associating data with an item in the list box. It associates the item that has the index specified by Index with the integer specified by AData.

See Also

SetItemData (see page 2334)

29.1.14.5.22 TCustomListBox.ItemAtPos Method

Returns the index of the list box item indicated by the coordinates of a point on the control.

Pascal

```
function ItemAtPos(Pos: TPoint; Existing: Boolean): Integer;
```

C++

```
__fastcall int ItemAtPos(TPoint Pos, Boolean Existing);
```

Description

Use ItemAtPos to detect if an item exists at a particular point in the control.

The Pos (see page 3720) parameter is the point in the control in window coordinates. If Pos (see page 3720) is beyond the last item in the list box, the value of the Existing variable determines the returned value. If Existing is set to true, ItemAtPos returns -1, indicating that no item exists at that point. If Existing is set to false, ItemAtPos returns the index of the last item in the list box plus one.

C++ Examples:

```
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
```

```
  the OnMouseUp event handler for the list box.  The following
  code fills a list box with the names of all components on the
  form when the user clicks the button. References to the
  components themselves are inserted along with the names. The
  components are all inserted at the front of the list, so that
  the last component added to the form is the first component
  in the list.  When the user right-clicks the name of an
  object in the list, the component's coordinates are displayed
  on the status bar. Note that because we are using the right-
  click, the item need not be selected.
  */
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    for (int i = 0; i < ComponentCount; i++)
      ListBox1->Items->InsertObject(0,
                                    Components[i]->Name,
                                    dynamic_cast<TObject *>(Components[i]));
  }

  void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
        TShiftState Shift, int X, int Y)
  {
    if (Button == mbRight)
    {
      TClass ClassRef;
      int Index = ListBox1->ItemAtPos(Point(X,Y), true);
      // only components that are controls have a position
      // make sure the component is a control
      for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
           ClassRef != NULL;
           ClassRef = ClassRef->ClassParent())
        if (String(ClassRef->ClassName()) == "TControl")
        {
          TControl *TheObject = dynamic_cast<TControl *>(ListBox1->Items->Objects[Index]);
          StatusBar1->SimpleText =
            TheObject->Name + " is at (" +
            IntToStr(TheObject->Left) + ", " +
            IntToStr(TheObject->Top) + ")";
          break;
        }
      if (ClassRef == NULL) // if it wasn't a control
        MessageBeep(0);
    }
  }
```

Delphi Examples:

```
  {
  For the following example, add a button, a status bar, and a
  list box to the form. Set the SimplePanel property of the
  status bar to true, using the object inspector. Also, populate
  the OnMouseUp event handler for the list box.  The following
  code fills a list box with the names of all components on the
  form when the user clicks the button. References to the
  components themselves are inserted along with the names. The
  components are all inserted at the front of the list, so that
  the last component added to the form is the first component
  in the list.  When the user right-clicks the name of an
  object in the list, the component's coordinates are displayed
  on the status bar. Note that because we are using the right-
  click, the item need not be selected.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I: Integer;
  begin
    for I := 0 to Form1.ComponentCount-1 do
```

```
      ListBox1.Items.InsertObject(
        0, Form1.Components[I].Name,
        Form1.Components[I] as TObject);
  end;

  procedure TForm1.ListBox1MouseUp(
    Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X,Y: integer);
  var
    APoint: TPoint;
    Index: integer;
    TheObject: TControl;
  begin
    if Button = mbRight then
    begin
    APoint.X := X;
    APoint.Y := Y;
    Index := ListBox1.ItemAtPos(APoint, True);
    if (ListBox1.Items.Objects[Index] is TControl) then
    begin
      TheObject :=
        (ListBox1.Items.Objects[Index] as TControl);
      StatusBar1.SimpleText := TheObject.Name + ' is at (' +
                               IntToStr(TheObject.Left) + ', ' +
                               IntToStr(TheObject.Top) + ') ';
    end
    else
      Beep;
    end;
  end;
```

See Also

ItemIndex

Items (see page 2346)

29.1.14.5.23 TCustomListBox.ItemRect Method

Returns the rectangle that surrounds the item specified in the Item parameter.

Pascal

```
function ItemRect(Index: Integer): TRect;
```

C++

```
__fastcall TRect ItemRect(int Index);
```

Description

Use ItemRect to get the coordinates of a particular item in the list box. For example, ItemRect is used internally by the ItemAtPos (see page 2329) method.

The Item parameter is the ItemIndex of the item whose position is queried.

C++ Examples:

```
/*
This example uses a list box on a form. When the user clicks
one of the items in the list box, a beep occurs if the mouse
is in the first half of the item. A similar technique can be
used to detect "hot" regions in an owner-draw list box:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Hello");
```

```
  ListBox1->Items->Add("New");
  ListBox1->Items->Add("World");
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  TRect ItemBounds;
  if (Button == mbLeft)
  {
    ItemBounds = ListBox1->ItemRect(ListBox1->ItemIndex);
    if (Y > ItemBounds.Top &&
        Y < ItemBounds.Bottom &&
        X > ItemBounds.Left &&
        X < (ItemBounds.Left + ItemBounds.Right)/2)
      MessageBeep(0);
  }
}
```

Delphi Examples:

```
{
This example uses a list box on a form. When the user clicks
one of the items in the list box, a beep occurs if the mouse
is in the first half of the item. A similar technique can be
used to detect "hot" regions in an owner-draw list box:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with ListBox1 do
  begin
    Items.Add('Hello');
    Items.Add('New');
    Items.Add('World');
  end;
end;

procedure TForm1.ListBox1MouseUp (Sender: TObject; Button: TMouseButton; Shift: TShiftState;
X, Y: Integer);
var
  ListBoxItem: TRect;
begin
  if Button = mbLeft then
  begin
    ListBoxItem := ListBox1.ItemRect(ListBox1.ItemIndex);
    if (Y > ListBoxItem.Top) and
       (Y < ListBoxItem.Bottom) and
       (X > ListBoxItem.Left) and
       (X < (ListBoxItem.Left + ListBoxItem.Right) div 2) then
      Beep;
  end;
 end;
```

See Also

ItemAtPos (see page 2329)

ItemIndex

29.1.14.5.24 TCustomListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete (see page 2340) property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress

29.1.14.5.25 TCustomListBox.LoadRecreateItems Method

Pascal

```
procedure LoadRecreateItems(RecreateItems: TStrings); virtual;
```

C++

```
virtual __fastcall LoadRecreateItems(TStrings RecreateItems);
```

Description

This is LoadRecreateItems, a member of class TCustomListBox.

29.1.14.5.26 TCustomListBox.MeasureItem Method

Generates an OnMeasureItem (see page 2359) event.

Pascal

```
procedure MeasureItem(Index: Integer; var Height: Integer); virtual;
```

C++

```
virtual __fastcall MeasureItem(int Index, int Height);
```

Description

MeasureItem is called whenever a visual aspect of a variable owner-draw list box changes and the value of the Style (see page 2353) property is csOwnerDrawVariable.

Before drawing its items, a variable owner-draw list box calls MeasureItem once for each visible item, passing the index of the item to measure, and the default height of the item. Since Height is passed by reference (a var parameter), MeasureItem can increase or reduce the height of each item as needed.

By default, the MeasureItem method does nothing except call any event handler attached to the OnMeasureItem (see page 2359) event. Override MeasureItem to change or add functionality to the default behavior.

See Also

DrawItem (see page 2326)

ItemHeight (see page 2346)

ItemIndex

OnDrawItem (see page 2357)

OnMeasureItem (see page 2359)

Style (see page 2353)

29.1.14.5.27 TCustomListBox.ResetContent Method

Removes all of the items from a list box.

Pascal

```
procedure ResetContent; dynamic;
```

C++

```
__fastcall ResetContent();
```

Description

ResetContent is used to remove the items from the list box. ResetContent is used, for example, by the Clear (see page 2321) method.

See Also

Clear (see page 2321)

29.1.14.5.28 TCustomListBox.SaveRecreateItems Method

Pascal

```
procedure SaveRecreateItems(RecreateItems: TStrings); virtual;
```

C++

```
virtual __fastcall SaveRecreateItems(TStrings RecreateItems);
```

Description

This is SaveRecreateItems, a member of class TCustomListBox.

29.1.14.5.29 TCustomListBox.SelectAll Method

Selects the entire block of text in the list box.

Pascal

```
procedure SelectAll; override;
```

C++

```
virtual __fastcall SelectAll();
```

Description

Use SelectAll to select the entire block of text in the list box. To select only part of the text, use the SelStart and SelLength properties.

29.1.14.5.30 TCustomListBox.SetItemData Method

Sets the 32-bit value associated with the specified item in a list box.

Pascal

```
procedure SetItemData(Index: Integer; AData: TCustomLongData); dynamic;
```

C++

```
__fastcall SetItemData(int Index, TCustomLongData AData);
```

Description

Use SetItemData to set the data associated with a particular item in a list box. This value can be displayed as that list box item, or it can be a value (such as a pointer) represented by the list box item.

See Also

GetItemData (see page 2327)

29.1.14.5.31 TCustomListBox.SetItemIndex Method

Gives focus to the item with a specified index.

Pascal

```
procedure SetItemIndex(const Value: Integer); override;
```

C++

```
virtual __fastcall SetItemIndex(const int Value);
```

Description

SetItemIndex is the protected write implementation for the ItemIndex property. Value is the index of the item that should receive focus.

See Also

ItemIndex

29.1.14.5.32 TCustomListBox.SetMultiSelect Method

Sets the MultiSelect property.

Pascal

```
procedure SetMultiSelect(Value: Boolean); override;
```

C++

```
virtual __fastcall SetMultiSelect(Boolean Value);
```

Description

SetMultiSelect is the protected write implementation for the MultiSelect property. Value is true if the list box should allow more than one item to be selected, false if only one item can be selected at a time.

See Also

MultiSelect

29.1.14.5.33 TCustomListBox.WndProc Method

Handles Windows messages.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc overrides the inherited WndProc to provide specialized responses to messages that allows the list box to handle auto

drag mode itself. Then it calls the inherited WndProc to handle all other messages.

When overriding the WndProc method, be sure to call the inherited WndProc at the end to dispatch any other messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/

29.1.14.6 TCustomListBox Properties

The properties of the TCustomListBox class are listed here.

Protected Properties

	Name	Description
	BorderStyle (see page 2341)	Determines whether the list box has a border.
	Columns (see page 2344)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	ExtendedSelect (see page 2345)	Determines if the user can select a sequential range of items in the list box.
	IntegralHeight (see page 2345)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2346)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 2349)	Determines where a control looks for its color information.
	Sorted (see page 2352)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2353)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 2354)	Specifies the size of the tabs in the list box.

Public Properties

	Name	Description
	AutoComplete (see page 2340)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2341)	Specifies the delay between a key press and an attempt to autocomplete the field.
R	Canvas (see page 2341)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2357) event of an owner-draw list box.
	Count (see page 2344)	Indicates the number of items in the list box.
	Items (see page 2346)	Contains the strings that appear in the list box.
	ScrollWidth (see page 2349)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	Selected (see page 2350)	Indicates whether a particular item is selected.
	TopIndex (see page 2354)	Specifies the index number of the item that appears at the top of the list box.

Published Properties

	Name	Description
	TabStop (see page 2354)	Determines if the user can tab to a control.

29.1.14.6.1 TCustomListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

29.1.14.6.2 TCustomListBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2340) is true.

See Also

AutoComplete (see page 2340)

29.1.14.6.3 TCustomListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D

29.1.14.6.4 TCustomListBox.Canvas Property

Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2357) event of an owner-draw list box.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Canvas is only useful for applications that control the drawing of list box items, that is, for owner-draw list boxes. Canvas is used to draw graphical images that can be used as items in a list box.

By default a TControlCanvas object is created for the Canvas property in the list box constructor. To create an owner-draw list box that uses a canvas, set the Style (see page 2353) property accordingly.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = (dynamic_cast<TListBox *>(Control))->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
      pBitmap,
      Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TListBox *myListBox;
```

```
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TListBox")
  {
    myListBox = dynamic_cast<TListBox *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myListBox->Canvas->MoveTo(myListBox->ClientRect.Left, myListBox->ClientRect.Top);
    myListBox->Canvas->LineTo(myListBox->ClientRect.Right, myListBox->ClientRect.Bottom);
    myListBox = NULL;
  }
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
  ListBox1.Items.AddObject('Butterfly', bitmap2);
end;

procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
TOwnerDrawState);
var
  Bitmap: TBitmap;      { temporary variable for the item's bitmap }
  Offset: Integer;      { text offset width }
begin
  Bitmap := TBitmap.Create;
  with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
  begin
    FillRect(Rect);       { clear the rectangle }
    Offset := 2;          { provide default offset }
    Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
    if Bitmap <> nil then
    begin
      BrushCopy(
        Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
        Bitmap,
        Bounds(0, 0, Bitmap.Width, Bitmap.Height),
        clRed);  {render bitmap}
      Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
    end;
    TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
text }
  end;
end;
```

```
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TListBox) then
  begin
    myListBox:= (ListBox1.Items.Objects[Index] as TListBox);
    with myListBox.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myListBox.Canvas.MoveTo(Left, Top);
      myListBox.Canvas.LineTo(Right, Bottom);
    end;
  myListBox:= nil;
  end;
```

Style (see page 2353)

TCanvas

TControlCanvas

29.1.14.6.5 TCustomListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 2346)

Width

29.1.14.6.6 TCustomListBox.Count Property

Indicates the number of items in the list box.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of items in the list box. You can only set Count when the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw, in which case you must set this property.

See Also

Style (see page 2353)

29.1.14.6.7 TCustomListBox.ExtendedSelect Property

Determines if the user can select a sequential range of items in the list box.

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

ExtendedSelect works with the MultiSelect property. If ExtendedSelect is true and MultiSelect is true, the user can select an item then hold down the Shift key and select another and all the items in between the two selected items also become selected.

If the user doesn't hold down the Shift or Ctrl key while selecting a second item, the first selected item becomes unselected— in other words, the user must use the Ctrl key to select multiple noncontiguous items, or the Shift key to select a range of items.

If ExtendedSelect is false and MultiSelect is true, the user can select multiple items without using the Shift or Ctrl key, but they can't select a range of items in one operation.

If MultiSelect is false, the setting of ExtendedSelect has no effect as the user will not be able to select more than one item at a time in the list box.

See Also

MultiSelect

29.1.14.6.8 TCustomListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style (see page 2353) property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight (see page 2346) property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style (see page 2353) property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

Style (see page 2353)

Using TDBListBox and TDBComboBox

29.1.14.6.9 TCustomListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style (see page 2353) property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight (see page 2345) property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style (see page 2353) property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

OnMeasureItem (see page 2359)

Style (see page 2353)

Using TDBListBox and TDBComboBox

29.1.14.6.10 TCustomListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

29.1.14.6.11 TCustomListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

29.1.14.6.12 TCustomListBox.ScrollWidth Property

Specifies the width, in pixels, by which the list box can scroll horizontally.

Pascal

```
property ScrollWidth: Integer;
```

C++

```
__property int ScrollWidth;
```

Description

Use ScrollWidth to get or set the logical width of the list box. When ScrollWidth is greater than the client width of the list box, the list box gets a horizontal scroll bar. When ScrollWidth is less than or equal to ClientWidth, the horizontal scroll bar disappears.

See Also

Columns (see page 2344)

ClientWidth

29.1.14.6.13 TCustomListBox.Selected Property

Indicates whether a particular item is selected.

Pascal

```
property Selected [Index: Integer]: Boolean;
```

C++

```
__property Boolean Selected[int Index];
```

Description

Use Selected to query the state of a particular item in the list box. If the item specified by the Index parameter is selected in the list box, the value of the Selected property is true. If the specified item is not selected, Selected is false. Set Selected to change the currently selected item.

The Index parameter is the item referenced by its position in the list box, with the first item having an Index value of 0.

An item is selected when the user highlights it. More than one item in the list box can be selected by setting the MultiSelect property to true. In this case, the Selected item is the one that has focus when the list box has input focus.

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          String("File " + FileListBox1->Items->Strings[i] + "not found").t_str(),
```

```
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(AnsiString(FileListBox1->Items->Strings[i]).t_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(int(statbuf.st_size)));
      fclose(F);
    }
  }
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.

SelCount

29.1.14.6.14 TCustomListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
}
```

Delphi Examples:

```
{
```

```
  This example uses an edit box, a list box, and two buttons
  on a form. The buttons are named Add and Sort. When the user
  clicks the Add button, the text in the edit box is added to
  the list in the list box. Before the user clicks the sort
  button, any new items are added to the end of the list.
  After the user clicks the Sort button, the list in the list
  box is sorted and remains sorted, even if additional strings
  are added.  If the user clicks the sort button again, the
  list box remains sorted, but any new strings are again added
  to the end of the list.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  procedure TForm1.AddClick(Sender: TObject);
  begin
    ListBox1.Items.Add(Edit1.Text);
  end;

  procedure TForm1.SortClick(Sender: TObject);
  begin
    ListBox1.Sorted := True;
  end;
```

Items (see page 2346)

Style (see page 2353)

29.1.14.6.15 TCustomListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

OnDataFind (see page 2356)

OnDataObject (see page 2357)

29.1.14.6.16 TCustomListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.14.6.17 TCustomListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

29.1.14.6.18 TCustomListBox.TopIndex Property

Specifies the index number of the item that appears at the top of the list box.

Pascal

```
property TopIndex: Integer;
```

C++

```
__property int TopIndex;
```

Description

Use TopIndex property to find or set the first item displayed at the top of the list box. TopIndex can be used, for example, to change the topmost item to a different item in the list.

C++ Examples:

```
/*
The following example uses a list box containing a list of
strings, a button, and an edit box on a form. When the user
runs the application and clicks the button, the third item
in the list becomes the first item, and the index value of
that item appears in the edit box. The index value displayed
is 2, indicating the third item in the list (the first item
in the list has an index value of 0):
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListBox1->TopIndex = 2;
  Edit1->Text = IntToStr(ListBox1->TopIndex);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int Number = 1; Number <= 20; Number++)
    ListBox1->Items->Add("Item " + IntToStr(Number));
}
```

Delphi Examples:

```
{
The following example uses a list box containing a list of
strings, a button, and an edit box on a form. When the user
runs the application and clicks the button, the third item
in the list becomes the first item, and the index value of
that item appears in the edit box. The index value displayed
is 2, indicating the third item in the list (the first item
in the list has an index value of 0):
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.TopIndex := 2;
  Edit1.Text := IntToStr(ListBox1.TopIndex);
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  Number: Integer;
begin
  for Number := 1 to 20 do
    ListBox1.Items.Add('Item ' + IntToStr(Number));
end;
```

29.1.14.7 TCustomListBox Events

The events of the TCustomListBox class are listed here.

Protected Events

	Name	Description
	OnData (see page 2356)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2356)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2357)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDrawItem (see page 2357)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnMeasureItem (see page 2359)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

29.1.14.7.1 TCustomListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataFind (see page 2356)

OnDataObject (see page 2357)

Style (see page 2353)

Count (see page 2344)

29.1.14.7.2 TCustomListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style (see page 2353) property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 2356)

OnDataObject (see page 2357)

Style (see page 2353)

Count (see page 2344)

29.1.14.7.3 TCustomListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

See Also

OnData (see page 2356)

OnDataFind (see page 2356)

Style (see page 2353)

Count (see page 2344)

29.1.14.7.4 TCustomListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style (see page 2353) values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight (see page 2346) property for fixed owner-draw list boxes or by the response to the OnMeasureItem (see page 2359) event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
```

```
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = (dynamic_cast<TListBox *>(Control))->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
      pBitmap,
      Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
  ListBox1.Items.AddObject('Butterfly', bitmap2);
end;

procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
TOwnerDrawState);
```

```
var
  Bitmap: TBitmap;      { temporary variable for the item's bitmap }
  Offset: Integer;      { text offset width }
begin
  Bitmap := TBitmap.Create;
  with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
  begin
    FillRect(Rect);       { clear the rectangle }
    Offset := 2;          { provide default offset }
    Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
    if Bitmap <> nil then
    begin
      BrushCopy(
        Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
        Bitmap,
        Bounds(0, 0, Bitmap.Width, Bitmap.Height),
        clRed);  {render bitmap}
      Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
    end;
    TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
text }
  end;
end;
```

29.1.14.7.5 TCustomListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style (see page 2353) property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent (see page 2918) which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the

control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem (see page 2357) event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
      int &Height)
{
  Graphics::TBitmap *bitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (bitmap && bitmap->Height > Height)
    Height = bitmap->Height;
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}

#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Making these static keeps them around until the project terminates.
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);
  bitmap0->LoadFromFile("../littleB_64.bmp");
//  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Butterfly", bitmap0);
  ImageList1->GetBitmap(3, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1); // no bitmap, see if it leaves this height at
64.
  ImageList1->GetBitmap(4, bitmap2);
  ListBox1->Items->AddObject("Sunflower", bitmap2); // no bitmap, see if it leaves this height
at 64.
```

```

29.1.15 TCustomMemo Class

TCustomMemo is the base type for memo components, which are multiline edit boxes, including TMemo (see page 2649) and TDBMemo.

Class Hierarchy

Pascal

```
TCustomMemo = class(TCustomEdit);
```

C++

```
class TCustomMemo : public TCustomEdit;
```

File

StdCtrls

Description

TCustomMemo introduces new properties and methods to expand the capabilities of TCustomEdit (see page 2263) for handling multiline edit boxes.

Do not create instances of TCustomMemo. Use TCustomMemo as a base class when declaring control objects that implement a multiline edit control. Properties and methods of TCustomMemo provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TDBMemo

TMemo (see page 2649)

29.1.15.1 TCustomMemo Members

The following tables list the members exposed by TCustomMemo.

Protected Events

	Name	Description
	OnChange (see page 2299)	Occurs when the text for the edit control may have changed.

Protected Methods

	Name	Description
	Change (see page 2266)	Generates an OnChange (see page 2299) event.
	CreateParams (see page 2364)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateWindowHandle (see page 2365)	Creates a window based on the window-creation parameter record.
	CreateWnd (see page 2270)	Creates a Windows control corresponding to the edit control.
	DestroyWnd (see page 2273)	Destroys the Windows control that corresponds to the edit control.
	DoSetMaxLength (see page 2273)	Sets the MaxLength (see page 2286) property.
	DoSetTextHint (see page 2273)	This is DoSetTextHint, a member of class TCustomEdit.
	GetCaretPos (see page 2365)	Returns the value of the CaretPos (see page 2368) property.
	GetSelLength (see page 2274)	Returns the SelLength (see page 2289) property.
	GetSelStart (see page 2274)	Returns the SelStart (see page 2293) property.
	GetSelText (see page 2275)	Returns the SelText (see page 2296) property.
	KeyPress (see page 2366)	Ensures that return characters are not entered into the text when WantReturns (see page 2372) is false.
	Loaded (see page 2366)	Initializes the memo control when it is first loaded into memory.
	SetAlignment (see page 2279)	Sets the Alignment (see page 2283) property.
	SetAutoSize (see page 2279)	Sets the AutoSize (see page 2284) property.
	SetCaretPos (see page 2366)	Sets the CaretPos (see page 2368) property.
	SetLines (see page 2367)	Sets the Lines (see page 2368) property.
	SetScrollBars (see page 2367)	Sets the ScrollBars (see page 2369) property.
	SetSelLength (see page 2280)	Sets the SelLength (see page 2289) property.
	SetSelStart (see page 2280)	Sets the SelStart (see page 2293) property.
	SetWordWrap (see page 2367)	Sets the WordWrap (see page 2372) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2284)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2284)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2285)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2286)	Determines the case of the text within the edit control.
	HideSelection (see page 2286)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2286)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2287)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2288)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2288)	Determines where a control looks for its color information.
	PasswordChar (see page 2289)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	ScrollBars (see page 2369)	Determines whether the memo control has scroll bars.
	WantReturns (see page 2372)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2372)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2372)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Public Methods

	Name	Description
	Clear (see page 2267)	Deletes all text from the edit control.
	ClearSelection (see page 2267)	Removes the selected text from the edit control.
	ClearUndo (see page 2268)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2268)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2363)	Creates and initializes an instance of TCustomMemo (see page 2361).

	CutToClipboard (see page 2271)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 2272)	Provides message handling for all messages that the control does not fully process itself.
V	Destroy (see page 2364)	Destroys an instance of TCustomMemo (see page 2361).
V	GetControlsAlignment (see page 2274)	Indicates how text is aligned within the control.
V	GetSelTextBuf (see page 2275)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2276)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2278)	Selects all text in the edit control.
	SetSelText (see page 2281)	Sets the SelText (see page 2296) property.
	SetSelTextBuf (see page 2281)	Replaces the selected text with a null-terminated string.
	Undo (see page 2282)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	Alignment (see page 2283)	Determines how the text is aligned within the text edit control.
R	CanUndo (see page 2285)	Indicates whether the edit control contains changes that can be backed out.
	CaretPos (see page 2368)	Indicates the position of the caret in the client area of the memo.
	Lines (see page 2368)	Contains the individual lines of text in the memo control.
	Modified (see page 2287)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2289)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2289)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2293)	Specifies the position of the first selected character in the text.
	SelText (see page 2296)	Specifies the selected portion of the edit control's text.
	Text (see page 2297)	Contains a text string associated with the control.
	TextHint (see page 2299)	A hint or message to be displayed when the Text (see page 2297) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2297)	Determines if the user can tab to a control.

29.1.15.2 TCustomMemo.Create Constructor

Creates and initializes an instance of TCustomMemo (see page 2361).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomMemo(TComponent * AOwner);
```

Description

Call Create to instantiate a TCustomMemo (see page 2361) object.

AOwner is the component, typically the form, that is responsible for freeing the memo object. This becomes the value of the Owner property.

Derived objects that override the Create method should call the inherited Create before making any additional initializations.

See Also

Owner

29.1.15.3 TCustomMemo.Destroy Destructor

Destroys an instance of TCustomMemo (see page 2361).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomMemo();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TCustomMemo (see page 2361) reference is not nil, and only then calls Destroy.

Destroy frees the TStrings object that implements the Lines (see page 2368) property before calling the inherited destructor.

See Also

System::TObject::Free (see page 3382)

Lines (see page 2368)

TStrings

29.1.15.4 TCustomMemo Methods

The methods of the TCustomMemo class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2364)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateWindowHandle (see page 2365)	Creates a window based on the window-creation parameter record.
	GetCaretPos (see page 2365)	Returns the value of the CaretPos (see page 2368) property.
	KeyPress (see page 2366)	Ensures that return characters are not entered into the text when WantReturns (see page 2372) is false.
	Loaded (see page 2366)	Initializes the memo control when it is first loaded into memory.
	SetCaretPos (see page 2366)	Sets the CaretPos (see page 2368) property.
	SetLines (see page 2367)	Sets the Lines (see page 2368) property.
	SetScrollBars (see page 2367)	Sets the ScrollBars (see page 2369) property.
	SetWordWrap (see page 2367)	Sets the WordWrap (see page 2372) property.

29.1.15.4.1 TCustomMemo.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2270) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 2365). TCustomMemo (see page 2361) overrides the inherited method to specify a scrollable multiline edit control.

The Params parameter is updated to reflect the current values of the Alignment (see page 2283), ScrollBars (see page 2369), and WordWrap (see page 2372) properties, in addition to the BorderStyle (see page 2285), HideSelection (see page 2286), PasswordChar (see page 2289), and ReadOnly (see page 2289) properties that the inherited method specifies.

See Also

Alignment

BorderStyle (see page 2285)

CreateWindowHandle (see page 2365)

CreateWnd (see page 2270)

HideSelection (see page 2286)

PasswordChar (see page 2289)

ReadOnly (see page 2289)

ScrollBars (see page 2369)

WordWrap (see page 2372)

29.1.15.4.2 TCustomMemo.CreateWindowHandle Method

Creates a window based on the window-creation parameter record.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

The CreateWnd (see page 2270) method calls CreateWindowHandle to create the edit control window once it has been specified in the window-creation parameters. CreateWindowHandle creates the window by calling the CreateWindowEx API function, passing parameters from the record passed in the Params parameter. CreateWindowHandle overrides the inherited method to interpret the Caption in Params as the initial text rather than as the window caption.

See Also

CreateParams (see page 2364)

CreateWnd (see page 2270)

29.1.15.4.3 TCustomMemo.GetCaretPos Method

Returns the value of the CaretPos (see page 2368) property.

Pascal

```
function GetCaretPos: TPoint; virtual;
```

C++

```
virtual __fastcall TPoint GetCaretPos();
```

Description

CaretPos (see page 2368) represents the coordinates of the cursor. GetCaretPos is the protected implementation of the CaretPos (see page 2368) property. Override this method to change the way the caret position is computed.

See Also

CaretPos (see page 2368)

29.1.15.4.4 TCustomMemo.KeyPress Method

Ensures that return characters are not entered into the text when WantReturns (see page 2372) is false.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the user presses a key. After calling the inherited KeyPress, which calls the OnKeyPress event handler, KeyPress discards return characters when WantReturns (see page 2372) is false.

See Also

WantReturns (see page 2372)

29.1.15.4.5 TCustomMemo.Loaded Method

Initializes the memo control when it is first loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Loaded overrides the inherited method so that the Modified (see page 2287) property is set to false when the form containing the memo is first loaded into memory. Derived classes can override the Loaded method to perform additional initializations after the memo's form is loaded.

See Also

Modified (see page 2287)

29.1.15.4.6 TCustomMemo.SetCaretPos Method

Sets the CaretPos (see page 2368) property.

Pascal

```
procedure SetCaretPos(const Value: TPoint); virtual;
```

C++

```
virtual __fastcall SetCaretPos(const TPoint Value);
```

Description

SetCaretPos is the property write access method for the CaretPos (see page 2368) property. The CaretPos (see page 2368) property returns the coordinates of the cursor. SetCaretPos sets the cursor position to Value.

See Also

CaretPos (see page 2368)

29.1.15.4.7 TCustomMemo.SetLines Method

Sets the Lines (see page 2368) property.

Pascal

```
procedure SetLines(Value: TStrings);
```

C++

```
__fastcall SetLines(TStrings Value);
```

Description

SetLines is the protected write implementation for the Lines (see page 2368) property.

SetLines is exposed as a protected method so derived classes can customize their implementation of the Lines (see page 2368) property.

See Also

Lines (see page 2368)

29.1.15.4.8 TCustomMemo.SetScrollBars Method

Sets the ScrollBars (see page 2369) property.

Pascal

```
procedure SetScrollBars(Value: TScrollStyle);
```

C++

```
__fastcall SetScrollBars(TScrollStyle Value);
```

Description

SetScrollBars is the property access method for the ScrollBars (see page 2369) property.

SetScrollBars is exposed as a protected method so derived classes can customize their implementation of the ScrollBars (see page 2369) property.

See Also

ScrollBars (see page 2369)

29.1.15.4.9 TCustomMemo.SetWordWrap Method

Sets the WordWrap (see page 2372) property.

Pascal

```
procedure SetWordWrap(Value: Boolean);
```

C++

```
__fastcall SetWordWrap(Boolean Value);
```

Description

SetWordWrap is the property access method for the WordWrap (see page 2372) property.

See Also

WordWrap (see page 2372)

29.1.15.5 TCustomMemo Properties

The properties of the TCustomMemo class are listed here.

Protected Properties

	Name	Description
	ScrollBars (see page 2369)	Determines whether the memo control has scroll bars.
	WantReturns (see page 2372)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2372)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2372)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Public Properties

	Name	Description
	CaretPos (see page 2368)	Indicates the position of the caret in the client area of the memo.
	Lines (see page 2368)	Contains the individual lines of text in the memo control.

29.1.15.5.1 TCustomMemo.CaretPos Property

Indicates the position of the caret in the client area of the memo.

Pascal

```
property CaretPos: TPoint;
```

C++

```
__property TPoint CaretPos;
```

Description

Use CaretPos to determine the coordinates of the cursor. CaretPos defines a location onscreen, in characters, with the origin in the top left corner of the memo. X specifies the horizontal coordinate of the point, Y specifies the vertical coordinate.

To determine the position of the caret in terms of characters of text only (rather than X/Y location), use the SelStart (see page 2293) property.

See Also

ClientRect

ClientOrigin

SelStart (see page 2293)

29.1.15.5.2 TCustomMemo.Lines Property

Contains the individual lines of text in the memo control.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Use Lines to manipulate text in an memo control on a line-by-line basis. Lines is a TStrings object, so the TStrings methods may be used for Lines to perform manipulations such as counting the lines of text, adding new lines, deleting lines, or replacing lines with new text.

To work with all the text at once, use the Text (see page 2297) property. To manipulate individual lines of text, the Lines property works better.

Note: Although Lines is implemented as a TStrings descendant, it does not implement the support for associating objects with the strings in the list.

C++ Examples:

```
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.LoadFromFile('readme.txt');
  Caption:= Memo1.Lines[4];
end;
```

See Also

TStrings

SelText (see page 2296)

SetLines (see page 2367)

Text

WordWrap (see page 2372)

29.1.15.5.3 TCustomMemo.ScrollBars Property

Determines whether the memo control has scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give a multiline edit control horizontal or vertical scroll bars. ScrollBars can take one of the following values:

Value	Meaning
ssNone	The control has no scroll bars.
ssHorizontal	The control has a single scroll bar on the bottom edge.
ssVertical	The control has a single scroll bar on the right edge.
ssBoth	The control has a scroll bar on both the bottom and right edges.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
```

```
  style of the RichEdit. Toggling the Check Box turns
  HideScrollBars on and off.  Clicking the button loads the
  Rich Edit with a large amount of contiguous text.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I: Integer;
  begin
    RichEdit1.Lines.Clear;
    for I := 0 to 500 do
    begin
      RichEdit1.Text :=
        RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
      if (i mod 4 = 0) then
        RichEdit1.Text := RichEdit1.Text + Chr(13);
    end;
    // move text cursor to top of editend;
    RichEdit1.SelStart := 0;
  end;

  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    RichEdit1.HideScrollbars := CheckBox1.Checked;
  end;

  procedure TForm1.RadioGroup1Click(Sender: TObject);
  const
    ScrollBarA: array[0..3] of TScrollStyle = (
      ssBoth,
      ssHorizontal,
      ssNone,
      ssVertical);
  begin
    RichEdit1.ScrollBars :=
      ScrollBarA[RadioGroup1.ItemIndex];
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    with RadioGroup1, Items do
    begin
      Caption := 'Scroll Bars';
      Clear;
      Add('ssBoth');
      Add('ssHorizontal');
      Add('ssNone');
      Add('ssVertical');
    end;
    with CheckBox1 do
    begin
      Caption := 'HideScrollBars';
      Checked := True;
    end;
    Button1.Caption := 'Loaded';
    RichEdit1.Text := 'Just a little text.';
    RichEdit1.WordWrap := False;
  end;
```

Displaying and Editing Text in a Memo Control

29.1.15.5.4 TCustomMemo.WantReturns Property

Determines whether the user can insert return characters into the text.

Pascal

```
property WantReturns: Boolean;
```

C++

```
__property Boolean WantReturns;
```

Description

Set WantReturns to true to allow users to enter return characters into the text. Set WantReturns to false to allow the form to handle return characters instead.

For example, in a form with a default button (such as an OK button) and a memo control, if WantReturns is false, pressing Enter chooses the default button. If WantReturns is true, pressing Enter inserts a return character in the text.

Note: If WantReturns is false, users can still enter return characters into the text by pressing Ctrl+Enter.

See Also

Text

WantTabs (see page 2372)

WordWrap (see page 2372)

29.1.15.5.5 TCustomMemo.WantTabs Property

Determines whether the user can insert tab characters into the text.

Pascal

```
property WantTabs: Boolean;
```

C++

```
__property Boolean WantTabs;
```

Description

Set WantTabs to true to allow users to enter tab characters into the text. Set WantTabs to false if you want the tab character to select the next control on the form instead.

Note: If WantTabs is true, users can tab into the edit control, but they can't tab out.

WantReturns (see page 2372)

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

29.1.15.5.6 TCustomMemo.WordWrap Property

Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to make the edit control wrap text at the right margin so it fits in the client area. The wrapping is cosmetic only. The text does not include any return characters that were not explicitly entered. Set WordWrap to false to have the edit control show a separate line only where return characters were explicitly entered into the text.

Note: There should be no use for a horizontal scroll bar if WordWrap is true.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
  // move text cursor to top of editend;
  RichEdit1.SelStart := 0;
end;

procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  RichEdit1.HideScrollbars := CheckBox1.Checked;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
const
  ScrollBarA: array[0..3] of TScrollStyle = (
    ssBoth,
    ssHorizontal,
    ssNone,
    ssVertical);
begin
  RichEdit1.ScrollBars :=
    ScrollBarA[RadioGroup1.ItemIndex];
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with RadioGroup1, Items do
  begin
    Caption := 'Scroll Bars';
    Clear;
    Add('ssBoth');
    Add('ssHorizontal');
    Add('ssNone');
    Add('ssVertical');
  end;
  with CheckBox1 do
  begin
    Caption := 'HideScrollBars';
    Checked := True;
  end;
  Button1.Caption := 'Loaded';
  RichEdit1.Text := 'Just a little text.';
  RichEdit1.WordWrap := False;
end;

Displaying and Editing Text in a Memo Control

29.1.16 TCustomStaticText Class

TCustomStaticText is the base class for TStaticText (see page 2853).

Class Hierarchy

Pascal

```
TCustomStaticText = class(TWinControl);
```

C++

```
class TCustomStaticText : public TWinControl;
```

File

StdCtrls

Description

TCustomStaticText is the base class for TStaticText (see page 2853), a windowed control that displays text on a form. This component functions like TLabel (see page 2522), except that it has a window handle.

TCustomStaticText cannot receive focus or contain other controls.

See Also

TLabel (see page 2522)

TStaticText (see page 2853)

29.1.16.1 TCustomStaticText Members

The following tables list the members exposed by TCustomStaticText.

Protected Methods

	Name	Description
	CreateParams (see page 2376)	Initializes a window-creation parameter data structure.
	Loaded (see page 2377)	Initializes the control after it is loaded from a stream.
	Notification (see page 2377)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2378)	This is SetAutoSize, a member of class TCustomStaticText.

Protected Properties

	Name	Description
	Alignment (see page 2378)	Determines how text is aligned within the component.
	AutoSize (see page 2379)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BorderStyle (see page 2379)	Determines the appearance of the control's border.
	FocusControl (see page 2379)	Links the component with another windowed control.
	ShowAccelChar (see page 2380)	Enables accelerator characters.

	Transparent (see page 2380)	Specifies whether the background of the image obscures objects below the image object.

Public Methods

	Name	Description
	Create (see page 2376)	Creates and initializes a TCustomStaticText (see page 2375) instance.

29.1.16.2 TCustomStaticText.Create Constructor

Creates and initializes a TCustomStaticText (see page 2375) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomStaticText(TComponent * AOwner);
```

Description

Create calls the inherited constructor, then initializes the TCustomStaticText (see page 2375) instance

See Also

autosize (see page 2379)

ControlStyle

ShowAccelChar (see page 2380)

29.1.16.3 TCustomStaticText Methods

The methods of the TCustomStaticText class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2376)	Initializes a window-creation parameter data structure.
	Loaded (see page 2377)	Initializes the control after it is loaded from a stream.
	Notification (see page 2377)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2378)	This is SetAutoSize, a member of class TCustomStaticText.

29.1.16.3.1 TCustomStaticText.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information

needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

29.1.16.3.2 TCustomStaticText.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

29.1.16.3.3 TCustomStaticText.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

Notification

29.1.16.3.4 TCustomStaticText.SetAutoSize Method

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

This is SetAutoSize, a member of class TCustomStaticText.

29.1.16.4 TCustomStaticText Properties

The properties of the TCustomStaticText class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 2378)	Determines how text is aligned within the component.
	AutoSize (see page 2379)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BorderStyle (see page 2379)	Determines the appearance of the control's border.
	FocusControl (see page 2379)	Links the component with another windowed control.
	ShowAccelChar (see page 2380)	Enables accelerator characters.
	Transparent (see page 2380)	Specifies whether the background of the image obscures objects below the image object.

29.1.16.4.1 TCustomStaticText.Alignment Property

Determines how text is aligned within the component.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

The possible values of Alignment are

Value	Meaning
taLeftJustify	Text is aligned at the left of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is aligned at the right of the control.

See Also

Font

Caption

29.1.16.4.2 TCustomStaticText.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

29.1.16.4.3 TCustomStaticText.BorderStyle Property

Determines the appearance of the control's border.

Pascal

```
property BorderStyle: TStaticBorderStyle;
```

C++

```
__property TStaticBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify the appearance of the border, if any, that appears around the text.

29.1.16.4.4 TCustomStaticText.FocusControl Property

Links the component with another windowed control.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Use the FocusControl property to link the TCustomStaticText (see page 2375) instance with another windowed control. If the text of Caption includes an accelerator key, the component specified by FocusControl receives focus when the accelerator is pressed.

See Also

Caption

FocusControl (see page 2313)

TWinControl

29.1.16.4.5 TCustomStaticText.ShowAccelChar Property

Enables accelerator characters.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

If ShowAccelChar is true, an ampersand in the component's Caption text appears as an underline and makes the character after it into an accelerator key. If ShowAccelChar is false, ampersands appear as ampersands.

See Also

Caption

29.1.16.4.6 TCustomStaticText.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TCustomStaticText (see page 2375) object to show through the background of the image. Set Transparent to false to make the background of the image opaque.

29.1.17 TEdit Class

TEdit is a wrapper for a Windows single-line edit control.

Class Hierarchy

Pascal

```
TEdit = class(TCustomEdit);
```

C++

```
class TEdit : public TCustomEdit;
```

File

StdCtrls

Description

Use a TEdit object to put a standard Windows edit control on a form. Edit controls are used to retrieve text that users type. Edit controls can also display text to the user.

When only displaying text to the user, choose an edit control to allow users to select text and copy it to the Clipboard. Choose a label object if the selection capabilities of an edit control are not needed.

TEdit implements the generic behavior introduced in TCustomEdit (see page 2263). TEdit publishes many of the properties inherited from TCustomEdit (see page 2263), but does not introduce any new behavior. For specialized edit controls, use other descendant classes of TCustomEdit (see page 2263) or derive from it.

Edit Controls

29.1.17.1 TEdit Members

The following tables list the members exposed by TEdit.

Protected Methods

	Name	Description
	Change (see page 2266)	Generates an OnChange (see page 2299) event.
V	CreateParams (see page 2269)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2270)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2270)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2273)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2273)	Sets the MaxLength (see page 2286) property.
V	DoSetTextHint (see page 2273)	This is DoSetTextHint, a member of class TCustomEdit.
V	GetSelLength (see page 2274)	Returns the SelLength (see page 2289) property.
V	GetSelStart (see page 2274)	Returns the SelStart (see page 2293) property.
V	GetSelText (see page 2275)	Returns the SelText (see page 2296) property.
	SetAlignment (see page 2279)	Sets the Alignment (see page 2283) property.
V	SetAutoSize (see page 2279)	Sets the AutoSize (see page 2284) property.
V	SetSelLength (see page 2280)	Sets the SelLength (see page 2289) property.
V	SetSelStart (see page 2280)	Sets the SelStart (see page 2293) property.

Public Methods

	Name	Description
	Clear (see page 2267)	Deletes all text from the edit control.
	ClearSelection (see page 2267)	Removes the selected text from the edit control.
	ClearUndo (see page 2268)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2268)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2265)	Creates an instance of TCustomEdit (see page 2263).
	CutToClipboard (see page 2271)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2272)	Provides message handling for all messages that the control does not fully process itself.
	GetControlsAlignment (see page 2274)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2275)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2276)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2278)	Selects all text in the edit control.
	SetSelText (see page 2281)	Sets the SelText (see page 2296) property.
	SetSelTextBuf (see page 2281)	Replaces the selected text with a null-terminated string.
	Undo (see page 2282)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	CanUndo (see page 2285)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2287)	Indicates whether the user edited the text of the edit control.
	SelLength (see page 2289)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2293)	Specifies the position of the first selected character in the text.
	SelText (see page 2296)	Specifies the selected portion of the edit control's text.

Published Events

	Name	Description
	OnChange (see page 2419)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2419)	Occurs when the user clicks the control.
	OnContextPopup (see page 2421)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2422)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2422)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2425)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2428)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2429)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2430)	Occurs when a control receives the input focus.
	OnExit (see page 2432)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2435)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2438)	Occurs when a key is pressed.
	OnKeyUp (see page 2440)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2441)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2442)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2445)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2445)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2445)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 2447)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2450)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2450)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2385)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2388)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2389)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 2389)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2390)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 2391)	Specifies which edges of the control are beveled.
	BevelInner (see page 2391)	Specifies the cut of the inner bevel.
	BevelKind (see page 2392)	Specifies the control's bevel style.
	BevelOuter (see page 2392)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2392)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2393)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2393)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2394)	Determines the case of the text within the edit control.
	Color (see page 2394)	Specifies the background color of the control.
	Constraints (see page 2395)	Specifies the size constraints for the control.
	Ctl3D (see page 2395)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2396)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2398)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2398)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2398)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2400)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2400)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2402)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2402)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2403)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	MaxLength (see page 2403)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2404)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2404)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2404)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2405)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2405)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2406)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2406)	Determines where a control looks for its font information.
	ParentShowHint (see page 2406)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 2407)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 2407)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2412)	Determines whether the user can change the text of the edit control.

	ShowHint (see page 2413)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2414)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2415)	Determines if the user can tab to a control.
	Text (see page 2415)	Contains a text string associated with the control.
	TextHint (see page 2416)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 2417)	Determines whether the component appears onscreen.

29.1.17.2 TEdit Properties

The properties of the TEdit class are listed here.

Published Properties

	Name	Description
	Align (see page 2385)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2388)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2389)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 2389)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2390)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 2391)	Specifies which edges of the control are beveled.
	BevelInner (see page 2391)	Specifies the cut of the inner bevel.
	BevelKind (see page 2392)	Specifies the control's bevel style.
	BevelOuter (see page 2392)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2392)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2393)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2393)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2394)	Determines the case of the text within the edit control.
	Color (see page 2394)	Specifies the background color of the control.
	Constraints (see page 2395)	Specifies the size constraints for the control.
	Ctl3D (see page 2395)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2396)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2398)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2398)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2398)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2400)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2400)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2402)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2402)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2403)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	MaxLength (see page 2403)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2404)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2404)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2404)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2405)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2405)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 2406)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2406)	Determines where a control looks for its font information.
	ParentShowHint (see page 2406)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 2407)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 2407)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2412)	Determines whether the user can change the text of the edit control.
	ShowHint (see page 2413)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2414)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2415)	Determines if the user can tab to a control.
	Text (see page 2415)	Contains a text string associated with the control.
	TextHint (see page 2416)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 2417)	Determines whether the component appears onscreen.

29.1.17.2.1 TEdit.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
```

```
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
    }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var

Anchors

29.1.17.2.2 TEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control

taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

Displaying and Editing Fields in an Edit Box

29.1.17.2.3 TEdit.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.17.2.4 TEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect: Boolean;
```

C++

```
__property Boolean AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

See Also

SelectAll (see page 2278)

SelLength (see page 2289)

SelStart (see page 2293)

SelText (see page 2296)

SetSelTextBuf (see page 2281)

29.1.17.2.5 TEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

29.1.17.2.6 TEdit.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

29.1.17.2.7 TEdit.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

29.1.17.2.8 TEdit.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

29.1.17.2.9 TEdit.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

29.1.17.2.10 TEdit.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

29.1.17.2.11 TEdit.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

29.1.17.2.12 TEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If

BorderStyle is bsNone, there will be no border.

29.1.17.2.13 TEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

29.1.17.2.14 TEdit.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
```

```
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

29.1.17.2.15 TEdit.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

29.1.17.2.16 TEdit.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

29.1.17.2.17 TEdit.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
```

```
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;

29.1.17.2.18 TEdit.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.17.2.19 TEdit.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.17.2.20 TEdit.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
```

```
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

29.1.17.2.21 TEdit.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.17.2.22 TEdit.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

29.1.17.2.23 TEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

29.1.17.2.24 TEdit.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

SetIme

SetImeCompositionWindow

29.1.17.2.25 TEdit.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

29.1.17.2.26 TEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

29.1.17.2.27 TEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly: Boolean;
```

C++

```
__property Boolean NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

29.1.17.2.28 TEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

Text

29.1.17.2.29 TEdit.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

29.1.17.2.30 TEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.17.2.31 TEdit.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.17.2.32 TEdit.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.17.2.33 TEdit.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

29.1.17.2.34 TEdit.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.17.2.35 TEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar: Char;
```

C++

```
__property Char PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text property reflects the actual characters that are typed.

Text

29.1.17.2.36 TEdit.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
```

```
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
```

```
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and

29.1.17.2.37 TEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then

be manipulated by the application, or copied to the Clipboard.

CopyToClipboard (see page 2268)

GetSelTextBuf (see page 2275)

29.1.17.2.38 TEdit.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

29.1.17.2.39 TEdit.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the

control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

29.1.17.2.40 TEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.17.2.41 TEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
```

```
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                        //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

Caption

29.1.17.2.42 TEdit.TextHint Property

A hint or message to be displayed when the Text property is empty.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

29.1.17.2.43 TEdit.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;

29.1.17.3 TEdit Events

The events of the TEdit class are listed here.

Published Events

	Name	Description
	OnChange (see page 2419)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2419)	Occurs when the user clicks the control.
	OnContextPopup (see page 2421)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2422)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2422)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2425)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2428)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2429)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2430)	Occurs when a control receives the input focus.
	OnExit (see page 2432)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2435)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2438)	Occurs when a key is pressed.
	OnKeyUp (see page 2440)	Occurs when the user releases a key that has been pressed.

	OnMouseActivate (see page 2441)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2442)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2445)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2445)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2445)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2447)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2450)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2450)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.17.3.1 TEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 2266)

Text

29.1.17.3.2 TEdit.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).

- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

29.1.17.3.3 TEdit.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

29.1.17.3.4 TEdit.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

29.1.17.3.5 TEdit.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
```

```
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
```

```
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{

29.1.17.3.9 TEdit.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
```

```
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{

29.1.17.3.10 TEdit.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);

OnEnter

ActiveControl

29.1.17.3.11 TEdit.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
```

```
  Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
  event to FormKeyUp.  Set the KeyPreview on the form to True.
  Behavior is dependent on keyboard driver(USB, serial, etc).

OnKeyPress

OnKeyUp

29.1.17.3.12 TEdit.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyUp

KeyPreview

29.1.17.3.13 TEdit.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the

OnKeyPress

29.1.17.3.14 TEdit.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

29.1.17.3.15 TEdit.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)

29.1.17.3.16 TEdit.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.17.3.17 TEdit.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.17.3.18 TEdit.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

29.1.17.3.20 TEdit.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

29.1.17.3.21 TEdit.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.18 TGroupBox Class

TGroupBox represents a Windows group box.

Class Hierarchy

Pascal

```
TGroupBox = class(TCustomGroupBox);
```

C++

```
class TGroupBox : public TCustomGroupBox;
```

File

StdCtrls

Description

The TGroupBox component represents a standard Windows group box, used to group related controls on a form. When another control component is placed within a group box, the group box becomes the parent of that component.

Grouping Controls

29.1.18.1 TGroupBox Members

The following tables list the members exposed by TGroupBox.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2301)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2301)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2302)	Renders the onscreen image of the group box.

Public Methods

	Name	Description
	Create (see page 2300)	Creates and initializes a TCustomGroupBox (see page 2299) instance.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2482)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2482)	Occurs when an object with custom alignment is aligned.
	OnClick (see page 2483)	Occurs when the user clicks the control.
	OnContextPopup (see page 2485)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2486)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 2486)	Occurs when another control is docked to the control.
	OnDockOver (see page 2488)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 2490)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2493)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2496)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2497)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2498)	Occurs when a control receives the input focus.
	OnExit (see page 2500)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 2503)	Returns the control's docking information.
	OnMouseActivate (see page 2505)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2506)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2508)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2508)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2509)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2511)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2513)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2514)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 2514)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 2454)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2457)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2458)	Specifies the bi-directional mode for the control.
	Caption (see page 2458)	Specifies a text string that identifies the control to the user.
	Color (see page 2461)	Specifies the background color of the control.
	Constraints (see page 2462)	Specifies the size constraints for the control.
	Ctl3D (see page 2462)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 2463)	Specifies whether the control can be the target of drag-and-dock operations.

	DoubleBuffered (see page 2464)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2465)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2466)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2466)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2468)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2468)	Controls the attributes of text written on or in the control.
	Padding (see page 2469)	Specifies the padding of a control.
	ParentBackground (see page 2469)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 2470)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2470)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2471)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2471)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2471)	Determines where a control looks for its font information.
	ParentShowHint (see page 2472)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2472)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2477)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2479)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2479)	Determines if the user can tab to a control.
	Visible (see page 2480)	Determines whether the component appears onscreen.

29.1.18.2 TGroupBox Properties

The properties of the TGroupBox class are listed here.

Published Properties

	Name	Description
	Align (see page 2454)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2457)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2458)	Specifies the bi-directional mode for the control.
	Caption (see page 2458)	Specifies a text string that identifies the control to the user.
	Color (see page 2461)	Specifies the background color of the control.
	Constraints (see page 2462)	Specifies the size constraints for the control.
	Ctl3D (see page 2462)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 2463)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 2464)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2465)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2466)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2466)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2468)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2468)	Controls the attributes of text written on or in the control.
	Padding (see page 2469)	Specifies the padding of a control.
	ParentBackground (see page 2469)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 2470)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2470)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2471)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2471)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

	ParentFont (see page 2471)	Determines where a control looks for its font information.
	ParentShowHint (see page 2472)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2472)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2477)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2479)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2479)	Determines if the user can tab to a control.
	Visible (see page 2480)	Determines whether the component appears onscreen.

29.1.18.2.1 TGroupBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
```

```
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}

Parent

Anchors

29.1.18.2.2 TGroupBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other

aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.18.2.3 TGroupBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

29.1.18.2.4 TGroupBox.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
```

```
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;
```

```
procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

29.1.18.2.5 TGroupBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

29.1.18.2.6 TGroupBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

29.1.18.2.7 TGroupBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

29.1.18.2.8 TGroupBox.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
```

```
  UpdateCaption(Client);
end;
```

29.1.18.2.9 TGroupBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
```

```
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

29.1.18.2.10 TGroupBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.18.2.11 TGroupBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.18.2.12 TGroupBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
```

```
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

29.1.18.2.13 TGroupBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.18.2.14 TGroupBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
```

```
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

29.1.18.2.15 TGroupBox.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

29.1.18.2.16 TGroupBox.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

29.1.18.2.17 TGroupBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

29.1.18.2.18 TGroupBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.18.2.19 TGroupBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.18.2.20 TGroupBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.18.2.21 TGroupBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

29.1.18.2.22 TGroupBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.18.2.23 TGroupBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
```

```
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)

                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
```

```
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

29.1.18.2.24 TGroupBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
```

```
example.

29.1.18.2.25 TGroupBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

29.1.18.2.26 TGroupBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.18.2.27 TGroupBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

29.1.18.3 TGroupBox Events

The events of the TGroupBox class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2482)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2482)	Occurs when an object with custom alignment is aligned.
	OnClick (see page 2483)	Occurs when the user clicks the control.
	OnContextPopup (see page 2485)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2486)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 2486)	Occurs when another control is docked to the control.
	OnDockOver (see page 2488)	Occurs when another control is dragged over the control.

	OnDragDrop (see page 2490)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2493)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2496)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2497)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2498)	Occurs when a control receives the input focus.
	OnExit (see page 2500)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 2503)	Returns the control's docking information.
	OnMouseActivate (see page 2505)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2506)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2508)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2508)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2509)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2511)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2513)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2514)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 2514)	Occurs when the application tries to undock a control that is docked to the windowed control.

29.1.18.3.1 TGroupBox.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

CustomAlignInsertBefore

Align

TAlignInsertBeforeEvent

29.1.18.3.2 TGroupBox.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

TAlignPositionEvent

29.1.18.3.3 TGroupBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).

- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
```

```
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

Adding Silent Video Clips to an Application

29.1.18.3.4 TGroupBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

29.1.18.3.5 TGroupBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

29.1.18.3.6 TGroupBox.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}
```

```
void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
```

```
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

OnDockOver

29.1.18.3.7 TGroupBox.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}
```

```
void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
```

```
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

OnDockDrop

OnGetSiteInfo

TDragDockObject

29.1.18.3.8 TGroupBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}
```

```
void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

OnStartDrag

TDragObject

29.1.18.3.9 TGroupBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
```

```
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

OnStartDrag

DragKind

29.1.18.3.12 TGroupBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{

OnExit

ActiveControl

OnActivate

Using a Single Navigator for Multiple Datasets

29.1.18.3.13 TGroupBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```

ActiveControl

29.1.18.3.14 TGroupBox.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

TDragDockObject

29.1.18.3.15 TGroupBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the

OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

29.1.18.3.16 TGroupBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
```

```
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else

29.1.18.3.17 TGroupBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.18.3.18 TGroupBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.18.3.19 TGroupBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
```

```
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;

29.1.18.3.21 TGroupBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

29.1.18.3.22 TGroupBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.18.3.23 TGroupBox.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);

29.1.19 TImageMargins Class

Margins of image on button.

Class Hierarchy

Pascal

```
TImageMargins = class(TPersistent);
```

C++

```
class TImageMargins : public TPersistent;
```

File

StdCtrls

Description

A button image may be positioned using margins. TImageMargins defines the margins of an image on a TButton (see page 1961). The margin values are in the Bottom (see page 2520), Top (see page 2521), Left (see page 2520) and Right (see page 2520) properties.

The OnChange (see page 2521) event is triggered when a margin changes.

The TButton.ImageMargins property contains a TImageMargins instance.

See Also

Bottom (see page 2520)

ImageMargins (see page 1984)

Left (see page 2520)

Right (see page 2520)

Top (see page 2521)

OnChange (see page 2521)

29.1.19.1 TImageMargins Members

The following tables list the members exposed by TImageMargins.

Protected Methods

	Name	Description
	Change (see page 2519)	This is Change, a member of class TImageMargins.

Public Events

	Name	Description
	OnChange (see page 2521)	Margin changed.

Public Methods

	Name	Description
	Assign (see page 2518)	Copies the contents of another, similar object.

Published Properties

	Name	Description
	Bottom (see page 2520)	Bottom margin of image on button.
	Left (see page 2520)	Left margin of image on button.
	Right (see page 2520)	Right margin of image on button.
	Top (see page 2521)	Top margin of image on button.

29.1.19.2 TImageMargins Methods

The methods of the TImageMargins class are listed here.

Protected Methods

	Name	Description
	Change (see page 2519)	This is Change, a member of class TImageMargins.

Public Methods

	Name	Description
	Assign (see page 2518)	Copies the contents of another, similar object.

29.1.19.2.1 TImageMargins.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent calls the source object's AssignTo method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

AssignTo

EConvertError (see page 3985)

29.1.19.2.2 TImageMargins.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TImageMargins.

29.1.19.3 TImageMargins Properties

The properties of the TImageMargins class are listed here.

Published Properties

	Name	Description
	Bottom (see page 2520)	Bottom margin of image on button.
	Left (see page 2520)	Left margin of image on button.
	Right (see page 2520)	Right margin of image on button.
	Top (see page 2521)	Top margin of image on button.

29.1.19.3.1 TImageMargins.Bottom Property

Bottom margin of image on button.

Pascal

```
property Bottom: Integer;
```

C++

```
__property int Bottom;
```

Description

A button image may be positioned using margins. Bottom is the bottom margin of an image on a TButton (see page 1961).

See Also

ImageMargins (see page 1984)

Left (see page 2520)

Right (see page 2520)

Top (see page 2521)

29.1.19.3.2 TImageMargins.Left Property

Left margin of image on button.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

A button image may be positioned using margins. Left is the left margin of an image on a TButton (see page 1961).

See Also

Bottom (see page 2520)

ImageMargins (see page 1984)

Right (see page 2520)

Top (see page 2521)

29.1.19.3.3 TImageMargins.Right Property

Right margin of image on button.

Pascal

```
property Right: Integer;
```

C++

```
__property int Right;
```

Description

A button image may be positioned using margins. Right is the right margin of an image on a TButton (see page 1961).

See Also

Bottom (see page 2520)

ImageMargins (see page 1984)

Left (see page 2520)

Top (see page 2521)

29.1.19.3.4 TImageMargins.Top Property

Top margin of image on button.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

A button image may be positioned using margins. Top is the top margin of an image on a TButton (see page 1961).

See Also

Bottom (see page 2520)

ImageMargins (see page 1984)

Left (see page 2520)

Right (see page 2520)

29.1.19.4 TImageMargins Events

The events of the TImageMargins class are listed here.

Public Events

	Name	Description
	OnChange (see page 2521)	Margin changed.

29.1.19.4.1 TImageMargins.OnChange Event

Margin changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

OnChange occurs when a margin changes.

See Also

ImageMargins (see page 1984)

29.1.20 TLabel Class

TLabel is a nonwindowed control that displays text on a form.

Class Hierarchy

Pascal

```
TLabel = class(TCustomLabel);
```

C++

```
class TLabel : public TCustomLabel;
```

File

StdCtrls

Description

Use TLabel to add text that the user can't edit to a form. This text can be used to label another control, and can set focus to that control when the user types an accelerator key.

Because TLabel is not a descendant of TWinControl, it does not have its own window and can't receive direct input from the keyboard. To add an object to a form that can respond to keyboard input (other than setting focus to another object when an accelerator key is typed) in addition to displaying text, use TStaticText (see page 2853).

To add an object to a form that displays text that a user can scroll or edit, use TEdit (see page 2380).

See Also

TEdit (see page 2380)

TStaticText (see page 2853)

Labels

Display Controls

29.1.20.1 TLabel Members

The following tables list the members exposed by TLabel.

Protected Methods

	Name	Description
	AdjustBounds (see page 2304)	Resizes the label when the text changes.
	DoDrawText (see page 2304)	Renders the text in the client area.

	GetLabelText (see page 2305)	Returns the value of the Caption (see page 2310) property.
	Loaded (see page 2305)	Adjusts the size of the label when it is first loaded. .
	Notification (see page 2305)	Responds to notifications when objects are about to be created or destroyed.
	Paint (see page 2306)	Draws the image of the label.
	SetAutoSize (see page 2306)	Sets the AutoSize (see page 2307) property.

Public Methods

	Name	Description
	Create (see page 2303)	Creates and initializes an instance of TCustomLabel (see page 2302).

Public Properties

	Name	Description
	Canvas (see page 2308)	Provides the drawing surface used by the graphic control.

Published Events

	Name	Description
	OnClick (see page 2552)	Occurs when the user clicks the control.
	OnContextPopup (see page 2554)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2554)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2555)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2558)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2561)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2561)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2562)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2563)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2566)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2566)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2566)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2568)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2571)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2571)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2525)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2528)	Controls the horizontal placement of the text within the label.
	Anchors (see page 2528)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2529)	Determines whether the size of the label automatically resizes to accommodate the text.
	BiDiMode (see page 2530)	Specifies the bi-directional mode for the control.
	Caption (see page 2530)	Specifies a text string that identifies the control to the user.
	Color (see page 2533)	Specifies the background color of the control.
	Constraints (see page 2534)	Specifies the size constraints for the control.
	DragCursor (see page 2534)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2535)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2535)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EllipsisPosition (see page 2537)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	Enabled (see page 2537)	Controls whether the control responds to mouse, keyboard, and timer events.

	FocusControl (see page 2538)	Designates a windowed control associated with the label.
	Font (see page 2538)	Controls the attributes of text written on or in the control.
	GlowSize (see page 2539)	This is GlowSize, a member of class TLabel.
	Layout (see page 2539)	Specifies the vertical placement of the text within the label.
	ParentBiDiMode (see page 2540)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2540)	Determines where a control looks for its color information.
	ParentFont (see page 2540)	Determines where a control looks for its font information.
	ParentShowHint (see page 2541)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2542)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2547)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 2547)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Transparent (see page 2549)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Visible (see page 2549)	Determines whether the component appears onscreen.
	WordWrap (see page 2551)	Specifies whether the label text wraps when it is too long for the width of the label.

29.1.20.2 TLabel Properties

The properties of the TLabel class are listed here.

Published Properties

	Name	Description
	Align (see page 2525)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2528)	Controls the horizontal placement of the text within the label.
	Anchors (see page 2528)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2529)	Determines whether the size of the label automatically resizes to accommodate the text.
	BiDiMode (see page 2530)	Specifies the bi-directional mode for the control.
	Caption (see page 2530)	Specifies a text string that identifies the control to the user.
	Color (see page 2533)	Specifies the background color of the control.
	Constraints (see page 2534)	Specifies the size constraints for the control.
	DragCursor (see page 2534)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2535)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2535)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EllipsisPosition (see page 2537)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	Enabled (see page 2537)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2538)	Designates a windowed control associated with the label.
	Font (see page 2538)	Controls the attributes of text written on or in the control.
	GlowSize (see page 2539)	This is GlowSize, a member of class TLabel.
	Layout (see page 2539)	Specifies the vertical placement of the text within the label.
	ParentBiDiMode (see page 2540)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2540)	Determines where a control looks for its color information.
	ParentFont (see page 2540)	Determines where a control looks for its font information.
	ParentShowHint (see page 2541)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2542)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2547)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 2547)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Transparent (see page 2549)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Visible (see page 2549)	Determines whether the component appears onscreen.
	WordWrap (see page 2551)	Specifies whether the label text wraps when it is too long for the width of the label.

29.1.20.2.1 TLabel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);

Anchors

29.1.20.2.2 TLabel.Alignment Property

Controls the horizontal placement of the text within the label.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Set Alignment to specify how the text of the label is justified within the ClientRect of the label control.

The effect of the Alignment property is more obvious if the WordWrap property is true and the label includes more than one line of text.

See Also

ClientRect

GetLabelText (see page 2305)

Layout (see page 2314)

WordWrap (see page 2316)

29.1.20.2.3 TLabel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.20.2.4 TLabel.AutoSize Property

Determines whether the size of the label automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the label adjust its size automatically so the client area accommodates the height and width of the text. When AutoSize is false, the label is fixed in size. When AutoSize is true, the size of the label readjusts whenever the text changes. The size of the label is also readjusts when the Font property changes.

When WordWrap is true, the width of the label is fixed. If AutoSize is also true, changes to the text cause the label to change in height. When AutoSize is true and WordWrap is false, the font determines the height of the label, and changes to the text cause the label to change in width.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
```

```
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
```

Layout (see page 2314)

29.1.20.2.5 TLabel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

29.1.20.2.6 TLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
```

```
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
```

```
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

29.1.20.2.7 TLabel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

29.1.20.2.8 TLabel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

29.1.20.2.9 TLabel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.20.2.10 TLabel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.20.2.11 TLabel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);

29.1.20.2.12 TLabel.EllipsisPosition Property

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
property EllipsisPosition: TEllipsisPosition;
```

C++

```
__property TEllipsisPosition EllipsisPosition;
```

Description

Set EllipsisPosition to determine how an ellipsis is placed in text that does not fit in its allocated rectangle. This is a TEllipsisPosition constant and its value corresponds to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

29.1.20.2.13 TLabel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Set FocusControl to the windowed control that should receive focus when the user presses the accelerator key specified by the label. Specify an accelerator key by preceding a character in the label text with an ampersand (&) and setting the ShowAccelChar property to true.

See Also

ShowAccelChar (see page 2314)

29.1.20.2.15 TLabel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

29.1.20.2.16 TLabel.GlowSize Property

Pascal

```
property GlowSize: Integer;
```

C++

```
__property int GlowSize;
```

Description

This is GlowSize, a member of class TLabel.

29.1.20.2.17 TLabel.Layout Property

Specifies the vertical placement of the text within the label.

Pascal

```
property Layout: TTextLayout;
```

C++

```
__property TTextLayout Layout;
```

Description

Set Layout to specify how the text of the label is placed within the ClientRect of the label control. Layout is the vertical analog to the Alignment property.

See Also

Alignment (see page 2307)

ClientRect

29.1.20.2.18 TLabel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

29.1.20.2.19 TLabel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.20.2.20 TLabel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

29.1.20.2.21 TLabel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.20.2.22 TLabel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

29.1.20.2.23 TLabel.ShowAccelChar Property

Determines how an ampersand in the label text is displayed.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

Set ShowAccelChar to true to allow the label to display an underlined accelerator key value. When ShowAccelChar is true, any character preceded by an ampersand (&) appears underlined. If the FocusControl property is set, the windowed control specified by the FocusControl property receives input focus when the user types that underlined character. To display an ampersand when ShowAccelChar is true, use two ampersands (&&) to stand for the single ampersand that is displayed.

Set ShowAccelChar to false to display the label text with all ampersands appearing as ampersands. When ShowAccelChar is false, the value of the FocusControl property is not used.

C++ Examples:

```
/*
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label1->ShowAccelChar = true;
  Label1->Caption = "An &Underlined character appears here";
  Label2->ShowAccelChar = false;
  Label2->Caption = "An ampersand (&) appears here";
}
```

Delphi Examples:

```
{
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label1.ShowAccelChar := True;
  Label1.Caption := 'An &Underlined character appears here';
  Label2.ShowAccelChar := False;
  Label2.Caption := 'An ampersand (&) appears here';
end;
```

FocusControl (see page 2313)

GetLabelText (see page 2305)

29.1.20.2.24 TLabel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
```

```
    Edit1.Hint := 'Enter your name';
    Edit1.ShowHint := True;
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }

Displaying Fly-over Help

29.1.20.2.25 TLabel.Transparent Property

Specifies whether controls that sit below the label on a form can be seen through the label.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to prevent the label from obscuring other controls on the form. For example, if the label is used to add text to a graphic, set Transparent to true so that the label does not stand out as a separate object.

Writing text so that the background is transparent is slower than writing text when Transparent is false. If the label is not obscuring a complicated image, performance can be improved by setting the background color of the label to match the object beneath it and setting Transparent to false.

Color

ParentColor

29.1.20.2.26 TLabel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
```

```
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;

29.1.20.2.27 TLabel.WordWrap Property

Specifies whether the label text wraps when it is too long for the width of the label.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the label to display multiple line of text. When WordWrap is true, text that is too wide for the label control wraps at the right margin and continues in additional lines.

Set WordWrap to false to limit the label to a single line. When WordWrap is false, text that is too wide for the label appears truncated.

29.1.20.3 TLabel Events

The events of the TLabel class are listed here.

Published Events

	Name	Description
	OnClick (see page 2552)	Occurs when the user clicks the control.
	OnContextPopup (see page 2554)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2554)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2555)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2558)	Occurs when the user drags an object over a control.

	OnEndDock (see page 2561)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2561)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2562)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2563)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2566)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2566)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2566)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2568)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2571)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2571)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.20.3.1 TLabel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
```

```
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

29.1.20.3.2 TLabel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

29.1.20.3.3 TLabel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

29.1.20.3.4 TLabel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

29.1.20.3.5 TLabel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

29.1.20.3.7 TLabel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
```

```
  control was successfully dropped into and accepted by a
  another control.
  */
  void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
       int Y)
  {
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }
  }
```

Delphi Examples:

```
  {
  This code displays a message in a label named Status. The
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else

OnStartDrag

DragKind

29.1.20.3.8 TLabel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
```

```
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

29.1.20.3.9 TLabel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:

  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
```

```
  button, moves the mouse, and releases the mouse button, a
  rectangle is drawn on the form. When the mouse button is
  released, the rectangle appears on the form's canvas. Its
  top-left and bottom-right corners are defined by the
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  }
  procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin

MouseCapture

29.1.20.3.10 TLabel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.20.3.11 TLabel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.20.3.12 TLabel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*

OnMouseUp

MouseCapture

29.1.20.3.13 TLabel.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

29.1.20.3.14 TLabel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnEndDock

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

29.1.20.3.15 TLabel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.21 TListBox Class

TListBox displays a collection of items in a scrollable list.

Class Hierarchy

Pascal

```
TListBox = class(TCustomListBox);
```

C++

```
class TListBox : public TCustomListBox;
```

File

StdCtrls

Description

Use TListBox to display a scrollable list of items that users can select, add, or delete. TListBox is a wrapper for the Windows listbox control. For specialized list boxes, use other descendant classes of TCustomListBox (see page 2316) or derive your own class from TCustomListBox (see page 2316).

TListBox implements the generic behavior introduced in TCustomListBox (see page 2316). TListBox publishes many of the properties inherited from TCustomListBox (see page 2316), but does not introduce any new behavior.

List Boxes and Check-list Boxes

29.1.21.1 TListBox Members

The following tables list the members exposed by TListBox.

Protected Fields

	Name	Description
	FMoving (see page 2319)	This is FMoving, a member of class TCustomListBox.

Protected Methods

	Name	Description
	CreateParams (see page 2322)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateWnd (see page 2323)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2324)	Deletes a string from the list box.
	DestroyWnd (see page 2324)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2325)	Returns the index of a string in the list box.
	DoGetData (see page 2325)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2326)	Returns the object associated with an item in a virtual list box.
	DragCanceled (see page 2326)	Sends a mouse message canceling the drag-and-drop operation.
	DrawItem (see page 2326)	Generates an OnDrawItem (see page 2357) event.
	GetItemData (see page 2327)	Returns a 32-bit value associated with the specified item in a list box.
	GetItemIndex (see page 2328)	Returns the value of the ItemIndex property.
	GetSelCount (see page 2328)	Returns the number of selected items.
	GetSelected (see page 2328)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2328)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2329)	Associates an integer with a specified item in the list box.
	KeyPress (see page 2332)	Responds when the user presses a key.
	LoadRecreateItems (see page 2333)	This is LoadRecreateItems, a member of class TCustomListBox.
	MeasureItem (see page 2333)	Generates an OnMeasureItem (see page 2359) event.
	ResetContent (see page 2334)	Removes all of the items from a list box.
	SaveRecreateItems (see page 2334)	This is SaveRecreateItems, a member of class TCustomListBox.
	SetItemData (see page 2334)	Sets the 32-bit value associated with the specified item in a list box.
	SetItemIndex (see page 2335)	Gives focus to the item with a specified index.
	SetMultiSelect (see page 2335)	Sets the MultiSelect property.
	WndProc (see page 2335)	Handles Windows messages.

Public Methods

	Name	Description
	AddItem (see page 2320)	Adds an item to the list box
	Clear (see page 2321)	Deletes all items from the list box.
	ClearSelection (see page 2321)	Deselects all selected items in the list box, if possible.
	CopySelection (see page 2322)	Copies the selected items to another list-type control
	Create (see page 2318)	Instantiates a list box control.
	DeleteSelected (see page 2324)	Deletes the selected items from the list box
	Destroy (see page 2319)	Destroys the instance of a list box control.
	GetCount (see page 2327)	Returns the value of the Count (see page 2344) property.
	ItemAtPos (see page 2329)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2331)	Returns the rectangle that surrounds the item specified in the Item parameter.
	SelectAll (see page 2334)	Selects the entire block of text in the list box.

Public Properties

	Name	Description
	Canvas (see page 2341)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2357) event of an owner-draw list box.
	Count (see page 2344)	Indicates the number of items in the list box.
	Selected (see page 2350)	Indicates whether a particular item is selected.
	TopIndex (see page 2354)	Specifies the index number of the item that appears at the top of the list box.

Published Events

	Name	Description
	OnClick (see page 2612)	Occurs when the user clicks the control.

	OnContextPopup (see page 2614)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2615)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2615)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2616)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2616)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2616)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2619)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2623)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2625)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2625)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2626)	Occurs when a control receives the input focus.
	OnExit (see page 2629)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2631)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2635)	Occurs when a key is pressed.
	OnKeyUp (see page 2636)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2638)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2639)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2640)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2643)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2643)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2643)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2646)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2648)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2648)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2576)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2580)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2580)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2580)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 2581)	Specifies which edges of the control are beveled.
	BevelInner (see page 2581)	Specifies the cut of the inner bevel.
	BevelKind (see page 2582)	Specifies the control's bevel style.
	BevelOuter (see page 2582)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2582)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2583)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2583)	Determines whether the list box has a border.
	Color (see page 2584)	Specifies the background color of the control.
	Columns (see page 2585)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2585)	Specifies the size constraints for the control.
	Ctl3D (see page 2586)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2586)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2588)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2588)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 2589)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2590)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 2591)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 2591)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2592)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2593)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2593)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2594)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2594)	Contains the strings that appear in the list box.
	MultiSelect (see page 2597)	Specifies whether the user can select more than one item.
	ParentBiDiMode (see page 2597)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2598)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2598)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2599)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2599)	Determines where a control looks for its font information.
	ParentShowHint (see page 2599)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2600)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 2605)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 2605)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2607)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2608)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2609)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2609)	Determines if the user can tab to a control.
	TabWidth (see page 2610)	Specifies the size of the tabs in the list box.
	Visible (see page 2610)	Determines whether the component appears onscreen.

29.1.21.2 TListBox Properties

The properties of the TListBox class are listed here.

Published Properties

	Name	Description
	Align (see page 2576)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2580)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2580)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2580)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 2581)	Specifies which edges of the control are beveled.
	BevelInner (see page 2581)	Specifies the cut of the inner bevel.
	BevelKind (see page 2582)	Specifies the control's bevel style.
	BevelOuter (see page 2582)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2582)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2583)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2583)	Determines whether the list box has a border.
	Color (see page 2584)	Specifies the background color of the control.
	Columns (see page 2585)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2585)	Specifies the size constraints for the control.
	Ctl3D (see page 2586)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2586)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

	DragCursor (see page 2588)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2588)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2589)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2590)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 2591)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 2591)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2592)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2593)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2593)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2594)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2594)	Contains the strings that appear in the list box.
	MultiSelect (see page 2597)	Specifies whether the user can select more than one item.
	ParentBiDiMode (see page 2597)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2598)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2598)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2599)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2599)	Determines where a control looks for its font information.
	ParentShowHint (see page 2599)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2600)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 2605)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 2605)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2607)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2608)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2609)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2609)	Determines if the user can tab to a control.
	TabWidth (see page 2610)	Specifies the size of the tabs in the list box.
	Visible (see page 2610)	Determines whether the component appears onscreen.

29.1.21.2.1 TListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
```

```
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
```

```
  the bottom of the form.
  }

  var
    I: Integer;

  procedure TForm1.Button1Click(Sender: TObject);

Parent

Anchors

29.1.21.2.2 TListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.21.2.3 TListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

29.1.21.2.4 TListBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2580) is true.

See Also

AutoComplete (see page 2580)

29.1.21.2.5 TListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

29.1.21.2.6 TListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

29.1.21.2.7 TListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

29.1.21.2.8 TListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

29.1.21.2.9 TListBox.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

29.1.21.2.10 TListBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

29.1.21.2.11 TListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D

29.1.21.2.12 TListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

29.1.21.2.13 TListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 2346)

Width

29.1.21.2.14 TListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

Align

Anchors

OnConstrainedResize

OnCanResize

29.1.21.2.15 TListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

29.1.21.2.16 TListBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
```

```
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;
```

```
// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

29.1.21.2.17 TListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.21.2.18 TListBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.21.2.19 TListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
```

```
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

Arranging the Order of Persistent Columns

29.1.21.2.20 TListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.21.2.21 TListBox.ExtendedSelect Property

Makes list item multi-select operate with Shift and CTRL keys.

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

ExtendedSelect only has effect when the MultiSelect (see page 2597) is true.

When ExtendedSelect is true, the Shift key (in conjunction with the left mouse button, or arrow keys) is used to select a contiguous sequence of list items. And the Ctrl key is used (in conjunction with the left mouse buttton) to select non-contiguous list items.

When ExtendedSelect is false, Multi-Select operates very differently. The Shift and Ctrl keys are not recognised. List items are always selected individually in any sequence. Reselecting a selected list item will deselect it. Use the arrow and spacebar keys, or the left mouse button to make selections.

See Also

MultiSelect (see page 2597)

29.1.21.2.22 TListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

29.1.21.2.23 TListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the

control already has input focus, call the SetIme method.

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

29.1.21.2.24 TListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

29.1.21.2.25 TListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 2346)

Items (see page 2346)

Style (see page 2353)

Using TDBListBox and TDBComboBox

29.1.21.2.26 TListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

Using TDBListBox and TDBComboBox

29.1.21.2.27 TListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          String("File " + FileListBox1->Items->Strings[i] + "not found").t_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(AnsiString(FileListBox1->Items->Strings[i]).t_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(int(statbuf.st_size)));
      fclose(F);
    }
  }
}
/*
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)

TStrings

29.1.21.2.28 TListBox.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect;
```

C++

```
__property MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount property indicates the number of selected items. When MultiSelect is false, the user can only select one item, which is indicated by the ItemIndex property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl descendant, override the protected SetMultiSelect method.

See Also

SelCount

ItemIndex

29.1.21.2.29 TListBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

29.1.21.2.30 TListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.21.2.31 TListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.21.2.32 TListBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.21.2.33 TListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

29.1.21.2.34 TListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

ShowHint

29.1.21.2.35 TListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
```

```
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}
```

```
void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
```

```
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

29.1.21.2.36 TListBox.ScrollWidth Property

Specifies the width, in pixels, by which the list box can scroll horizontally.

Pascal

```
property ScrollWidth: Integer;
```

C++

```
__property int ScrollWidth;
```

Description

Use ScrollWidth to get or set the logical width of the list box. When ScrollWidth is greater than the client width of the list box, the list box gets a horizontal scroll bar. When ScrollWidth is less than or equal to ClientWidth, the horizontal scroll bar disappears.

Columns (see page 2344)

ClientWidth

29.1.21.2.37 TListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
```

```
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

29.1.21.2.38 TListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
```

```
}
```

Delphi Examples:

```
{
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

procedure TForm1.AddClick(Sender: TObject);
begin
  ListBox1.Items.Add(Edit1.Text);
end;

procedure TForm1.SortClick(Sender: TObject);
begin
  ListBox1.Sorted := True;
end;
```

See Also

Items (see page 2346)

Style (see page 2353)

29.1.21.2.39 TListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

29.1.21.2.40 TListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

29.1.21.2.41 TListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.21.2.42 TListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

29.1.21.2.43 TListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
```

```
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);

29.1.21.3 TListBox Events

The events of the TListBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 2612)	Occurs when the user clicks the control.
	OnContextPopup (see page 2614)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2615)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2615)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2616)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2616)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2616)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2619)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2623)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2625)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2625)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2626)	Occurs when a control receives the input focus.
	OnExit (see page 2629)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2631)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2635)	Occurs when a key is pressed.
	OnKeyUp (see page 2636)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2638)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2639)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2640)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2643)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2643)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2643)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2646)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2648)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2648)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.21.3.1 TListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that

action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

29.1.21.3.2 TListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property

of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

29.1.21.3.3 TListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataFind (see page 2356)

OnDataObject (see page 2357)

Style (see page 2353)

Count (see page 2344)

29.1.21.3.4 TListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 2356)

OnDataObject (see page 2357)

Style (see page 2353)

Count (see page 2344)

29.1.21.3.5 TListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

See Also

OnData (see page 2356)

29.1.21.3.6 TListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

29.1.21.3.7 TListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

29.1.21.3.8 TListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
  property OnDragOver;
```

C++

```
  __property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*

29.1.21.3.9 TListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight property for fixed owner-draw list boxes or by the response to the OnMeasureItem event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = (dynamic_cast<TListBox *>(Control))->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
```

```
      pBitmap,
      Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
  ListBox1.Items.AddObject('Butterfly', bitmap2);
end;

procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
TOwnerDrawState);
var
  Bitmap: TBitmap;      { temporary variable for the item's bitmap }
  Offset: Integer;      { text offset width }
begin
  Bitmap := TBitmap.Create;
  with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
  begin
    FillRect(Rect);       { clear the rectangle }
    Offset := 2;          { provide default offset }
    Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
    if Bitmap <> nil then
    begin
      BrushCopy(
        Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
        Bitmap,
        Bounds(0, 0, Bitmap.Width, Bitmap.Height),
        clRed);  {render bitmap}
      Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
    end;
    TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
text }
  end;
end;
```

OnStartDock

29.1.21.3.11 TListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

29.1.21.3.12 TListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}

29.1.21.3.13 TListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);

OnEnter

ActiveControl

29.1.21.3.14 TListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

29.1.21.3.15 TListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not

generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

29.1.21.3.17 TListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
```

```
      int &Height)
{
  Graphics::TBitmap *bitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (bitmap && bitmap->Height > Height)
    Height = bitmap->Height;
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}

#include <memory>       //for STL auto_ptr class

29.1.21.3.18 TListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

29.1.21.3.19 TListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
```

```
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

29.1.21.3.20 TListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.21.3.21 TListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.21.3.22 TListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseUp

MouseCapture

29.1.21.3.23 TListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseMove

Responding to a Mouse-up Action

29.1.21.3.24 TListBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

29.1.21.3.25 TListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.22 TMemo Class

TMemo is a wrapper for a Windows multiline edit control.

Class Hierarchy

Pascal

```
TMemo = class(TCustomMemo);
```

C++

```
class TMemo : public TCustomMemo;
```

File

StdCtrls

Description

Use TMemo to put a standard Windows multiline edit control on a form. Multiline edit boxes allow the user to enter more than one line of text. They are appropriate for representing lengthy information.

TMemo implements the generic behavior introduced in TCustomMemo (see page 2361). TMemo publishes many of the properties inherited from TCustomMemo (see page 2361), but does not introduce any new behavior.

Note: Under Win 9x, there is a limit of 64k of text for this control.

29.1.22.1 TMemo Members

The following tables list the members exposed by TMemo.

Protected Methods

	Name	Description
	Change (see page 2266)	Generates an OnChange (see page 2299) event.
V	CreateParams (see page 2269)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateParams (see page 2364)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2270)	Creates a Windows control to represent the control.
V	CreateWindowHandle (see page 2365)	Creates a window based on the window-creation parameter record.
V	CreateWnd (see page 2270)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2273)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2273)	Sets the MaxLength (see page 2286) property.
V	DoSetTextHint (see page 2273)	This is DoSetTextHint, a member of class TCustomEdit.
V	GetCaretPos (see page 2365)	Returns the value of the CaretPos (see page 2368) property.
V	GetSelLength (see page 2274)	Returns the SelLength (see page 2289) property.
V	GetSelStart (see page 2274)	Returns the SelStart (see page 2293) property.
V	GetSelText (see page 2275)	Returns the SelText (see page 2296) property.
V	KeyPress (see page 2366)	Ensures that return characters are not entered into the text when WantReturns (see page 2372) is false.
V	Loaded (see page 2366)	Initializes the memo control when it is first loaded into memory.
	SetAlignment (see page 2279)	Sets the Alignment (see page 2283) property.
V	SetAutoSize (see page 2279)	Sets the AutoSize (see page 2284) property.
V	SetCaretPos (see page 2366)	Sets the CaretPos (see page 2368) property.
	SetLines (see page 2367)	Sets the Lines (see page 2368) property.
	SetScrollBars (see page 2367)	Sets the ScrollBars (see page 2369) property.
V	SetSelLength (see page 2280)	Sets the SelLength (see page 2289) property.
V	SetSelStart (see page 2280)	Sets the SelStart (see page 2293) property.
	SetWordWrap (see page 2367)	Sets the WordWrap (see page 2372) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2284)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2284)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	NumbersOnly (see page 2287)	Allows only numbers to be typed into the text edit.

	PasswordChar (see page 2289)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Methods

	Name	Description
	Clear (see page 2267)	Deletes all text from the edit control.
	ClearSelection (see page 2267)	Removes the selected text from the edit control.
	ClearUndo (see page 2268)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2268)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2265)	Creates an instance of TCustomEdit (see page 2263).
	Create (see page 2363)	Creates and initializes an instance of TCustomMemo (see page 2361).
	CutToClipboard (see page 2271)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2272)	Provides message handling for all messages that the control does not fully process itself.
	Destroy (see page 2364)	Destroys an instance of TCustomMemo (see page 2361).
	GetControlsAlignment (see page 2274)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2275)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2276)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2278)	Selects all text in the edit control.
	SetSelText (see page 2281)	Sets the SelText (see page 2296) property.
	SetSelTextBuf (see page 2281)	Replaces the selected text with a null-terminated string.
	Undo (see page 2282)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	CanUndo (see page 2285)	Indicates whether the edit control contains changes that can be backed out.
	CaretPos (see page 2368)	Indicates the position of the caret in the client area of the memo.
	Modified (see page 2287)	Indicates whether the user edited the text of the edit control.
	SelLength (see page 2289)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2293)	Specifies the position of the first selected character in the text.
	SelText (see page 2296)	Specifies the selected portion of the edit control's text.
	Text (see page 2297)	Contains a text string associated with the control.
	TextHint (see page 2299)	A hint or message to be displayed when the Text (see page 2297) property is empty.

Published Events

	Name	Description
	OnChange (see page 2690)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2690)	Occurs when the user clicks the control.
	OnContextPopup (see page 2692)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2693)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2693)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2696)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2699)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2700)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2701)	Occurs when a control receives the input focus.
	OnExit (see page 2703)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2706)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2710)	Occurs when a key is pressed.
	OnKeyUp (see page 2711)	Occurs when the user releases a key that has been pressed.

	OnMouseActivate (see page 2713)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2714)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2716)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2716)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2716)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2719)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2721)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2721)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2654)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2657)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2658)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 2658)	Specifies which edges of the control are beveled.
	BevelInner (see page 2659)	Specifies the cut of the inner bevel.
	BevelKind (see page 2659)	Specifies the control's bevel style.
	BevelOuter (see page 2660)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2660)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2660)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2661)	Determines the case of the text within the edit control.
	Color (see page 2661)	Specifies the background color of the control.
	Constraints (see page 2662)	Specifies the size constraints for the control.
	Ctl3D (see page 2663)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2663)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2665)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2665)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2666)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2667)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2668)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2669)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2669)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2670)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Lines (see page 2670)	Contains the individual lines of text in the memo control.
	MaxLength (see page 2671)	Specifies the maximum number of characters the user can enter into the edit control.
	OEMConvert (see page 2672)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2672)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2673)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2673)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2673)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2674)	Determines where a control looks for its font information.
	ParentShowHint (see page 2674)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2675)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2680)	Determines whether the user can change the text of the edit control.

	ScrollBars (see page 2680)	Determines whether the memo control has scroll bars.
	ShowHint (see page 2682)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2684)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2684)	Determines if the user can tab to a control.
	Visible (see page 2685)	Determines whether the component appears onscreen.
	WantReturns (see page 2686)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2687)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2687)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

29.1.22.2 TMemo Properties

The properties of the TMemo class are listed here.

Published Properties

	Name	Description
	Align (see page 2654)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2657)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2658)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 2658)	Specifies which edges of the control are beveled.
	BevelInner (see page 2659)	Specifies the cut of the inner bevel.
	BevelKind (see page 2659)	Specifies the control's bevel style.
	BevelOuter (see page 2660)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2660)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2660)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2661)	Determines the case of the text within the edit control.
	Color (see page 2661)	Specifies the background color of the control.
	Constraints (see page 2662)	Specifies the size constraints for the control.
	Ctl3D (see page 2663)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2663)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2665)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2665)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2666)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2667)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2668)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2669)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2669)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2670)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Lines (see page 2670)	Contains the individual lines of text in the memo control.
	MaxLength (see page 2671)	Specifies the maximum number of characters the user can enter into the edit control.
	OEMConvert (see page 2672)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2672)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2673)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2673)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2673)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2674)	Determines where a control looks for its font information.

	ParentShowHint (see page 2674)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2675)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2680)	Determines whether the user can change the text of the edit control.
	ScrollBars (see page 2680)	Determines whether the memo control has scroll bars.
	ShowHint (see page 2682)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2684)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2684)	Determines if the user can tab to a control.
	Visible (see page 2685)	Determines whether the component appears onscreen.
	WantReturns (see page 2686)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2687)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2687)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

29.1.22.2.1 TMemo.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
```

```
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
    }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Anchors

29.1.22.2.2 TMemo.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.

taRightJustify	Align text to the right side of the control.

SetAlignment (see page 2279)

Text

Displaying and Editing Fields in an Edit Box

29.1.22.2.3 TMemo.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

29.1.22.2.4 TMemo.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

29.1.22.2.5 TMemo.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

29.1.22.2.6 TMemo.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelEdges

BevelOuter

BevelInner

BevelWidth

29.1.22.2.7 TMemo.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

29.1.22.2.8 TMemo.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

29.1.22.2.9 TMemo.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

29.1.22.2.10 TMemo.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

29.1.22.2.11 TMemo.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
```

```
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

29.1.22.2.12 TMemo.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

29.1.22.2.13 TMemo.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

29.1.22.2.14 TMemo.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
```

```
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

29.1.22.2.15 TMemo.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.22.2.16 TMemo.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.22.2.17 TMemo.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
```

```
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);

29.1.22.2.18 TMemo.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.22.2.19 TMemo.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

29.1.22.2.20 TMemo.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

29.1.22.2.21 TMemo.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

29.1.22.2.22 TMemo.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

29.1.22.2.23 TMemo.Lines Property

Contains the individual lines of text in the memo control.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Use Lines to manipulate text in an memo control on a line-by-line basis. Lines is a TStrings object, so the TStrings methods may be used for Lines to perform manipulations such as counting the lines of text, adding new lines, deleting lines, or replacing lines with new text.

To work with all the text at once, use the Text property. To manipulate individual lines of text, the Lines property works better.

Note: Although Lines is implemented as a TStrings descendant, it does not implement the support for associating objects with

the strings in the list.

C++ Examples:

```
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.LoadFromFile('readme.txt');
  Caption:= Memo1.Lines[4];
end;
```

WordWrap (see page 2372)

29.1.22.2.24 TMemo.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

Displaying and Editing Text in a Rich Edit Memo Control

29.1.22.2.25 TMemo.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

Text

29.1.22.2.26 TMemo.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

29.1.22.2.27 TMemo.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.22.2.28 TMemo.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.22.2.29 TMemo.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.22.2.30 TMemo.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

29.1.22.2.31 TMemo.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.22.2.32 TMemo.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
```

```
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
```

```
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

29.1.22.2.33 TMemo.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

29.1.22.2.34 TMemo.ScrollBars Property

Determines whether the memo control has scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give a multiline edit control horizontal or vertical scroll bars. ScrollBars can take one of the following values:

Value	Meaning
ssNone	The control has no scroll bars.
ssHorizontal	The control has a single scroll bar on the bottom edge.
ssVertical	The control has a single scroll bar on the right edge.
ssBoth	The control has a scroll bar on both the bottom and right edges.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
```

```
    // move text cursor to top of editend;
    RichEdit1.SelStart := 0;
  end;

Displaying and Editing Text in a Memo Control

29.1.22.2.35 TMemo.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
```

```
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

ShowHint

Displaying Fly-over Help

29.1.22.2.36 TMemo.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

29.1.22.2.37 TMemo.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.22.2.38 TMemo.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
```

```
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

29.1.22.2.39 TMemo.WantReturns Property

Determines whether the user can insert return characters into the text.

Pascal

```
property WantReturns: Boolean;
```

C++

```
__property Boolean WantReturns;
```

Description

Set WantReturns to true to allow users to enter return characters into the text. Set WantReturns to false to allow the form to handle return characters instead.

For example, in a form with a default button (such as an OK button) and a memo control, if WantReturns is false, pressing Enter chooses the default button. If WantReturns is true, pressing Enter inserts a return character in the text.

Note: If WantReturns is false, users can still enter return characters into the text by pressing Ctrl+Enter.

See Also

Text

WantTabs (see page 2372)

29.1.22.2.40 TMemo.WantTabs Property

Determines whether the user can insert tab characters into the text.

Pascal

```
property WantTabs: Boolean;
```

C++

```
__property Boolean WantTabs;
```

Description

Set WantTabs to true to allow users to enter tab characters into the text. Set WantTabs to false if you want the tab character to select the next control on the form instead.

Note: If WantTabs is true, users can tab into the edit control, but they can't tab out.

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

29.1.22.2.41 TMemo.WordWrap Property

Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to make the edit control wrap text at the right margin so it fits in the client area. The wrapping is cosmetic only. The text does not include any return characters that were not explicitly entered. Set WordWrap to false to have the edit control show a separate line only where return characters were explicitly entered into the text.

Note: There should be no use for a horizontal scroll bar if WordWrap is true.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/

Displaying and Editing Text in a Memo Control

29.1.22.3 TMemo Events

The events of the TMemo class are listed here.

Published Events

	Name	Description
	OnChange (see page 2690)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2690)	Occurs when the user clicks the control.

	OnContextPopup (see page 2692)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2693)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2693)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2696)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2699)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2700)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2701)	Occurs when a control receives the input focus.
	OnExit (see page 2703)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2706)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2710)	Occurs when a key is pressed.
	OnKeyUp (see page 2711)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2713)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2714)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2716)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2716)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2716)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2719)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2721)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2721)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.22.3.1 TMemo.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 2266)

Text

29.1.22.3.2 TMemo.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

29.1.22.3.3 TMemo.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The

OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

29.1.22.3.4 TMemo.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

29.1.22.3.5 TMemo.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{

29.1.22.3.6 TMemo.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor

property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

DragKind

29.1.22.3.9 TMemo.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

29.1.22.3.10 TMemo.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);

OnEnter

ActiveControl

29.1.22.3.11 TMemo.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

KeyPreview

OnKeyPress

OnKeyUp

29.1.22.3.12 TMemo.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
```

```
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

OnKeyDown

OnKeyPress

29.1.22.3.14 TMemo.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

29.1.22.3.15 TMemo.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
```

```
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);

29.1.22.3.16 TMemo.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.22.3.17 TMemo.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.22.3.18 TMemo.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseUp

MouseCapture

29.1.22.3.19 TMemo.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

29.1.22.3.20 TMemo.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

29.1.22.3.21 TMemo.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.23 TPushButtonActionLink Class

Class Hierarchy

Pascal

```
TPushButtonActionLink = class(TButtonActionLink);
```

C++

```
class TPushButtonActionLink : public TButtonActionLink;
```

File

StdCtrls

Description

This is class StdCtrls.TPushButtonActionLink.

29.1.23.1 TPushButtonActionLink Members

The following tables list the members exposed by TPushButtonActionLink.

Protected Fields

	Name	Description
	FClient (see page 2031)	This is FClient, a member of class TButtonActionLink.

Protected Methods

	Name	Description
	AssignClient (see page 2032)	Assigns a client button that is linked to the associated action.
	IsCheckedLinked (see page 2032)	Indicates whether the checked state for the action and the client are linked.
	IsImageIndexLinked (see page 2723)	Indicates whether the image index for the action and the client are linked.
	SetChecked (see page 2032)	Sets the checked state of a button control if the client is linked to the action for this property.
	SetImageIndex (see page 2724)	Introduces an interface for setting the image index for a client.

29.1.23.2 TPushButtonActionLink Methods

The methods of the TPushButtonActionLink class are listed here.

Protected Methods

	Name	Description
	IsImageIndexLinked (see page 2723)	Indicates whether the image index for the action and the client are linked.
	SetImageIndex (see page 2724)	Introduces an interface for setting the image index for a client.

29.1.23.2.1 TPushButtonActionLink.IsImageIndexLinked Method

Indicates whether the image index for the action and the client are linked.

Pascal

```
function IsImageIndexLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsImageIndexLinked();
```

Description

TActionLink descendants call IsImageIndexLinked to determine whether they need to propagate changes to the ImageIndex property of the action so that they are reflected by the client object. When IsImageIndexLinked returns true, the action controls the ImageIndex property: Changes to the ImageIndex property of the action are reflected by changes to the corresponding property of the client object. When IsImageIndexLinked returns false, the client object does not reflect the ImageIndex property of its action, either because it does not have a corresponding property, or, more commonly, because it manages the value of its corresponding property independently.

As implemented in TActionLink, IsImageIndexLinked merely checks that the Action property specifies a descendant of TCustomAction (that is, it is an action that has an ImageIndex property). Descendant classes override IsImageIndexLinked to determine whether the ImageIndex property is linked with the appropriate client property.

ImageIndex

ImageIndex

SetImageIndex

Action

29.1.23.2.2 TPushButtonActionLink.SetImageIndex Method

Introduces an interface for setting the image index for a client.

Pascal

```
procedure SetImageIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetImageIndex(int Value);
```

Description

The associated action calls SetImageIndex when its ImageIndex property changes so that the action link can propagate the new ImageIndex value to the client object.

Value specifies the new value of the ImageIndex property.

As implemented in TActionLink, SetImageIndex does nothing. Descendant classes override SetImageIndex to set the client property that corresponds to the action's ImageIndex property if the IsImageIndexLinked method returns true.

29.1.24 TRadioButton Class

TRadioButton is a wrapper for a system radio button.

Class Hierarchy

Pascal

```
TRadioButton = class(TButtonControl);
```

C++

```
class TRadioButton : public TButtonControl;
```

File

StdCtrls

Description

Use TRadioButton to add a radio button to a form. Radio buttons present a set of mutually exclusive options to the user- that is, only one radio button in a set can be selected at a time. When the user selects a radio button, the previously selected radio button becomes unselected. Radio buttons are frequently grouped in a radio group box (TGroupBox (see page 2451)). Add the group box to the form first, then get the radio buttons from the Component palette and put them into the group box. Or you can add a TRadioGroup, a group that already has radio buttons in it, so that you do not have to get the buttons from the Tool

Palette.

By default, all radio buttons that are directly contained in the same windowed control container, such as a TRadioGroup or TPanel, are grouped. For example, two radio buttons on a form can be checked at the same time only if they are contained in separate containers, such as two different group boxes.

Radio Buttons

29.1.24.1 TRadioButton Members

The following tables list the members exposed by TRadioButton.

Protected Methods

	Name	Description
	ActionChange (see page 2034)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2727)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2728)	Creates the underlying window.
	GetActionLinkClass (see page 2035)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2728)	Returns whether the button control is checked.
	SetChecked (see page 2729)	Sets the Checked property.
	WndProc (see page 2036)	Handles Windows messages.

Protected Properties

	Name	Description
	ClicksDisabled (see page 2039)	Specifies whether the button control accepts mouse clicks.

Public Methods

	Name	Description
	Create (see page 2726)	Creates an instance of TRadioButton (see page 2724).
	GetControlsAlignment (see page 2728)	Returns the alignment of any text in the control.

Published Events

	Name	Description
	OnClick (see page 2758)	Occurs when the user clicks the control.
	OnContextPopup (see page 2760)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2761)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2761)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2764)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2767)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2768)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2769)	Occurs when a control receives the input focus.
	OnExit (see page 2771)	Occurs when the input focus shifts away from one control to another.

	OnKeyDown (see page 2774)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2777)	Occurs when a key is pressed.
	OnKeyUp (see page 2779)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2780)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2781)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2784)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2784)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2784)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2786)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2789)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2789)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Action (see page 2730)	Designates the action associated with the control.
	Align (see page 2730)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2734)	Determines the position of the caption relative to the radio button.
	Anchors (see page 2734)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2735)	Specifies the bi-directional mode for the control.
	Caption (see page 2735)	Specifies a text string that identifies the control to the user.
	Checked (see page 2738)	Determines whether the option represented by the radio button is selected.
	Color (see page 2738)	Specifies the background color of the control.
	Constraints (see page 2739)	Specifies the size constraints for the control.
	Ctl3D (see page 2740)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2740)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2742)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2742)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2743)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2744)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2745)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2746)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2746)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2747)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2747)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2747)	Determines where a control looks for its font information.
	ParentShowHint (see page 2748)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2748)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2753)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2755)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2755)	Determines if the user can tab to a control.
	Visible (see page 2756)	Determines whether the component appears onscreen.
	WordWrap (see page 2757)	Specifies whether the button text wraps to fit the width of the control.

29.1.24.2 TRadioButton.Create Constructor

Creates an instance of TRadioButton (see page 2724).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRadioButton(TComponent * AOwner);
```

Description

Call Create to instantiate a radio button at runtime. Radio buttons added to forms at design time are created automatically.

AOwner is the component, typically a form, that becomes the value of the Owner property. The Owner is responsible for freeing the radio button object.

Owner

29.1.24.3 TRadioButton Methods

The methods of the TRadioButton class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2727)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2728)	Creates the underlying window.
	GetChecked (see page 2728)	Returns whether the button control is checked.
	SetChecked (see page 2729)	Sets the Checked property.

Public Methods

	Name	Description
	GetControlsAlignment (see page 2728)	Returns the alignment of any text in the control.

29.1.24.3.1 TRadioButton.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

29.1.24.3.2 TRadioButton.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

29.1.24.3.3 TRadioButton.GetChecked Method

Returns whether the button control is checked.

Pascal

```
function GetChecked: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetChecked();
```

Description

GetChecked is the read implementation of the Checked property.

See Also

Checked (see page 2037)

29.1.24.3.4 TRadioButton.GetControlsAlignment Method

Returns the alignment of any text in the control.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the orientation of text in controls that do not have an Alignment (see page 2734) property.

GetControlsAlignment overrides the inherited method, returning taRightJustify if UseRightToLeftAlignment returns false. If UseRightToLeftAlignment returns true, GetControlsAlignment returns the opposite of the Alignment (see page 2734) property.

29.1.24.3.5 TRadioButton.SetChecked Method

Sets the Checked property.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked is the write implementer for the Checked property.

See Also

Checked (see page 2037)

29.1.24.4 TRadioButton Properties

The properties of the TRadioButton class are listed here.

Published Properties

	Name	Description
	Action (see page 2730)	Designates the action associated with the control.
	Align (see page 2730)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2734)	Determines the position of the caption relative to the radio button.
	Anchors (see page 2734)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2735)	Specifies the bi-directional mode for the control.
	Caption (see page 2735)	Specifies a text string that identifies the control to the user.
	Checked (see page 2738)	Determines whether the option represented by the radio button is selected.
	Color (see page 2738)	Specifies the background color of the control.
	Constraints (see page 2739)	Specifies the size constraints for the control.
	Ctl3D (see page 2740)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2740)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2742)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2742)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2743)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2744)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2745)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2746)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2746)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2747)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2747)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

	ParentFont (see page 2747)	Determines where a control looks for its font information.
	ParentShowHint (see page 2748)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2748)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2753)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2755)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2755)	Determines if the user can tab to a control.
	Visible (see page 2756)	Determines whether the component appears onscreen.
	WordWrap (see page 2757)	Specifies whether the button text wraps to fit the width of the control.

29.1.24.4.1 TRadioButton.Action Property

Designates the action associated with the control.

Pascal

```
property Action;
```

C++

```
__property Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

Delphi Examples:

```
{
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
}
procedure TForm1.ChangeColor(Sender: TObject);
begin
  { randomly change the color of the form }
  Color := Random($FFFF);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { allocate memory for the Action property }
  Action := TBasicAction.Create(Self);

  { set the OnExecute event handler }
  Action.OnExecute := ChangeColor;

  { initialize the random number generator }
  Randomize;
end;
```

29.1.24.4.2 TRadioButton.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;
```

```
  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
```

```
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Anchors

29.1.24.4.3 TRadioButton.Alignment Property

Determines the position of the caption relative to the radio button.

Pascal

```
property Alignment: TLeftRight;
```

C++

```
__property TLeftRight Alignment;
```

Description

Set Alignment to determine whether the caption of the radio button should appear to the left of the radio button (taLeftJustify) or to the right of the radio button (taRightJustify).

Note: Do not confuse the Alignment property with the alignment of the caption in the text area of the radio button. The caption always appears left aligned. Alignment only controls on which side of the button the text area appears.

See Also

Caption

29.1.24.4.4 TRadioButton.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.24.4.5 TRadioButton.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

29.1.24.4.6 TRadioButton.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
```

```
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
```

```
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

29.1.24.4.7 TRadioButton.Checked Property

Determines whether the option represented by the radio button is selected.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Read (see page 3727) Checked to determine whether the radio button is selected. Set Checked to true to select the radio button and deselect all other radio buttons in the same container. Set Checked to false to deselect the radio button, leaving no radio button in the group selected.

See Also

TRadioGroup

29.1.24.4.8 TRadioButton.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
```

```
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

29.1.24.4.9 TRadioButton.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

29.1.24.4.10 TRadioButton.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

29.1.24.4.11 TRadioButton.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
```

```
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.
```

```
procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

29.1.24.4.12 TRadioButton.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.24.4.13 TRadioButton.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.24.4.14 TRadioButton.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
```

```
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

29.1.24.4.15 TRadioButton.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.24.4.16 TRadioButton.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

ParentFont

Displaying and Editing Text in a Memo Control

29.1.24.4.17 TRadioButton.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

BiDiMode

29.1.24.4.18 TRadioButton.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.24.4.19 TRadioButton.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.24.4.20 TRadioButton.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.24.4.21 TRadioButton.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

29.1.24.4.22 TRadioButton.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.24.4.23 TRadioButton.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

OnContextPopup

29.1.24.4.24 TRadioButton.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

29.1.24.4.25 TRadioButton.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

29.1.24.4.26 TRadioButton.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

29.1.24.4.27 TRadioButton.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

29.1.24.4.28 TRadioButton.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

29.1.24.5 TRadioButton Events

The events of the TRadioButton class are listed here.

Published Events

	Name	Description
	OnClick (see page 2758)	Occurs when the user clicks the control.
	OnContextPopup (see page 2760)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2761)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2761)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2764)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2767)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2768)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2769)	Occurs when a control receives the input focus.
	OnExit (see page 2771)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2774)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2777)	Occurs when a key is pressed.
	OnKeyUp (see page 2779)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2780)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2781)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2784)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2784)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2784)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2786)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2789)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2789)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.24.5.1 TRadioButton.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.

- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

29.1.24.5.2 TRadioButton.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

29.1.24.5.3 TRadioButton.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

29.1.24.5.4 TRadioButton.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
```

```
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

TDragObject

29.1.24.5.5 TRadioButton.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
```

```
Note: Set the label's DragMode property to dmAutomatic.

    if (Source is TLabel) and (State = dsDragEnter) then
      (Source as TLabel).EndDrag(False);
  end;
  {
  This code requires a list box and three labels, each with a
  different font and color.  The DragMode property for each of
  the labels is dmAutomatic.  The user can select a label and
  drag it to a list box and drop it. When the label is dropped,
  the items in the list box assume the color and font of the
  dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:
```

```
procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

29.1.24.5.7 TRadioButton.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

29.1.24.5.8 TRadioButton.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

Using a Single Navigator for Multiple Datasets

29.1.24.5.9 TRadioButton.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated

An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,

OnEnter

ActiveControl

29.1.24.5.10 TRadioButton.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
```

```
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

29.1.24.5.11 TRadioButton.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyUp

KeyPreview

29.1.24.5.12 TRadioButton.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;

OnKeyPress

29.1.24.5.13 TRadioButton.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

29.1.24.5.14 TRadioButton.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {

29.1.24.5.15 TRadioButton.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.24.5.16 TRadioButton.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.24.5.17 TRadioButton.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled

OnMouseMove

Responding to a Mouse-up Action

29.1.24.5.19 TRadioButton.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

29.1.24.5.20 TRadioButton.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.25 TScrollBar Class

TScrollBar is a Windows scroll bar, which is used to scroll the contents of a window, form, or control.

Class Hierarchy

Pascal

```
TScrollBar = class(TWinControl);
```

C++

```
class TScrollBar : public TWinControl;
```

File

StdCtrls

Description

Use TScrollBar to add a free-standing scroll bar to a form. Many controls have properties that add scroll bars which are an integral part of the control (TControlScrollBar objects). TScrollBar allows controls that do not have integrated scroll bars or groupings of controls to be scrolled when the user manipulates the TScrollBar object.

When the bi-directional mode of a scroll bar is changed, its coordinate system is reversed. Position (see page 2820) zero in left-to-right mode is the left side, and position zero in right-to-left mode is the right side.

Specialized Input Controls

29.1.25.1 TScrollBar Members

The following tables list the members exposed by TScrollBar.

Protected Methods

	Name	Description
	Change (see page 2793)	This is Change, a member of class TScrollBar.
	CreateParams (see page 2793)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2793)	Creates the underlying window.
	Scroll (see page 2794)	This is Scroll, a member of class TScrollBar.

Public Methods

	Name	Description
	Create (see page 2792)	Creates and initializes an instance of TScrollBar (see page 2790).
	SetParams (see page 2794)	Sets the Position (see page 2820), Max (see page 2808), and Min (see page 2810) property values all at once.

Published Events

	Name	Description
	OnChange (see page 2829)	Occurs immediately after the value of Position (see page 2820) changes.
	OnContextPopup (see page 2829)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2830)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2833)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2836)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2836)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2837)	Occurs when a control receives the input focus.
	OnExit (see page 2840)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2842)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2846)	Occurs when a key is pressed.
	OnKeyUp (see page 2847)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 2849)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2849)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 2849)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 2851)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2852)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2795)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2799)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2799)	Specifies the bi-directional mode for the control.
	Constraints (see page 2800)	Specifies the size constraints for the control.
	Ctl3D (see page 2800)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2801)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2802)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2803)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2803)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2805)	Controls whether the control responds to mouse, keyboard, and timer events.

	Kind (see page 2805)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 2806)	Determines how much Position (see page 2820) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Max (see page 2808)	Specifies the maximum position represented by the scroll bar.
	Min (see page 2810)	Specifies the minimum position represented by the scroll bar.
	PageSize (see page 2812)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 2814)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 2814)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2814)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 2815)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2815)	Identifies the pop-up menu associated with the control.
	Position (see page 2820)	Indicates the current position of the scroll bar.
	ShowHint (see page 2822)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 2824)	Determines how much Position (see page 2820) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 2826)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2826)	Determines if the user can tab to a control.
	Visible (see page 2827)	Determines whether the component appears onscreen.

29.1.25.2 TScrollBar.Create Constructor

Creates and initializes an instance of TScrollBar (see page 2790).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScrollBar(TComponent * AOwner);
```

Description

Call Create to create an instance of TScrollBar (see page 2790) at runtime. Scroll (see page 2794) bars placed on a form at design time are created automatically.

AOwner is the component that is responsible for freeing the scroll bar. This becomes the value of the Owner property.

Owner

29.1.25.3 TScrollBar Methods

The methods of the TScrollBar class are listed here.

Protected Methods

	Name	Description
	Change (see page 2793)	This is Change, a member of class TScrollBar.
V	CreateParams (see page 2793)	Initializes a window-creation parameter data structure.
V	CreateWnd (see page 2793)	Creates the underlying window.
	Scroll (see page 2794)	This is Scroll, a member of class TScrollBar.

Public Methods

	Name	Description
	SetParams (see page 2794)	Sets the Position (see page 2820), Max (see page 2808), and Min (see page 2810) property values all at once.

29.1.25.3.1 TScrollBar.Change Method

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

This is Change, a member of class TScrollBar.

29.1.25.3.2 TScrollBar.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWnd

AddBiDiModeExStyle

29.1.25.3.3 TScrollBar.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

CreateWindowHandle

Perform

DestroyWnd

29.1.25.3.4 TScrollBar.Scroll Method

Pascal

```
procedure Scroll(ScrollCode: TScrollCode; var ScrollPos: Integer); dynamic;
```

C++

```
__fastcall Scroll(TScrollCode ScrollCode, int ScrollPos);
```

Description

This is Scroll, a member of class TScrollBar.

29.1.25.3.5 TScrollBar.SetParams Method

Sets the Position (see page 2820), Max (see page 2808), and Min (see page 2810) property values all at once.

Pascal

```
procedure SetParams(APosition: Integer; AMin: Integer; AMax: Integer);
```

C++

```
__fastcall SetParams(int APosition, int AMin, int AMax);
```

Description

Use the SetParams method to set the Position (see page 2820), Min (see page 2810), and Max (see page 2808) property values all at once, preventing repaints that would occur if each property value were set separately.

See Also

Max (see page 2808)

Min (see page 2810)

Position (see page 2820)

29.1.25.4 TScrollBar Properties

The properties of the TScrollBar class are listed here.

Published Properties

	Name	Description
	Align (see page 2795)	Determines how the control aligns within its container (parent control).

	Anchors (see page 2799)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2799)	Specifies the bi-directional mode for the control.
	Constraints (see page 2800)	Specifies the size constraints for the control.
	Ctl3D (see page 2800)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2801)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2802)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2803)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2803)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2805)	Controls whether the control responds to mouse, keyboard, and timer events.
	Kind (see page 2805)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 2806)	Determines how much Position (see page 2820) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Max (see page 2808)	Specifies the maximum position represented by the scroll bar.
	Min (see page 2810)	Specifies the minimum position represented by the scroll bar.
	PageSize (see page 2812)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 2814)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 2814)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2814)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 2815)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2815)	Identifies the pop-up menu associated with the control.
	Position (see page 2820)	Indicates the current position of the scroll bar.
	ShowHint (see page 2822)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 2824)	Determines how much Position (see page 2820) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 2826)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2826)	Determines if the user can tab to a control.
	Visible (see page 2827)	Determines whether the component appears onscreen.

29.1.25.4.1 TScrollBar.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
```

```
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
```

```
  the bottom of the form.
  }

  var
    I: Integer;

Parent

Anchors

29.1.25.4.2 TScrollBar.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

29.1.25.4.3 TScrollBar.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

Including Bi-directional Functionality in Applications

29.1.25.4.4 TScrollBar.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

29.1.25.4.5 TScrollBar.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

29.1.25.4.6 TScrollBar.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;

29.1.25.4.7 TScrollBar.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.25.4.8 TScrollBar.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.25.4.9 TScrollBar.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;

29.1.25.4.10 TScrollBar.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.25.4.11 TScrollBar.Kind Property

Specifies whether the scroll bar is horizontal or vertical.

Pascal

```
property Kind: TScrollBarKind;
```

C++

```
__property TScrollBarKind Kind;
```

Description

Set Kind to indicate the orientation of the scroll bar. These are the possible values:

Value	Meaning
sbHorizontal	Scroll (see page 2794) bar is horizontal
sbVertical	Scroll (see page 2794) bar is vertical

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

29.1.25.4.12 TScrollBar.LargeChange Property

Determines how much Position (see page 2820) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.

Pascal

```
property LargeChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc LargeChange;
```

Description

Set LargeChange to specify how much to change the value of Position (see page 2820) when the user clicks on the side of the thumb tab (that is, on the thumb tab track, but not on the thumb tab itself). The Max (see page 2808) and Min (see page 2810) properties define the total range over which Position (see page 2820) can vary.

For example, if Max (see page 2808) is 30000 and Min (see page 2810) is 0, the scroll box can assume 30,000 positions. If the LargeChange property setting is 10000 and the Position (see page 2820) property is 0, the user can click the scroll bar track three times after the thumb tab before it moves all the way to the end of the scroll bar (30000 / 10000 = 3).

LargeChange should correspond to the portion of this range that the user sees in one page or screen, expressed in the logical units used by the Max (see page 2808), Min (see page 2810), and Position (see page 2820) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];
  for (int i = 0; i < PageControl1->PageCount; i++)
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
  /* set up the scrollbar to reflect
     the structure of the page control */
  ScrollBar1->Max = PageControl1->PageCount - 1;
  ScrollBar1->Min = 0;
  ScrollBar1->SmallChange = 1;
  // set LargeChange to a single row of tabs
  ScrollBar1->LargeChange = PageControl1->ClientWidth / PageControl1->TabWidth;
}

void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  ScrollBar1->Position = (dynamic_cast<TPageControl *>(Sender))->ActivePage->PageIndex;
}

void __fastcall TForm1::ScrollBar1Scroll(TObject *Sender,
      TScrollCode ScrollCode, int &ScrollPos)
{
  PageControl1->ActivePage = PageControl1->Pages[ScrollPos];
}
```

Delphi Examples:

```
{
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in

29.1.25.4.13 TScrollBar.Max Property

Specifies the maximum position represented by the scroll bar.

Pascal

```
property Max: Integer;
```

C++

```
__property int Max;
```

Description

Set Max to the maximum value the Position (see page 2820) property can take. The Max and Min (see page 2810) properties define the total range over which Position (see page 2820) can vary.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
```

```
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/

29.1.25.4.14 TScrollBar.Min Property

Specifies the minimum position represented by the scroll bar.

Pascal

```
property Min: Integer;
```

C++

```
__property int Min;
```

Description

Set Min to the minimum value the Position (see page 2820) property can take. The Min and Max (see page 2808) properties define the total range over which Position (see page 2820) can vary.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the

29.1.25.4.15 TScrollBar.PageSize Property

Specifies the size of the thumb tab.

Pascal

```
property PageSize: Integer;
```

C++

```
__property int PageSize;
```

Description

PageSize is the size of the thumb tab, measured in the same units as Position (see page 2820), Min (see page 2810), and Max (see page 2808) (not pixels).

C++ Examples:

```
/*
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
*/
void __fastcall SetThumbTab()
{
  // Get the minimum (default) size of the thumb tab
  int MinHeight = GetSystemMetrics(SM_CYVTHUMB);
  // Get the size of the scrollbar track
  int TrackHeight = Form1->ScrollBar1->ClientHeight - 2*GetSystemMetrics(SM_CYVSCROLL);
  // set PageSize to represent the visible portion of the scrolling range:
  Form1->ScrollBar1->PageSize = TrackHeight/(Form1->ScrollBar1->Max - Form1->ScrollBar1->Min +
1);
  // Don't let the thumb tab get too small
  if (Form1->ScrollBar1->PageSize < MinHeight)
  Form1->ScrollBar1->PageSize = MinHeight;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
```

```
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::ScrollBar1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1EndDrag(TObject *Sender, TObject *Target,
      int X, int Y)
{
 SetThumbTab();
}
```

Delphi Examples:

```
{
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
}
procedure SetThumbTab(wincontrol: TWinControl);
var
  TrackHeight: Integer; { the size of the scroll bar track }
  MinHeight: Integer; { the default size of the thumb tab }
begin
  MinHeight := GetSystemMetrics(SM_CYVTHUMB); { save default size }
  with Form1.ScrollBar1 do
  begin
    TrackHeight := wincontrol.ClientHeight - 2 * GetSystemMetrics(SM_CYVSCROLL);
    PageSize := TrackHeight div (Max - Min + 1);
    if PageSize < MinHeight then PageSize := MinHeight;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  SetThumbTab(RichEdit1);
end;
procedure TForm1.RichEdit1Change(Sender: TObject);
begin
  SetThumbTab(RichEdit1);
end;
```

29.1.25.4.16 TScrollBar.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

29.1.25.4.17 TScrollBar.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

29.1.25.4.18 TScrollBar.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of

the parent's DoubleBuffered property.

29.1.25.4.19 TScrollBar.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.25.4.20 TScrollBar.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
```

```
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
```

```
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
```

```
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

29.1.25.4.21 TScrollBar.Position Property

Indicates the current position of the scroll bar.

Pascal

```
property Position: Integer;
```

C++

```
__property int Position;
```

Description

Read (see page 3727) Position to determine the current position of the thumb tab. This value can be used to determine how to scroll any components controlled by the scroll bar. When the user scrolls the scroll bar, the value of Position changes. Set Position to programmatically move the thumb tab of the scroll bar.

The number of possible positions on the scroll bar is determined by the difference between the Max (see page 2808) property and the Min (see page 2810) property. If Position has the same value as Min (see page 2810), the thumb tab appears at the far left of a horizontal scroll bar or the top of a vertical scroll bar. If Position has the same value as Max (see page 2808), the thumb tab appears at the far right of a horizontal scroll bar or the bottom of a vertical scroll bar.

C++ Examples:

```
/*
```

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];
  for (int i = 0; i < PageControl1->PageCount; i++)
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
  /* set up the scrollbar to reflect
     the structure of the page control */
  ScrollBar1->Max = PageControl1->PageCount - 1;
  ScrollBar1->Min = 0;
  ScrollBar1->SmallChange = 1;
  // set LargeChange to a single row of tabs
  ScrollBar1->LargeChange = PageControl1->ClientWidth / PageControl1->TabWidth;
}

void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  ScrollBar1->Position = (dynamic_cast<TPageControl *>(Sender))->ActivePage->PageIndex;
}

void __fastcall TForm1::ScrollBar1Scroll(TObject *Sender,
      TScrollCode ScrollCode, int &ScrollPos)
{
  PageControl1->ActivePage = PageControl1->Pages[ScrollPos];
}
```

Delphi Examples:

```
{
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
const
  colorpalette: Array[0..11] of TColor = (clRed, clGreen, clYellow, clBlue, clWhite,
clFuchsia, clTeal, clNavy, clMaroon, clLime, clOlive, clPurple);
begin
  { First, initialize the page control }
  PageControl1.TabWidth := PageControl1.ClientWidth div 4 - 1;
```

```
    PageControl1.ActivePage := PageControl1.Pages[0];
    for i := 0 to PageControl1.PageCount - 1 do
      PageControl1.Pages[i].Brush.Color:= colorPalette[i];
    { set up the scrollbar to reflect the structure of the page control}
    with ScrollBar1 do
    begin
      Max := PageControl1.PageCount - 1;
      Min := 0;
      SmallChange := 1;
      { set LargeChange to a single row of tabs }
      LargeChange := PageControl1.ClientWidth div PageControl1.TabWidth;
    end;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    with Sender as TPageControl do
      ScrollBar1.Position := ActivePage.PageIndex;
  end;

  procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
    var ScrollPos: Integer);
  begin
    PageControl1.ActivePage := PageControl1.Pages[ScrollPos];
  end;
```

29.1.25.4.22 TScrollBar.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
```

```
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

29.1.25.4.23 TScrollBar.SmallChange Property

Determines how much Position (see page 2820) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.

Pascal

```
property SmallChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc SmallChange;
```

Description

Set SmallChange to specify how much to change the value of Position (see page 2820) when the user clicks on the arrow buttons. The Max (see page 2808) and Min (see page 2810) properties define the total range over which Position (see page 2820) can vary.

For example, if Max (see page 2808) is 100 and Min (see page 2810) is 0, the scroll box can assume 100 positions. If the SmallChange property setting is 5 and the Position (see page 2820) property is 0, the user can click the down or right arrow button 20 times before the thumb tab is moved all the way to the end of the scroll bar.

SmallChange should correspond to the portion of this range that the user sees as one line or one item, expressed in the logical units used by the Max (see page 2808), Min (see page 2810), and Position (see page 2820) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.

29.1.25.4.24 TScrollBar.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

29.1.25.4.25 TScrollBar.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

29.1.25.4.26 TScrollBar.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

29.1.25.5 TScrollBar Events

The events of the TScrollBar class are listed here.

Published Events

	Name	Description
	OnChange (see page 2829)	Occurs immediately after the value of Position (see page 2820) changes.
	OnContextPopup (see page 2829)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2830)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2833)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2836)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2836)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2837)	Occurs when a control receives the input focus.
	OnExit (see page 2840)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2842)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2846)	Occurs when a key is pressed.
	OnKeyUp (see page 2847)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 2849)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2849)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 2849)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 2851)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2852)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.25.5.1 TScrollBar.OnChange Event

Occurs immediately after the value of Position (see page 2820) changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3789) an OnChange event handler to control another object or group of objects using TScrollBar (see page 2790). Adjust the objects controlled by the scroll bar to reflect the new value of Position (see page 2820).

OnChange occurs whether the value of Position (see page 2820) is changed by the user or programmatically. If the value of Position (see page 2820) is changed by the user, OnChange occurs immediately after the OnScroll (see page 2849) event.

OnScroll (see page 2849)

Position (see page 2820)

29.1.25.5.2 TScrollBar.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

29.1.25.5.3 TScrollBar.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}
```

```
/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

29.1.25.5.4 TScrollBar.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

29.1.25.5.6 TScrollBar.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

29.1.25.5.7 TScrollBar.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

29.1.25.5.8 TScrollBar.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,

ActiveControl

29.1.25.5.9 TScrollBar.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)

OnKeyPress

OnKeyUp

29.1.25.5.10 TScrollBar.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not

generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

29.1.25.5.12 TScrollBar.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.25.5.13 TScrollBar.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.25.5.14 TScrollBar.OnScroll Event

Occurs when the user scrolls the scroll bar with the mouse or keyboard.

Pascal

```
property OnScroll: TScrollEvent;
```

C++

```
__property TScrollEvent OnScroll;
```

Description

Write (see page 3789) an OnScroll to alter the way the scrollbar adjusts its position when the user scrolls the scroll bar.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/

29.1.25.5.15 TScrollBar.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is

automatically created.

Note: This information applies to Win32 applications only.

29.1.25.5.16 TScrollBar.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.1.26 TStaticText Class

TStaticText is a windowed control that displays text on a form.

Class Hierarchy

Pascal

```
TStaticText = class(TCustomStaticText);
```

C++

```
class TStaticText : public TCustomStaticText;
```

File

StdCtrls

Description

The TStaticText component functions like TLabel (see page 2522), except that it descends from TWinControl and therefore has a window handle. Use TStaticText instead of TLabel (see page 2522) when the component's accelerator key must belong to a windowed control—for example, on an ActiveX property page.

Display Controls

29.1.26.1 TStaticText Members

The following tables list the members exposed by TStaticText.

Protected Methods

	Name	Description
	CreateParams (see page 2376)	Initializes a window-creation parameter data structure.
	Loaded (see page 2377)	Initializes the control after it is loaded from a stream.
	Notification (see page 2377)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2378)	This is SetAutoSize, a member of class TCustomStaticText.

Public Methods

	Name	Description
	Create (see page 2376)	Creates and initializes a TCustomStaticText (see page 2375) instance.

Published Events

	Name	Description
	OnClick (see page 2885)	Occurs when the user clicks the control.
	OnContextPopup (see page 2887)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 2887)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2888)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2891)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2894)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2894)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2895)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2896)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2899)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2899)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2899)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2901)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2904)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2904)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2855)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2859)	Determines how text is aligned within the component.
	Anchors (see page 2859)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2860)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 2860)	Specifies which edges of the control are beveled.
	BevelInner (see page 2861)	Specifies the cut of the inner bevel.
	BevelKind (see page 2861)	Specifies the control's bevel style.
	BevelOuter (see page 2862)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2862)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2862)	Determines the appearance of the control's border.
	Caption (see page 2863)	Specifies a text string that identifies the control to the user.
	Color (see page 2865)	Specifies the background color of the control.
	Constraints (see page 2866)	Specifies the size constraints for the control.
	DoubleBuffered (see page 2867)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2868)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2869)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2869)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2871)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2871)	Links the component with another windowed control.
	Font (see page 2872)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2873)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2873)	Determines where a control looks for its color information.
	ParentDoubleBuffered (see page 2874)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2874)	Determines where a control looks for its font information.
	ParentShowHint (see page 2874)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2875)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2880)	Enables accelerator characters.
	ShowHint (see page 2880)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2882)	Indicates the position of the control in its parent's tab order.

	TabStop (see page 2882)	Determines if the user can tab to a control.
	Transparent (see page 2883)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 2883)	Determines whether the component appears onscreen.

29.1.26.2 TStaticText Properties

The properties of the TStaticText class are listed here.

Published Properties

	Name	Description
	Align (see page 2855)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2859)	Determines how text is aligned within the component.
	Anchors (see page 2859)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2860)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 2860)	Specifies which edges of the control are beveled.
	BevelInner (see page 2861)	Specifies the cut of the inner bevel.
	BevelKind (see page 2861)	Specifies the control's bevel style.
	BevelOuter (see page 2862)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2862)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2862)	Determines the appearance of the control's border.
	Caption (see page 2863)	Specifies a text string that identifies the control to the user.
	Color (see page 2865)	Specifies the background color of the control.
	Constraints (see page 2866)	Specifies the size constraints for the control.
	DoubleBuffered (see page 2867)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2868)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2869)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2869)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2871)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2871)	Links the component with another windowed control.
	Font (see page 2872)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2873)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2873)	Determines where a control looks for its color information.
	ParentDoubleBuffered (see page 2874)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2874)	Determines where a control looks for its font information.
	ParentShowHint (see page 2874)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2875)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2880)	Enables accelerator characters.
	ShowHint (see page 2880)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2882)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2882)	Determines if the user can tab to a control.
	Transparent (see page 2883)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 2883)	Determines whether the component appears onscreen.

29.1.26.2.1 TStaticText.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;
```

```
  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
```

```
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    ProgressBar: TProgressBar;
  begin
    ProgressBar := TProgressBar.Create(Self);
    with ProgressBar do
    begin
      Parent := Self;
      Align := alBottom;
    end;
  end;
  {
  This example dynamically creates a Page Control, then a
  series of Tab Sheets on the Page Control.
  }
  var
    PageControl1: TPageControl;

  const
    TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

  procedure TForm1.FormCreate(Sender: TObject);
  const
    colorpalette: Array[0..11] of TColor = (
      clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
      clNavy, clMaroon, clLime, clOlive, clPurple);
  var
    i: Integer;
  begin
    PageControl1 := TPageControl.Create(Self);
    PageControl1.Parent := Self;
    PageControl1.Align := alClient;
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i]:= TTabSheet.Create(PageControl1);
      with pts[i] do
```

```
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

Anchors

29.1.26.2.2 TStaticText.Alignment Property

Determines how text is aligned within the component.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

The possible values of Alignment are

Value	Meaning
taLeftJustify	Text is aligned at the left of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is aligned at the right of the control.

See Also

Font

Caption

29.1.26.2.3 TStaticText.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent

Align

29.1.26.2.4 TStaticText.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

29.1.26.2.5 TStaticText.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

29.1.26.2.6 TStaticText.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

29.1.26.2.7 TStaticText.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

29.1.26.2.8 TStaticText.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

29.1.26.2.9 TStaticText.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

29.1.26.2.10 TStaticText.BorderStyle Property

Determines the appearance of the control's border.

Pascal

```
property BorderStyle: TStaticBorderStyle;
```

C++

```
__property TStaticBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify the appearance of the border, if any, that appears around the text.

29.1.26.2.11 TStaticText.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
```

```
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

29.1.26.2.12 TStaticText.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

29.1.26.2.13 TStaticText.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

29.1.26.2.14 TStaticText.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

29.1.26.2.15 TStaticText.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

29.1.26.2.16 TStaticText.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

29.1.26.2.17 TStaticText.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);

Arranging the Order of Persistent Columns

29.1.26.2.18 TStaticText.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

29.1.26.2.19 TStaticText.FocusControl Property

Links the component with another windowed control.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Use the FocusControl property to link the TCustomStaticText instance with another windowed control. If the text of Caption includes an accelerator key, the component specified by FocusControl receives focus when the accelerator is pressed.

See Also

Caption

FocusControl (see page 2313)

29.1.26.2.20 TStaticText.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

29.1.26.2.21 TStaticText.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

29.1.26.2.22 TStaticText.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

29.1.26.2.23 TStaticText.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

29.1.26.2.24 TStaticText.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

29.1.26.2.25 TStaticText.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

29.1.26.2.26 TStaticText.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {

            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    PopupMenu1.AutoPopup := True;
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then

29.1.26.2.27 TStaticText.ShowAccelChar Property

Enables accelerator characters.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

If ShowAccelChar is true, an ampersand in the component's Caption text appears as an underline and makes the character after it into an accelerator key. If ShowAccelChar is false, ampersands appear as ampersands.

Caption

29.1.26.2.28 TStaticText.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

29.1.26.2.29 TStaticText.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

29.1.26.2.30 TStaticText.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

29.1.26.2.31 TStaticText.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TCustomStaticText object to show through the background of the image. Set Transparent to false to make the background of the image opaque.

29.1.26.2.32 TStaticText.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/

29.1.26.3 TStaticText Events

The events of the TStaticText class are listed here.

Published Events

	Name	Description
	OnClick (see page 2885)	Occurs when the user clicks the control.

	OnContextPopup (see page 2887)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2887)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2888)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2891)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2894)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2894)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2895)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2896)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2899)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2899)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2899)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2901)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2904)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2904)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

29.1.26.3.1 TStaticText.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
```

```

29.1.26.3.2 TStaticText.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

OnClick

Responding to User Actions at Runtime

29.1.26.3.4 TStaticText.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
```

```
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,

29.1.26.3.5 TStaticText.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}
```

```
void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

29.1.26.3.7 TStaticText.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;

29.1.26.3.8 TStaticText.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse

button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

29.1.26.3.9 TStaticText.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area

of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

29.1.26.3.10 TStaticText.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

29.1.26.3.11 TStaticText.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

29.1.26.3.12 TStaticText.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled

  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

29.1.26.3.14 TStaticText.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

29.1.26.3.15 TStaticText.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

29.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCheckBoxState (see page 2906)	TCheckBoxState indicates the state of a check box control.
	TComboBoxStyle (see page 2907)	TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 1959) unit.
	TEditCharCase (see page 2907)	TEditCharCase indicates how a control forces the case of characters, if at all.
	TEllipsisPosition (see page 2908)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	TImageAlignment (see page 2909)	Alignment of image on TButton (see page 1961).
	TListBoxStyle (see page 2910)	TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.
	TScrollCode (see page 2911)	TScrollCode indicates what action the user performed on a scroll bar.
	TScrollStyle (see page 2912)	Identifies a set of scrollbars by their orientation.
	TStaticBorderStyle (see page 2913)	TStaticBorderStyle determines the appearance of the border on a static text control.
	TTextLayout (see page 2914)	TTextLayout indicates where text appears within the client area of a control.

Records

	Name	Description
	TSelection (see page 2913)	TSelection definese the start and position of a selection.

29.2.1 StdCtrls.TCheckBoxState Enumeration

TCheckBoxState indicates the state of a check box control.

Pascal

```
TCheckBoxState = (
  cbUnchecked,
  cbChecked,
  cbGrayed
);
```

C++

```
enum TCheckBoxState {
  cbUnchecked,
  cbChecked,
  cbGrayed
};
```

File

StdCtrls

Description

Following are the possible values of TCheckBoxState:

Value	Meaning
cbUnchecked	The check box has no check mark, indicating that the user has not selected the option.
cbChecked	The check box has a check mark in it, indicating that the user has selected the option.

cbGrayed	The check box has a check mark in it, but it is grayed.

29.2.2 StdCtrls.TComboBoxStyle Enumeration

TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 1959) unit.

Pascal

```
TComboBoxStyle = (
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
);
```

C++

```
enum TComboBoxStyle {
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
};
```

File

StdCtrls

Description

These are the values in the TComboBoxStyle type:

Value	Meaning
csDropDown	Creates a drop-down list with an edit box for manually entered text. All items are strings of the same height.
csSimple	Creates an edit box with a fixed list (list box) underneath. The length of the list is determined by the Height of the combo box.
csDropDownList	Creates a drop-down list with no edit box; the user cannot enter text manually. All items are strings of the same height.
csOwnerDrawFixed	Creates an owner-draw drop-down list with no edit box. Each item in the list is the height specified by the ItemHeight property.
csOwnerDrawVariable	Creates an owner-draw drop-down list with no edit box. List items can have varying heights.

29.2.3 StdCtrls.TEditCharCase Enumeration

TEditCharCase indicates how a control forces the case of characters, if at all.

Pascal

```
TEditCharCase = (
  ecNormal,
  ecUpperCase,
```

```
    ecLowerCase
  );
```

C++

```
  enum TEditCharCase {
    ecNormal,
    ecUpperCase,
    ecLowerCase
  };
```

File

StdCtrls

Description

TEditCharCase specifies what case is given to text typed into a control. It can have one of the following values:

Value	Meaning
ecLowerCase	The text is converted to lowercase.
ecNormal	The text appears in mixed case. It is not forced into any case.
ecUpperCase	The text is converted to uppercase.

29.2.4 StdCtrls.TEllipsisPosition Enumeration

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
  TEllipsisPosition = (
    epNone,
    epPathEllipsis,
    epEndEllipsis,
    epWordEllipsis
  );
```

C++

```
  enum TEllipsisPosition {
    epNone,
    epPathEllipsis,
    epEndEllipsis,
    epWordEllipsis
  };
```

File

StdCtrls

Description

TEllipsisPosition specifies how an ellipsis is placed in text that does not fit in its allocated rectangle. The constants here correspond to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

The following table lists values for TEllipsisPosition:

Value	Meaning
epNone	An ellipsis is not inserted.

epPathEllipsis	Replaces text in the middle with an ellipsis so that the resulting text fits in the rectangle specified. If the text contains backslash (\) characters, treat the text as a path and attempt to preserve as much text as possible after the last backslash. Corresponds to a value of DT_PATH_ELLIPSIS in the **dwDTFormat** parameter.
epEndEllipsis	Replaces text at the end with an ellipsis so that the resulting text fits in the rectangle specified. Any word not fitting in the rectangle is truncated without adding an ellipsis. Corresponds to a value of DT_END_ELLIPSIS in the **dwDTFormat** parameter.
epWordEllipsis	Truncates any word that doesn't fit in the rectangle and adds ellipses. Corresponds to a value of DT_WORD_ELLIPSIS in the **dwDTFormat** parameter.

29.2.5 StdCtrls.TImageAlignment Enumeration

Alignment of image on TButton (see page 1961).

Pascal

```
TImageAlignment = (
  iaLeft,
  iaRight,
  iaTop,
  iaBottom,
  iaCenter
);
```

C++

```
enum TImageAlignment {
  iaLeft,
  iaRight,
  iaTop,
  iaBottom,
  iaCenter
};
```

File

StdCtrls

Description

TImageAlignment indicates the alignment of an image on a TButton (see page 1961), which is the value of its ImageAlignment property. Following are the possible values of TImageAlignment:

Value	Meaning
iaLeft	Left aligned.
iaRight	Right aligned.
iaTop	Top aligned.
iaBottom	Bottom aligned.
iaCenter	Center aligned.

See Also

TButton (see page 1961)

ImageAlignment (see page 1983)

29.2.6 StdCtrls.TListBoxStyle Enumeration

TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.

Pascal

```
TListBoxStyle = (
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
);
```

C++

```
enum TListBoxStyle {
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
};
```

File

StdCtrls

Description

The following table lists the values for the TListBoxStyle type:

Value	Meaning
lbStandard	All items are strings, with each item the same height.
lbOwnerDrawFixed	The list box is owner-drawn, but each item in the list box is the height specified by the ItemHeight property. Each time an item is displayed in an lbOwnerDrawFixed list box, the OnDrawItem event occurs. The event handler for OnDrawItem draws the specified item. The ItemHeight property determines the height of each of the items.
lbOwnerDrawVariable	The list box is owner-drawn, and items in the list box can be of varying heights. Each time an item is displayed in an lbOwnerDrawVariable list box, two events occur. The first is the OnMeasureItem event. The code for the OnMeasureItem handler can set the height of each item. Then the OnDrawItem event occurs. The code for the OnDrawItem handler draws each item in the list box using the size specified by the OnMeasureItem handler.
lbVirtual	The list box is virtual, but all items are strings with the same height. You must indicate the number of items in the list box by setting the Count property. You must supply the items in the list box using an OnData event handler. If the items have associated objects, you must supply them using an OnDataObject event handler. In addition, you must supply an OnDataFind event handler to provide the mapping from the strings in the list box to their indexes.
lbVirtualOwnerDraw	The list box is virtual and owner-drawn. All items are the same height. As with lbOwnerDrawFixed, the item height is specified by the ItemHeight property, and you must draw items using an OnDrawItem event handler. As with lbVirtual, you must set the Count property and supply OnData and OnDataFind event handlers to provide the mapping between items and indexes. If items are associated with objects, you must also supply an OnDataObject event handler.

29.2.7 StdCtrls.TScrollCode Enumeration

TScrollCode indicates what action the user performed on a scroll bar.

Pascal

```
TScrollCode = (
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
);
```

C++

```
enum TScrollCode {
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
};
```

File

StdCtrls

Description

TScrollCode describes the type of scrolling action requested. It can be any of the following values:

Value	Meaning
scLineUp	User clicked the top or left scroll arrow or pressed the Up or Left arrow key.
scLineDown	User clicked the bottom or right scroll arrow or pressed the Down or Right arrow key.
scPageUp	User clicked the area to the left of the thumb tab or pressed the PgUp key.
scPageDown	User clicked the area to the right of the thumb tab or pressed the PgDn key.
scPosition	User positioned the thumb tab and released it.
scTrack	User is moving the thumb tab.
scTop	User moved the thumb tab to the top or far left on the scroll bar.
scBottom	User moved the thumb tab to the bottom or far right on the scroll bar.
scEndScroll	User finished moving the thumb tab on the scroll bar.

29.2.8 StdCtrls.TScrollStyle Enumeration

Identifies a set of scrollbars by their orientation.

Pascal

```
TScrollStyle = (
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
);
```

C++

```
enum TScrollStyle {
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
};
```

File

StdCtrls

Description

TScrollStyle can have one of the following values:

Value	Meaning
ssNone	No scrollbars are indicated.
ssHorizontal	Only a horizontal scrollbar.
ssVertical	Only a vertical scrollbar.
ssBoth	Both a horizontal and a vertical scrollbar.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

29.2.9 StdCtrls.TSelection Record

TSelection definese the start and position of a selection.

Pascal

```
TSelection = record
  EndPos: Integer;
  StartPos: Integer;
end;
```

C++

```
struct TSelection {
  int EndPos;
  int StartPos;
};
```

File

StdCtrls

Description

TSelection is used internally in Delphi to hold the start and end position of a selection.

29.2.10 StdCtrls.TStaticBorderStyle Enumeration

TStaticBorderStyle determines the appearance of the border on a static text control.

Pascal

```
TStaticBorderStyle = (
  sbsNone,
  sbsSingle,
  sbsSunken
);
```

C++

```
enum TStaticBorderStyle {
  sbsNone,
  sbsSingle,
  sbsSunken
};
```

File

StdCtrls

Description

These are the values in the TStaticBorderStyle type:

Value	Meaning
sbsNone	No visible border.
sbsSingle	Single-line border.
sbsSunken	Raised border.

29.2.11 StdCtrls.TTextLayout Enumeration

TTextLayout indicates where text appears within the client area of a control.

Pascal

```
TTextLayout = (
  tlTop,
  tlCenter,
  tlBottom
);
```

C++

```
enum TTextLayout {
  tlTop,
  tlCenter,
  tlBottom
};
```

File

StdCtrls

Description

The following table describes the possible values:

Value	Meaning
tlTop	The text appears at the top of the its control.
tlCenter	The text is vertically centered in the control.
tlBottom	The text appears along the bottom of the control.

29.3 Types

The following table lists types in this documentation.

Types

Name	Description
TButtonActionLinkClass (see page 2915)	TButtonActionLinkClass defines the metaclass for TButtonActionLink (see page 2030).
TCustomComboBoxStringsClass (see page 2915)	TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 2257).
TDrawItemEvent (see page 2916)	TScrollEvent (see page 2920) is the type of an OnScroll event handler.
TFNDrawText (see page 2916)	This is type StdCtrls.TFNDrawText.
TLBFindDataEvent (see page 2917)	TLBFindDataEvent is the type of the list box OnDataFind event handler.
TLBGetDataEvent (see page 2917)	TLBGetDataEvent is the type of the list box OnData event handler.
TLBGetDataObjectEvent (see page 2918)	TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.
TMeasureItemEvent (see page 2918)	TMeasureItemEvent is the type for the OnMeasureItem event handler.
TOwnerDrawState (see page 2918)	Indicates state information that can influence how an item is drawn.
TPushButtonActionLinkClass (see page 2919)	This is type StdCtrls.TPushButtonActionLinkClass.
TScrollEvent (see page 2920)	This is type StdCtrls.TScrollEvent.

29.3.1 StdCtrls.TButtonActionLinkClass Type

TButtonActionLinkClass defines the metaclass for TButtonActionLink (see page 2030).

Pascal

```
TButtonActionLinkClass = class of TButtonActionLink;
```

C++

```
TButtonActionLink TButtonActionLinkClass;
```

File

StdCtrls

Description

TButtonActionLinkClass is the metaclass for TButtonActionLink (see page 2030). Its value is the class reference for TButtonActionLink (see page 2030) or for one of its descendants.

See Also

TButtonActionLink (see page 2030)

29.3.2 StdCtrls.TCustomComboBoxStringsClass Type

TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 2257).

Pascal

```
TCustomComboBoxStringsClass = class of TCustomComboBoxStrings;
```

C++

```
TCustomComboBoxStrings TCustomComboBoxStringsClass;
```

File

StdCtrls

Description

TCustomComboBoxStringsClass is the type for a class reference of TCustomComboBoxStrings (see page 2257) or any of its descendants. It is a pointer to the runtime type information (RTTI) for the class type.

29.3.3 StdCtrls.TDrawItemEvent Type

TScrollEvent (see page 2920) is the type of an OnScroll event handler.

Pascal

```
TDrawItemEvent = procedure (Control: TWinControl; Index: Integer; Rect: TRect; State:
TOwnerDrawState) of object;
```

C++

```
(Control: TWinControl; Index: Integer; Rect: TRect; State: TOwnerDrawState) (
TDrawItemEvent)();
```

File

StdCtrls

Description

TScrollEvent (see page 2920) defines the type of method procedure that you must define in order to implement the OnScroll event of a visual component such as TScroll.

The OnScroll event occurs when the user scrolls a scroll bar with the mouse or keyboard.

Sender is a reference to the component invoking the OnScroll event.

ScrollCode defines the user scroll action that was performed.

ScrollPos provides the new scroll position.

See Also

OnScroll

TScrollCode (see page 2911)

29.3.4 StdCtrls.TFNDrawText Type

Pascal

```
TFNDrawText = procedure (DC: HDC; const Text: UnicodeString; var TextRect: TRect; TextFlags:
Cardinal) of object;
```

C++

```
(DC: HDC; const Text: UnicodeString; var TextRect: TRect; TextFlags: Cardinal) (
TFNDrawText)();
```

File

StdCtrls

Description

This is type StdCtrls.TFNDrawText.

29.3.5 StdCtrls.TLBFindDataEvent Type

TLBFindDataEvent is the type of the list box OnDataFind event handler.

Pascal

```
TLBFindDataEvent = function (Control: TWinControl; FindString: string): Integer of object;
```

C++

```
(Control: TWinControl; FindString: string): Integer ( TLBFindDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item index is needed.

FindString is the text of the item whose index is needed.

The event handler returns the index of the item identified by FindString. This return value must be in the range from 0 to one less than the value of the Count property.

29.3.6 StdCtrls.TLBGetDataEvent Type

TLBGetDataEvent is the type of the list box OnData event handler.

Pascal

```
TLBGetDataEvent = procedure (Control: TWinControl; Index: Integer; var Data: string) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var Data: string) ( TLBGetDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item is needed.

Index is the index of the desired item. Index must be less than the value of the Count property.

Data returns the string that is the value of the specified item.

29.3.7 StdCtrls.TLBGetDataObjectEvent Type

TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.

Pascal

```
TLBGetDataObjectEvent = procedure (Control: TWinControl; Index: Integer; var DataObject:
TObject) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var DataObject: TObject) ( TLBGetDataObjectEvent)();
```

File

StdCtrls

Description

Control is the virtual list box that contains the item associated with the object.

Index is the index of the desired item. Index must be less than the value of the Count property.

DataObject returns the object associated with the specified item.

29.3.8 StdCtrls.TMeasureItemEvent Type

TMeasureItemEvent is the type for the OnMeasureItem event handler.

Pascal

```
TMeasureItemEvent = procedure (Control: TWinControl; Index: Integer; var Height: Integer) of
object;
```

C++

```
(Control: TWinControl; Index: Integer; var Height: Integer) ( TMeasureItemEvent)();
```

File

StdCtrls

Description

TMeasureItemEvent is the type for event handlers on custom-drawn controls that allow different items in a list to have different heights.

Control is a reference to the control that contains the item.

Index is the index of the item in the Items property.

Height is the default height of the item, in pixels. The event handler can reset Height to the appropriate value.

29.3.9 StdCtrls.TOwnerDrawState Type

Indicates state information that can influence how an item is drawn.

Pascal

```
TOwnerDrawState = Windows.TOwnerDrawState;
```

C++

```
Windows.TOwnerDrawState TOwnerDrawState;
```

File

StdCtrls

Description

TOwnerDrawState is used by event handlers in owner-draw controls to indicate the state of an item about to be drawn. It is a set that includes zero or more of the following:

Value	Meaning
odSelected	The item is selected.
odGrayed	The item should appear grayed.
odDisabled	The item is disabled.
odChecked	The item should appear checked. (This does not apply to all objects)
odFocused	Keyboard input is directed to the item.
odDefault	The item is the default item (This does not apply to all objects)
odHotLight	The item is hot-lighted because under the mouse (only if the operating system supports hot-lighting)
odInactive	The item and its associated menu are inactive
odNoAccel	Any underline of an accelerator character should be skipped when drawing the control
odNoFocusRect	Do not display visual cues that indicate focus
odReserved1	Not currently used.
odReserved2	Not currently used.
odComboBoxEdit	The drawing takes place in the edit box of a combo box control.

29.3.10 StdCtrls.TPushButtonActionLinkClass Type

Pascal

```
TPushButtonActionLinkClass = class of TPushButtonActionLink;
```

C++

```
TPushButtonActionLink TPushButtonActionLinkClass;
```

File

StdCtrls

Description

This is type StdCtrls.TPushButtonActionLinkClass.

29.3.11 StdCtrls.TScrollEvent Type

Pascal

```
TScrollEvent = procedure (Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) of object;
```

C++

```
(Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) ( TScrollEvent)();
```

File

StdCtrls

Description

This is type StdCtrls.TScrollEvent.

30 StdStyleActnCtrls Namespace

This is namespace StdStyleActnCtrls.

Topics

Name	Description
Classes (see page 2922)	The following table lists classes in this documentation.
Variables (see page 2925)	The following table lists variables in this documentation.

Classes

	Name	Description
	TStandardStyleActionBars (see page 2922)	This is class StdStyleActnCtrls.TStandardStyleActionBars.

Variables

Name	Description
StandardStyle (see page 2925)	This is variable StdStyleActnCtrls.StandardStyle.

30.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TStandardStyleActionBars (see page 2922)	This is class StdStyleActnCtrls.TStandardStyleActionBars.

30.1.1 TStandardStyleActionBars Class

Class Hierarchy

Pascal

```
TStandardStyleActionBars = class(TActionBarStyleEx);
```

C++

```
class TStandardStyleActionBars : public TActionBarStyleEx;
```

File

StdStyleActnCtrls

Description

This is class StdStyleActnCtrls.TStandardStyleActionBars.

30.1.1.1 TStandardStyleActionBars Members

The following tables list the members exposed by TStandardStyleActionBars.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 2923)	Returns the base class for ActionBand menus for customizing action bands.
	GetColorMapClass (see page 2923)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 2923)	Returns the control class type on an action bar item.
	GetPopupClass (see page 2924)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 2924)	This is GetScrollBtnClass, a member of class TStandardStyleActionBars.
	GetStyleName (see page 2924)	Returns the style associated with action manager.

30.1.1.2 TStandardStyleActionBars Methods

The methods of the TStandardStyleActionBars class are listed here.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 2923)	Returns the base class for ActionBand menus for customizing action bands.

	GetColorMapClass (see page 2923)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 2923)	Returns the control class type on an action bar item.
	GetPopupClass (see page 2924)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 2924)	This is GetScrollBtnClass, a member of class TStandardStyleActionBars.
	GetStyleName (see page 2924)	Returns the style associated with action manager.

30.1.1.2.1 TStandardStyleActionBars.GetAddRemoveItemClass Method

Returns the base class for ActionBand menus for customizing action bands.

Pascal

```
function GetAddRemoveItemClass(ActionBar: TCustomActionBar): TCustomAddRemoveItemClass;
override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass(TCustomActionBar ActionBar);
```

Description

Call GetAddRemoveItemClass to customize action bands.

See Also

TCustomAddRemoveItem

30.1.1.2.2 TStandardStyleActionBars.GetColorMapClass Method

Returns the class type of the colormap for an action bar.

Pascal

```
function GetColorMapClass(ActionBar: TCustomActionBar): TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetColorMapClass(TCustomActionBar ActionBar);
```

Description

Returns the class type TCustomActionBarColorMap, which is a colormap associated with an action bar. Override this method to customize the appearance of your applications.

30.1.1.2.3 TStandardStyleActionBars.GetControlClass Method

Returns the control class type on an action bar item.

Pascal

```
function GetControlClass(ActionBar: TCustomActionBar; AnItem: TActionClientItem):
TCustomActionControlClass; override;
```

C++

```
virtual __fastcall TCustomActionControlClass GetControlClass(TCustomActionBar ActionBar,
TActionClientItem AnItem);
```

Description

Returns the control class type on an item in the action bar, such as a button or menu item.

30.1.1.2.4 TStandardStyleActionBars.GetPopupClass Method

Returns the popup class added to a menu action band.

Pascal

```
function GetPopupClass(ActionBar: TCustomActionBar): TCustomPopupClass; override;
```

C++

```
virtual __fastcall TCustomPopupClass GetPopupClass(TCustomActionBar ActionBar);
```

Description

Call GetPopupClass to find the popup menu associated with a menu action band. Override GetPopupClass to change which popup class is associated with a menu action band depending on the state of the control.

See Also

TCustomActionPopupMenu

30.1.1.2.5 TStandardStyleActionBars.GetScrollBtnClass Method

Pascal

```
function GetScrollBtnClass: TCustomToolScrollBtnClass; override;
```

C++

```
virtual __fastcall TCustomToolScrollBtnClass GetScrollBtnClass();
```

Description

This is GetScrollBtnClass, a member of class TStandardStyleActionBars.

30.1.1.2.6 TStandardStyleActionBars.GetStyleName Method

Returns the style associated with action manager.

Pascal

```
function GetStyleName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetStyleName();
```

Description

Returns the value of the Style property.

30.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
StandardStyle (see page 2925)	This is variable StdStyleActnCtrls.StandardStyle.

30.2.1 StdStyleActnCtrls.StandardStyle Variable

Pascal

```
StandardStyle: TStandardStyleActionBars;
```

C++

```
TStandardStyleActionBars StandardStyle;
```

File

StdStyleActnCtrls

Description

This is variable StdStyleActnCtrls.StandardStyle.

31 StdVCL Namespace

This is namespace StdVCL.

Topics

Name	Description
Interfaces (see page 2928)	The following table lists interfaces in this documentation.
Constants (see page 2944)	The following table lists constants in this documentation.

Constants

Name	Description
IID_IDataBroker (see page 2944)	This is constant StdVCL.IID_IDataBroker.
IID_IProvider (see page 2944)	This is constant StdVCL.IID_IProvider.
IID_IStrings (see page 2945)	This is constant StdVCL.IID_IStrings.
LIBID_StdVCL (see page 2945)	This is constant StdVCL.LIBID_StdVCL.

Interfaces

	Name	Description
	IDataBroker (see page 2928)	This is class StdVCL.IDataBroker.
	IDataBrokerDisp (see page 2929)	This is class StdVCL.IDataBrokerDisp.
	IProvider (see page 2930)	This is class StdVCL.IProvider.
	IProviderDisp (see page 2934)	This is class StdVCL.IProviderDisp.
	IStrings (see page 2937)	This is class StdVCL.IStrings.
	IStringsDisp (see page 2940)	This is class StdVCL.IStringsDisp.

31.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDataBroker (see page 2928)	This is class StdVCL.IDataBroker.
	IDataBrokerDisp (see page 2929)	This is class StdVCL.IDataBrokerDisp.
	IProvider (see page 2930)	This is class StdVCL.IProvider.
	IProviderDisp (see page 2934)	This is class StdVCL.IProviderDisp.
	IStrings (see page 2937)	This is class StdVCL.IStrings.
	IStringsDisp (see page 2940)	This is class StdVCL.IStringsDisp.

31.1.1 IDataBroker Interface

Class Hierarchy

Pascal

```
IDataBroker = interface(IDispatch);
```

C++

```
__interface IDataBroker : public IDispatch;
```

File

StdVCL

Description

This is class StdVCL.IDataBroker.

31.1.1.1 IDataBroker Members

The following tables list the members exposed by IDataBroker.

Public Methods

	Name	Description
	GetIDsOfNames (see page 3499)	This is GetIDsOfNames, a member of class IDispatch.
	GetProviderNames (see page 2929)	This is GetProviderNames, a member of class IDataBroker.
	GetTypeInfo (see page 3499)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 3499)	This is GetTypeInfoCount, a member of class IDispatch.
	Invoke (see page 3499)	This is Invoke, a member of class IDispatch.

31.1.1.2 IDataBroker Methods

The methods of the IDataBroker class are listed here.

Public Methods

	Name	Description
	GetProviderNames (see page 2929)	This is GetProviderNames, a member of class IDataBroker.

31.1.1.2.1 IDataBroker.GetProviderNames Method

Pascal

```
function GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant GetProviderNames();
```

Description

This is GetProviderNames, a member of class IDataBroker.

31.1.2 IDataBrokerDisp Interface

Class Hierarchy

StdVCL.IDataBrokerDisp

Pascal

```
IDataBrokerDisp = dispinterface;
```

C++

```
class IDataBrokerDisp;
```

File

StdVCL

Description

This is class StdVCL.IDataBrokerDisp.

31.1.2.1 IDataBrokerDisp Members

The following tables list the members exposed by IDataBrokerDisp.

Public Methods

	Name	Description
	GetProviderNames (see page 2930)	This is GetProviderNames, a member of class IDataBrokerDisp.

31.1.2.2 IDataBrokerDisp Methods

The methods of the IDataBrokerDisp class are listed here.

Public Methods

	Name	Description
	GetProviderNames (see page 2930)	This is GetProviderNames, a member of class IDataBrokerDisp.

31.1.2.2.1 IDataBrokerDisp.GetProviderNames Method

Pascal

```
function GetProviderNames: OleVariant;
```

C++

```
__fastcall OleVariant GetProviderNames();
```

Description

This is GetProviderNames, a member of class IDataBrokerDisp.

31.1.3 IProvider Interface

Class Hierarchy

Pascal

```
IProvider = interface(IDispatch);
```

C++

```
__interface IProvider : public IDispatch;
```

File

StdVCL

Description

This is class StdVCL.IProvider.

31.1.3.1 IProvider Members

The following tables list the members exposed by IProvider.

Public Methods

	Name	Description
	ApplyUpdates (see page 2931)	This is ApplyUpdates, a member of class IProvider.
	DataRequest (see page 2931)	This is DataRequest, a member of class IProvider.
	Get_Constraints (see page 2931)	This is Get_Constraints, a member of class IProvider.
	Get_Data (see page 2932)	This is Get_Data, a member of class IProvider.
	GetIDsOfNames (see page 3499)	This is GetIDsOfNames, a member of class IDispatch.
	GetMetaData (see page 2932)	This is GetMetaData, a member of class IProvider.
	GetRecords (see page 2932)	This is GetRecords, a member of class IProvider.
	GetTypeInfo (see page 3499)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 3499)	This is GetTypeInfoCount, a member of class IDispatch.
	Invoke (see page 3499)	This is Invoke, a member of class IDispatch.
	Reset (see page 2932)	This is Reset, a member of class IProvider.
	Set_Constraints (see page 2933)	This is Set_Constraints, a member of class IProvider.
	SetParams (see page 2933)	This is SetParams, a member of class IProvider.

Public Properties

	Name	Description
	Constraints (see page 2933)	This is Constraints, a member of class IProvider.
R	Data (see page 2933)	This is Data, a member of class IProvider.

31.1.3.2 IProvider Methods

The methods of the IProvider class are listed here.

Public Methods

	Name	Description
	ApplyUpdates (see page 2931)	This is ApplyUpdates, a member of class IProvider.
	DataRequest (see page 2931)	This is DataRequest, a member of class IProvider.
	Get_Constraints (see page 2931)	This is Get_Constraints, a member of class IProvider.
	Get_Data (see page 2932)	This is Get_Data, a member of class IProvider.
	GetMetaData (see page 2932)	This is GetMetaData, a member of class IProvider.
	GetRecords (see page 2932)	This is GetRecords, a member of class IProvider.
	Reset (see page 2932)	This is Reset, a member of class IProvider.
	Set_Constraints (see page 2933)	This is Set_Constraints, a member of class IProvider.
	SetParams (see page 2933)	This is SetParams, a member of class IProvider.

31.1.3.2.1 IProvider.ApplyUpdates Method

Pascal

```
function ApplyUpdates(Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer):
OleVariant; safecall;
```

C++

```
__fastcall OleVariant ApplyUpdates(OleVariant Delta, int MaxErrors, int ErrorCount);
```

Description

This is ApplyUpdates, a member of class IProvider.

31.1.3.2.2 IProvider.DataRequest Method

Pascal

```
function DataRequest(Input: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant DataRequest(OleVariant Input);
```

Description

This is DataRequest, a member of class IProvider.

31.1.3.2.3 IProvider.Get_Constraints Method

Pascal

```
function Get_Constraints: WordBool; safecall;
```

C++

```
__fastcall WordBool Get_Constraints();
```

Description

This is Get_Constraints, a member of class IProvider.

31.1.3.2.4 IProvider.Get_Data Method

Pascal

```
function Get_Data: OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_Data();
```

Description

This is Get_Data, a member of class IProvider.

31.1.3.2.5 IProvider.GetMetaData Method

Pascal

```
function GetMetaData: OleVariant; safecall;
```

C++

```
__fastcall OleVariant GetMetaData();
```

Description

This is GetMetaData, a member of class IProvider.

31.1.3.2.6 IProvider.GetRecords Method

Pascal

```
function GetRecords(Count: Integer; out RecsOut: Integer): OleVariant; safecall;
```

C++

```
__fastcall OleVariant GetRecords(int Count, int RecsOut);
```

Description

This is GetRecords, a member of class IProvider.

31.1.3.2.7 IProvider.Reset Method

Pascal

```
procedure Reset(MetaData: WordBool); safecall;
```

C++

```
__fastcall Reset(WordBool MetaData);
```

Description

This is Reset, a member of class IProvider.

31.1.3.2.8 IProvider.Set_Constraints Method

Pascal

```
procedure Set_Constraints(Value: WordBool); safecall;
```

C++

```
__fastcall Set_Constraints(WordBool Value);
```

Description

This is Set_Constraints, a member of class IProvider.

31.1.3.2.9 IProvider.SetParams Method

Pascal

```
procedure SetParams(Values: OleVariant); safecall;
```

C++

```
__fastcall SetParams(OleVariant Values);
```

Description

This is SetParams, a member of class IProvider.

31.1.3.3 IProvider Properties

The properties of the IProvider class are listed here.

Public Properties

	Name	Description
	Constraints (see page 2933)	This is Constraints, a member of class IProvider.
R	Data (see page 2933)	This is Data, a member of class IProvider.

31.1.3.3.1 IProvider.Constraints Property

Pascal

```
property Constraints: WordBool;
```

C++

```
__property WordBool Constraints;
```

Description

This is Constraints, a member of class IProvider.

31.1.3.3.2 IProvider.Data Property

Pascal

```
property Data: OleVariant;
```

C++

```
__property OleVariant Data;
```

Description

This is Data, a member of class IProvider.

31.1.4 IProviderDisp Interface

Class Hierarchy

Pascal

```
IProviderDisp = dispinterface;
```

C++

```
class IProviderDisp;
```

File

StdVCL

Description

This is class StdVCL.IProviderDisp.

31.1.4.1 IProviderDisp Members

The following tables list the members exposed by IProviderDisp.

Public Methods

	Name	Description
	ApplyUpdates (see page 2935)	This is ApplyUpdates, a member of class IProviderDisp.
	DataRequest (see page 2935)	This is DataRequest, a member of class IProviderDisp.
	GetMetaData (see page 2935)	This is GetMetaData, a member of class IProviderDisp.
	GetRecords (see page 2935)	This is GetRecords, a member of class IProviderDisp.
	Reset (see page 2936)	This is Reset, a member of class IProviderDisp.
	SetParams (see page 2936)	This is SetParams, a member of class IProviderDisp.

Public Properties

	Name	Description
	Constraints (see page 2936)	This is Constraints, a member of class IProviderDisp.
	Data (see page 2936)	This is Data, a member of class IProviderDisp.

31.1.4.2 IProviderDisp Methods

The methods of the IProviderDisp class are listed here.

Public Methods

	Name	Description
	ApplyUpdates (see page 2935)	This is ApplyUpdates, a member of class IProviderDisp.
	DataRequest (see page 2935)	This is DataRequest, a member of class IProviderDisp.
	GetMetaData (see page 2935)	This is GetMetaData, a member of class IProviderDisp.
	GetRecords (see page 2935)	This is GetRecords, a member of class IProviderDisp.

	Reset (see page 2936)	This is Reset, a member of class IProviderDisp.
	SetParams (see page 2936)	This is SetParams, a member of class IProviderDisp.

31.1.4.2.1 IProviderDisp.ApplyUpdates Method

Pascal

```
function ApplyUpdates(Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer):
OleVariant;
```

C++

```
__fastcall OleVariant ApplyUpdates(OleVariant Delta, int MaxErrors, int ErrorCount);
```

Description

This is ApplyUpdates, a member of class IProviderDisp.

31.1.4.2.2 IProviderDisp.DataRequest Method

Pascal

```
function DataRequest(Input: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant DataRequest(OleVariant Input);
```

Description

This is DataRequest, a member of class IProviderDisp.

31.1.4.2.3 IProviderDisp.GetMetaData Method

Pascal

```
function GetMetaData: OleVariant;
```

C++

```
__fastcall OleVariant GetMetaData();
```

Description

This is GetMetaData, a member of class IProviderDisp.

31.1.4.2.4 IProviderDisp.GetRecords Method

Pascal

```
function GetRecords(Count: Integer; out RecsOut: Integer): OleVariant;
```

C++

```
__fastcall OleVariant GetRecords(int Count, int RecsOut);
```

Description

This is GetRecords, a member of class IProviderDisp.

31.1.4.2.5 IProviderDisp.Reset Method

Pascal

```
procedure Reset(MetaData: WordBool);
```

C++

```
__fastcall Reset(WordBool MetaData);
```

Description

This is Reset, a member of class IProviderDisp.

31.1.4.2.6 IProviderDisp.SetParams Method

Pascal

```
procedure SetParams(Values: OleVariant);
```

C++

```
__fastcall SetParams(OleVariant Values);
```

Description

This is SetParams, a member of class IProviderDisp.

31.1.4.3 IProviderDisp Properties

The properties of the IProviderDisp class are listed here.

Public Properties

	Name	Description
	Constraints (see page 2936)	This is Constraints, a member of class IProviderDisp.
	Data (see page 2936)	This is Data, a member of class IProviderDisp.

31.1.4.3.1 IProviderDisp.Constraints Property

Pascal

```
property Constraints: WordBool;
```

C++

```
__property WordBool Constraints;
```

Description

This is Constraints, a member of class IProviderDisp.

31.1.4.3.2 IProviderDisp.Data Property

Pascal

```
property Data: OleVariant;
```

C++

```
__property OleVariant Data;
```

Description

This is Data, a member of class IProviderDisp.

31.1.5 IStrings Interface

Class Hierarchy

Pascal

```
IStrings = interface(IDispatch);
```

C++

```
__interface IStrings : public IDispatch;
```

File

StdVCL

Description

This is class StdVCL.IStrings.

31.1.5.1 IStrings Members

The following tables list the members exposed by IStrings.

Public Methods

	Name	Description
	_NewEnum (see page 2938)	This is _NewEnum, a member of class IStrings.
	Add (see page 2938)	This is Add, a member of class IStrings.
	Clear (see page 2938)	This is Clear, a member of class IStrings.
	Count (see page 2938)	This is Count, a member of class IStrings.
	Get_ControlDefault (see page 2939)	This is Get_ControlDefault, a member of class IStrings.
	Get_Item (see page 2939)	This is Get_Item, a member of class IStrings.
	GetIDsOfNames (see page 3499)	This is GetIDsOfNames, a member of class IDispatch.
	GetTypeInfo (see page 3499)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 3499)	This is GetTypeInfoCount, a member of class IDispatch.
	Invoke (see page 3499)	This is Invoke, a member of class IDispatch.
	Remove (see page 2939)	This is Remove, a member of class IStrings.
	Set_ControlDefault (see page 2939)	This is Set_ControlDefault, a member of class IStrings.
	Set_Item (see page 2940)	This is Set_Item, a member of class IStrings.

Public Properties

	Name	Description
	ControlDefault (see page 2940)	This is ControlDefault, a member of class IStrings.
	Item (see page 2940)	This is Item, a member of class IStrings.

31.1.5.2 IStrings Methods

The methods of the IStrings class are listed here.

Public Methods

	Name	Description
	_NewEnum (see page 2938)	This is _NewEnum, a member of class IStrings.
	Add (see page 2938)	This is Add, a member of class IStrings.
	Clear (see page 2938)	This is Clear, a member of class IStrings.
	Count (see page 2938)	This is Count, a member of class IStrings.
	Get_ControlDefault (see page 2939)	This is Get_ControlDefault, a member of class IStrings.
	Get_Item (see page 2939)	This is Get_Item, a member of class IStrings.
	Remove (see page 2939)	This is Remove, a member of class IStrings.
	Set_ControlDefault (see page 2939)	This is Set_ControlDefault, a member of class IStrings.
	Set_Item (see page 2940)	This is Set_Item, a member of class IStrings.

31.1.5.2.1 IStrings._NewEnum Method

Pascal

```
function _NewEnum: IUnknown; safecall;
```

C++

```
__fastcall IUnknown _NewEnum();
```

Description

This is _NewEnum, a member of class IStrings.

31.1.5.2.2 IStrings.Add Method

Pascal

```
function Add(Item: OleVariant): Integer; safecall;
```

C++

```
__fastcall int Add(OleVariant Item);
```

Description

This is Add, a member of class IStrings.

31.1.5.2.3 IStrings.Clear Method

Pascal

```
procedure Clear; safecall;
```

C++

```
__fastcall Clear();
```

Description

This is Clear, a member of class IStrings.

31.1.5.2.4 IStrings.Count Method

Pascal

```
function Count: Integer; safecall;
```

C++

```
__fastcall int Count();
```

Description

This is Count, a member of class IStrings.

31.1.5.2.5 IStrings.Get_ControlDefault Method

Pascal

```
function Get_ControlDefault(Index: Integer): OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_ControlDefault(int Index);
```

Description

This is Get_ControlDefault, a member of class IStrings.

31.1.5.2.6 IStrings.Get_Item Method

Pascal

```
function Get_Item(Index: Integer): OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_Item(int Index);
```

Description

This is Get_Item, a member of class IStrings.

31.1.5.2.7 IStrings.Remove Method

Pascal

```
procedure Remove(Index: Integer); safecall;
```

C++

```
__fastcall Remove(int Index);
```

Description

This is Remove, a member of class IStrings.

31.1.5.2.8 IStrings.Set_ControlDefault Method

Pascal

```
procedure Set_ControlDefault(Index: Integer; Value: OleVariant); safecall;
```

C++

```
__fastcall Set_ControlDefault(int Index, OleVariant Value);
```

Description

This is Set_ControlDefault, a member of class IStrings.

31.1.5.2.9 IStrings.Set_Item Method

Pascal

```
procedure Set_Item(Index: Integer; Value: OleVariant); safecall;
```

C++

```
__fastcall Set_Item(int Index, OleVariant Value);
```

Description

This is Set_Item, a member of class IStrings.

31.1.5.3 IStrings Properties

The properties of the IStrings class are listed here.

Public Properties

	Name	Description
	ControlDefault (see page 2940)	This is ControlDefault, a member of class IStrings.
	Item (see page 2940)	This is Item, a member of class IStrings.

31.1.5.3.1 IStrings.ControlDefault Property

Pascal

```
property ControlDefault [Index: Integer]: OleVariant;
```

C++

```
__property OleVariant ControlDefault[int Index];
```

Description

This is ControlDefault, a member of class IStrings.

31.1.5.3.2 IStrings.Item Property

Pascal

```
property Item [Index: Integer]: OleVariant;
```

C++

```
__property OleVariant Item[int Index];
```

Description

This is Item, a member of class IStrings.

31.1.6 IStringsDisp Interface

Class Hierarchy

Pascal

```
IStringsDisp = dispinterface;
```

C++

```
class IStringsDisp;
```

File

StdVCL

Description

This is class StdVCL.IStringsDisp.

31.1.6.1 IStringsDisp Members

The following tables list the members exposed by IStringsDisp.

Public Methods

	Name	Description
	_NewEnum (see page 2941)	This is _NewEnum, a member of class IStringsDisp.
	Add (see page 2942)	This is Add, a member of class IStringsDisp.
	Clear (see page 2942)	This is Clear, a member of class IStringsDisp.
	Count (see page 2942)	This is Count, a member of class IStringsDisp.
	Remove (see page 2942)	This is Remove, a member of class IStringsDisp.

Public Properties

	Name	Description
	ControlDefault (see page 2943)	This is ControlDefault, a member of class IStringsDisp.
	Item (see page 2943)	This is Item, a member of class IStringsDisp.

31.1.6.2 IStringsDisp Methods

The methods of the IStringsDisp class are listed here.

Public Methods

	Name	Description
	_NewEnum (see page 2941)	This is _NewEnum, a member of class IStringsDisp.
	Add (see page 2942)	This is Add, a member of class IStringsDisp.
	Clear (see page 2942)	This is Clear, a member of class IStringsDisp.
	Count (see page 2942)	This is Count, a member of class IStringsDisp.
	Remove (see page 2942)	This is Remove, a member of class IStringsDisp.

31.1.6.2.1 IStringsDisp._NewEnum Method

Pascal

```
function _NewEnum: IUnknown;
```

C++

```
__fastcall IUnknown _NewEnum();
```

Description

This is _NewEnum, a member of class IStringsDisp.

31.1.6.2.2 IStringsDisp.Add Method

Pascal

```
function Add(Item: OleVariant): Integer;
```

C++

```
__fastcall int Add(OleVariant Item);
```

Description

This is Add, a member of class IStringsDisp.

31.1.6.2.3 IStringsDisp.Clear Method

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

This is Clear, a member of class IStringsDisp.

31.1.6.2.4 IStringsDisp.Count Method

Pascal

```
function Count: Integer;
```

C++

```
__fastcall int Count();
```

Description

This is Count, a member of class IStringsDisp.

31.1.6.2.5 IStringsDisp.Remove Method

Pascal

```
procedure Remove(Index: Integer);
```

C++

```
__fastcall Remove(int Index);
```

Description

This is Remove, a member of class IStringsDisp.

31.1.6.3 IStringsDisp Properties

The properties of the IStringsDisp class are listed here.

Public Properties

	Name	Description
	ControlDefault (see page 2943)	This is ControlDefault, a member of class IStringsDisp.
	Item (see page 2943)	This is Item, a member of class IStringsDisp.

31.1.6.3.1 IStringsDisp.ControlDefault Property

Pascal

```
property ControlDefault [Index: Integer]: OleVariant;
```

C++

```
__property OleVariant ControlDefault[int Index];
```

Description

This is ControlDefault, a member of class IStringsDisp.

31.1.6.3.2 IStringsDisp.Item Property

Pascal

```
property Item [Index: Integer]: OleVariant;
```

C++

```
__property OleVariant Item[int Index];
```

Description

This is Item, a member of class IStringsDisp.

31.2 Constants

The following table lists constants in this documentation.

Constants

Name	Description
IID_IDataBroker (see page 2944)	This is constant StdVCL.IID_IDataBroker.
IID_IProvider (see page 2944)	This is constant StdVCL.IID_IProvider.
IID_IStrings (see page 2945)	This is constant StdVCL.IID_IStrings.
LIBID_StdVCL (see page 2945)	This is constant StdVCL.LIBID_StdVCL.

31.2.1 StdVCL.IID_IDataBroker Constant

Pascal

```
IID_IDataBroker: TGUID = '{6539BF65-6FE7-11D0-9E8C-00A02457621F}';
```

C++

```
TGUID IID_IDataBroker = '{6539BF65-6FE7-11D0-9E8C-00A02457621F}';
```

File

StdVCL

Description

This is constant StdVCL.IID_IDataBroker.

31.2.2 StdVCL.IID_IProvider Constant

Pascal

```
IID_IProvider: TGUID = '{6E644935-51F7-11D0-8D41-00A0248E4B9A}';
```

C++

```
TGUID IID_IProvider = '{6E644935-51F7-11D0-8D41-00A0248E4B9A}';
```

File

StdVCL

Description

This is constant StdVCL.IID_IProvider.

31.2.3 StdVCL.IID_IStrings Constant

Pascal

```
IID_IStrings: TGUID = '{EE05DFE2-5549-11D0-9EA9-0020AF3D82DA}';
```

C++

```
TGUID IID_IStrings = '{EE05DFE2-5549-11D0-9EA9-0020AF3D82DA}';
```

File

StdVCL

Description

This is constant StdVCL.IID_IStrings.

31.2.4 StdVCL.LIBID_StdVCL Constant

Pascal

```
LIBID_StdVCL: TGUID = '{EE05DFE0-5549-11D0-9EA9-0020AF3D82DA}';
```

C++

```
TGUID LIBID_StdVCL = '{EE05DFE0-5549-11D0-9EA9-0020AF3D82DA}';
```

File

StdVCL

Description

This is constant StdVCL.LIBID_StdVCL.

32 StrHlpr Namespace

This is namespace StrHlpr.

Topics

Name	Description
Functions (see page 2949)	The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiAppend (see page 2950)	This is function StrHlpr.AnsiAppend.
	AnsiAssign (see page 2950)	This is function StrHlpr.AnsiAssign.
	AnsiCat (see page 2950)	This is function StrHlpr.AnsiCat.
	AnsiCopy (see page 2951)	This is function StrHlpr.AnsiCopy.
	AnsiDelete (see page 2951)	This is function StrHlpr.AnsiDelete.
	AnsiEqual (see page 2951)	This is function StrHlpr.AnsiEqual.
	AnsiFree (see page 2952)	This is function StrHlpr.AnsiFree.
	AnsiFromPChar (see page 2952)	This is function StrHlpr.AnsiFromPChar.
	AnsiFromPWideChar (see page 2952)	This is function StrHlpr.AnsiFromPWideChar.
	AnsiFromUnicode (see page 2953)	This is function StrHlpr.AnsiFromUnicode.
	AnsiFromWide (see page 2953)	This is function StrHlpr.AnsiFromWide.
	AnsiInsert (see page 2953)	This is function StrHlpr.AnsiInsert.
	AnsiPos (see page 2954)	This is function StrHlpr.AnsiPos.
	AnsiSetLength (see page 2954)	This is function StrHlpr.AnsiSetLength.
	UnicodeAppend (see page 2954)	This is function StrHlpr.UnicodeAppend.
	UnicodeAssign (see page 2955)	This is function StrHlpr.UnicodeAssign.
	UnicodeCat (see page 2955)	This is function StrHlpr.UnicodeCat.
	UnicodeCopy (see page 2955)	This is function StrHlpr.UnicodeCopy.
	UnicodeDelete (see page 2956)	This is function StrHlpr.UnicodeDelete.
	UnicodeEqual (see page 2956)	This is function StrHlpr.UnicodeEqual.
	UnicodeFree (see page 2956)	This is function StrHlpr.UnicodeFree.
	UnicodeFromAnsi (see page 2957)	This is function StrHlpr.UnicodeFromAnsi.
	UnicodeFromPChar (see page 2957)	This is function StrHlpr.UnicodeFromPChar.
	UnicodeFromPWideChar (see page 2957)	This is function StrHlpr.UnicodeFromPWideChar.
	UnicodeFromWide (see page 2958)	This is function StrHlpr.UnicodeFromWide.
	UnicodeGreater (see page 2958)	This is function StrHlpr.UnicodeGreater.
	UnicodeInsert (see page 2958)	This is function StrHlpr.UnicodeInsert.

	UnicodeLess (see page 2959)	This is function StrHlpr.UnicodeLess.
	UnicodePos (see page 2959)	This is function StrHlpr.UnicodePos.
	UnicodeSetLength (see page 2959)	This is function StrHlpr.UnicodeSetLength.
	WideAppend (see page 2960)	This is function StrHlpr.WideAppend.
	WideAssign (see page 2960)	This is function StrHlpr.WideAssign.
	WideCat (see page 2960)	This is function StrHlpr.WideCat.
	WideCopy (see page 2961)	This is function StrHlpr.WideCopy.
	WideDelete (see page 2961)	This is function StrHlpr.WideDelete.
	WideEqual (see page 2961)	This is function StrHlpr.WideEqual.
	WideFree (see page 2962)	This is function StrHlpr.WideFree.
	WideFromAnsi (see page 2962)	This is function StrHlpr.WideFromAnsi.
	WideFromPChar (see page 2962)	This is function StrHlpr.WideFromPChar.
	WideFromUnicode (see page 2963)	This is function StrHlpr.WideFromUnicode.
	WideGreater (see page 2963)	This is function StrHlpr.WideGreater.
	WideInsert (see page 2963)	This is function StrHlpr.WideInsert.
	WideLength (see page 2964)	This is function StrHlpr.WideLength.
	WideLess (see page 2964)	This is function StrHlpr.WideLess.
	WidePos (see page 2964)	This is function StrHlpr.WidePos.
	WideSetLength (see page 2965)	This is function StrHlpr.WideSetLength.

32.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiAppend (see page 2950)	This is function StrHlpr.AnsiAppend.
	AnsiAssign (see page 2950)	This is function StrHlpr.AnsiAssign.
	AnsiCat (see page 2950)	This is function StrHlpr.AnsiCat.
	AnsiCopy (see page 2951)	This is function StrHlpr.AnsiCopy.
	AnsiDelete (see page 2951)	This is function StrHlpr.AnsiDelete.
	AnsiEqual (see page 2951)	This is function StrHlpr.AnsiEqual.
	AnsiFree (see page 2952)	This is function StrHlpr.AnsiFree.
	AnsiFromPChar (see page 2952)	This is function StrHlpr.AnsiFromPChar.
	AnsiFromPWideChar (see page 2952)	This is function StrHlpr.AnsiFromPWideChar.
	AnsiFromUnicode (see page 2953)	This is function StrHlpr.AnsiFromUnicode.
	AnsiFromWide (see page 2953)	This is function StrHlpr.AnsiFromWide.
	AnsiInsert (see page 2953)	This is function StrHlpr.AnsiInsert.
	AnsiPos (see page 2954)	This is function StrHlpr.AnsiPos.
	AnsiSetLength (see page 2954)	This is function StrHlpr.AnsiSetLength.
	UnicodeAppend (see page 2954)	This is function StrHlpr.UnicodeAppend.
	UnicodeAssign (see page 2955)	This is function StrHlpr.UnicodeAssign.
	UnicodeCat (see page 2955)	This is function StrHlpr.UnicodeCat.
	UnicodeCopy (see page 2955)	This is function StrHlpr.UnicodeCopy.
	UnicodeDelete (see page 2956)	This is function StrHlpr.UnicodeDelete.
	UnicodeEqual (see page 2956)	This is function StrHlpr.UnicodeEqual.
	UnicodeFree (see page 2956)	This is function StrHlpr.UnicodeFree.
	UnicodeFromAnsi (see page 2957)	This is function StrHlpr.UnicodeFromAnsi.
	UnicodeFromPChar (see page 2957)	This is function StrHlpr.UnicodeFromPChar.
	UnicodeFromPWideChar (see page 2957)	This is function StrHlpr.UnicodeFromPWideChar.
	UnicodeFromWide (see page 2958)	This is function StrHlpr.UnicodeFromWide.
	UnicodeGreater (see page 2958)	This is function StrHlpr.UnicodeGreater.
	UnicodeInsert (see page 2958)	This is function StrHlpr.UnicodeInsert.
	UnicodeLess (see page 2959)	This is function StrHlpr.UnicodeLess.
	UnicodePos (see page 2959)	This is function StrHlpr.UnicodePos.
	UnicodeSetLength (see page 2959)	This is function StrHlpr.UnicodeSetLength.
	WideAppend (see page 2960)	This is function StrHlpr.WideAppend.
	WideAssign (see page 2960)	This is function StrHlpr.WideAssign.
	WideCat (see page 2960)	This is function StrHlpr.WideCat.
	WideCopy (see page 2961)	This is function StrHlpr.WideCopy.
	WideDelete (see page 2961)	This is function StrHlpr.WideDelete.
	WideEqual (see page 2961)	This is function StrHlpr.WideEqual.
	WideFree (see page 2962)	This is function StrHlpr.WideFree.
	WideFromAnsi (see page 2962)	This is function StrHlpr.WideFromAnsi.
	WideFromPChar (see page 2962)	This is function StrHlpr.WideFromPChar.
	WideFromUnicode (see page 2963)	This is function StrHlpr.WideFromUnicode.
	WideGreater (see page 2963)	This is function StrHlpr.WideGreater.
	WideInsert (see page 2963)	This is function StrHlpr.WideInsert.
	WideLength (see page 2964)	This is function StrHlpr.WideLength.
	WideLess (see page 2964)	This is function StrHlpr.WideLess.

	WidePos (see page 2964)	This is function StrHlpr.WidePos.
	WideSetLength (see page 2965)	This is function StrHlpr.WideSetLength.

32.1.1 StrHlpr.AnsiAppend Function

Pascal

```
procedure AnsiAppend(var dst: RawByteString; const src: RawByteString);
```

C++

```
AnsiAppend(RawByteString dst, const RawByteString src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiAppend.

32.1.2 StrHlpr.AnsiAssign Function

Pascal

```
procedure AnsiAssign(var dst: RawByteString; var src: RawByteString);
```

C++

```
AnsiAssign(RawByteString dst, RawByteString src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiAssign.

32.1.3 StrHlpr.AnsiCat Function

Pascal

```
function AnsiCat(const x: RawByteString; const y: RawByteString): RawByteString;
```

C++

```
RawByteString AnsiCat(const RawByteString x, const RawByteString y);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiCat.

32.1.4 StrHlpr.AnsiCopy Function

Pascal

```
function AnsiCopy(const src: RawByteString; index: Integer; count: Integer): RawByteString;
```

C++

```
RawByteString AnsiCopy(const RawByteString src, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiCopy.

32.1.5 StrHlpr.AnsiDelete Function

Pascal

```
procedure AnsiDelete(var dst: RawByteString; index: Integer; count: Integer);
```

C++

```
AnsiDelete(RawByteString dst, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiDelete.

32.1.6 StrHlpr.AnsiEqual Function

Pascal

```
function AnsiEqual(const x: RawByteString; const y: RawByteString): Boolean;
```

C++

```
Boolean AnsiEqual(const RawByteString x, const RawByteString y);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiEqual.

32.1.7 StrHlpr.AnsiFree Function

Pascal

```
procedure AnsiFree(var s: RawByteString);
```

C++

```
AnsiFree(RawByteString s);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiFree.

32.1.8 StrHlpr.AnsiFromPChar Function

Pascal

```
procedure AnsiFromPChar(var dst: RawByteString; src: PAnsiChar);
```

C++

```
AnsiFromPChar(RawByteString dst, PAnsiChar src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiFromPChar.

32.1.9 StrHlpr.AnsiFromPWideChar Function

Pascal

```
procedure AnsiFromPWideChar(var dst: RawByteString; src: PWideChar);
```

C++

```
AnsiFromPWideChar(RawByteString dst, PWideChar src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiFromPWideChar.

32.1.10 StrHlpr.AnsiFromUnicode Function

Pascal

```
procedure AnsiFromUnicode(var dst: RawByteString; const src: UnicodeString);
```

C++

```
AnsiFromUnicode(RawByteString dst, const UnicodeString src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiFromUnicode.

32.1.11 StrHlpr.AnsiFromWide Function

Pascal

```
procedure AnsiFromWide(var dst: RawByteString; const src: WideString);
```

C++

```
AnsiFromWide(RawByteString dst, const BSTR src);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiFromWide.

32.1.12 StrHlpr.AnsiInsert Function

Pascal

```
procedure AnsiInsert(var dst: RawByteString; const src: RawByteString; index: Integer);
```

C++

```
AnsiInsert(RawByteString dst, const RawByteString src, int index);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiInsert.

32.1.13 StrHlpr.AnsiPos Function

Pascal

```
function AnsiPos(const src: RawByteString; const sub: RawByteString): Integer;
```

C++

```
int AnsiPos(const RawByteString src, const RawByteString sub);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiPos.

32.1.14 StrHlpr.AnsiSetLength Function

Pascal

```
procedure AnsiSetLength(var dst: RawByteString; len: Integer);
```

C++

```
AnsiSetLength(RawByteString dst, int len);
```

File

StrHlpr

Description

This is function StrHlpr.AnsiSetLength.

32.1.15 StrHlpr.UnicodeAppend Function

Pascal

```
procedure UnicodeAppend(var dst: UnicodeString; const src: UnicodeString);
```

C++

```
UnicodeAppend(UnicodeString dst, const UnicodeString src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeAppend.

32.1.16 StrHlpr.UnicodeAssign Function

Pascal

```
procedure UnicodeAssign(var dst: UnicodeString; var src: UnicodeString);
```

C++

```
UnicodeAssign(UnicodeString dst, UnicodeString src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeAssign.

32.1.17 StrHlpr.UnicodeCat Function

Pascal

```
function UnicodeCat(const x: UnicodeString; const y: UnicodeString): UnicodeString;
```

C++

```
UnicodeString UnicodeCat(const UnicodeString x, const UnicodeString y);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeCat.

32.1.18 StrHlpr.UnicodeCopy Function

Pascal

```
function UnicodeCopy(const src: UnicodeString; index: Integer; count: Integer): UnicodeString;
```

C++

```
UnicodeString UnicodeCopy(const UnicodeString src, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeCopy.

32.1.19 StrHlpr.UnicodeDelete Function

Pascal

```
procedure UnicodeDelete(var dst: UnicodeString; index: Integer; count: Integer);
```

C++

```
UnicodeDelete(UnicodeString dst, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeDelete.

32.1.20 StrHlpr.UnicodeEqual Function

Pascal

```
function UnicodeEqual(const x: UnicodeString; const y: UnicodeString): Boolean;
```

C++

```
Boolean UnicodeEqual(const UnicodeString x, const UnicodeString y);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeEqual.

32.1.21 StrHlpr.UnicodeFree Function

Pascal

```
procedure UnicodeFree(var s: UnicodeString);
```

C++

```
UnicodeFree(UnicodeString s);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeFree.

32.1.22 StrHlpr.UnicodeFromAnsi Function

Pascal

```
procedure UnicodeFromAnsi(var dst: UnicodeString; const src: RawByteString);
```

C++

```
UnicodeFromAnsi(UnicodeString dst, const RawByteString src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeFromAnsi.

32.1.23 StrHlpr.UnicodeFromPChar Function

Pascal

```
procedure UnicodeFromPChar(var dst: UnicodeString; src: PAnsiChar);
```

C++

```
UnicodeFromPChar(UnicodeString dst, PAnsiChar src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeFromPChar.

32.1.24 StrHlpr.UnicodeFromPWideChar Function

Pascal

```
procedure UnicodeFromPWideChar(var dst: UnicodeString; src: PWideChar);
```

C++

```
UnicodeFromPWideChar(UnicodeString dst, PWideChar src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeFromPWideChar.

32.1.25 StrHlpr.UnicodeFromWide Function

Pascal

```
procedure UnicodeFromWide(var dst: UnicodeString; const src: WideString);
```

C++

```
UnicodeFromWide(UnicodeString dst, const BSTR src);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeFromWide.

32.1.26 StrHlpr.UnicodeGreater Function

Pascal

```
function UnicodeGreater(const x: UnicodeString; const y: UnicodeString): Boolean;
```

C++

```
Boolean UnicodeGreater(const UnicodeString x, const UnicodeString y);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeGreater.

32.1.27 StrHlpr.UnicodeInsert Function

Pascal

```
procedure UnicodeInsert(var dst: UnicodeString; const src: UnicodeString; index: Integer);
```

C++

```
UnicodeInsert(UnicodeString dst, const UnicodeString src, int index);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeInsert.

32.1.28 StrHlpr.UnicodeLess Function

Pascal

```
function UnicodeLess(const x: UnicodeString; const y: UnicodeString): Boolean;
```

C++

```
Boolean UnicodeLess(const UnicodeString x, const UnicodeString y);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeLess.

32.1.29 StrHlpr.UnicodePos Function

Pascal

```
function UnicodePos(const src: UnicodeString; const sub: UnicodeString): Integer;
```

C++

```
int UnicodePos(const UnicodeString src, const UnicodeString sub);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodePos.

32.1.30 StrHlpr.UnicodeSetLength Function

Pascal

```
procedure UnicodeSetLength(var dst: UnicodeString; len: Integer);
```

C++

```
UnicodeSetLength(UnicodeString dst, int len);
```

File

StrHlpr

Description

This is function StrHlpr.UnicodeSetLength.

32.1.31 StrHlpr.WideAppend Function

Pascal

```
procedure WideAppend(var dst: WideString; const src: WideString);
```

C++

```
WideAppend(BSTR dst, const BSTR src);
```

File

StrHlpr

Description

This is function StrHlpr.WideAppend.

32.1.32 StrHlpr.WideAssign Function

Pascal

```
procedure WideAssign(var dst: WideString; var src: WideString);
```

C++

```
WideAssign(BSTR dst, BSTR src);
```

File

StrHlpr

Description

This is function StrHlpr.WideAssign.

32.1.33 StrHlpr.WideCat Function

Pascal

```
function WideCat(const x: WideString; const y: WideString): WideString;
```

C++

```
BSTR WideCat(const BSTR x, const BSTR y);
```

File

StrHlpr

Description

This is function StrHlpr.WideCat.

32.1.34 StrHlpr.WideCopy Function

Pascal

```
function WideCopy(const src: WideString; index: Integer; count: Integer): WideString;
```

C++

```
BSTR WideCopy(const BSTR src, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.WideCopy.

32.1.35 StrHlpr.WideDelete Function

Pascal

```
procedure WideDelete(var dst: WideString; index: Integer; count: Integer);
```

C++

```
WideDelete(BSTR dst, int index, int count);
```

File

StrHlpr

Description

This is function StrHlpr.WideDelete.

32.1.36 StrHlpr.WideEqual Function

Pascal

```
function WideEqual(const x: WideString; const y: WideString): Boolean;
```

C++

```
Boolean WideEqual(const BSTR x, const BSTR y);
```

File

StrHlpr

Description

This is function StrHlpr.WideEqual.

32.1.37 StrHlpr.WideFree Function

Pascal

```
procedure WideFree(var s: WideString);
```

C++

```
WideFree(BSTR s);
```

File

StrHlpr

Description

This is function StrHlpr.WideFree.

32.1.38 StrHlpr.WideFromAnsi Function

Pascal

```
procedure WideFromAnsi(var dst: WideString; const src: RawByteString);
```

C++

```
WideFromAnsi(BSTR dst, const RawByteString src);
```

File

StrHlpr

Description

This is function StrHlpr.WideFromAnsi.

32.1.39 StrHlpr.WideFromPChar Function

Pascal

```
procedure WideFromPChar(var dst: WideString; src: PAnsiChar);
```

C++

```
WideFromPChar(BSTR dst, PAnsiChar src);
```

File

StrHlpr

Description

This is function StrHlpr.WideFromPChar.

32.1.40 StrHlpr.WideFromUnicode Function

Pascal

```
procedure WideFromUnicode(var dst: WideString; const src: UnicodeString);
```

C++

```
WideFromUnicode(BSTR dst, const UnicodeString src);
```

File

StrHlpr

Description

This is function StrHlpr.WideFromUnicode.

32.1.41 StrHlpr.WideGreater Function

Pascal

```
function WideGreater(const x: WideString; const y: WideString): Boolean;
```

C++

```
Boolean WideGreater(const BSTR x, const BSTR y);
```

File

StrHlpr

Description

This is function StrHlpr.WideGreater.

32.1.42 StrHlpr.WideInsert Function

Pascal

```
procedure WideInsert(var dst: WideString; const src: WideString; index: Integer);
```

C++

```
WideInsert(BSTR dst, const BSTR src, int index);
```

File

StrHlpr

Description

This is function StrHlpr.WideInsert.

32.1.43 StrHlpr.WideLength Function

Pascal

```
function WideLength(const src: WideString): Integer;
```

C++

```
int WideLength(const BSTR src);
```

File

StrHlpr

Description

This is function StrHlpr.WideLength.

32.1.44 StrHlpr.WideLess Function

Pascal

```
function WideLess(const x: WideString; const y: WideString): Boolean;
```

C++

```
Boolean WideLess(const BSTR x, const BSTR y);
```

File

StrHlpr

Description

This is function StrHlpr.WideLess.

32.1.45 StrHlpr.WidePos Function

Pascal

```
function WidePos(const src: WideString; const sub: WideString): Integer;
```

C++

```
int WidePos(const BSTR src, const BSTR sub);
```

File

StrHlpr

Description

This is function StrHlpr.WidePos.

32.1.46 StrHlpr.WideSetLength Function

Pascal

```
procedure WideSetLength(var dst: WideString; len: Integer);
```

C++

```
WideSetLength(BSTR dst, int len);
```

File

StrHlpr

Description

This is function StrHlpr.WideSetLength.

33 StrUtils Namespace

This is namespace StrUtils.

Topics

Name	Description
Functions (see page 2970)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 3000)	The following table lists structs, records, enums in this documentation.
Types (see page 3001)	The following table lists types in this documentation.
Variables (see page 3003)	The following table lists variables in this documentation.
Constants (see page 3005)	The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 3005)	This is constant StrUtils.WordDelimiters.

Functions

	Name	Description
	AnsiContainsStr (see page 2971)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 2972)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 2972)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 2973)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 2973)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 2974)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 2974)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 2975)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 2975)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 2976)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 2977)	Replaces all occurrences of a substring with another string.
	AnsiReplaceText (see page 2977)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 2978)	Indicates whether two strings are similar.
	AnsiReverseString (see page 2978)	Returns reversed string.
	AnsiRightStr (see page 2979)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 2979)	Indicates whether one string is a (case-sensitive) prefix of another.
	AnsiStartsText (see page 2980)	Indicates whether one string is a (case-insensitive) prefix of another.

	ContainsStr (see page 2980)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 2981)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 2981)	Converts an integer representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 2982)	Converts a Word representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.
	DupeString (see page 2982)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 2983)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 2983)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 2984)	Conditionally returns one of two specified values.
	IndexStr (see page 2984)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 2985)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 2985)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 2986)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 2986)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 2987)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MatchText (see page 2987)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MidBStr (see page 2988)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 2988)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 2988)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 2989)	Returns the index value of a substring.
	RandomFrom (see page 2989)	Returns a randomly selected element from an array.
	ReplaceStr (see page 2990)	ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.
	ReplaceText (see page 2990)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 2991)	ResemblesText uses a Soundex (see page 2994) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 2994) method, and false otherwise.
	ReverseString (see page 2991)	Returns the reverse of a specified string.
	RightBStr (see page 2992)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 2992)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 2992)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 2993)	Locates a substring within a text buffer.
	SearchBuf (see page 2993)	Locates a substring within a text buffer.
	Soundex (see page 2994)	Converts a string into its Soundex representation.
	SoundexCompare (see page 2994)	Compares the Soundex (see page 2994) representations of two strings.
	SoundexInt (see page 2995)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 2996)	Indicates whether two strings are similar.
	SoundexSimilar (see page 2996)	Indicates whether two strings are similar.
	SoundexWord (see page 2997)	Converts a string into a Word that represents its phonetic value.

	StartsStr (see page 2998)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	StartsText (see page 2998)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 2999)	Inserts a substring into a specified position of a string, replacing the current characters.

Structs, Records, Enums

	Name	Description
	TStringSeachOption (see page 3000)	TStringSeachOption is an enumeration that describes the behavior of string searches.

Types

Name	Description
TCompareTextProc (see page 3001)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 3001)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 2995) function. The integer value can be from 1 to 8.
TSoundexLength (see page 3002)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 3002)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3000).

Variables

Name	Description
AnsiResemblesProc (see page 3003)	Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar.
ResemblesProc (see page 3003)	Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3003).

33.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiContainsStr (see page 2971)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 2972)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 2972)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 2973)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 2973)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 2974)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 2974)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 2975)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 2975)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 2976)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 2977)	Replaces all occurrences of a substring with another string.
	AnsiReplaceText (see page 2977)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 2978)	Indicates whether two strings are similar.
	AnsiReverseString (see page 2978)	Returns reversed string.
	AnsiRightStr (see page 2979)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 2979)	Indicates whether one string is a (case-sensitive) prefix of another.
	AnsiStartsText (see page 2980)	Indicates whether one string is a (case-insensitive) prefix of another.
	ContainsStr (see page 2980)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 2981)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 2981)	Converts an integer representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 2982)	Converts a Word representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.
	DupeString (see page 2982)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 2983)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 2983)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 2984)	Conditionally returns one of two specified values.
	IndexStr (see page 2984)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 2985)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 2985)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 2986)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 2986)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 2987)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MatchText (see page 2987)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

	MidBStr (see page 2988)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 2988)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 2988)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 2989)	Returns the index value of a substring.
	RandomFrom (see page 2989)	Returns a randomly selected element from an array.
	ReplaceStr (see page 2990)	ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.
	ReplaceText (see page 2990)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 2991)	ResemblesText uses a Soundex (see page 2994) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 2994) method, and false otherwise.
	ReverseString (see page 2991)	Returns the reverse of a specified string.
	RightBStr (see page 2992)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 2992)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 2992)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 2993)	Locates a substring within a text buffer.
	SearchBuf (see page 2993)	Locates a substring within a text buffer.
	Soundex (see page 2994)	Converts a string into its Soundex representation.
	SoundexCompare (see page 2994)	Compares the Soundex (see page 2994) representations of two strings.
	SoundexInt (see page 2995)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 2996)	Indicates whether two strings are similar.
	SoundexSimilar (see page 2996)	Indicates whether two strings are similar.
	SoundexWord (see page 2997)	Converts a string into a Word that represents its phonetic value.
	StartsStr (see page 2998)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	StartsText (see page 2998)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 2999)	Inserts a substring into a specified position of a string, replacing the current characters.

33.1.1 StrUtils.AnsiContainsStr Function

Indicates whether one string is a (case-sensitive) substring of another.

Pascal

```
function AnsiContainsStr(const AText: string; const ASubText: string): Boolean; overload;
```

C++

```
Boolean AnsiContainsStr(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

AnsiContainsStr returns true if the string specified by ASubText appears as a substring of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiResemblesText (see page 2978)

AnsiStartsStr (see page 2979)

AnsiEndsStr (see page 2972)

AnsiCompareStr

Pos

StringReplace

AnsiContainsText (see page 2972)

33.1.2 StrUtils.AnsiContainsText Function

Indicates whether one string is a (case-insensitive) substring of another.

Pascal

```
function AnsiContainsText(const AText: string; const ASubText: string): Boolean; overload;
```

C++

```
Boolean AnsiContainsText(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

AnsiContainsText returns true if the string specified by ASubText appears as a substring of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiResemblesText (see page 2978)

AnsiStartsText (see page 2980)

AnsiEndsText (see page 2973)

AnsiCompareText

Pos

StringReplace

AnsiContainsStr (see page 2971)

33.1.3 StrUtils.AnsiEndsStr Function

Indicates whether one string is a (case-sensitive) suffix of another.

Pascal

```
function AnsiEndsStr(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiEndsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiEndsStr returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiStartsStr (see page 2979)

AnsiContainsStr (see page 2971)

Pos

RightStr (see page 2992)

AnsiEndsText (see page 2973)

33.1.4 StrUtils.AnsiEndsText Function

Indicates whether one string is a (case-insensitive) suffix of another.

Pascal

```
function AnsiEndsText(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiEndsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiEndsText returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiStartsText (see page 2980)

AnsiContainsText (see page 2972)

Pos

RightStr (see page 2992)

33.1.5 StrUtils.AnsiIndexStr Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexStr(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int AnsiIndexStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexStr returns the 0-offset index of the first string it finds in AValues that matches AText case-sensitively. If the string specified by AText does not have an exact match in AValues, AnsiIndexStr returns –1.

See Also

AnsiMatchStr (see page 2975)

RandomFrom (see page 2989)

AnsiIndexText (see page 2974)

33.1.6 StrUtils.AnsiIndexText Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexText(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int AnsiIndexText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexText returns the 0-offset index of the first string it finds in AValues that matches AText case-insensitively. If the string specified by AText does not have a (possibly case-insensitive) match in AValues, AnsiIndexText returns –1. Comparisons are based on the current system locale.

See Also

AnsiMatchText (see page 2975)

RandomFrom (see page 2989)

AnsiIndexStr (see page 2973)

33.1.7 StrUtils.AnsiLeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function AnsiLeftStr(const AText: string; const ACount: Integer): string; overload;
```

C++

```
UnicodeString AnsiLeftStr(const UnicodeString AText, const int ACount);
```

File

StrUtils

Description

AnsiLeftStr returns the leading characters of AText up to a length of ACount characters.

See Also

Copy

TrimLeft

AnsiStartsText (see page 2980)

AnsiStartsStr (see page 2979)

LeftStr (see page 2986)

LeftBStr (see page 2985)

33.1.8 StrUtils.AnsiMatchStr Function

Indicates whether an array of strings contains an exact match to a specified string.

Pascal

```
function AnsiMatchStr(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean AnsiMatchStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchStr to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-sensitive.

See Also

AnsiIndexStr (see page 2973)

AnsiSameStr

AnsiMatchText (see page 2975)

33.1.9 StrUtils.AnsiMatchText Function

Indicates whether an array of strings contains a case-insensitive match to a specified string.

Pascal

```
function AnsiMatchText(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean AnsiMatchText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchText to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-insensitive and use the current system locale.

AText is the string to locate.

AValues is the array of strings to search.

Note: AValues_Size is the index of the last element in AValues (one less than the number of elements).

AnsiMatchText returns true if AText (or a string that matches except for case) appears in AValues, false if it does not appear in the array.

See Also

AnsiIndexText (see page 2974)

AnsiSameText

ANsiMatchStr

33.1.10 StrUtils.AnsiMidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function AnsiMidStr(const AText: string; const AStart: Integer; const ACount: Integer):
string; overload;
```

C++

```
UnicodeString AnsiMidStr(const UnicodeString AText, const int AStart, const int ACount);
```

File

StrUtils

Description

AnsiMidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, AnsiMidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

See Also

Copy

LeftStr (see page 2986)

RightStr (see page 2992)

MidStr (see page 2988)

MidBStr (see page 2988)

33.1.11 StrUtils.AnsiReplaceStr Function

Replaces all occurrences of a substring with another string.

Pascal

```
function AnsiReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string; overload;
```

C++

```
UnicodeString AnsiReplaceStr(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

Call AnsiReplaceStr to scan the string specified by AText and replace all occurrences of the string specified by AFromText with the string specified by AToText. Occurrences of AFromText are identified by a case-sensitive comparison. The identification of substrings is not recursive: if the substitution of AToText results in a new match for AFromText, that match is not replaced.

See Also

AnsiContainsStr (see page 2971)

AnsiReplaceText (see page 2977)

ANsiMatchStr

StringReplace

SearchBuf (see page 2993)

StuffString (see page 2999)

33.1.12 StrUtils.AnsiReplaceText Function

Replaces all case-insensitive matches of a substring with another string.

Pascal

```
function AnsiReplaceText(const AText: string; const AFromText: string; const AToText: string):
string; overload;
```

C++

```
UnicodeString AnsiReplaceText(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

Call AnsiReplaceText to scan the string specified by AText and replace all occurrences of the string specified by AFromText with the string specified by AToText. Occurrences of AFromText are identified by a case-insensitive comparison that uses the current system locale. The identification of substrings is not recursive: if the substitution of AToText results in a new match for

AFromText, that match is not replaced.

See Also

AnsiContainsText (see page 2972)

AnsiReplaceStr (see page 2977)

StringReplace

SearchBuf (see page 2993)

StuffString (see page 2999)

33.1.13 StrUtils.AnsiResemblesText Function

Indicates whether two strings are similar.

Pascal

```
function AnsiResemblesText(const AText: string; const AOther: string): Boolean; overload;
```

C++

```
Boolean AnsiResemblesText(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

Description

AnsiResemblesText returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

The algorithm that controls whether AnsiResemblesText considers two strings similar is specified by the AnsiResemblesProc (see page 3003) variable. By default, AnsiResemblesProc (see page 3003) is set to SoundExProc, which converts both strings to a phonetic representation using a SoundEx algorithm and compares up to 4 characters of the resulting phonetic representation. By changing the function assigned to AnsiResemblesProc (see page 3003), you can change the comparison made by AnsiResemblesText.

See Also

AnsiResemblesProc (see page 3003)

SoundExProc

33.1.14 StrUtils.AnsiReverseString Function

Returns reversed string.

Pascal

```
function AnsiReverseString(const AText: string): string; overload;
```

C++

```
UnicodeString AnsiReverseString(const UnicodeString AText);
```

File

StrUtils

Description

AnsiReverseString returns AText with its characters reversed.

33.1.15 StrUtils.AnsiRightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function AnsiRightStr(const AText: string; const ACount: Integer): string; overload;
```

C++

```
UnicodeString AnsiRightStr(const UnicodeString AText, const int ACount);
```

File

StrUtils

Description

AnsiRightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, AnsiRightStr returns the string "grammer".

See Also

Copy

TrimRight

AnsiEndsText (see page 2973)

AnsiEndsStr (see page 2972)

RightStr (see page 2992)

RightBStr (see page 2992)

33.1.16 StrUtils.AnsiStartsStr Function

Indicates whether one string is a (case-sensitive) prefix of another.

Pascal

```
function AnsiStartsStr(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiStartsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiStartsStr returns true if the string specified by ASubText appears as the leading part of the string specified by AText.

Comparison is performed case-sensitively.

See Also

AnsiEndsStr (see page 2972)

AnsiContainsStr (see page 2971)

Pos

LeftStr (see page 2986)

AnsiStartsText (see page 2980)

33.1.17 StrUtils.AnsiStartsText Function

Indicates whether one string is a (case-insensitive) prefix of another.

Pascal

```
function AnsiStartsText(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiStartsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiStartsText returns true if the string specified by ASubText appears as the leading part of the string specified by AText. Comparison is performed case-insensitively and uses the current system locale.

See Also

AnsiEndsText (see page 2973)

AnsiContainsText (see page 2972)

Pos

LeftStr (see page 2986)

AnsiStartsStr (see page 2979)

33.1.18 StrUtils.ContainsStr Function

Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsStr(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsStr(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

For a case insensitive search, use the ContainsText (see page 2981) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsText (see page 2981)

33.1.19 StrUtils.ContainsText Function

Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsText(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsText(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

For a case sensitive search, use the ContainsStr (see page 2980) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsStr (see page 2980)

33.1.20 StrUtils.DecodeSoundexInt Function

Converts an integer representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexInt(AValue: Integer): string;
```

C++

```
UnicodeString DecodeSoundexInt(int AValue);
```

File

StrUtils

Description

Call DecodeSoundexInt to convert the integer representation of a string returned by the SoundexInt (see page 2995) function into the corresponding Soundex (see page 2994) string representation.

A Soundex (see page 2994) representation of a string is a phonetic encoding where each character of the Soundex (see page 2994) representation represents a family of similar phonemes.

See Also

SoundexInt (see page 2995)

DecodeSoundexWord (see page 2982)

Soundex (see page 2994)

33.1.21 StrUtils.DecodeSoundexWord Function

Converts a Word representation of a Soundex (see page 2994) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexWord(AValue: Word): string;
```

C++

```
UnicodeString DecodeSoundexWord(Word AValue);
```

File

StrUtils

Description

Call DecodeSoundexWord to convert the unsigned 16-bit representation of a string returned by the SoundexWord (see page 2997) function into the corresponding Soundex (see page 2994) string representation.

A Soundex (see page 2994) representation of a string is a phonetic encoding where each character of the Soundex (see page 2994) representation represents a family of similar phonemes.

See Also

SoundexWord (see page 2997)

DecodeSoundexInt (see page 2981)

Soundex (see page 2994)

33.1.22 StrUtils.DupeString Function

Returns the concatenation of a string with itself a specified number of repeats.

Pascal

```
function DupeString(const AText: string; ACount: Integer): string; overload;
```

C++

```
UnicodeString DupeString(const UnicodeString AText, int ACount);
```

File

StrUtils

Description

DupeString returns a string containing ACount repeats of the string specified by AText. For example,

S := DupeString('Ha', 5);

sets S to the string 'HaHaHaHaHa'.

See Also

StringOfChar

StringReplace

33.1.23 StrUtils.EndsStr Function

Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the EndsText (see page 2983) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsText (see page 2983)

33.1.24 StrUtils.EndsText Function

Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the EndsStr (see page 2983) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsStr (see page 2983)

33.1.25 StrUtils.IfThen Function

Conditionally returns one of two specified values.

Pascal

```
function IfThen(AValue: Boolean; const ATrue: string; AFalse: string = ''): string; overload;
```

C++

```
UnicodeString IfThen(Boolean AValue, const UnicodeString ATrue, UnicodeString AFalse = '');
```

File

StrUtils

Description

IfThen checks the expression passed as AValue and returns ATrue if it evaluates to true, or AFalse if it evaluates to false. In Delphi, if the AFalse parameter is omitted, IfThen returns 0 or an empty string when AValue evaluates to False.

33.1.26 StrUtils.IndexStr Function

IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexStr(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int IndexStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive comparison, use the IndexText (see page 2985) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexText (see page 2985)

33.1.27 StrUtils.IndexText Function

IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexText(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int IndexText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the IndexStr (see page 2984) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexStr (see page 2984)

33.1.28 StrUtils.LeftBStr Function

Returns the substring of a specified number of bytes that appears at the start of a string.

Pascal

```
function LeftBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString LeftBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

LeftBStr returns the leading bytes of AText up to a length of AByteCount bytes.

Note: LeftBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use LeftStr (see page 2986).

See Also

Copy

TrimLeft

AnsiStartsText (see page 2980)

AnsiStartsStr (see page 2979)

AnsiLeftStr (see page 2974)

LeftStr (see page 2986)

33.1.29 StrUtils.LeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function LeftStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function LeftStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString LeftStr(const AnsiString AText, const int ACount);
BSTR LeftStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

LeftStr returns the leading characters of AText up to a length of ACount characters.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, LeftStr may return more than ACount bytes. To return a specific number of bytes, use LeftBStr (see page 2985).

See Also

Copy

LeftBStr (see page 2985)

33.1.30 StrUtils.MatchStr Function

MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchStr(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean MatchStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive match, use the MatchText (see page 2987) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchText (see page 2987)

33.1.31 StrUtils.MatchText Function

MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchText(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean MatchText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the MatchStr (see page 2987) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchStr (see page 2987)

33.1.32 StrUtils.MidBStr Function

Returns the substring of a specified number of bytes that appears at a specified position in a string.

Pascal

```
function MidBStr(const AText: AnsiString; const AByteStart: Integer; const AByteCount:
Integer): AnsiString;
```

C++

```
AnsiString MidBStr(const AnsiString AText, const int AByteStart, const int AByteCount);
```

File

StrUtils

Description

MidBStr returns a substring AByteCount bytes beginning at AByteStart bytes.

If AByteStart is larger than the length of AText in bytes, MidBStr returns an empty string.

If AByteCount specifies more bytes than are available, only the available bytes are returned.

Note: MidBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use MidStr (see page 2988).

See Also

Copy

LeftStr (see page 2986)

RightStr (see page 2992)

AnsiMidStr (see page 2976)

MidStr (see page 2988)

33.1.33 StrUtils.MidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function MidStr(const AText: AnsiString; const AStart: Integer; const ACount: Integer):
AnsiString; overload;
function MidStr(const AText: WideString; const AStart: Integer; const ACount: Integer):
WideString; overload;
```

C++

```
AnsiString MidStr(const AnsiString AText, const int AStart, const int ACount);
BSTR MidStr(const BSTR AText, const int AStart, const int ACount);
```

File

StrUtils

Description

MidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, MidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, MidStr may return more than ACount bytes. To return a specific number of bytes, use MidBStr (see page 2988).

See Also

Copy

LeftStr (see page 2986)

RightStr (see page 2992)

AnsiMidStr (see page 2976)

MidBStr (see page 2988)

33.1.34 StrUtils.PosEx Function

Returns the index value of a substring.

Pascal

```
function PosEx(const SubStr: string; const S: string; Offset: Integer = 1): Integer; overload;
```

C++

```
int PosEx(const UnicodeString SubStr, const UnicodeString S, int Offset = 1);
```

File

StrUtils

Description

PosEx returns the index of SubStr in S, beginning the search at Offset. If Offset is 1 (default), PosEx is equivalent to Pos (see page 3720).

PosEx returns 0 if SubStr is not found, if Offset is greater than the length of S, or if Offset is less than 1.

See Also

Pos

33.1.35 StrUtils.RandomFrom Function

Returns a randomly selected element from an array.

Pascal

```
function RandomFrom(const AValues: array of string): string; overload;
```

C++

```
UnicodeString RandomFrom(const array of string AValues);
```

File

StrUtils

Description

RandomFrom returns a randomly selected element from the array passed as the AValues argument. In C++, AValues_Size is the index of the last array element (one less than the number of elements.)

To initialize the random number generator, add a single call Randomize (see page 3726) or assign a value to the RandSeed (see page 3902) variable before making any calls to RandomFrom.

See Also

Randomize

RandSeed

33.1.36 StrUtils.ReplaceStr Function

ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.

Pascal

```
function ReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
UnicodeString ReplaceStr(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

For a case insensitive replacement, use the ReplaceText (see page 2990) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ReplaceText (see page 2990)

33.1.37 StrUtils.ReplaceText Function

ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.

Pascal

```
function ReplaceText(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
UnicodeString ReplaceText(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

For a case sensitive replacement, use the ReplaceStr (see page 2990) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ReplaceStr (see page 2990)

33.1.38 StrUtils.ResemblesText Function

ResemblesText uses a Soundex (see page 2994) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 2994) method, and false otherwise.

Pascal

```
function ResemblesText(const AText: string; const AOther: string): Boolean; overload;
```

C++

```
Boolean ResemblesText(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

See Also

Commonly Used Long String Routines

String Types

String Constants

AnsiResemblesText (see page 2978)

33.1.39 StrUtils.ReverseString Function

Returns the reverse of a specified string.

Pascal

```
function ReverseString(const AText: string): string; overload;
```

C++

```
UnicodeString ReverseString(const UnicodeString AText);
```

File

StrUtils

Description

ReverseString returns the string specified by AText with the characters in reverse order.

See Also

DupeString (see page 2982)

33.1.40 StrUtils.RightBStr Function

Returns the substring of a specified number of bytes that appears at the end of a string.

Pascal

```
function RightBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString RightBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

RightBStr returns the trailing bytes of AText up to a length of AByteCount bytes.

Note: RightBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use RightStr (see page 2992).

See Also

Copy

TrimRight

AnsiEndsText (see page 2973)

AnsiEndsStr (see page 2972)

AnsiRightStr (see page 2979)

33.1.41 StrUtils.RightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function RightStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function RightStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString RightStr(const AnsiString AText, const int ACount);
BSTR RightStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

RightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, RightStr returns the string "grammer".

Note: If AText is an AnsiString and the current locale uses multi-byte characters, RightStr may return more than ACount bytes. To return a specific number of bytes, use RightBStr (see page 2992).

See Also

Copy

TrimRight

AnsiEndsText (see page 2973)

AnsiEndsStr (see page 2972)

AnsiRightStr (see page 2979)

33.1.42 StrUtils.SearchBuf Function

Locates a substring within a text buffer.

Pascal

```
function SearchBuf(Buf: PAnsiChar; BufLen: Integer; SelStart: Integer; SelLength: Integer;
SearchString: AnsiString; Options: TStringSearchOptions = [soDown]): PAnsiChar; overload;
function SearchBuf(Buf: PWideChar; BufLen: Integer; SelStart: Integer; SelLength: Integer;
SearchString: UnicodeString; Options: TStringSearchOptions = [soDown]): PWideChar; overload;
```

C++

```
PAnsiChar SearchBuf(PAnsiChar Buf, int BufLen, int SelStart, int SelLength, AnsiString
SearchString, TStringSearchOptions Options = [soDown]);
PWideChar SearchBuf(PWideChar Buf, int BufLen, int SelStart, int SelLength, UnicodeString
SearchString, TStringSearchOptions Options = [soDown]);
```

File

StrUtils

Description

Call SearchBuf to search for a specified search string within a text buffer.

Buf is the text buffer to search.

BufLen is the length, in bytes, of Buf.

SelStart is the first character of the search when Options indicates a backward search (does not include soDown). The first character in Buf has position 0.

SelLength is the number of characters after SelStart that the search begins when Options indicates a forward search (includes soDown).

SearchString is the string to find in Buf.

Options determines whether the search runs forward (soDown) or backward from SelStart or SelStart+SelLength, whether the search is case sensitive (soMatchCase), and whether the matching string must be a whole word (soWholeWord).

If SearchBuf finds a match, it returns a pointer to the first character of the matching string in Buf. If it does not find a match, SearchBuf returns nil (Delphi) or NULL (C++).

See Also

TFindDialog

33.1.43 StrUtils.Soundex Function

Converts a string into its Soundex representation.

Pascal

```
function Soundex(const AText: string; ALength: TSoundexLength = 4): string;
```

C++

```
UnicodeString Soundex(const UnicodeString AText, TSoundexLength ALength = 4);
```

File

StrUtils

Description

Soundex converts the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It returns up to the first ALength Soundex codes in the resulting string representation.

See Also

SoundexWord (see page 2997)

SoundexInt (see page 2995)

SoundexSimilar (see page 2996)

SoundexCompare (see page 2994)

SoundexProc (see page 2996)

33.1.44 StrUtils.SoundexCompare Function

Compares the Soundex (see page 2994) representations of two strings.

Pascal

```
function SoundexCompare(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Integer;
```

C++

```
int SoundexCompare(const UnicodeString AText, const UnicodeString AOther, TSoundexLength
ALength = 4);
```

File

StrUtils

Description

SoundexCompare uses a Soundex (see page 2994) algorithm to convert the strings specified by AText and AOther into

phonetic representations where each character of the resulting string represents one of six families of similar phonemes. It then compares the first ALength characters of the resulting representations by calling AnsiCompareStr (see page 4114).

SoundexCompare returns 0 if the first ALength characters of the phonetic representations are identical, a value less then 0 if the representation of AText is less than the representation of AOther, and a value greater than 0 if the representation of AText is greater than the representation of AOther.

See Also

SoundexSimilar (see page 2996)

SoundexWord (see page 2997)

SoundexInt (see page 2995)

AnsiCompareStr

Soundex (see page 2994)

SoundexProc (see page 2996)

33.1.45 StrUtils.SoundexInt Function

Converts a string into an integer that represents its phonetic value.

Pascal

```
function SoundexInt(const AText: string; ALength: TSoundexIntLength = 4): Integer;
```

C++

```
int SoundexInt(const UnicodeString AText, TSoundexIntLength ALength = 4);
```

File

StrUtils

Description

SoundexInt uses a Soundex (see page 2994) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an integer that uniquely represents the first ALength Soundex (see page 2994) codes in that string representation.

Note: The TSoundexIntLength (see page 3001) type represents an integer between 1 and 8. This is because the size of the integer return value limits the number of Soundex (see page 2994) codes that can be used in the final representation.

See Also

SoundexSimilar (see page 2996)

SoundexWord (see page 2997)

DecodeSoundexInt (see page 2981)

SoundexCompare (see page 2994)

Soundex (see page 2994)

SoundexProc (see page 2996)

33.1.46 StrUtils.SoundexProc Function

Indicates whether two strings are similar.

Pascal

```
function SoundexProc(const AText: string; const AOther: string): Boolean;
```

C++

```
Boolean SoundexProc(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

Description

SoundexProc returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar. SoundexProc is the default value of the AnsiResemblesProc (see page 3003) variable, which provides the underlying implementation of AnsiResemblesText (see page 2978).

SoundexProc uses a Soundex (see page 2994) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to 4 digits in the resulting representation, returning true if they are all the same and false if they are not.

Note: SoundexProc is the same as the SoundexSimilar (see page 2996) function using an ALength value of 4.

See Also

AnsiResemblesProc (see page 3003)

SoundexSimilar (see page 2996)

SoundexCompare (see page 2994)

SoundexWord (see page 2997)

SOundexInt

Soundex (see page 2994)

AnsiResemblesText (see page 2978)

33.1.47 StrUtils.SoundexSimilar Function

Indicates whether two strings are similar.

Pascal

```
function SoundexSimilar(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Boolean;
```

C++

```
Boolean SoundexSimilar(const UnicodeString AText, const UnicodeString AOther, TSoundexLength
ALength = 4);
```

File

StrUtils

Description

SoundexSimilar returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

SoundexSimilar uses a Soundex (see page 2994) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to ALength digits in the resulting representation, returning true if they are all the same and false if they are not.

See Also

SOundexCompare

SoundexWord (see page 2997)

SoundexInt (see page 2995)

Soundex (see page 2994)

SoundexProc (see page 2996)

33.1.48 StrUtils.SoundexWord Function

Converts a string into a Word that represents its phonetic value.

Pascal

```
function SoundexWord(const AText: string): Word;
```

C++

```
Word SoundexWord(const UnicodeString AText);
```

File

StrUtils

Description

SoundexWord uses a Soundex (see page 2994) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an unsigned 16-bit value that uniquely represents the first 4 Soundex (see page 2994) codes in that string representation.

See Also

SoundexSimilar (see page 2996)

SoundexInt (see page 2995)

DecodeSoundexWord (see page 2982)

SoundexCompare (see page 2994)

Soundex (see page 2994)

SoundexProc (see page 2996)

33.1.49 StrUtils.StartsStr Function

Enter a short sentence, starting with a verb, that states the basic purpose of the property.

Pascal

```
function StartsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the StartsText (see page 2998) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsText (see page 2998)

33.1.50 StrUtils.StartsText Function

StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.

Pascal

```
function StartsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the StartsStr (see page 2998) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsStr (see page 2998)

33.1.51 StrUtils.StuffString Function

Inserts a substring into a specified position of a string, replacing the current characters.

Pascal

```
function StuffString(const AText: string; AStart: Cardinal; ALength: Cardinal; const ASubText:
string): string; overload;
```

C++

```
UnicodeString StuffString(const UnicodeString AText, unsigned AStart, unsigned ALength, const
UnicodeString ASubText);
```

File

StrUtils

Description

StuffString returns a new string that is constructed by replacing the characters of AText specified by AStart and ALength with the string specified by ASubText.

AText is the string to which ASubText is added. It is not modified by StuffString.

AStart is the index of the first character in AText to be replaced, where 1 identifies the first character, 2 identifies the second character, and so on.

ALength is the number of characters in AText that are replaced by ASubText. If ALength is 0, ASubText is inserted into AText without removing any characters. If AText is negative, the characters preceding the insertion point are duplicated after the occurrence of ASubText in the result string.

ASubText is the substring to insert into AText, replacing the characters specified by AStart and ALength.

33.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TStringSeachOption (see page 3000)	TStringSeachOption is an enumeration that describes the behavior of string searches.

33.2.1 StrUtils.TStringSeachOption Enumeration

TStringSeachOption is an enumeration that describes the behavior of string searches.

Pascal

```
TStringSeachOption = (
  soDown,
  soMatchCase,
  soWholeWord
);
```

C++

```
enum TStringSeachOption {
  soDown,
  soMatchCase,
  soWholeWord
};
```

File

StrUtils

Description

Note the unusual spelling. TStringSeachOptioncan have one of the following values:

Value	Meaning
soDown	A forward search is performed through the target text from the specified start point to the end of the search buffer. If soDown is not specified a reverse search is performed from the start point to the begining of the search buffer.
soMatchCase	Performs a case sensitive search.
soWholeWord	Match whole words, not pieces of words. Whole words are determined using standard identifier parser rules.

String Types

String Constants

TStringSearchOptions (see page 3002)

33.3 Types

The following table lists types in this documentation.

Types

Name	Description
TCompareTextProc (see page 3001)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 3001)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 2995) function. The integer value can be from 1 to 8.
TSoundexLength (see page 3002)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 3002)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3000).

33.3.1 StrUtils.TCompareTextProc Type

TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.

Pascal

```
TCompareTextProc = function (const AText, AOther: string): Boolean;
```

C++

```
(const AText, AOther: string): Boolean ( TCompareTextProc)();
```

File

StrUtils

See Also

TStringSeachOption (see page 3000)

33.3.2 StrUtils.TSoundexIntLength Type

TSoundexIntLength The maximum calculation length for the SoundexInt (see page 2995) function. The integer value can be from 1 to 8.

Pascal

```
TSoundexIntLength = 1..8;
```

C++

```
1..8 TSoundexIntLength;
```

File

StrUtils

Description

This value determines how many characters to use when generating the soundex string from the source string. There is a maximum of 8 characters due to the maximum capacity of the Integer type.

See Also

SoundexLength

33.3.3 StrUtils.TSoundexLength Type

TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.

Pascal

```
TSoundexLength = 1..MaxInt;
```

C++

```
1..MaxInt TSoundexLength;
```

File

StrUtils

See Also

SoundexIntLength

33.3.4 StrUtils.TStringSearchOptions Type

TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3000).

Pascal

```
TStringSearchOptions = set of TStringSeachOption;
```

C++

```
TStringSeachOption TStringSearchOptions;
```

File

StrUtils

Description

Note the unusual spelling of the enumeration.

See Also

TStringSeachOption (see page 3000)

33.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AnsiResemblesProc (see page 3003)	Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar.
ResemblesProc (see page 3003)	Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3003).

33.4.1 StrUtils.AnsiResemblesProc Variable

Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar.

Pascal

```
AnsiResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc AnsiResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 2978) function uses the function assigned to AnsiResemblesProc to determine when two strings should be considered similar. By default, AnsiResemblesProc is set to SoundExProc.

To make AnsiResemblesText (see page 2978) use a different algorithm, you can change AnsiResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundExSimilar than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

See Also

AnsiResemblesText (see page 2978)

SoundExSimilar

33.4.2 StrUtils.ResemblesProc Variable

Controls the algorithm used by AnsiResemblesText (see page 2978) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3003).

Pascal

```
ResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc ResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 2978) function uses the function assigned to ResemblesProc to determine when two strings should be considered similar. By default, ResemblesProc is set to SoundExProc.

To make AnsiResemblesText (see page 2978) use a different algorithm, you can change ResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundExSimilar than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

33.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 3005)	This is constant StrUtils.WordDelimiters.

33.5.1 StrUtils.WordDelimiters Constant

Pascal

```
WordDelimiters: set of AnsiChar = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

C++

```
set of AnsiChar WordDelimiters = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

File

StrUtils

Description

This is constant StrUtils.WordDelimiters.

34 SvcMgr Namespace

This is namespace SvcMgr.

Topics

Name	Description
Classes (see page 3009)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 3048)	The following table lists structs, records, enums in this documentation.
Types (see page 3052)	The following table lists types in this documentation.
Variables (see page 3055)	The following table lists variables in this documentation.
Constants (see page 3056)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDependencies (see page 3009)	TDependencies is a container for TDependency (see page 3012) objects.
	TDependency (see page 3012)	TDependency object represents a dependent service or load ordering group used by TService (see page 3017) objects.
	TEventLogger (see page 3014)	This is class SvcMgr.TEventLogger.
	TService (see page 3017)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 3035)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 3041)	TServiceThread represents the thread associated with a specific service (TService (see page 3017) object).

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 3056)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

Structs, Records, Enums

	Name	Description
	TCurrentStatus (see page 3048)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 3049)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 3049)	TServiceType indicates the type of a service.
	TStartType (see page 3050)	TStartType indicates how a service starts up.

Types

Name	Description
TContinueEvent (see page 3052)	This is type SvcMgr.TContinueEvent.

TPauseEvent (see page 3052)	This is type SvcMgr.TPauseEvent.
TServiceController (see page 3053)	This is type SvcMgr.TServiceController.
TServiceEvent (see page 3053)	This is type SvcMgr.TServiceEvent.
TStartEvent (see page 3053)	This is type SvcMgr.TStartEvent.
TStopEvent (see page 3054)	This is type SvcMgr.TStopEvent.

Variables

Name	Description
Application (see page 3055)	This is variable SvcMgr.Application.

34.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDependencies (see page 3009)	TDependencies is a container for TDependency (see page 3012) objects.
	TDependency (see page 3012)	TDependency object represents a dependent service or load ordering group used by TService (see page 3017) objects.
	TEventLogger (see page 3014)	This is class SvcMgr.TEventLogger.
	TService (see page 3017)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 3035)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 3041)	TServiceThread represents the thread associated with a specific service (TService (see page 3017) object).

34.1.1 TDependencies Class

TDependencies is a container for TDependency (see page 3012) objects.

Class Hierarchy

Pascal

```
TDependencies = class(TCollection);
```

C++

```
class TDependencies : public TCollection;
```

File

SvcMgr

Description

TDependencies is a collection of TDependency (see page 3012) objects, each of which represents a dependent service or load ordering group for a service (TService (see page 3017) instance). TDependencies objects are the implementation of the Dependencies property of TService (see page 3017).

See Also

TDependency (see page 3012)

TService (see page 3017)

TService (see page 3017)

TService (see page 3017)

34.1.1.1 TDependencies Members

The following tables list the members exposed by TDependencies.

Protected Methods

	Name	Description
	GetOwner (see page 3010)	Returns the owner of an object.

Public Methods

	Name	Description
	Create (see page 3010)	Creates an instance of a TDependencies (see page 3009) object.

Public Properties

	Name	Description
	Items (see page 3011)	Lists the dependency objects in the dependencies collection.

34.1.1.2 TDependencies.Create Constructor

Creates an instance of a TDependencies (see page 3009) object.

Pascal

```
constructor Create(Owner: TPersistent);
```

C++

```
__fastcall TDependencies(TPersistent * Owner);
```

Description

Applications should not need to call the constructor directly. Instances of TService (see page 3017) create the TDependencies (see page 3009) object from their own constructors. The Owner parameter is the TService (see page 3017) instance that uses the TDependencies (see page 3009) object to implement its Dependencies property.

Create sets the TDependency (see page 3012) owner to the Owner parameter and calls the inherited Create.

See Also

Create

TService (see page 3017)

34.1.1.3 TDependencies Methods

The methods of the TDependencies class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 3010)	Returns the owner of an object.

34.1.1.3.1 TDependencies.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath

TCollection

TComponent

Owner

34.1.1.4 TDependencies Properties

The properties of the TDependencies class are listed here.

Public Properties

	Name	Description
	Items (see page 3011)	Lists the dependency objects in the dependencies collection.

34.1.1.4.1 TDependencies.Items Property

Lists the dependency objects in the dependencies collection.

Pascal

```
property Items [Index: Integer]: TDependency;
```

C++

```
__property TDependency Items[int Index];
```

Description

The value of the Index parameter corresponds to the Index property of each TDependency (see page 3012) object in the collection. It represents the position of the dependency object in the dependencies collection.

Note: In Delphi, Items is the default property of TDependencies (see page 3009). This means that you can omit the property names. For example

Note: Service1.Dependencies.Items[i]

Note: can be written

Note: Service1.Dependencies[i]

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

Index

operator_[]

34.1.2 TDependency Class

TDependency object represents a dependent service or load ordering group used by TService (see page 3017) objects.

Class Hierarchy

Pascal

```
TDependency = class(TCollectionItem);
```

C++

```
class TDependency : public TCollectionItem;
```

File

SvcMgr

Description

A TDependency object represents a new service or load ordering group that must start before the service represented by a TService (see page 3017) object. Collections of dependency objects are TDependencies (see page 3009) objects. TService (see page 3017) has Dependencies and LoadGroup properties that use dependency collections. Each dependency has a Name (see page 3014) property that identifies the service or load ordering group, and a boolean IsGroup (see page 3013) property to indicate whether the dependency represents a load ordering group.

See Also

TDependencies (see page 3009)

TService (see page 3017)

TService (see page 3017)

Service Name Properties

34.1.2.1 TDependency Members

The following tables list the members exposed by TDependency.

Protected Methods

	Name	Description
	GetDisplayName (see page 3013)	Returns the name of the collection item as it appears in the collection editor.

Published Properties

	Name	Description
	IsGroup (see page 3013)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 3017) object).
	Name (see page 3014)	Identifies the dependent service or load ordering group used by a TService (see page 3017) object.

34.1.2.2 TDependency Methods

The methods of the TDependency class are listed here.

Protected Methods

	Name	Description
	GetDisplayName (see page 3013)	Returns the name of the collection item as it appears in the collection editor.

34.1.2.2.1 TDependency.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName

GetNamePath

34.1.2.3 TDependency Properties

The properties of the TDependency class are listed here.

Published Properties

	Name	Description
	IsGroup (see page 3013)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 3017) object).
	Name (see page 3014)	Identifies the dependent service or load ordering group used by a TService (see page 3017) object.

34.1.2.3.1 TDependency.IsGroup Property

Indicates whether the dependency represents a load ordering group for a service (TService (see page 3017) object).

Pascal

```
property IsGroup: Boolean;
```

C++

```
__property Boolean IsGroup;
```

Description

IsGroup indicates whether the dependency represents a load ordering group.

Note: : Because services and service groups share the same name space, group names must be prefixed by the SC_GROUP_IDENTIFIER character to distinguish them from service names. If IsGroup is set to true, SC_GROUP_IDENTIFIER will automatically be prefixed to the Dependency name (Name (see page 3014) property). DisplayName is not modified.

See Also

Name (see page 3014)

LoadGroup (see page 3026)

34.1.2.3.2 TDependency.Name Property

Identifies the dependent service or load ordering group used by a TService (see page 3017) object.

Pascal

```
property Name: String;
```

C++

```
__property UnicodeString Name;
```

Description

Name is the name identifying the service or load ordering group. If Name is the name of a service, Name reflects the actual ServiceStartName of a TService (see page 3017) instance.

The property editor for the Dependencies property of TService (see page 3017) technically uses the dependency's DisplayName to identify the dependency service in its collection list. However, Name and DisplayName are nearly always the same.

Dependency objects that are load ordering groups are prefixed by SC_GROUP_IDENTIFIER. Setting the IsGroup (see page 3013) property handles prefixing the Name automatically.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

DisplayName

LoadGroup (see page 3026)

TService (see page 3017)

34.1.3 TEventLogger Class

Class Hierarchy

Pascal

```
TEventLogger = class(TObject);
```

C++

```
class TEventLogger : public TObject;
```

File

SvcMgr

Description

This is class SvcMgr.TEventLogger.

34.1.3.1 TEventLogger Members

The following tables list the members exposed by TEventLogger.

Public Methods

	Name	Description
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3015)	This is Create, a member of class TEventLogger.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3016)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	LogMessage (see page 3016)	This is LogMessage, a member of class TEventLogger.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.

34.1.3.2 TEventLogger.Create Constructor

Pascal

```
constructor Create(Name: String);
```

C++

```
__fastcall TEventLogger(UnicodeString Name);
```

Description

This is Create, a member of class TEventLogger.

34.1.3.3 TEventLogger.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEventLogger();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3382)

34.1.3.4 TEventLogger Methods

The methods of the TEventLogger class are listed here.

Public Methods

	Name	Description
	LogMessage (see page 3016)	This is LogMessage, a member of class TEventLogger.

34.1.3.4.1 TEventLogger.LogMessage Method

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Word = 0; ID: DWord = 0);
```

C++

```
__fastcall LogMessage(UnicodeString Message, DWord EventType = 1, Word Category = 0, DWord ID
= 0);
```

Description

This is LogMessage, a member of class TEventLogger.

34.1.4 TService Class

TService encapsulates a Windows NT service.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TService = class(TDataModule);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TService : public TDataModule;
```

File

SvcMgr

Description

TService encapsulates a Windows NT service in an NT service application. A Win32 service is accessed via the Service Control Manager and can be started automatically at system boot, by a user through the Services control panel applet, or by a Win32-based application that uses the service functions. Services can execute even when no user is logged on to the system. Windows NT also supports a driver service that does not interact with the SCM.

34.1.4.1 TService Members

The following tables list the members exposed by TService.

Protected Methods

	Name	Description
	Controller (see page 3020)	This is Controller, a member of class TService.
V	DoContinue (see page 3020)	This is DoContinue, a member of class TService.
V	DoCustomControl (see page 3020)	This is DoCustomControl, a member of class TService.
V	DoInterrogate (see page 3020)	This is DoInterrogate, a member of class TService.
V	DoPause (see page 3021)	This is DoPause, a member of class TService.
V	DoShutdown (see page 3021)	This is DoShutdown, a member of class TService.
V	DoStart (see page 3021)	This is DoStart, a member of class TService.
V	DoStop (see page 3021)	This is DoStop, a member of class TService.
	Main (see page 3023)	This is Main, a member of class TService.

Public Methods

	Name	Description
	CreateNew (see page 3019)	Instantiates and initializes a TService (see page 3017) object.
	Destroy (see page 3019)	Disposes of a TService (see page 3017) instance.
	GetServiceController (see page 3022)	Returns the service's registered handler function.
	LogMessage (see page 3022)	Sends an error message to the event log.
	ReportStatus (see page 3023)	Updates the Service Control Manager's status information for the calling service.

Public Properties

	Name	Description
	ErrCode (see page 3025)	Contains the service specific error code returned on starting or stopping the service.
	Param (see page 3027)	Lists the parameters to the service.
	ParamCount (see page 3027)	Indicates the number of startup parameters for the service.
	ServiceThread (see page 3028)	Identifies the dedicated thread for the service.
	Status (see page 3029)	Indicates the current state of the service.
	Terminated (see page 3030)	Indicates whether the service thread has terminated.
	Win32ErrCode (see page 3031)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Events

	Name	Description
	AfterInstall (see page 3031)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 3032)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 3032)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 3033)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 3033)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnExecute (see page 3034)	Occurs when the thread associated with the service starts up.
	OnPause (see page 3034)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 3034)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 3035)	OnStartup occurs when the service first starts up, before the OnExecute (see page 3034) event.
	OnStop (see page 3035)	Occurs when the Service Control manager stops the service.

Published Properties

	Name	Description
	AllowPause (see page 3024)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 3024)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 3024)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 3025)	Identifies the service in the Windows Service Control Manager.
	ErrorSeverity (see page 3026)	Indicates the severity of service startup failure.
	Interactive (see page 3026)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 3026)	Names of the load ordering group that includes the service.
	Password (see page 3027)	Specifies the password, optionally used depending upon the ServiceStartName (see page 3028), for accessing the service.
	ServiceStartName (see page 3028)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 3029)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 3029)	Indicates when or how the service starts.
	TagID (see page 3030)	Specifies a unique tag for the service within its LoadGroup (see page 3026).
	WaitHint (see page 3030)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

34.1.4.2 TService.CreateNew Constructor

Instantiates and initializes a TService (see page 3017) object.

Pascal

```
constructor CreateNew(AOwner: TComponent; Dummy: Integer = 0); override;
```

C++

```
virtual __fastcall TService(TComponent * AOwner, int Dummy = 0);
```

Description

Call CreateNew to instantiate a service object at runtime. Services added at design time are created automatically. The AOwner parameter specifies the TServiceApplication (see page 3035) object that is responsible for ultimately freeing the service. The Dummy parameter is not used. Use CreateNew rather than the Create constructor to instantiate a new service object at runtime. CreateNew does not attempt to stream in an associated DFM file that indicates any components added to the service at design time.

See Also

Owner

Create (see page 3010)

TServiceApplication (see page 3035)

34.1.4.3 TService.Destroy Destructor

Disposes of a TService (see page 3017) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TService();
```

Description

Destroy frees the memory associated with the objects for the Params and Dependencies (see page 3024) properties that were created in the constructor, and for the EventLogger object created in the LogMessage (see page 3022) method. Then it calls the inherited Destroy.

See Also

System::TObject::Free (see page 3382)

LogMessage (see page 3022)

34.1.4.4 TService Methods

The methods of the TService class are listed here.

Protected Methods

	Name	Description
	Controller (see page 3020)	This is Controller, a member of class TService.
	DoContinue (see page 3020)	This is DoContinue, a member of class TService.

	DoCustomControl (see page 3020)	This is DoCustomControl, a member of class TService.
	DoInterrogate (see page 3020)	This is DoInterrogate, a member of class TService.
	DoPause (see page 3021)	This is DoPause, a member of class TService.
	DoShutdown (see page 3021)	This is DoShutdown, a member of class TService.
	DoStart (see page 3021)	This is DoStart, a member of class TService.
	DoStop (see page 3021)	This is DoStop, a member of class TService.
	Main (see page 3023)	This is Main, a member of class TService.

Public Methods

	Name	Description
	GetServiceController (see page 3022)	Returns the service's registered handler function.
	LogMessage (see page 3022)	Sends an error message to the event log.
	ReportStatus (see page 3023)	Updates the Service Control Manager's status information for the calling service.

34.1.4.4.1 TService.Controller Method

Pascal

```
procedure Controller(CtrlCode: DWord);
```

C++

```
__fastcall Controller(DWord CtrlCode);
```

Description

This is Controller, a member of class TService.

34.1.4.4.2 TService.DoContinue Method

Pascal

```
function DoContinue: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoContinue();
```

Description

This is DoContinue, a member of class TService.

34.1.4.4.3 TService.DoCustomControl Method

Pascal

```
function DoCustomControl(CtrlCode: DWord): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoCustomControl(DWord CtrlCode);
```

Description

This is DoCustomControl, a member of class TService.

34.1.4.4.4 TService.DoInterrogate Method

Pascal

```
procedure DoInterrogate; virtual;
```

C++

```
virtual __fastcall DoInterrogate();
```

Description

This is DoInterrogate, a member of class TService.

34.1.4.4.5 TService.DoPause Method

Pascal

```
function DoPause: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoPause();
```

Description

This is DoPause, a member of class TService.

34.1.4.4.6 TService.DoShutdown Method

Pascal

```
procedure DoShutdown; virtual;
```

C++

```
virtual __fastcall DoShutdown();
```

Description

This is DoShutdown, a member of class TService.

34.1.4.4.7 TService.DoStart Method

Pascal

```
procedure DoStart; virtual;
```

C++

```
virtual __fastcall DoStart();
```

Description

This is DoStart, a member of class TService.

34.1.4.4.8 TService.DoStop Method

Pascal

```
function DoStop: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoStop();
```

Description

This is DoStop, a member of class TService.

34.1.4.4.9 TService.GetServiceController Method

Returns the service's registered handler function.

Pascal

```
function GetServiceController: TServiceController; virtual; abstract;
```

C++

```
virtual __fastcall TServiceController GetServiceController() = 0;
```

Description

GetServiceController returns the handler for the service. You do not need to call this function directly. The service object's main function calls it automatically.

Note: Each service in the service application has a main function for that service. When a request is made to start the service, the main thread of the service calls the RegisterServiceCtrlHandler function to register this control handler function. TService (see page 3017) automatically calls RegisterServiceCtrlHandler and returns this handler function. Because this function cannot be a class method (member function), the Service application wizard generates code that creates a non-member handler, (ServiceController) for your service object. This routine returns the service object's Handler (Controller (see page 3020)).

34.1.4.4.10 TService.LogMessage Method

Sends an error message to the event log.

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Integer = 0; ID: Integer
= 0);
```

C++

```
__fastcall LogMessage(UnicodeString Message, DWord EventType = 1, int Category = 0, int ID =
0);
```

Description

LogMessage sends an error message to the event log when an error or exception occurs. By default the EventType is EVENTLOG_ERROR_TYPE (usually indicating a loss of functionality or data) and the category and ID are zero. For example, if a service cannot be loaded as the system boots, it can log an error event, and the category and ID are zero.

The EventType specifies the type of event being logged. This parameter can be one of the following values:

Value	Meaning
EVENTLOG_WARNING_TYPE	Warning event
EVENTLOG_INFORMATION_TYPE	Information event
EVENTLOG_AUDIT_SUCCESS	Success Audit event
EVENTLOG_AUDIT_FAILURE	Failure Audit event

EVENTLOG_ERROR_TYPEError event

The Category parameter specifies the event category, which is source-specific information and can have any value.

The ID parameter specifies the event identifier, which is the message that goes with this event as an entry in the message file associated with the event source.

34.1.4.4.11 TService.Main Method

Pascal

```
procedure Main(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall Main(DWord Argc, PLPSTR Argv);
```

Description

This is Main, a member of class TService.

34.1.4.4.12 TService.ReportStatus Method

Updates the Service Control Manager's status information for the calling service.

Pascal

```
procedure ReportStatus;
```

C++

```
__fastcall ReportStatus();
```

Description

ReportStatus sends current status information about the calling service to the Service Control Manager.

See Also

LogMessage (see page 3022)

Status (see page 3029)

WaitHint (see page 3030)

34.1.4.5 TService Properties

The properties of the TService class are listed here.

Public Properties

	Name	Description
	ErrCode (see page 3025)	Contains the service specific error code returned on starting or stopping the service.
R	Param (see page 3027)	Lists the parameters to the service.
R	ParamCount (see page 3027)	Indicates the number of startup parameters for the service.
R	ServiceThread (see page 3028)	Identifies the dedicated thread for the service.
	Status (see page 3029)	Indicates the current state of the service.
R	Terminated (see page 3030)	Indicates whether the service thread has terminated.
	Win32ErrCode (see page 3031)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Properties

	Name	Description
	AllowPause (see page 3024)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 3024)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 3024)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 3025)	Identifies the service in the Windows Service Control Manager.

	ErrorSeverity (see page 3026)	Indicates the severity of service startup failure.
	Interactive (see page 3026)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 3026)	Names of the load ordering group that includes the service.
	Password (see page 3027)	Specifies the password, optionally used depending upon the ServiceStartName (see page 3028), for accessing the service.
	ServiceStartName (see page 3028)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 3029)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 3029)	Indicates when or how the service starts.
	TagID (see page 3030)	Specifies a unique tag for the service within its LoadGroup (see page 3026).
	WaitHint (see page 3030)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

34.1.4.5.1 TService.AllowPause Property

Indicates whether clients are allowed to pause the service.

Pascal

```
property AllowPause: Boolean;
```

C++

```
__property Boolean AllowPause;
```

Description

AllowPause indicates whether clients of the service can pause and resume the service by calling the Windows API ControlService function. When AllowPause is true, an OnPause (see page 3034) event occurs before the service pauses, and an OnContinue (see page 3033) event occurs when the service resumes.

See Also

OnPause (see page 3034)

OnContinue (see page 3033)

34.1.4.5.2 TService.AllowStop Property

Indicates whether clients are allowed to stop the service.

Pascal

```
property AllowStop: Boolean;
```

C++

```
__property Boolean AllowStop;
```

Description

AllowStop indicates whether clients of the service can stop it by calling the Windows API ControlService function. When AllowStop is true, an OnStop (see page 3035) event occurs before the service stops.

See Also

OnStop (see page 3035)

34.1.4.5.3 TService.Dependencies Property

Lists the services or load ordering groups on which the service depends.

Pascal

```
property Dependencies: TDependencies;
```

C++

```
__property TDependencies Dependencies;
```

Description

Dependencies is a container for TDependency (see page 3012) objects, which are dependent services or load ordering groups that must start before this service. If the container is empty, the service has no dependencies.

Dependency on a service means that this service can only run if the service it depends on is running. Dependency on a group means that this service can run if at least one member of the group is running after an attempt to start all members of the group.

See Also

TDependency (see page 3012)

LoadGroup (see page 3026)

34.1.4.5.4 TService.DisplayName Property

Identifies the service in the Windows Service Control Manager.

Pascal

```
property DisplayName: String;
```

C++

```
__property UnicodeString DisplayName;
```

Description

DisplayName contains a string, with a maximum length of 256 characters, that is the name of the service as displayed in the Service Control Manager. User interface programs use DisplayName to identify the service. DisplayName is case-preserved in the Service Control Manager, however display name comparisons are always case-insensitive.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Name

ServiceStartName (see page 3028)

34.1.4.5.5 TService.ErrCode Property

Contains the service specific error code returned on starting or stopping the service.

Pascal

```
property ErrCode: DWord;
```

C++

```
__property DWord ErrCode;
```

Description

ErrCode specifies a service specific error code that the service returns when an error occurs while the service is starting or stopping. If ErrCode is not defined, the Win32ErrCode (see page 3031) property is used instead.

See Also

ReportStatus (see page 3023)

Win32ErrCode (see page 3031)

34.1.4.5.6 TService.ErrorSeverity Property

Indicates the severity of service startup failure.

Pascal

```
property ErrorSeverity: TErrorSeverity;
```

C++

```
__property TErrorSeverity ErrorSeverity;
```

Description

ErrorSeverity indicates the severity if this service fails to start during startup of the service application.

See Also

ErrCode (see page 3025)

ReportStatus (see page 3023)

Win32ErrCode (see page 3031)

34.1.4.5.7 TService.Interactive Property

Indicates whether the service is interactive with the Windows desktop.

Pascal

```
property Interactive: Boolean;
```

C++

```
__property Boolean Interactive;
```

Description

Interactive indicates whether the service can interact with the Windows desktop. Interactive only has an effect when ServiceType (see page 3029) is stWin32. For more information about creating interactive NT services, see the Microsoft Help.

See Also

ServiceType (see page 3029)

34.1.4.5.8 TService.LoadGroup Property

Names of the load ordering group that includes the service.

Pascal

```
property LoadGroup: String;
```

C++

```
__property UnicodeString LoadGroup;
```

Description

LoadGroup is the name of the load-ordering group that includes the service. This is used by other services that have

dependencies on the load ordering group (See Dependencies (see page 3024)). The registry lists load-ordering groups at HKEY_LOCAL_MACHINE\System (see page 3165)\CurrentControlSet\Control\ServiceGroupOrder. The order in which services are loaded depends on the order of the load groups in the Registry and the dependencies listed in service Dependencies (see page 3024) properties.

Because services and service groups share the same name space, the SC_GROUP_IDENTIFIER character must prefix group names to distinguish them from service names. This is automatically prefixed if the TDependency (see page 3012)'s IsGroup property is true.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Dependencies (see page 3024)

TagID (see page 3030)

34.1.4.5.9 TService.Param Property

Lists the parameters to the service.

Pascal

```
property Param [Index: Integer]: String;
```

C++

```
__property UnicodeString Param[int Index];
```

Description

Param is an indexed property that contains the parameters to the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

ParamCount (see page 3027)

34.1.4.5.10 TService.ParamCount Property

Indicates the number of startup parameters for the service.

Pascal

```
property ParamCount: Integer;
```

C++

```
__property int ParamCount;
```

Description

ParamCount is the number of parameters for the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

Param (see page 3027)

34.1.4.5.11 TService.Password Property

Specifies the password, optionally used depending upon the ServiceStartName (see page 3028), for accessing the service.

Pascal

```
property Password: String;
```

C++

```
__property UnicodeString Password;
```

Description

Password is the password for the account name specified by the ServiceStartName (see page 3028) property if the ServiceType (see page 3029) is stWin32.

If Password is nil (Delphi) or NULL (C++), or if it points to an empty string, the service has no password. If ServiceType (see page 3029) is stDevice or stFileSystem, this parameter is ignored.

See Also

ServiceStartName (see page 3028)

34.1.4.5.12 TService.ServiceStartName Property

ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.

Pascal

```
property ServiceStartName: String;
```

C++

```
__property UnicodeString ServiceStartName;
```

Description

ServiceStartName is the name used to start the service.

If ServiceType (see page 3029) is stWin32, ServiceStartName is the account name (in the form "DomainName\Username") which the service process is logged on as when it runs. If the account belongs to the built-in domain, ".\Username" can be specified. If the service application includes more than one service, leave ServiceStartName blank, and leave the Password (see page 3027) property blank.

If the service type is not stWin32, ServiceStartName is the driver object name (\FileSytems\Rdr or \Driver\Xns) which the input and output system uses to load the device driver. With device drivers or file systems drivers, you can leave ServiceStartName blank and the I/O system will create a default name based on the service name.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Password (see page 3027)

34.1.4.5.13 TService.ServiceThread Property

Identifies the dedicated thread for the service.

Pascal

```
property ServiceThread: TServiceThread;
```

C++

```
__property TServiceThread ServiceThread;
```

Description

ServiceThread is the instance of the TServiceThread (see page 3041) class that is the dedicated thread for the service. Each service in the service application has a dedicated thread that contains a loop in its Execute method for processing service requests. Often a service will spawn a new thread, derived from TThread, to free the service thread to continue processing service requests.

See Also

ProcessRequests (see page 3046)

TThread

34.1.4.5.14 TService.ServiceType Property

Identifies the type of the service as Win32, device driver, or file system driver.

Pascal

```
property ServiceType: TServiceType;
```

C++

```
__property TServiceType ServiceType;
```

Description

ServiceType indicates the type of service. ServiceType can be stWin32 (a Win32 service – the default), stDevice (a device driver), or stFileSystem (a file system driver).

See Also

Interactive (see page 3026)

34.1.4.5.15 TService.StartType Property

Indicates when or how the service starts.

Pascal

```
property StartType: TStartType;
```

C++

```
__property TStartType StartType;
```

Description

StartType specifies how and why the service starts

34.1.4.5.16 TService.Status Property

Indicates the current state of the service.

Pascal

```
property Status: TCurrentStatus;
```

C++

```
__property TCurrentStatus Status;
```

Description

Status indicates the current state of the service. The status information is displayed in the Service Control Manager.

See Also

ReportStatus (see page 3023)

34.1.4.5.17 TService.TagID Property

Specifies a unique tag for the service within its LoadGroup (see page 3026).

Pascal

```
property TagID: DWord;
```

C++

```
__property DWord TagID;
```

Description

TagID is the unique tag value for this service in its LoadGroup (see page 3026). If no tag is requested, this property is 0. Tags are only evaluated when the ServiceType (see page 3029) is not stWin32 and the StartType (see page 3029) is stBoot or stSystem.

See Also

Dependencies (see page 3024)

LoadGroup (see page 3026)

34.1.4.5.18 TService.Terminated Property

Indicates whether the service thread has terminated.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

Terminated indicates whether the dedicated thread that the service is running in has terminated.

See Also

Terminated

Terminate

34.1.4.5.19 TService.WaitHint Property

Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

Pascal

```
property WaitHint: Integer;
```

C++

```
__property int WaitHint;
```

Description

WaitHint specifies the amount of time, in milliseconds, that can elapse between a pending start, stop, pause, or continue

operation and the service setting its status with a call to the Windows API. Normally this is handled automatically. If the service performs a lengthy operation of more than WaitHint time in one of its event handlers, you should call ReportStatus (see page 3023) method to update to the Service Control Manager.

See Also

ReportStatus (see page 3023)

34.1.4.5.20 TService.Win32ErrCode Property

Indicates the Win32 error code reported by the service if a service specific code is not defined.

Pascal

```
property Win32ErrCode: DWord;
```

C++

```
__property DWord Win32ErrCode;
```

Description

Win32ErrCode specifies a Win32 error code that the service uses to report an error that occurs when it is starting or stopping. If an error code specific to the service is defined, this property is automatically set to ERROR_SERVICE_SPECIFIC_ERROR and the service specific error is reported instead.

See Also

ErrCode (see page 3025)

ReportStatus (see page 3023)

34.1.4.6 TService Events

The events of the TService class are listed here.

Published Events

	Name	Description
	AfterInstall (see page 3031)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 3032)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 3032)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 3033)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 3033)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnExecute (see page 3034)	Occurs when the thread associated with the service starts up.
	OnPause (see page 3034)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 3034)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 3035)	OnStartup occurs when the service first starts up, before the OnExecute (see page 3034) event.
	OnStop (see page 3035)	Occurs when the Service Control manager stops the service.

34.1.4.6.1 TService.AfterInstall Event

Occurs immediately after the service is registered with the Windows Service Control manager.

Pascal

```
property AfterInstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterInstall;
```

Description

Write (see page 3789) an AfterInstall event handler to take specific action immediately after the service is registered. Install services by running the service application with the INSTALL switch.

See Also

AfterUninstall (see page 3032)

OnStart (see page 3035)

OnExecute (see page 3034)

OnCreate

BeforeInstall (see page 3032)

34.1.4.6.2 TService.AfterUninstall Event

Occurs immediately after the service is removed from the Service Control manager's database.

Pascal

```
property AfterUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterUninstall;
```

Description

Write (see page 3789) an AfterUninstall event handler to take specific action immediately after the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterInstall (see page 3031)

OnStop (see page 3035)

BeforeUninstall (see page 3033)

Destroy

OnShutdown (see page 3034)

34.1.4.6.3 TService.BeforeInstall Event

Occurs before the service is first registered with the Windows Service Control manager.

Pascal

```
property BeforeInstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeInstall;
```

Description

Write (see page 3789) a BeforeInstall event handler to take specific action immediately before the service is first registered. Install services by running the service application with the INSTALL switch.

See Also

AfterInstall (see page 3031)

OnStart (see page 3035)

OnExecute (see page 3034)

OnCreate

BeforeUninstall (see page 3033)

34.1.4.6.4 TService.BeforeUninstall Event

Occurs immediately before the service is removed from the Service Control manager's database.

Pascal

```
property BeforeUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeUninstall;
```

Description

Write (see page 3789) a BeforeUninstall event handler to take specific action immediately before the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterUninstall (see page 3032)

OnStop (see page 3035)

BeforeInstall (see page 3032)

Destroy

OnShutdown (see page 3034)

34.1.4.6.5 TService.OnContinue Event

Occurs when the Service Control manager resumes the service after it has been paused.

Pascal

```
property OnContinue: TContinueEvent;
```

C++

```
__property TContinueEvent OnContinue;
```

Description

Write (see page 3789) an OnContinue event handler to take specific action when the Service Control manager resumes the service after it has been paused.

See Also

OnPause (see page 3034)

34.1.4.6.6 TService.OnExecute Event

Occurs when the thread associated with the service starts up.

Pascal

```
property OnExecute: TServiceEvent;
```

C++

```
__property TServiceEvent OnExecute;
```

Description

If you are not spawning a new thread to handle individual service requests in an OnStart (see page 3035) event handler, this is where you implement the service. When the OnExecute event handler finishes, the service thread terminates. Most OnExecute event handlers contain a loop that calls the service thread's ProcessRequests method so that other service requests are not locked out.

See Also

ProcessRequests (see page 3046)

OnStart (see page 3035)

34.1.4.6.7 TService.OnPause Event

Occurs when the Service Control manager pauses the service temporarily.

Pascal

```
property OnPause: TPauseEvent;
```

C++

```
__property TPauseEvent OnPause;
```

Description

Write (see page 3789) an OnPause event handler to take specific action when the service is temporarily paused.

See Also

OnContinue (see page 3033)

34.1.4.6.8 TService.OnShutdown Event

Occurs when the system running the service application is about to shut down.

Pascal

```
property OnShutdown: TServiceEvent;
```

C++

```
__property TServiceEvent OnShutdown;
```

Description

Write (see page 3789) an OnShutdown event handler to take specific action just before the service shuts down. The service application terminates immediately after OnShutdown.

See Also

OnStop (see page 3035)

OnStart (see page 3035)

OnPause (see page 3034)

34.1.4.6.9 TService.OnStart Event

OnStartup occurs when the service first starts up, before the OnExecute (see page 3034) event.

Pascal

```
property OnStart: TStartEvent;
```

C++

```
__property TStartEvent OnStart;
```

Description

This event should be used to initialize the service. For example, if each service request is handled in a separate thread (a good idea if handling the request takes much time) the thread for a request is spawned in an OnStart event handler.

See Also

OnStop (see page 3035)

OnContinue (see page 3033)

OnExecute (see page 3034)

34.1.4.6.10 TService.OnStop Event

Occurs when the Service Control manager stops the service.

Pascal

```
property OnStop: TStopEvent;
```

C++

```
__property TStopEvent OnStop;
```

Description

Write (see page 3789) an OnStop event handler to take specific action when the service stops.

See Also

OnShutdown (see page 3034)

OnStart (see page 3035)

OnPause (see page 3034)

34.1.5 TServiceApplication Class

TServiceApplication encapsulates a Windows NT service application.

Class Hierarchy

Pascal

```
[RootDesignerSerializerAttribute('', '', False)]
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TServiceApplication = class(TComponent);
```

C++

```
[RootDesignerSerializerAttribute('', '', False)]
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TServiceApplication : public TComponent;
```

File

SvcMgr

Description

TServiceApplication encapsulates a Windows NT application type known as a service. TServiceApplication provides the fundamental behavior of this type of application. Each Service project automatically declares an Application (see page 3055) variable of type TServiceApplication as the instance of the application. The Application (see page 3055) variable is added to a project by selecting File | New (see page 3712) from the menu of the IDE main window and selecting Service Application (see page 3055) in the New (see page 3712) Items dialog.

TServiceApplication contains TService (see page 3017) objects, each of which encapsulates a Windows NT service. The service application object provides methods to create service objects and to install, register, dispatch, and uninstall services.

When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

Note: Do not add the Forms or Httpapp units to the uses list of the project (Delphi) or includ the unit header for these units in the project source (C++). Those units declare conflicting Application (see page 3055) variables of types TApplication and TWebApplication, respectively.

See Also

Application (see page 3055)

TService (see page 3017)

Service Applications

Service Name\ Properties

34.1.5.1 TServiceApplication Members

The following tables list the members exposed by TServiceApplication.

Protected Methods

	Name	Description
	DispatchServiceMain (see page 3038)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 3038)	This is DoHandleException, a member of class TServiceApplication.
	Hook (see page 3039)	This is Hook, a member of class TServiceApplication.
	RegisterServices (see page 3039)	This is RegisterServices, a member of class TServiceApplication.

Public Methods

	Name	Description
	Create (see page 3037)	Instantiates a TServiceApplication (see page 3035) object.
	CreateForm (see page 3038)	Creates the service object or objects for the service application.

	Destroy (see page 3037)	Disposes of an instance of a TServiceApplication (see page 3035) object.
	Initialize (see page 3039)	Sets the initial state of the application and hides any associated MainForm.
	Installing (see page 3039)	This is Installing, a member of class TServiceApplication.
	Run (see page 3040)	Installs, registers, and adds services to its component list, and creates a thread for the service application.

Public Properties

	Name	Description
	DelayInitialize (see page 3040)	This is DelayInitialize, a member of class TServiceApplication.
	ServiceCount (see page 3040)	Indicates the number of services in the service application.
	Title (see page 3041)	Indicates the name of the title application.

34.1.5.2 TServiceApplication.Create Constructor

Instantiates a TServiceApplication (see page 3035) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TServiceApplication(TComponent * AOwner);
```

Description

Applications do not need to call the constructor directly. TServiceApplication (see page 3035) is instantiated by selecting File | New (see page 3712) from the menu of the IDE main window and selecting Service Application (see page 3055) in the New (see page 3712) Items dialog. An Application (see page 3055) variable of type TServiceApplication (see page 3035) is declared and initialized as the instance of the application.

34.1.5.3 TServiceApplication.Destroy Destructor

Disposes of an instance of a TServiceApplication (see page 3035) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TServiceApplication();
```

Description

You do not need to call the destructor directly. TServiceApplication (see page 3035) is destroyed when your application closes.

The destructor frees the memory associated with sub-objects.

See Also

System::TObject::Free (see page 3382)

34.1.5.4 TServiceApplication Methods

The methods of the TServiceApplication class are listed here.

Protected Methods

	Name	Description
	DispatchServiceMain (see page 3038)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 3038)	This is DoHandleException, a member of class TServiceApplication.
	Hook (see page 3039)	This is Hook, a member of class TServiceApplication.
	RegisterServices (see page 3039)	This is RegisterServices, a member of class TServiceApplication.

Public Methods

	Name	Description
	CreateForm (see page 3038)	Creates the service object or objects for the service application.
	Initialize (see page 3039)	Sets the initial state of the application and hides any associated MainForm.
	Installing (see page 3039)	This is Installing, a member of class TServiceApplication.
	Run (see page 3040)	Installs, registers, and adds services to its component list, and creates a thread for the service application.

34.1.5.4.1 TServiceApplication.CreateForm Method

Creates the service object or objects for the service application.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference); virtual;
```

C++

```
virtual __fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Do not call CreateForm in an application. The module manager calls CreateForm internally to register the service objects of the service application.

CreateForm instantiates a TService (see page 3017) object for each service contained in the service application. CreateForm is called automatically, for the first service, when the service application is first created. Subsequently, CreateForm is called for each new service added to the application. To add a new service, select File | New (see page 3712) from the menu of the IDE main window and choose Service in the New (see page 3712) Items dialog.

34.1.5.4.2 TServiceApplication.DispatchServiceMain Method

Pascal

```
procedure DispatchServiceMain(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall DispatchServiceMain(DWord Argc, PLPSTR Argv);
```

Description

This is DispatchServiceMain, a member of class TServiceApplication.

34.1.5.4.3 TServiceApplication.DoHandleException Method

Pascal

```
procedure DoHandleException(E: Exception); dynamic;
```

C++

```
__fastcall DoHandleException(Exception E);
```

Description

This is DoHandleException, a member of class TServiceApplication.

34.1.5.4.4 TServiceApplication.Hook Method

Pascal

```
function Hook(var Message: TMessage): Boolean;
```

C++

```
__fastcall Boolean Hook(TMessage Message);
```

Description

This is Hook, a member of class TServiceApplication.

34.1.5.4.5 TServiceApplication.Initialize Method

Sets the initial state of the application and hides any associated MainForm.

Pascal

```
procedure Initialize; virtual;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize sets the initial state of the application to hide any main form that may be associated with the application. Service applications are rarely interactive and do not typically have a form associated with them. If a form has been added to the application, Initialize hides it on start. Initialize then follows the standard (default) VCL application initialization process.

34.1.5.4.6 TServiceApplication.Installing Method

Pascal

```
function Installing: Boolean;
```

C++

```
__fastcall Boolean Installing();
```

Description

This is Installing, a member of class TServiceApplication.

34.1.5.4.7 TServiceApplication.RegisterServices Method

Pascal

```
procedure RegisterServices(Install: Boolean; Silent: Boolean);
```

C++

```
__fastcall RegisterServices(Boolean Install, Boolean Silent);
```

Description

This is RegisterServices, a member of class TServiceApplication.

34.1.5.4.8 TServiceApplication.Run Method

Installs, registers, and adds services to its component list, and creates a thread for the service application.

Pascal

```
procedure Run; virtual;
```

C++

```
virtual __fastcall Run();
```

Description

Run handles installing and uninstalling services, depending on the command line switches. When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

If not called with the /INSTALL or /UNINSTALL switch, Run creates a service application thread that responds to Windows messages from clients. Note that this thread is for the application and differs from the dedicated TServiceThread (see page 3041) instances associated with individual services in the application.

34.1.5.5 TServiceApplication Properties

The properties of the TServiceApplication class are listed here.

Public Properties

	Name	Description
	DelayInitialize (see page 3040)	This is DelayInitialize, a member of class TServiceApplication.
R	ServiceCount (see page 3040)	Indicates the number of services in the service application.
	Title (see page 3041)	Indicates the name of the title application.

34.1.5.5.1 TServiceApplication.DelayInitialize Property

Pascal

```
property DelayInitialize: Boolean;
```

C++

```
__property Boolean DelayInitialize;
```

Description

This is DelayInitialize, a member of class TServiceApplication.

34.1.5.5.2 TServiceApplication.ServiceCount Property

Indicates the number of services in the service application.

Pascal

```
property ServiceCount: Integer;
```

C++

```
__property int ServiceCount;
```

Description

ServiceCount is the number of services in the service application. Each service is encapsulated by a TService (see page 3017) instance and has its own dedicated service thread.

Note: If the Service application requires a user name and password, the application must implement only a single service.

See Also

TService (see page 3017)

34.1.5.5.3 TServiceApplication.Title Property

Indicates the name of the title application.

Pascal

```
property Title: string;
```

C++

```
__property UnicodeString Title;
```

Description

Title is the name of the service application. This text string appears below the icon of the application when it is minimized.

34.1.6 TServiceThread Class

TServiceThread represents the thread associated with a specific service (TService (see page 3017) object).

Class Hierarchy

Pascal

```
TServiceThread = class(TThread);
```

C++

```
class TServiceThread : public TThread;
```

File

SvcMgr

Description

TServiceThread is the thread associated with a service. Each service application has one or more service objects, each of which has its own dedicated thread. TServiceThread instances represent those threads.

Note: Service threads.

See Also

TService (see page 3017)

TService (see page 3017)

TServiceApplication (see page 3035)

TServiceThread

IDH

Service Threads

34.1.6.1 TServiceThread Members

The following tables list the members exposed by TServiceThread.

Protected Methods

	Name	Description
	Execute (see page 3043)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
	Create (see page 3042)	Instantiates and initializes a TServiceThread (see page 3041) object.
	ProcessRequests (see page 3046)	Allows clients to invoke the service associated with the service thread.

34.1.6.2 TServiceThread.Create Constructor

Instantiates and initializes a TServiceThread (see page 3041) object.

Pascal

```
constructor Create(Service: TService);
```

C++

```
__fastcall TServiceThread(TService Service);
```

Description

Applications do not need to call the constructor directly. Instances of TService (see page 3017) create the TServiceThread (see page 3041) object on startup. The Service parameter is the TService (see page 3017) instance for which the TServiceThread (see page 3041) is the dedicated thread.

The constructor sets the FreeOnTerminate property to true and then calls the base class constructor so that the thread object is created with its Suspended property set to false.

See Also

FreeOnTerminate

Suspended

34.1.6.3 TServiceThread Methods

The methods of the TServiceThread class are listed here.

Protected Methods

	Name	Description
	Execute (see page 3043)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
	ProcessRequests (see page 3046)	Allows clients to invoke the service associated with the service thread.

34.1.6.3.1 TServiceThread.Execute Method

Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Pascal

```
procedure Execute; override;
```

C++

```
virtual __fastcall Execute();
```

Description

Override Execute and insert the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated property to determine if the thread needs to exit.

A thread executes when Create is called if CreateSuspended set to false, or when Resume is first called after the thread is created if CreateSuspended set to true.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize method.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

__fastcall TYouThread::TYouThread(bool suspended)
```

```
    : TThread(suspended)
{
}

void __fastcall TMyThread::Execute()
{
  Form1->Memo1->Lines->Add("Process has been running for this many seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo1->Lines->Add("Low priority process " + IntToStr(I));
    Sleep(1000);
  }
  mythreadRunning = FALSE;
}

void __fastcall TYouThread::Execute()
{
  Form1->Memo3->Lines->Add("Second low priority process has been running for this many
seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo3->Lines->Add("Second low priority process " + IntToStr(I));
    Sleep(1000);
  }
  youthreadRunning = FALSE;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMyThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (mythreadRunning == FALSE)
  {
    mythreadRunning = TRUE;
    SecondProcess = new TMyThread(True); // create suspended - secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form1->Memo2->Lines->Add("Do some work in the main process for 10 seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo2->Lines->Add("Main process " + IntToStr(I));
    Sleep(1000);
  }
}

void __fastcall TForm1::Button3Click(TObject *Sender)
{
  TYouThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (youthreadRunning == FALSE)
  {
    youthreadRunning = TRUE;
    SecondProcess = new TYouThread(True); // create suspended - secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
```

```
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  mythreadRunning = FALSE;
  youthreadRunning = FALSE;
}
```

Delphi Examples:

```
{
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes.  The
Execute procedure must be overridden in the extension class
of TThread or an "Abstract Error" will result. To create the
extension choose the File | New | Other | Thread Object menu.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (mythreadRunning = FALSE) then
  begin
    mythreadRunning:= TRUE;
    MyProcess := TMyThread.Create(True); { create suspended - secondprocess does not run yet }
    MyProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    MyProcess.Priority := tpLower;  // set the priority to lower than normal
    MyProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  if mythreadRunning then MyProcess.Terminate();
end;

procedure TMyThread.Execute;
var I: Integer;
begin
  Form1.Memo1.Lines.Add('Process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo1.Lines.Add('Low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
  mythreadRunning:= FALSE;
end;

procedure TYouThread.Execute;
var I: Integer;
begin
  Form1.Memo3.Lines.Add('Second low priority process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo3.Lines.Add('Second low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
    youthreadRunning:= FALSE;
end;

procedure TForm1.Button2Click(Sender: TObject);
```

```
var   I: Integer;
begin
  Form1.Memo2.Lines.Add('Do some work in the main process for 10 seconds:');
  for I := 0 to 10 do
  begin
    Form1.Memo2.Lines.Add('Main process ' + InttoStr(I));
    Sleep(1000);
  end;
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  if (youthreadRunning = FALSE) then
  begin
    youthreadRunning:= TRUE;
    YouProcess := TYouThread.Create(True); { create suspended – secondprocess does not run yet
}
    YouProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    YouProcess.Priority := tpLower;  // set the priority to lower than normal
    YouProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  if youthreadRunning then YouProcess.Terminate();
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  mythreadRunning:= FALSE;
  youthreadRunning:= FALSE;
end;
```

34.1.6.3.2 TServiceThread.ProcessRequests Method

Allows clients to invoke the service associated with the service thread.

Pascal

```
procedure ProcessRequests(WaitForMessage: Boolean);
```

C++

```
__fastcall ProcessRequests(Boolean WaitForMessage);
```

Description

TServiceThread (see page 3041)'s ProcessRequests is called in the Execute (see page 3043) method after any associated service's OnExecute event handler has finished executing. For more information about optimizing service execution by spawning individual threads for each service request, see the Developer's Guide.

See Also

OnExecute (see page 3034)

34.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCurrentStatus (see page 3048)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 3049)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 3049)	TServiceType indicates the type of a service.
	TStartType (see page 3050)	TStartType indicates how a service starts up.

34.2.1 SvcMgr.TCurrentStatus Enumeration

TCurrentStatus indicates the state of a service.

Pascal

```
TCurrentStatus = (
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
);
```

C++

```
enum TCurrentStatus {
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
};
```

File

SvcMgr

Description

TCurrentStatus can have one of the following values:

Value	Meaning
csStopped	The service is not running.
csStartPending	The service is starting.
csStopPending	The service is stopping.
csRunning	The service is running.

csContinuePending	The service continue is pending.
csPausePending	The service pause is pending.
csPaused	The service is paused

34.2.2 SvcMgr.TErrorSeverity Enumeration

TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.

Pascal

```
TErrorSeverity = (
  esIgnore,
  esNormal,
  esSevere,
  esCritical
);
```

C++

```
enum TErrorSeverity {
  esIgnore,
  esNormal,
  esSevere,
  esCritical
};
```

File

SvcMgr

Description

TErrorSeverity can have one of the following values:

Value	What the startup program does
esIgnore	Logs the error and continues.
esNormal	Logs the error and displays a message, but continues.
esSevere	Logs the error but continues only if the last-known-good configuration is being started; otherwise the last-known-good configuration is started instead.
esCritical	Logs the error and starts up the last-known-good configuration instead. If this is the last-known-good configuration, the startup operation fails.

34.2.3 SvcMgr.TServiceType Enumeration

TServiceType indicates the type of a service.

Pascal

```
TServiceType = (
  stWin32,
  stDevice,
  stFileSystem
);
```

C++

```
enum TServiceType {
  stWin32,
  stDevice,
  stFileSystem
};
```

File

SvcMgr

Description

TServiceType can have one of the following values:

Value	Meaning
stWin32	a Win32 service.
stDevice	a device driver.
stFileSystem	a file system driver.

34.2.4 SvcMgr.TStartType Enumeration

TStartType indicates how a service starts up.

Pascal

```
TStartType = (
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
);
```

C++

```
enum TStartType {
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
};
```

File

SvcMgr

Description

The following table lists the possible values of TStartType:

StartType value	Service is started
stBoot(used only when ServiceType is not stWin32)	by the operating system loader
stSystem(used only when ServiceType is not stWin32)	after boot systems are initialized
stAuto	automatically during system startup

stManual	when a process calls the Windows StartService function
stDisabled	the service can't be started except by an administrator

34.3 Types

The following table lists types in this documentation.

Types

Name	Description
TContinueEvent (see page 3052)	This is type SvcMgr.TContinueEvent.
TPauseEvent (see page 3052)	This is type SvcMgr.TPauseEvent.
TServiceController (see page 3053)	This is type SvcMgr.TServiceController.
TServiceEvent (see page 3053)	This is type SvcMgr.TServiceEvent.
TStartEvent (see page 3053)	This is type SvcMgr.TStartEvent.
TStopEvent (see page 3054)	This is type SvcMgr.TStopEvent.

34.3.1 SvcMgr.TContinueEvent Type

Pascal

```
TContinueEvent = procedure (Sender: TService; var Continued: Boolean) of object;
```

C++

```
(Sender: TService; var Continued: Boolean) ( TContinueEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TContinueEvent.

34.3.2 SvcMgr.TPauseEvent Type

Pascal

```
TPauseEvent = procedure (Sender: TService; var Paused: Boolean) of object;
```

C++

```
(Sender: TService; var Paused: Boolean) ( TPauseEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TPauseEvent.

34.3.3 SvcMgr.TServiceController Type

Pascal

```
TServiceController = procedure (CtrlCode: DWord);
```

C++

```
(CtrlCode: DWord) ( TServiceController)();
```

File

SvcMgr

Description

This is type SvcMgr.TServiceController.

34.3.4 SvcMgr.TServiceEvent Type

Pascal

```
TServiceEvent = procedure (Sender: TService) of object;
```

C++

```
(Sender: TService) ( TServiceEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TServiceEvent.

34.3.5 SvcMgr.TStartEvent Type

Pascal

```
TStartEvent = procedure (Sender: TService; var Started: Boolean) of object;
```

C++

```
(Sender: TService; var Started: Boolean) ( TStartEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TStartEvent.

34.3.6 SvcMgr.TStopEvent Type

Pascal

```
TStopEvent = procedure (Sender: TService; var Stopped: Boolean) of object;
```

C++

```
(Sender: TService; var Stopped: Boolean) ( TStopEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TStopEvent.

34.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Application (see page 3055)	This is variable SvcMgr.Application.

34.4.1 SvcMgr.Application Variable

Pascal

```
Application: TServiceApplication = nil;
```

C++

```
TServiceApplication Application = nil;
```

File

SvcMgr

Description

This is variable SvcMgr.Application.

34.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 3056)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

34.5.1 SvcMgr.CM_SERVICE_CONTROL_CODE Constant

Pascal

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

C++

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

File

SvcMgr

Description

This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

35 SyncObjs Namespace

This is namespace SyncObjs.

Topics

Name	Description
Classes (see page 3058)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 3094)	The following table lists structs, records, enums in this documentation.
Types (see page 3095)	The following table lists types in this documentation.

Classes

	Name	Description
	TConditionVariableCS (see page 3058)	This is class SyncObjs.TConditionVariableCS.
	TConditionVariableHelper (see page 3062)	This is class SyncObjs.TConditionVariableHelper.
	TConditionVariableMutex (see page 3064)	This is class SyncObjs.TConditionVariableMutex.
	TCriticalSection (see page 3068)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TCriticalSectionHelper (see page 3072)	This is class SyncObjs.TCriticalSectionHelper.
	TEvent (see page 3074)	TEvent represents an external event.
	THandleObject (see page 3078)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 3083)	This is class SyncObjs.TMutex.
	TSemaphore (see page 3086)	This is class SyncObjs.TSemaphore.
	TSimpleEvent (see page 3090)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 3091)	TSynchroObject is the base class for all thread synchronization objects.

Structs, Records, Enums

	Name	Description
	TWaitResult (see page 3094)	TWaitResult indicates the reason an event object stopped waiting for its signal.

Types

Name	Description
THandleObjectArray (see page 3095)	This is type SyncObjs.THandleObjectArray.

35.1 Classes

The following table lists classes in this documentation.

Class Helpers

Name	Description
TConditionVariableHelper (see page 3062)	This is class SyncObjs.TConditionVariableHelper.
TCriticalSectionHelper (see page 3072)	This is class SyncObjs.TCriticalSectionHelper.

Classes

	Name	Description
	TConditionVariableCS (see page 3058)	This is class SyncObjs.TConditionVariableCS.
	TConditionVariableMutex (see page 3064)	This is class SyncObjs.TConditionVariableMutex.
	TCriticalSection (see page 3068)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TEvent (see page 3074)	TEvent represents an external event.
	THandleObject (see page 3078)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 3083)	This is class SyncObjs.TMutex.
	TSemaphore (see page 3086)	This is class SyncObjs.TSemaphore.
	TSimpleEvent (see page 3090)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 3091)	TSynchroObject is the base class for all thread synchronization objects.

35.1.1 TConditionVariableCS Class

Class Hierarchy

Pascal

```
TConditionVariableCS = class(TSynchroObject);
```

C++

```
class TConditionVariableCS : public TSynchroObject;
```

File

SyncObjs

Description

This is class SyncObjs.TConditionVariableCS.

35.1.1.1 TConditionVariableCS Members

The following tables list the members exposed by TConditionVariableCS.

Protected Fields

	Name	Description
	FConditionVariable (see page 3060)	This is FConditionVariable, a member of class TConditionVariableCS.

Public Methods

	Name	Description
	Acquire (see page 3060)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3059)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3366)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3061)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ReleaseAll (see page 3061)	This is ReleaseAll, a member of class TConditionVariableCS.
	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
	WaitFor (see page 3061)	This is the overview for the WaitFor method overload.

35.1.1.2 TConditionVariableCS.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
__fastcall TConditionVariableCS();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3366)

System::TObject::Free (see page 3382)

35.1.1.3 TConditionVariableCS Fields

The fields of the TConditionVariableCS class are listed here.

Protected Fields

	Name	Description
	FConditionVariable (see page 3060)	This is FConditionVariable, a member of class TConditionVariableCS.

35.1.1.3.1 TConditionVariableCS.FConditionVariable Field

Pascal

```
FConditionVariable: TRTLConditionVariable;
```

C++

```
TRTLConditionVariable FConditionVariable;
```

Description

This is FConditionVariable, a member of class TConditionVariableCS.

35.1.1.4 TConditionVariableCS Methods

The methods of the TConditionVariableCS class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3060)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3061)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ReleaseAll (see page 3061)	This is ReleaseAll, a member of class TConditionVariableCS.
	WaitFor (see page 3061)	This is the overview for the WaitFor method overload.

35.1.1.4.1 TConditionVariableCS.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3093)

35.1.1.4.2 TConditionVariableCS.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3092)

35.1.1.4.3 TConditionVariableCS.ReleaseAll Method

Pascal

```
procedure ReleaseAll;
```

C++

```
__fastcall ReleaseAll();
```

Description

This is ReleaseAll, a member of class TConditionVariableCS.

35.1.1.4.4 WaitFor Method

This is the overview for the WaitFor method overload.

Overload List

	Name	Description
	TConditionVariableCS.WaitFor (TCriticalSection, LongWord) (see page 3062)	This is WaitFor, a member of class TConditionVariableCS.
	TConditionVariableCS.WaitFor (TRTLCriticalSection, LongWord) (see page 3062)	This is WaitFor, a member of class TConditionVariableCS.

35.1.1.4.4.1 TConditionVariableCS.WaitFor Method (TCriticalSection, LongWord)

Pascal

```
function WaitFor(CriticalSection: TCriticalSection; TimeOut: LongWord = INFINITE):
TWaitResult; overload;
```

C++

```
__fastcall TWaitResult WaitFor(TCriticalSection CriticalSection, LongWord TimeOut = INFINITE);
```

Description

This is WaitFor, a member of class TConditionVariableCS.

35.1.1.4.4.2 TConditionVariableCS.WaitFor Method (TRTLCriticalSection, LongWord)

Pascal

```
function WaitFor(var CriticalSection: TRTLCriticalSection; TimeOut: LongWord = INFINITE):
TWaitResult; overload;
```

C++

```
__fastcall TWaitResult WaitFor(TRTLCriticalSection CriticalSection, LongWord TimeOut =
INFINITE);
```

Description

This is WaitFor, a member of class TConditionVariableCS.

35.1.2 TConditionVariableHelper Class Helper

Class Hierarchy

SyncObjs.TConditionVariableHelper

Pascal

```
TConditionVariableHelper = class helper for TRTLConditionVariable;
```

C++

```
class TConditionVariableHelper;
```

File

SyncObjs

Description

This is class SyncObjs.TConditionVariableHelper.

35.1.2.1 TConditionVariableHelper Members

The following tables list the members exposed by TConditionVariableHelper.

Public Methods

	Name	Description
	Create (see page 3063)	This is Create, a member of class TConditionVariableHelper.
	Free (see page 3063)	This is Free, a member of class TConditionVariableHelper.

	SleepCS (see page 3063)	This is SleepCS, a member of class TConditionVariableHelper.
	Wake (see page 3064)	This is Wake, a member of class TConditionVariableHelper.
	WakeAll (see page 3064)	This is WakeAll, a member of class TConditionVariableHelper.

35.1.2.2 TConditionVariableHelper Methods

The methods of the TConditionVariableHelper class are listed here.

Public Methods

	Name	Description
	Create (see page 3063)	This is Create, a member of class TConditionVariableHelper.
	Free (see page 3063)	This is Free, a member of class TConditionVariableHelper.
	SleepCS (see page 3063)	This is SleepCS, a member of class TConditionVariableHelper.
	Wake (see page 3064)	This is Wake, a member of class TConditionVariableHelper.
	WakeAll (see page 3064)	This is WakeAll, a member of class TConditionVariableHelper.

35.1.2.2.1 TConditionVariableHelper.Create Method

Pascal

```
class function Create: TRTLConditionVariable; static;
```

C++

```
static __fastcall TRTLConditionVariable Create();
```

Description

This is Create, a member of class TConditionVariableHelper.

35.1.2.2.2 TConditionVariableHelper.Free Method

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

This is Free, a member of class TConditionVariableHelper.

35.1.2.2.3 TConditionVariableHelper.SleepCS Method

Pascal

```
function SleepCS(var CriticalSection: TRTLCriticalSection; dwMilliseconds: DWORD): Boolean;
```

C++

```
__fastcall Boolean SleepCS(TRTLCriticalSection CriticalSection, DWORD dwMilliseconds);
```

Description

This is SleepCS, a member of class TConditionVariableHelper.

35.1.2.2.4 TConditionVariableHelper.Wake Method

Pascal

```
procedure Wake;
```

C++

```
__fastcall Wake();
```

Description

This is Wake, a member of class TConditionVariableHelper.

35.1.2.2.5 TConditionVariableHelper.WakeAll Method

Pascal

```
procedure WakeAll;
```

C++

```
__fastcall WakeAll();
```

Description

This is WakeAll, a member of class TConditionVariableHelper.

35.1.3 TConditionVariableMutex Class

Class Hierarchy

Pascal

```
TConditionVariableMutex = class(TSynchroObject);
```

C++

```
class TConditionVariableMutex : public TSynchroObject;
```

File

SyncObjs

Description

This is class SyncObjs.TConditionVariableMutex.

35.1.3.1 TConditionVariableMutex Members

The following tables list the members exposed by TConditionVariableMutex.

Public Methods

	Name	Description
	Acquire (see page 3066)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.

	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3065)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
V	Destroy (see page 3066)	Disposes of an object instance.
V	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
V	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
V	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3067)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ReleaseAll (see page 3067)	This is ReleaseAll, a member of class TConditionVariableMutex.
V	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
	WaitFor (see page 3067)	This is WaitFor, a member of class TConditionVariableMutex.

35.1.3.2 TConditionVariableMutex.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
__fastcall TConditionVariableMutex();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3366)

System::TObject::Free (see page 3382)

35.1.3.3 TConditionVariableMutex.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TConditionVariableMutex();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3382)

35.1.3.4 TConditionVariableMutex Methods

The methods of the TConditionVariableMutex class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3066)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3067)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ReleaseAll (see page 3067)	This is ReleaseAll, a member of class TConditionVariableMutex.
	WaitFor (see page 3067)	This is WaitFor, a member of class TConditionVariableMutex.

35.1.3.4.1 TConditionVariableMutex.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3093)

35.1.3.4.2 TConditionVariableMutex.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3092)

35.1.3.4.3 TConditionVariableMutex.ReleaseAll Method

Pascal

```
procedure ReleaseAll;
```

C++

```
__fastcall ReleaseAll();
```

Description

This is ReleaseAll, a member of class TConditionVariableMutex.

35.1.3.4.4 TConditionVariableMutex.WaitFor Method

Pascal

```
function WaitFor(AExternalMutex: TMutex; TimeOut: LongWord = INFINITE): TWaitResult;
```

C++

```
__fastcall TWaitResult WaitFor(TMutex AExternalMutex, LongWord TimeOut = INFINITE);
```

Description

This is WaitFor, a member of class TConditionVariableMutex.

35.1.4 TCriticalSection Class

TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.

Class Hierarchy

Pascal

```
TCriticalSection = class(TSynchroObject);
```

C++

```
class TCriticalSection : public TSynchroObject;
```

File

SyncObjs

Description

Use TCriticalSection to safeguard operations that may be disrupted if another thread executes certain sections of code before the operation is completed. Critical sections work like gates that allow only a single thread to enter at a time. Because they block the execution of other threads, overusing critical sections can seriously interfere with performance.

Critical sections must be global in scope so that they are available to all threads. In every thread, any action that could interfere with the operations safeguarded by the critical section should only take place after calling the Acquire (see page 3070) or Enter (see page 3071) method. Threads that do not use the critical section for relevant operations can introduce bugs.

See Also

TThread

TCOMCriticalSection

Using Critical Sections

35.1.4.1 TCriticalSection Members

The following tables list the members exposed by TCriticalSection.

Protected Fields

	Name	Description
	FSection (see page 3070)	This is FSection, a member of class TCriticalSection.

Public Methods

	Name	Description
	Acquire (see page 3070)	Binds the critical section to the calling thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.

	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3069)	Creates an instance of TCriticalSection (see page 3068).
V	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
V	Destroy (see page 3069)	Destroys an instance of TCriticalSection (see page 3068).
V	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Enter (see page 3071)	Blocks other threads when the calling thread enters a thread-sensitive section.
V	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
V	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	Leave (see page 3071)	Allows other threads to use the critical section.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
V	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3072)	Allows other threads to use the critical section.
V	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3391)	Returns a string containing the class name.
	TryEnter (see page 3072)	This is TryEnter, a member of class TCriticalSection.
	UnitName (see page 3392)	Returns a string containing the unit name.

35.1.4.2 TCriticalSection.Create Constructor

Creates an instance of TCriticalSection (see page 3068).

Pascal

```
constructor Create;
```

C++

```
__fastcall TCriticalSection();
```

Description

Call Create to create and initialize an instance of TCriticalSection (see page 3068). A TCriticalSection (see page 3068) object can be created for a single object that contains thread-sensitive code, or as a global object to be shared by several threads.

See Also

System::TObject::Create (see page 3366)

35.1.4.3 TCriticalSection.Destroy Destructor

Destroys an instance of TCriticalSection (see page 3068).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCriticalSection();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TCriticalSection (see page 3068) object is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3382)

35.1.4.4 TCriticalSection Fields

The fields of the TCriticalSection class are listed here.

Protected Fields

	Name	Description
	FSection (see page 3070)	This is FSection, a member of class TCriticalSection.

35.1.4.4.1 TCriticalSection.FSection Field

Pascal

```
FSection: TRTLCriticalSection;
```

C++

```
TRTLCriticalSection FSection;
```

Description

This is FSection, a member of class TCriticalSection.

35.1.4.5 TCriticalSection Methods

The methods of the TCriticalSection class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3070)	Binds the critical section to the calling thread.
	Enter (see page 3071)	Blocks other threads when the calling thread enters a thread-sensitive section.
	Leave (see page 3071)	Allows other threads to use the critical section.
	Release (see page 3072)	Allows other threads to use the critical section.
	TryEnter (see page 3072)	This is TryEnter, a member of class TCriticalSection.

35.1.4.5.1 TCriticalSection.Acquire Method

Binds the critical section to the calling thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire to block all other threads from acquiring this critical section until the Release (see page 3072) or Leave (see page 3071) method is called. Acquire does the same thing as the Enter (see page 3071) method.

See Also

Enter (see page 3071)

Leave (see page 3071)

Release (see page 3072)

Using Critical Sections

35.1.4.5.2 TCriticalSection.Enter Method

Blocks other threads when the calling thread enters a thread-sensitive section.

Pascal

```
procedure Enter;
```

C++

```
__fastcall Enter();
```

Description

Call Enter to block all other threads from entering code protected by this critical section until the Leave (see page 3071) or Release (see page 3072) method is called. Enter calls the Acquire (see page 3070) method to bind the critical section to the calling thread.

See Also

Acquire (see page 3070)

Leave (see page 3071)

Release (see page 3072)

35.1.4.5.3 TCriticalSection.Leave Method

Allows other threads to use the critical section.

Pascal

```
procedure Leave;
```

C++

```
__fastcall Leave();
```

Description

Call Leave at the end of a thread-sensitive section of code. Each call to Leave should be balanced by a call to Enter (see page 3071) or Acquire (see page 3070) at the beginning of the thread-sensitive section. Leave calls Release (see page 3072) to allow other threads to acquire the critical section.

See Also

Acquire (see page 3070)

Enter (see page 3071)

Release (see page 3072)

35.1.4.5.4 TCriticalSection.Release Method

Allows other threads to use the critical section.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release when the thread no longer needs to block other threads from executing code that is protected by this critical section. Each call to Release should be balance by an earlier call to Acquire (see page 3070) or Enter (see page 3071) that blocked other threads from executing. Release does the same thing as the Leave (see page 3071) method.

See Also

Acquire (see page 3070)

Enter (see page 3071)

Leave (see page 3071)

Using Critical Sections

35.1.4.5.5 TCriticalSection.TryEnter Method

Pascal

```
function TryEnter: Boolean;
```

C++

```
__fastcall Boolean TryEnter();
```

Description

This is TryEnter, a member of class TCriticalSection.

35.1.5 TCriticalSectionHelper Class Helper

Class Hierarchy

SyncObjs.TCriticalSectionHelper

Pascal

```
TCriticalSectionHelper = class helper for TRTLCriticalSection;
```

C++

```
class TCriticalSectionHelper;
```

File

SyncObjs

Description

This is class SyncObjs.TCriticalSectionHelper.

35.1.5.1 TCriticalSectionHelper Members

The following tables list the members exposed by TCriticalSectionHelper.

Public Methods

	Name	Description
	Destroy (see page 3073)	This is Destroy, a member of class TCriticalSectionHelper.
	Enter (see page 3073)	This is Enter, a member of class TCriticalSectionHelper.
	Free (see page 3074)	This is Free, a member of class TCriticalSectionHelper.
	Initialize (see page 3074)	This is Initialize, a member of class TCriticalSectionHelper.
	Leave (see page 3074)	This is Leave, a member of class TCriticalSectionHelper.
	TryEnter (see page 3074)	This is TryEnter, a member of class TCriticalSectionHelper.

35.1.5.2 TCriticalSectionHelper Methods

The methods of the TCriticalSectionHelper class are listed here.

Public Methods

	Name	Description
	Destroy (see page 3073)	This is Destroy, a member of class TCriticalSectionHelper.
	Enter (see page 3073)	This is Enter, a member of class TCriticalSectionHelper.
	Free (see page 3074)	This is Free, a member of class TCriticalSectionHelper.
	Initialize (see page 3074)	This is Initialize, a member of class TCriticalSectionHelper.
	Leave (see page 3074)	This is Leave, a member of class TCriticalSectionHelper.
	TryEnter (see page 3074)	This is TryEnter, a member of class TCriticalSectionHelper.

35.1.5.2.1 TCriticalSectionHelper.Destroy Method

Pascal

```
procedure Destroy;
```

C++

```
__fastcall Destroy();
```

Description

This is Destroy, a member of class TCriticalSectionHelper.

35.1.5.2.2 TCriticalSectionHelper.Enter Method

Pascal

```
procedure Enter;
```

C++

```
__fastcall Enter();
```

Description

This is Enter, a member of class TCriticalSectionHelper.

35.1.5.2.3 TCriticalSectionHelper.Free Method

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

This is Free, a member of class TCriticalSectionHelper.

35.1.5.2.4 TCriticalSectionHelper.Initialize Method

Pascal

```
procedure Initialize;
```

C++

```
__fastcall Initialize();
```

Description

This is Initialize, a member of class TCriticalSectionHelper.

35.1.5.2.5 TCriticalSectionHelper.Leave Method

Pascal

```
procedure Leave;
```

C++

```
__fastcall Leave();
```

Description

This is Leave, a member of class TCriticalSectionHelper.

35.1.5.2.6 TCriticalSectionHelper.TryEnter Method

Pascal

```
function TryEnter: Boolean;
```

C++

```
__fastcall Boolean TryEnter();
```

Description

This is TryEnter, a member of class TCriticalSectionHelper.

35.1.6 TEvent Class

TEvent represents an external event.

Class Hierarchy

Pascal

```
TEvent = class(THandleObject);
```

C++

```
class TEvent : public THandleObject;
```

File

SyncObjs

Description

Use TEvent to signal that an event has occurred or a state has been reached.

In a multi-threaded application, use TEvent to allow one thread to signal to other threads that an event has occurred.

The handle of a TEvent object can also be used to communicate with other processes, so that an application can coordinate the timing of events with other applications. For example, use the handle of a TEvent object to wait until another process is ready to transfer information.

In a single-threaded application, use TEvent to coordinate between sections of code that respond to asynchronous events such as system events.

See Also

TThread

Waiting for a Task to Be Completed

35.1.6.1 TEvent Members

The following tables list the members exposed by TEvent.

Protected Fields

	Name	Description
	FHandle (see page 3081)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3081)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3081)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3092)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3076)	This is the overview for the Create constructor overload.

	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3080)	Destroys an instance of THandleObject (see page 3078).
	Destroy (see page 3366)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3093)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ResetEvent (see page 3077)	Turns off the signal of the event object.
	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	SetEvent (see page 3078)	Turns on the signal of the event object.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
	WaitFor (see page 3082)	This is WaitFor, a member of class THandleObject.
	WaitForMultiple (see page 3082)	This is WaitForMultiple, a member of class THandleObject.

Public Properties

	Name	Description
	Handle (see page 3082)	Specifies the handle of the Windows object used by THandleObject (see page 3078).
	LastError (see page 3083)	Indicates the Windows error code obtained from Handle (see page 3082).

35.1.6.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TEvent.Create (Boolean) (see page 3076)	Instantiates a TEvent (see page 3074) object to represent an event object.
	TEvent.Create (PSecurityAttributes, Boolean, Boolean, string, Boolean) (see page 3076)	Instantiates a TEvent (see page 3074) object to represent an event object.

35.1.6.2.1 TEvent.Create Constructor (Boolean)

Instantiates a TEvent (see page 3074) object to represent an event object.

Pascal

```
constructor Create(EventAttributes: PSecurityAttributes; ManualReset: Boolean; InitialState:
Boolean; const Name: string; UseCOMWait: Boolean = False); overload;
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TEvent(PSecurityAttributes EventAttributes, Boolean ManualReset, Boolean
InitialState, const UnicodeString Name, Boolean UseCOMWait = False);
__fastcall TEvent(Boolean UseCOMWait = False);
```

Description

Call Create to create a TEvent (see page 3074) object. Create can generate a new event object or can provide access to an existing named event object.

Set the EventAttributes parameter to specify the access rights and inheritance capabilities of the new event object. Calling Create with EventAttributes set to nil (Delphi) or NULL (C++) creates an event object with a default set of security attributes. If the TEvent (see page 3074) object is created to access an existing named event object, only the bInheritHandle field of EventAttributes is used, as the access rights were determined when the event object was created.

Set ManualReset to specify whether the signal of the TEvent (see page 3074) object can only be turned off by a call to the ResetEvent (see page 3077) method, or whether it is automatically reset when a single waiting thread is released. When ManualReset is true, the TEvent (see page 3074) signal stays set until the ResetEvent (see page 3077) method turns it off. When ManualReset is false, the signal is automatically turned off when only a single thread waits on the signal and that thread is released. If the TEvent (see page 3074) object is created to access an existing named event object, the ManualReset parameter is ignored.

Set InitialState to indicate whether the TEvent (see page 3074) object should be created with the signal set, or turned off. When InitialState is true, the TEvent (see page 3074) object is created with the signal set. If the TEvent (see page 3074) object is created to access an existing named event object, the InitialState parameter is ignored.

Set Name to provide a name for a new event object or to specify an existing named event object. If no other thread or process will need to access the event object to wait for its signal, Name can be left blank. Name can be a string of up to 260 characters, not including the backslash character (\). If Name is used to specify an existing event object, the value must match the name of the existing event in a case-sensitive comparison. If Name matches the name of an existing semaphore, mutex, or file-mapping object, the TEvent (see page 3074) object will be created with Handle (see page 3082) set to 0 and all method calls will fail.

See Also

Handle (see page 3082)

ResetEvent (see page 3077)

35.1.6.3 TEvent Methods

The methods of the TEvent class are listed here.

Public Methods

	Name	Description
	ResetEvent (see page 3077)	Turns off the signal of the event object.
	SetEvent (see page 3078)	Turns on the signal of the event object.

35.1.6.3.1 TEvent.ResetEvent Method

Turns off the signal of the event object.

Pascal

```
procedure ResetEvent;
```

C++

```
__fastcall ResetEvent();
```

Description

Call ResetEvent to signal that the event has not occurred or the desired state was not achieved. Other threads or processes that wait for the event will wait until the signal is turned on again by the SetEvent (see page 3078) method, the event object is destroyed, or the waiting process times out.

See Also

SetEvent (see page 3078)

WaitFor

Waiting for a Task to Be Completed

35.1.6.3.2 TEvent.SetEvent Method

Turns on the signal of the event object.

Pascal

```
procedure SetEvent;
```

C++

```
__fastcall SetEvent();
```

Description

Call SetEvent to signal that the event has occurred or the desired state was achieved. Other threads or processes that wait for the event will resume execution with a return value indicating that the signal was set.

See Also

ResetEvent (see page 3077)

WaitFor

Waiting for a Task to Be Completed

35.1.7 THandleObject Class

THandleObject is the base class for all thread synchronization objects that use a handle.

Class Hierarchy

Pascal

```
THandleObject = class(TSynchroObject);
```

C++

```
class THandleObject : public TSynchroObject;
```

File

SyncObjs

Description

Use THandleObject as a base class when defining an object that uses a handle when coordinating the execution of different threads in a multi-threaded application. Handled synchronization objects include event objects that allow threads to signal when critical events have occurred.

Do not create instances of THandleObject. THandleObject is a base class that introduces properties for managing the handle of a synchronization object but does not provide a mechanism for acquiring that handle. Descendants of THandleObject must acquire the appropriate type of handle.

See Also

TThread

TEvent (see page 3074)

35.1.7.1 THandleObject Members

The following tables list the members exposed by THandleObject.

Protected Fields

	Name	Description
	FHandle (see page 3081)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3081)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3081)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3092)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3080)	This is Create, a member of class THandleObject.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3080)	Destroys an instance of THandleObject (see page 3078).
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
V	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3093)	Provides the interface for a method that releases the synchronization object for use by other threads.
V	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
V	WaitFor (see page 3082)	This is WaitFor, a member of class THandleObject.
	WaitForMultiple (see page 3082)	This is WaitForMultiple, a member of class THandleObject.

Public Properties

	Name	Description
R	Handle (see page 3082)	Specifies the handle of the Windows object used by THandleObject (see page 3078).
R	LastError (see page 3083)	Indicates the Windows error code obtained from Handle (see page 3082).

35.1.7.2 THandleObject.Create Constructor

Pascal

```
constructor Create(UseCOMWait: Boolean = False);
```

C++

```
__fastcall THandleObject(Boolean UseCOMWait = False);
```

Description

This is Create, a member of class THandleObject.

35.1.7.3 THandleObject.Destroy Destructor

Destroys an instance of THandleObject (see page 3078).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THandleObject();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the THandleObject (see page 3078) reference is not nil and only then calls Destroy.

See Also

System::TObject::Free (see page 3382)

Handle (see page 3082)

35.1.7.4 THandleObject Fields

The fields of the THandleObject class are listed here.

Protected Fields

	Name	Description
	FHandle (see page 3081)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3081)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3081)	This is FUseCOMWait, a member of class THandleObject.

35.1.7.4.1 THandleObject.FHandle Field

Pascal

```
FHandle: THandle;
```

C++

```
THandle FHandle;
```

Description

This is FHandle, a member of class THandleObject.

35.1.7.4.2 THandleObject.FLastError Field

Pascal

```
FLastError: Integer;
```

C++

```
int FLastError;
```

Description

This is FLastError, a member of class THandleObject.

35.1.7.4.3 THandleObject.FUseCOMWait Field

Pascal

```
FUseCOMWait: Boolean;
```

C++

```
Boolean FUseCOMWait;
```

Description

This is FUseCOMWait, a member of class THandleObject.

35.1.7.5 THandleObject Methods

The methods of the THandleObject class are listed here.

Public Methods

	Name	Description
	WaitFor (see page 3082)	This is WaitFor, a member of class THandleObject.

	WaitForMultiple (see page 3082)	This is WaitForMultiple, a member of class THandleObject.

35.1.7.5.1 THandleObject.WaitFor Method

Pascal

```
function WaitFor(Timeout: LongWord): TWaitResult; virtual;
```

C++

```
virtual __fastcall TWaitResult WaitFor(LongWord Timeout);
```

Description

This is WaitFor, a member of class THandleObject.

35.1.7.5.2 THandleObject.WaitForMultiple Method

Pascal

```
class function WaitForMultiple(const HandleObjs: THandleObjectArray; Timeout: LongWord; AAll:
Boolean; out SignaledObj: THandleObject; UseCOMWait: Boolean = False; Len: Integer = 0):
TWaitResult;
```

C++

```
__fastcall TWaitResult WaitForMultiple(const THandleObjectArray HandleObjs, LongWord Timeout,
Boolean AAll, THandleObject SignaledObj, Boolean UseCOMWait = False, int Len = 0);
```

Description

This is WaitForMultiple, a member of class THandleObject.

35.1.7.6 THandleObject Properties

The properties of the THandleObject class are listed here.

Public Properties

	Name	Description
R	Handle (see page 3082)	Specifies the handle of the Windows object used by THandleObject (see page 3078).
R	LastError (see page 3083)	Indicates the Windows error code obtained from Handle (see page 3082).

35.1.7.6.1 THandleObject.Handle Property

Specifies the handle of the Windows object used by THandleObject (see page 3078).

Pascal

```
property Handle: THandle;
```

C++

```
__property THandle Handle;
```

Description

Read (see page 3727) Handle to obtain the Windows handle for the synchronization object. Use Handle when making Windows API calls that require a handle to the synchronization object.

THandleObject (see page 3078) provides no mechanism for setting the Handle property. Descendants of THandleObject (see page 3078) set the Handle property to the handle for whatever Windows synchronization object they represent.

See Also

Destroy (see page 3080)

35.1.7.6.2 THandleObject.LastError Property

Indicates the Windows error code obtained from Handle (see page 3082).

Pascal

```
property LastError: Integer;
```

C++

```
__property int LastError;
```

Description

Read (see page 3727) LastError when an operation of the THandleObject (see page 3078) fails. LastError returns the Windows error code that represents the reason for the failure. If no operation failed, LastError is 0.

See Also

Handle (see page 3082)

35.1.8 TMutex Class

Class Hierarchy

Pascal

```
TMutex = class(THandleObject);
```

C++

```
class TMutex : public THandleObject;
```

File

SyncObjs

Description

This is class SyncObjs.TMutex.

35.1.8.1 TMutex Members

The following tables list the members exposed by TMutex.

Protected Fields

	Name	Description
	FHandle (see page 3081)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3081)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3081)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3086)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3084)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3080)	Destroys an instance of THandleObject (see page 3078).
	Destroy (see page 3366)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3086)	Provides the interface for a method that releases the synchronization object for use by other threads.
	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
	WaitFor (see page 3082)	This is WaitFor, a member of class THandleObject.
	WaitForMultiple (see page 3082)	This is WaitForMultiple, a member of class THandleObject.

Public Properties

	Name	Description
	Handle (see page 3082)	Specifies the handle of the Windows object used by THandleObject (see page 3078).
	LastError (see page 3083)	Indicates the Windows error code obtained from Handle (see page 3082).

35.1.8.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TMutex.Create (Boolean) (see page 3085)	This is Create, a member of class TMutex.
	TMutex.Create (LongWord, Boolean, string, Boolean) (see page 3085)	This is Create, a member of class TMutex.
	TMutex.Create (PSecurityAttributes, Boolean, string, Boolean) (see page 3085)	This is Create, a member of class TMutex.

35.1.8.2.1 TMutex.Create Constructor (Boolean)

Pascal

```
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

35.1.8.2.2 TMutex.Create Constructor (LongWord, Boolean, string, Boolean)

Pascal

```
constructor Create(DesiredAccess: LongWord; InheritHandle: Boolean; const Name: string;
UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(LongWord DesiredAccess, Boolean InheritHandle, const UnicodeString Name,
Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

35.1.8.2.3 TMutex.Create Constructor (PSecurityAttributes, Boolean, string, Boolean)

Pascal

```
constructor Create(MutexAttributes: PSecurityAttributes; InitialOwner: Boolean; const Name:
string; UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(PSecurityAttributes MutexAttributes, Boolean InitialOwner, const
UnicodeString Name, Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

35.1.8.3 TMutex Methods

The methods of the TMutex class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3086)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3086)	Provides the interface for a method that releases the synchronization object for use by other threads.

35.1.8.3.1 TMutex.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3093)

35.1.8.3.2 TMutex.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3092)

35.1.9 TSemaphore Class

Class Hierarchy

Pascal

```
TSemaphore = class(THandleObject);
```

C++

```
class TSemaphore : public THandleObject;
```

File

SyncObjs

Description

This is class SyncObjs.TSemaphore.

35.1.9.1 TSemaphore Members

The following tables list the members exposed by TSemaphore.

Protected Fields

	Name	Description
	FHandle (see page 3081)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3081)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3081)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3089)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.
	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3088)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3080)	Destroys an instance of THandleObject (see page 3078).
	Destroy (see page 3366)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3089)	This is the overview for the Release method overload.

	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.
	WaitFor (see page 3082)	This is WaitFor, a member of class THandleObject.
	WaitForMultiple (see page 3082)	This is WaitForMultiple, a member of class THandleObject.

Public Properties

	Name	Description
	Handle (see page 3082)	Specifies the handle of the Windows object used by THandleObject (see page 3078).
	LastError (see page 3083)	Indicates the Windows error code obtained from Handle (see page 3082).

35.1.9.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TSemaphore.Create (Boolean) (see page 3088)	This is Create, a member of class TSemaphore.
	TSemaphore.Create (LongWord, Boolean, string, Boolean) (see page 3088)	This is Create, a member of class TSemaphore.
	TSemaphore.Create (PSecurityAttributes, Integer, Integer, string, Boolean) (see page 3089)	This is Create, a member of class TSemaphore.

35.1.9.2.1 TSemaphore.Create Constructor (Boolean)

Pascal

```
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TSemaphore(Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TSemaphore.

35.1.9.2.2 TSemaphore.Create Constructor (LongWord, Boolean, string, Boolean)

Pascal

```
constructor Create(DesiredAccess: LongWord; InheritHandle: Boolean; const Name: string;
UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TSemaphore(LongWord DesiredAccess, Boolean InheritHandle, const UnicodeString Name,
Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TSemaphore.

35.1.9.2.3 TSemaphore.Create Constructor (PSecurityAttributes, Integer, Integer, string, Boolean)

Pascal

```
constructor Create(SemaphoreAttributes: PSecurityAttributes; AInitialCount: Integer;
AMaximumCount: Integer; const Name: string; UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TSemaphore(PSecurityAttributes SemaphoreAttributes, int AInitialCount, int
AMaximumCount, const UnicodeString Name, Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TSemaphore.

35.1.9.3 TSemaphore Methods

The methods of the TSemaphore class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3089)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3089)	This is the overview for the Release method overload.

35.1.9.3.1 TSemaphore.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3093)

35.1.9.3.2 Release Method

This is the overview for the Release method overload.

Overload List

	Name	Description
	TSemaphore.Release () (see page 3090)	Provides the interface for a method that releases the synchronization object for use by other threads.

	TSemaphore.Release (Integer) (see page 3090)	This is Release, a member of class TSemaphore.

35.1.9.3.2.1 TSemaphore.Release Method ()

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; override; overload;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3092)

35.1.9.3.2.2 TSemaphore.Release Method (Integer)

Pascal

```
function Release(AReleaseCount: Integer): Integer; overload; reintroduce;
```

C++

```
__fastcall int Release(int AReleaseCount);
```

Description

This is Release, a member of class TSemaphore.

35.1.10 TSimpleEvent Class

TSimpleEvent represents an unnamed manual event object.

Class Hierarchy

Pascal

```
TSimpleEvent = class(TEvent);
```

C++

```
class TSimpleEvent : public TEvent;
```

File

SyncObjs

Description

Use TSimpleEvent to coordinate between threads that all have access to the same simple event object. TSimpleEvent can also be used in a single-threaded application to coordinate sections of code that respond to different asynchronous events such as system messages or user actions.

Because TSimpleEvent represents an unnamed event object, a single TSimpleEvent object must be within the scope of all code that uses it. To coordinate with code that is out of scope, or with other applications, use a named TEvent (see page 3074) object.

See Also

TThread

TEvent (see page 3074)

35.1.11 TSynchroObject Class

TSynchroObject is the base class for all thread synchronization objects.

Class Hierarchy

Pascal

```
TSynchroObject = class(TObject);
```

C++

```
class TSynchroObject : public TObject;
```

File

SyncObjs

Description

Use TSynchroObject as a base class when defining an object that coordinates the execution of different threads in a multi-threaded application. Synchronization objects include critical sections that temporarily block the execution of other threads which may interfere with the successful completion of a section of code, and event objects that allow threads to signal when critical events have occurred.

See Also

TCriticalSection (see page 3068)

TEvent (see page 3074)

TThread

35.1.11.1 TSynchroObject Members

The following tables list the members exposed by TSynchroObject.

Public Methods

	Name	Description
	Acquire (see page 3092)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3367)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3368)	Responds before the first destructor executes.
	ClassInfo (see page 3368)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3369)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3371)	Determines whether an object is of a specific type.

	ClassParent (see page 3372)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3374)	Returns the class reference for the object's class.
	CleanupInstance (see page 3377)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3366)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3377)	Provides the interface for a method that processes message records.
	Destroy (see page 3366)	Disposes of an object instance.
	Dispatch (see page 3379)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3381)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3382)	This is the overview for the FieldAddress method overload.
	Free (see page 3382)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3386)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3391) method.
	GetHashCode (see page 3386)	Returns an integer containing the hash code.
	GetInterface (see page 3387)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3387)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3388)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3388)	Determines the relationship of two object types.
	InitInstance (see page 3389)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3389)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3389)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3390)	Returns the name of a class method by address.
	NewInstance (see page 3391)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3093)	Provides the interface for a method that releases the synchronization object for use by other threads.
	SafeCallException (see page 3391)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3391)	Returns a string containing the class name.
	UnitName (see page 3392)	Returns a string containing the unit name.

35.1.11.2 TSynchroObject Methods

The methods of the TSynchroObject class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3092)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3093)	Provides the interface for a method that releases the synchronization object for use by other threads.

35.1.11.2.1 TSynchroObject.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; virtual;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject (see page

3091) does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3093)

35.1.11.2.2 TSynchroObject.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; virtual;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject (see page 3091) does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3092)

35.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TWaitResult (see page 3094)	TWaitResult indicates the reason an event object stopped waiting for its signal.

35.2.1 SyncObjs.TWaitResult Enumeration

TWaitResult indicates the reason an event object stopped waiting for its signal.

Pascal

```
TWaitResult = (
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError,
  wrIOCompletion
);
```

C++

```
enum TWaitResult {
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError,
  wrIOCompletion
};
```

File

SyncObjs

Description

TWaitResult includes the following values:

Value	Meaning
wrSignaled	The signal of the event object was set.
wrTimeOut	The time specified by the TimeOut parameter elapsed without the signal being set.
wrAbandoned	The event object was destroyed before the TimeOut period elapsed.
wrError	An error occurred while waiting. Check the LastError property for an error code giving more information.

35.3 Types

The following table lists types in this documentation.

Types

Name	Description
THandleObjectArray (see page 3095)	This is type SyncObjs.THandleObjectArray.

35.3.1 SyncObjs.THandleObjectArray Type

Pascal

```
THandleObjectArray = array of THandleObject;
```

C++

```
array of THandleObject THandleObjectArray;
```

File

SyncObjs

Description

This is type SyncObjs.THandleObjectArray.

36 SysConst Namespace

This is namespace SysConst.

Topics

Name	Description
Constants (see page 3101)	The following table lists constants in this documentation.

Constants

Name	Description
SAbstractError (see page 3104)	This is constant SysConst.SAbstractError.
SAccessDenied (see page 3104)	This is constant SysConst.SAccessDenied.
SAccessViolationArg3 (see page 3104)	This is constant SysConst.SAccessViolationArg3.
SAccessViolationNoArg (see page 3105)	This is constant SysConst.SAccessViolationNoArg.
SArgumentMissing (see page 3105)	This is constant SysConst.SArgumentMissing.
SAssertError (see page 3105)	This is constant SysConst.SAssertError.
SAssertionFailed (see page 3106)	This is constant SysConst.SAssertionFailed.
SByteIndexOutOfBounds (see page 3106)	This is constant SysConst.SByteIndexOutOfBounds.
SCannotCreateDir (see page 3106)	This is constant SysConst.SCannotCreateDir.
SCannotReadPackageInfo (see page 3107)	This is constant SysConst.SCannotReadPackageInfo.
SCharIndexOutOfBounds (see page 3107)	This is constant SysConst.SCharIndexOutOfBounds.
SCodesetConversionError (see page 3107)	This is constant SysConst.SCodesetConversionError.
SControlC (see page 3108)	This is constant SysConst.SControlC.
SDateEncodeError (see page 3108)	This is constant SysConst.SDateEncodeError.
SDiskFull (see page 3108)	This is constant SysConst.SDiskFull.
SDispatchError (see page 3109)	This is constant SysConst.SDispatchError.
SDivByZero (see page 3109)	This is constant SysConst.SDivByZero.
SDuplicatePackageUnit (see page 3109)	This is constant SysConst.SDuplicatePackageUnit.
SEndOfFile (see page 3110)	This is constant SysConst.SEndOfFile.
sErrorLoadingPackage (see page 3110)	This is constant SysConst.sErrorLoadingPackage.
SException (see page 3110)	This is constant SysConst.SException.
SExceptTitle (see page 3111)	This is constant SysConst.SExceptTitle.
SExternalException (see page 3111)	This is constant SysConst.SExternalException.
SFileNotFound (see page 3111)	This is constant SysConst.SFileNotFound.
SFormatTooLong (see page 3112)	This is constant SysConst.SFormatTooLong.
SInOutError (see page 3112)	This is constant SysConst.SInOutError.
SIntfCastError (see page 3112)	This is constant SysConst.SIntfCastError.

SIntOverflow (see page 3113)	This is constant SysConst.SIntOverflow.
SInvalidBoolean (see page 3113)	This is constant SysConst.SInvalidBoolean.
SInvalidCast (see page 3113)	This is constant SysConst.SInvalidCast.
SInvalidCharCount (see page 3114)	This is constant SysConst.SInvalidCharCount.
SInvalidCodePage (see page 3114)	This is constant SysConst.SInvalidCodePage.
SInvalidCurrency (see page 3114)	This is constant SysConst.SInvalidCurrency.
SInvalidDate (see page 3115)	This is constant SysConst.SInvalidDate.
SInvalidDateTime (see page 3115)	This is constant SysConst.SInvalidDateTime.
SInvalidDateTimeFloat (see page 3115)	This is constant SysConst.SInvalidDateTimeFloat.
SInvalidDestinationArray (see page 3116)	This is constant SysConst.SInvalidDestinationArray.
SInvalidDestinationIndex (see page 3116)	This is constant SysConst.SInvalidDestinationIndex.
SInvalidFilename (see page 3116)	This is constant SysConst.SInvalidFilename.
SInvalidFloat (see page 3117)	This is constant SysConst.SInvalidFloat.
SInvalidFormat (see page 3117)	This is constant SysConst.SInvalidFormat.
SInvalidGUID (see page 3117)	This is constant SysConst.SInvalidGUID.
SInvalidInput (see page 3118)	This is constant SysConst.SInvalidInput.
SInvalidInteger (see page 3118)	This is constant SysConst.SInvalidInteger.
SInvalidOp (see page 3118)	This is constant SysConst.SInvalidOp.
SInvalidPackageFile (see page 3119)	This is constant SysConst.SInvalidPackageFile.
SInvalidPackageHandle (see page 3119)	This is constant SysConst.SInvalidPackageHandle.
SInvalidPointer (see page 3119)	This is constant SysConst.SInvalidPointer.
SInvalidSourceArray (see page 3120)	This is constant SysConst.SInvalidSourceArray.
SInvalidTime (see page 3120)	This is constant SysConst.SInvalidTime.
SInvalidTimeStamp (see page 3120)	This is constant SysConst.SInvalidTimeStamp.
SInvalidVarCast (see page 3121)	This is constant SysConst.SInvalidVarCast.
SInvalidVarNullOp (see page 3121)	This is constant SysConst.SInvalidVarNullOp.
SInvalidVarOp (see page 3121)	This is constant SysConst.SInvalidVarOp.
SInvalidVarOpWithHResult (see page 3122)	This is constant SysConst.SInvalidVarOpWithHResult.
SInvalidVarOpWithHResultWithPrefix (see page 3122)	This is constant SysConst.SInvalidVarOpWithHResultWithPrefix.
SLongDayNameFri (see page 3122)	This is constant SysConst.SLongDayNameFri.
SLongDayNameMon (see page 3123)	This is constant SysConst.SLongDayNameMon.
SLongDayNameSat (see page 3123)	This is constant SysConst.SLongDayNameSat.
SLongDayNameSun (see page 3123)	This is constant SysConst.SLongDayNameSun.
SLongDayNameThu (see page 3124)	This is constant SysConst.SLongDayNameThu.
SLongDayNameTue (see page 3124)	This is constant SysConst.SLongDayNameTue.
SLongDayNameWed (see page 3124)	This is constant SysConst.SLongDayNameWed.
SLongMonthNameApr (see page 3125)	This is constant SysConst.SLongMonthNameApr.
SLongMonthNameAug (see page 3125)	This is constant SysConst.SLongMonthNameAug.
SLongMonthNameDec (see page 3125)	This is constant SysConst.SLongMonthNameDec.
SLongMonthNameFeb (see page 3126)	This is constant SysConst.SLongMonthNameFeb.
SLongMonthNameJan (see page 3126)	This is constant SysConst.SLongMonthNameJan.
SLongMonthNameJul (see page 3126)	This is constant SysConst.SLongMonthNameJul.
SLongMonthNameJun (see page 3127)	This is constant SysConst.SLongMonthNameJun.
SLongMonthNameMar (see page 3127)	This is constant SysConst.SLongMonthNameMar.
SLongMonthNameMay (see page 3127)	This is constant SysConst.SLongMonthNameMay.
SLongMonthNameNov (see page 3128)	This is constant SysConst.SLongMonthNameNov.
SLongMonthNameOct (see page 3128)	This is constant SysConst.SLongMonthNameOct.
SLongMonthNameSep (see page 3128)	This is constant SysConst.SLongMonthNameSep.
SModuleAccessViolation (see page 3129)	This is constant SysConst.SModuleAccessViolation.
SMonitorLockException (see page 3129)	This is constant SysConst.SMonitorLockException.
SNL (see page 3129)	This is constant SysConst.SNL.
SNoMonitorSupportException (see page 3130)	This is constant SysConst.SNoMonitorSupportException.
SOperationAborted (see page 3130)	This is constant SysConst.SOperationAborted.
SOSError (see page 3130)	This is constant SysConst.SOSError.

SOutOfMemory (see page 3131)	This is constant SysConst.SOutOfMemory.
SOverflow (see page 3131)	This is constant SysConst.SOverflow.
SPrivilege (see page 3131)	This is constant SysConst.SPrivilege.
SQuit (see page 3132)	This is constant SysConst.SQuit.
SRangeError (see page 3132)	This is constant SysConst.SRangeError.
SReadAccess (see page 3132)	This is constant SysConst.SReadAccess.
SResultTooLong (see page 3133)	This is constant SysConst.SResultTooLong.
SSafecallException (see page 3133)	This is constant SysConst.SSafecallException.
SShortDayNameFri (see page 3133)	This is constant SysConst.SShortDayNameFri.
SShortDayNameMon (see page 3134)	This is constant SysConst.SShortDayNameMon.
SShortDayNameSat (see page 3134)	This is constant SysConst.SShortDayNameSat.
SShortDayNameSun (see page 3134)	This is constant SysConst.SShortDayNameSun.
SShortDayNameThu (see page 3135)	This is constant SysConst.SShortDayNameThu.
SShortDayNameTue (see page 3135)	This is constant SysConst.SShortDayNameTue.
SShortDayNameWed (see page 3135)	This is constant SysConst.SShortDayNameWed.
SShortMonthNameApr (see page 3136)	This is constant SysConst.SShortMonthNameApr.
SShortMonthNameAug (see page 3136)	This is constant SysConst.SShortMonthNameAug.
SShortMonthNameDec (see page 3136)	This is constant SysConst.SShortMonthNameDec.
SShortMonthNameFeb (see page 3137)	This is constant SysConst.SShortMonthNameFeb.
SShortMonthNameJan (see page 3137)	This is constant SysConst.SShortMonthNameJan.
SShortMonthNameJul (see page 3137)	This is constant SysConst.SShortMonthNameJul.
SShortMonthNameJun (see page 3138)	This is constant SysConst.SShortMonthNameJun.
SShortMonthNameMar (see page 3138)	This is constant SysConst.SShortMonthNameMar.
SShortMonthNameMay (see page 3138)	This is constant SysConst.SShortMonthNameMay.
SShortMonthNameNov (see page 3139)	This is constant SysConst.SShortMonthNameNov.
SShortMonthNameOct (see page 3139)	This is constant SysConst.SShortMonthNameOct.
SShortMonthNameSep (see page 3139)	This is constant SysConst.SShortMonthNameSep.
SStackOverflow (see page 3140)	This is constant SysConst.SStackOverflow.
STimeEncodeError (see page 3140)	This is constant SysConst.STimeEncodeError.
STooManyOpenFiles (see page 3140)	This is constant SysConst.STooManyOpenFiles.
SUnderflow (see page 3141)	This is constant SysConst.SUnderflow.
SUnknown (see page 3141)	This is constant SysConst.SUnknown.
sUnknownFromType (see page 3141)	This is constant SysConst.sUnknownFromType.
sUnknownToType (see page 3142)	This is constant SysConst.sUnknownToType.
SUnkOSError (see page 3142)	This is constant SysConst.SUnkOSError.
SUnkWin32Error (see page 3142)	This is constant SysConst.SUnkWin32Error.
SVarArrayBounds (see page 3143)	This is constant SysConst.SVarArrayBounds.
SVarArrayCreate (see page 3143)	This is constant SysConst.SVarArrayCreate.
SVarArrayLocked (see page 3143)	This is constant SysConst.SVarArrayLocked.
SVarArrayWithHResult (see page 3144)	This is constant SysConst.SVarArrayWithHResult.
SVarBadType (see page 3144)	This is constant SysConst.SVarBadType.
SVarDataCastToRecursing (see page 3144)	This is constant SysConst.SVarDataCastToRecursing.
SVarDataClearRecursing (see page 3145)	This is constant SysConst.SVarDataClearRecursing.
SVarDataCopyNoIndRecursing (see page 3145)	This is constant SysConst.SVarDataCopyNoIndRecursing.
SVarDataCopyRecursing (see page 3145)	This is constant SysConst.SVarDataCopyRecursing.
SVarDataInitRecursing (see page 3146)	This is constant SysConst.SVarDataInitRecursing.
SVarInvalid (see page 3146)	This is constant SysConst.SVarInvalid.
SVarIsEmpty (see page 3146)	This is constant SysConst.SVarIsEmpty.
SVarNotArray (see page 3147)	This is constant SysConst.SVarNotArray.
SVarNotImplemented (see page 3147)	This is constant SysConst.SVarNotImplemented.
SVarOutOfMemory (see page 3147)	This is constant SysConst.SVarOutOfMemory.
SVarOverflow (see page 3148)	This is constant SysConst.SVarOverflow.
SVarTypeAlreadyUsed (see page 3148)	This is constant SysConst.SVarTypeAlreadyUsed.
SVarTypeAlreadyUsedWithPrefix (see page 3148)	This is constant SysConst.SVarTypeAlreadyUsedWithPrefix.

SVarTypeConvertOverflow (see page 3149)	This is constant SysConst.SVarTypeConvertOverflow.
SVarTypeCouldNotConvert (see page 3149)	This is constant SysConst.SVarTypeCouldNotConvert.
SVarTypeNotUsable (see page 3149)	This is constant SysConst.SVarTypeNotUsable.
SVarTypeNotUsableWithPrefix (see page 3150)	This is constant SysConst.SVarTypeNotUsableWithPrefix.
SVarTypeOutOfRange (see page 3150)	This is constant SysConst.SVarTypeOutOfRange.
SVarTypeOutOfRangeWithPrefix (see page 3150)	This is constant SysConst.SVarTypeOutOfRangeWithPrefix.
SVarTypeRangeCheck1 (see page 3151)	This is constant SysConst.SVarTypeRangeCheck1.
SVarTypeRangeCheck2 (see page 3151)	This is constant SysConst.SVarTypeRangeCheck2.
SVarTypeTooManyCustom (see page 3151)	This is constant SysConst.SVarTypeTooManyCustom.
SVarTypeUnknown (see page 3152)	This is constant SysConst.SVarTypeUnknown.
SVarUnexpected (see page 3152)	This is constant SysConst.SVarUnexpected.
SWin32Error (see page 3152)	This is constant SysConst.SWin32Error.
SWriteAccess (see page 3153)	This is constant SysConst.SWriteAccess.
SZeroDivide (see page 3153)	This is constant SysConst.SZeroDivide.

36.1 Constants

The following table lists constants in this documentation.

Constants

Name	Description
SAbstractError (see page 3104)	This is constant SysConst.SAbstractError.
SAccessDenied (see page 3104)	This is constant SysConst.SAccessDenied.
SAccessViolationArg3 (see page 3104)	This is constant SysConst.SAccessViolationArg3.
SAccessViolationNoArg (see page 3105)	This is constant SysConst.SAccessViolationNoArg.
SArgumentMissing (see page 3105)	This is constant SysConst.SArgumentMissing.
SAssertError (see page 3105)	This is constant SysConst.SAssertError.
SAssertionFailed (see page 3106)	This is constant SysConst.SAssertionFailed.
SByteIndexOutOfBounds (see page 3106)	This is constant SysConst.SByteIndexOutOfBounds.
SCannotCreateDir (see page 3106)	This is constant SysConst.SCannotCreateDir.
SCannotReadPackageInfo (see page 3107)	This is constant SysConst.SCannotReadPackageInfo.
SCharIndexOutOfBounds (see page 3107)	This is constant SysConst.SCharIndexOutOfBounds.
SCodesetConversionError (see page 3107)	This is constant SysConst.SCodesetConversionError.
SControlC (see page 3108)	This is constant SysConst.SControlC.
SDateEncodeError (see page 3108)	This is constant SysConst.SDateEncodeError.
SDiskFull (see page 3108)	This is constant SysConst.SDiskFull.
SDispatchError (see page 3109)	This is constant SysConst.SDispatchError.
SDivByZero (see page 3109)	This is constant SysConst.SDivByZero.
SDuplicatePackageUnit (see page 3109)	This is constant SysConst.SDuplicatePackageUnit.
SEndOfFile (see page 3110)	This is constant SysConst.SEndOfFile.
sErrorLoadingPackage (see page 3110)	This is constant SysConst.sErrorLoadingPackage.
SException (see page 3110)	This is constant SysConst.SException.
SExceptTitle (see page 3111)	This is constant SysConst.SExceptTitle.
SExternalException (see page 3111)	This is constant SysConst.SExternalException.
SFileNotFound (see page 3111)	This is constant SysConst.SFileNotFound.
SFormatTooLong (see page 3112)	This is constant SysConst.SFormatTooLong.
SInOutError (see page 3112)	This is constant SysConst.SInOutError.
SIntfCastError (see page 3112)	This is constant SysConst.SIntfCastError.
SIntOverflow (see page 3113)	This is constant SysConst.SIntOverflow.
SInvalidBoolean (see page 3113)	This is constant SysConst.SInvalidBoolean.
SInvalidCast (see page 3113)	This is constant SysConst.SInvalidCast.
SInvalidCharCount (see page 3114)	This is constant SysConst.SInvalidCharCount.
SInvalidCodePage (see page 3114)	This is constant SysConst.SInvalidCodePage.
SInvalidCurrency (see page 3114)	This is constant SysConst.SInvalidCurrency.
SInvalidDate (see page 3115)	This is constant SysConst.SInvalidDate.
SInvalidDateTime (see page 3115)	This is constant SysConst.SInvalidDateTime.
SInvalidDateTimeFloat (see page 3115)	This is constant SysConst.SInvalidDateTimeFloat.
SInvalidDestinationArray (see page 3116)	This is constant SysConst.SInvalidDestinationArray.
SInvalidDestinationIndex (see page 3116)	This is constant SysConst.SInvalidDestinationIndex.
SInvalidFilename (see page 3116)	This is constant SysConst.SInvalidFilename.
SInvalidFloat (see page 3117)	This is constant SysConst.SInvalidFloat.
SInvalidFormat (see page 3117)	This is constant SysConst.SInvalidFormat.
SInvalidGUID (see page 3117)	This is constant SysConst.SInvalidGUID.
SInvalidInput (see page 3118)	This is constant SysConst.SInvalidInput.
SInvalidInteger (see page 3118)	This is constant SysConst.SInvalidInteger.

SInvalidOp (see page 3118)	This is constant SysConst.SInvalidOp.
SInvalidPackageFile (see page 3119)	This is constant SysConst.SInvalidPackageFile.
SInvalidPackageHandle (see page 3119)	This is constant SysConst.SInvalidPackageHandle.
SInvalidPointer (see page 3119)	This is constant SysConst.SInvalidPointer.
SInvalidSourceArray (see page 3120)	This is constant SysConst.SInvalidSourceArray.
SInvalidTime (see page 3120)	This is constant SysConst.SInvalidTime.
SInvalidTimeStamp (see page 3120)	This is constant SysConst.SInvalidTimeStamp.
SInvalidVarCast (see page 3121)	This is constant SysConst.SInvalidVarCast.
SInvalidVarNullOp (see page 3121)	This is constant SysConst.SInvalidVarNullOp.
SInvalidVarOp (see page 3121)	This is constant SysConst.SInvalidVarOp.
SInvalidVarOpWithHResult (see page 3122)	This is constant SysConst.SInvalidVarOpWithHResult.
SInvalidVarOpWithHResultWithPrefix (see page 3122)	This is constant SysConst.SInvalidVarOpWithHResultWithPrefix.
SLongDayNameFri (see page 3122)	This is constant SysConst.SLongDayNameFri.
SLongDayNameMon (see page 3123)	This is constant SysConst.SLongDayNameMon.
SLongDayNameSat (see page 3123)	This is constant SysConst.SLongDayNameSat.
SLongDayNameSun (see page 3123)	This is constant SysConst.SLongDayNameSun.
SLongDayNameThu (see page 3124)	This is constant SysConst.SLongDayNameThu.
SLongDayNameTue (see page 3124)	This is constant SysConst.SLongDayNameTue.
SLongDayNameWed (see page 3124)	This is constant SysConst.SLongDayNameWed.
SLongMonthNameApr (see page 3125)	This is constant SysConst.SLongMonthNameApr.
SLongMonthNameAug (see page 3125)	This is constant SysConst.SLongMonthNameAug.
SLongMonthNameDec (see page 3125)	This is constant SysConst.SLongMonthNameDec.
SLongMonthNameFeb (see page 3126)	This is constant SysConst.SLongMonthNameFeb.
SLongMonthNameJan (see page 3126)	This is constant SysConst.SLongMonthNameJan.
SLongMonthNameJul (see page 3126)	This is constant SysConst.SLongMonthNameJul.
SLongMonthNameJun (see page 3127)	This is constant SysConst.SLongMonthNameJun.
SLongMonthNameMar (see page 3127)	This is constant SysConst.SLongMonthNameMar.
SLongMonthNameMay (see page 3127)	This is constant SysConst.SLongMonthNameMay.
SLongMonthNameNov (see page 3128)	This is constant SysConst.SLongMonthNameNov.
SLongMonthNameOct (see page 3128)	This is constant SysConst.SLongMonthNameOct.
SLongMonthNameSep (see page 3128)	This is constant SysConst.SLongMonthNameSep.
SModuleAccessViolation (see page 3129)	This is constant SysConst.SModuleAccessViolation.
SMonitorLockException (see page 3129)	This is constant SysConst.SMonitorLockException.
SNL (see page 3129)	This is constant SysConst.SNL.
SNoMonitorSupportException (see page 3130)	This is constant SysConst.SNoMonitorSupportException.
SOperationAborted (see page 3130)	This is constant SysConst.SOperationAborted.
SOSError (see page 3130)	This is constant SysConst.SOSError.
SOutOfMemory (see page 3131)	This is constant SysConst.SOutOfMemory.
SOverflow (see page 3131)	This is constant SysConst.SOverflow.
SPrivilege (see page 3131)	This is constant SysConst.SPrivilege.
SQuit (see page 3132)	This is constant SysConst.SQuit.
SRangeError (see page 3132)	This is constant SysConst.SRangeError.
SReadAccess (see page 3132)	This is constant SysConst.SReadAccess.
SResultTooLong (see page 3133)	This is constant SysConst.SResultTooLong.
SSafecallException (see page 3133)	This is constant SysConst.SSafecallException.
SShortDayNameFri (see page 3133)	This is constant SysConst.SShortDayNameFri.
SShortDayNameMon (see page 3134)	This is constant SysConst.SShortDayNameMon.
SShortDayNameSat (see page 3134)	This is constant SysConst.SShortDayNameSat.
SShortDayNameSun (see page 3134)	This is constant SysConst.SShortDayNameSun.
SShortDayNameThu (see page 3135)	This is constant SysConst.SShortDayNameThu.
SShortDayNameTue (see page 3135)	This is constant SysConst.SShortDayNameTue.
SShortDayNameWed (see page 3135)	This is constant SysConst.SShortDayNameWed.
SShortMonthNameApr (see page 3136)	This is constant SysConst.SShortMonthNameApr.
SShortMonthNameAug (see page 3136)	This is constant SysConst.SShortMonthNameAug.

SShortMonthNameDec (see page 3136)	This is constant SysConst.SShortMonthNameDec.
SShortMonthNameFeb (see page 3137)	This is constant SysConst.SShortMonthNameFeb.
SShortMonthNameJan (see page 3137)	This is constant SysConst.SShortMonthNameJan.
SShortMonthNameJul (see page 3137)	This is constant SysConst.SShortMonthNameJul.
SShortMonthNameJun (see page 3138)	This is constant SysConst.SShortMonthNameJun.
SShortMonthNameMar (see page 3138)	This is constant SysConst.SShortMonthNameMar.
SShortMonthNameMay (see page 3138)	This is constant SysConst.SShortMonthNameMay.
SShortMonthNameNov (see page 3139)	This is constant SysConst.SShortMonthNameNov.
SShortMonthNameOct (see page 3139)	This is constant SysConst.SShortMonthNameOct.
SShortMonthNameSep (see page 3139)	This is constant SysConst.SShortMonthNameSep.
SStackOverflow (see page 3140)	This is constant SysConst.SStackOverflow.
STimeEncodeError (see page 3140)	This is constant SysConst.STimeEncodeError.
STooManyOpenFiles (see page 3140)	This is constant SysConst.STooManyOpenFiles.
SUnderflow (see page 3141)	This is constant SysConst.SUnderflow.
SUnknown (see page 3141)	This is constant SysConst.SUnknown.
sUnknownFromType (see page 3141)	This is constant SysConst.sUnknownFromType.
sUnknownToType (see page 3142)	This is constant SysConst.sUnknownToType.
SUnkOSError (see page 3142)	This is constant SysConst.SUnkOSError.
SUnkWin32Error (see page 3142)	This is constant SysConst.SUnkWin32Error.
SVarArrayBounds (see page 3143)	This is constant SysConst.SVarArrayBounds.
SVarArrayCreate (see page 3143)	This is constant SysConst.SVarArrayCreate.
SVarArrayLocked (see page 3143)	This is constant SysConst.SVarArrayLocked.
SVarArrayWithHResult (see page 3144)	This is constant SysConst.SVarArrayWithHResult.
SVarBadType (see page 3144)	This is constant SysConst.SVarBadType.
SVarDataCastToRecursing (see page 3144)	This is constant SysConst.SVarDataCastToRecursing.
SVarDataClearRecursing (see page 3145)	This is constant SysConst.SVarDataClearRecursing.
SVarDataCopyNoIndRecursing (see page 3145)	This is constant SysConst.SVarDataCopyNoIndRecursing.
SVarDataCopyRecursing (see page 3145)	This is constant SysConst.SVarDataCopyRecursing.
SVarDataInitRecursing (see page 3146)	This is constant SysConst.SVarDataInitRecursing.
SVarInvalid (see page 3146)	This is constant SysConst.SVarInvalid.
SVarIsEmpty (see page 3146)	This is constant SysConst.SVarIsEmpty.
SVarNotArray (see page 3147)	This is constant SysConst.SVarNotArray.
SVarNotImplemented (see page 3147)	This is constant SysConst.SVarNotImplemented.
SVarOutOfMemory (see page 3147)	This is constant SysConst.SVarOutOfMemory.
SVarOverflow (see page 3148)	This is constant SysConst.SVarOverflow.
SVarTypeAlreadyUsed (see page 3148)	This is constant SysConst.SVarTypeAlreadyUsed.
SVarTypeAlreadyUsedWithPrefix (see page 3148)	This is constant SysConst.SVarTypeAlreadyUsedWithPrefix.
SVarTypeConvertOverflow (see page 3149)	This is constant SysConst.SVarTypeConvertOverflow.
SVarTypeCouldNotConvert (see page 3149)	This is constant SysConst.SVarTypeCouldNotConvert.
SVarTypeNotUsable (see page 3149)	This is constant SysConst.SVarTypeNotUsable.
SVarTypeNotUsableWithPrefix (see page 3150)	This is constant SysConst.SVarTypeNotUsableWithPrefix.
SVarTypeOutOfRange (see page 3150)	This is constant SysConst.SVarTypeOutOfRange.
SVarTypeOutOfRangeWithPrefix (see page 3150)	This is constant SysConst.SVarTypeOutOfRangeWithPrefix.
SVarTypeRangeCheck1 (see page 3151)	This is constant SysConst.SVarTypeRangeCheck1.
SVarTypeRangeCheck2 (see page 3151)	This is constant SysConst.SVarTypeRangeCheck2.
SVarTypeTooManyCustom (see page 3151)	This is constant SysConst.SVarTypeTooManyCustom.
SVarTypeUnknown (see page 3152)	This is constant SysConst.SVarTypeUnknown.
SVarUnexpected (see page 3152)	This is constant SysConst.SVarUnexpected.
SWin32Error (see page 3152)	This is constant SysConst.SWin32Error.
SWriteAccess (see page 3153)	This is constant SysConst.SWriteAccess.
SZeroDivide (see page 3153)	This is constant SysConst.SZeroDivide.

36.1.1 SysConst.SAbstractError Constant

Pascal

```
SAbstractError = 'Abstract Error';
```

C++

```
SAbstractError = 'Abstract Error';
```

File

SysConst

Description

This is constant SysConst.SAbstractError.

36.1.2 SysConst.SAccessDenied Constant

Pascal

```
SAccessDenied = 'File access denied';
```

C++

```
SAccessDenied = 'File access denied';
```

File

SysConst

Description

This is constant SysConst.SAccessDenied.

36.1.3 SysConst.SAccessViolationArg3 Constant

Pascal

```
SAccessViolationArg3 = 'Access violation at address %p. %s of address %p';
```

C++

```
SAccessViolationArg3 = 'Access violation at address %p. %s of address %p';
```

File

SysConst

Description

This is constant SysConst.SAccessViolationArg3.

36.1.4 SysConst.SAccessViolationNoArg Constant

Pascal

```
SAccessViolationNoArg = 'Access violation';
```

C++

```
SAccessViolationNoArg = 'Access violation';
```

File

SysConst

Description

This is constant SysConst.SAccessViolationNoArg.

36.1.5 SysConst.SArgumentMissing Constant

Pascal

```
SArgumentMissing = 'No argument for format ''%s''';
```

C++

```
SArgumentMissing = 'No argument for format ''%s''';
```

File

SysConst

Description

This is constant SysConst.SArgumentMissing.

36.1.6 SysConst.SAssertError Constant

Pascal

```
SAssertError = '%s (%s, line %d)';
```

C++

```
SAssertError = '%s (%s, line %d)';
```

File

SysConst

Description

This is constant SysConst.SAssertError.

36.1.7 SysConst.SAssertionFailed Constant

Pascal

```
SAssertionFailed = 'Assertion failed';
```

C++

```
SAssertionFailed = 'Assertion failed';
```

File

SysConst

Description

This is constant SysConst.SAssertionFailed.

36.1.8 SysConst.SByteIndexOutOfBounds Constant

Pascal

```
SByteIndexOutOfBounds = 'Start index out of bounds (%d)';
```

C++

```
SByteIndexOutOfBounds = 'Start index out of bounds (%d)';
```

File

SysConst

Description

This is constant SysConst.SByteIndexOutOfBounds.

36.1.9 SysConst.SCannotCreateDir Constant

Pascal

```
SCannotCreateDir = 'Unable to create directory';
```

C++

```
SCannotCreateDir = 'Unable to create directory';
```

File

SysConst

Description

This is constant SysConst.SCannotCreateDir.

36.1.10 SysConst.SCannotReadPackageInfo Constant

Pascal

```
SCannotReadPackageInfo = 'Cannot access package information for package ''%s''';
```

C++

```
SCannotReadPackageInfo = 'Cannot access package information for package ''%s''';
```

File

SysConst

Description

This is constant SysConst.SCannotReadPackageInfo.

36.1.11 SysConst.SCharIndexOutOfBounds Constant

Pascal

```
SCharIndexOutOfBounds = 'Character index out of bounds (%d)';
```

C++

```
SCharIndexOutOfBounds = 'Character index out of bounds (%d)';
```

File

SysConst

Description

This is constant SysConst.SCharIndexOutOfBounds.

36.1.12 SysConst.SCodesetConversionError Constant

Pascal

```
SCodesetConversionError = 'Codeset conversion failure';
```

C++

```
SCodesetConversionError = 'Codeset conversion failure';
```

File

SysConst

Description

This is constant SysConst.SCodesetConversionError.

36.1.13 SysConst.SControlC Constant

Pascal

```
SControlC = 'Control-C hit';
```

C++

```
SControlC = 'Control-C hit';
```

File

SysConst

Description

This is constant SysConst.SControlC.

36.1.14 SysConst.SDateEncodeError Constant

Pascal

```
SDateEncodeError = 'Invalid argument to date encode';
```

C++

```
SDateEncodeError = 'Invalid argument to date encode';
```

File

SysConst

Description

This is constant SysConst.SDateEncodeError.

36.1.15 SysConst.SDiskFull Constant

Pascal

```
SDiskFull = 'Disk full';
```

C++

```
SDiskFull = 'Disk full';
```

File

SysConst

Description

This is constant SysConst.SDiskFull.

36.1.16 SysConst.SDispatchError Constant

Pascal

```
SDispatchError = 'Variant method calls not supported';
```

C++

```
SDispatchError = 'Variant method calls not supported';
```

File

SysConst

Description

This is constant SysConst.SDispatchError.

36.1.17 SysConst.SDivByZero Constant

Pascal

```
SDivByZero = 'Division by zero';
```

C++

```
SDivByZero = 'Division by zero';
```

File

SysConst

Description

This is constant SysConst.SDivByZero.

36.1.18 SysConst.SDuplicatePackageUnit Constant

Pascal

```
SDuplicatePackageUnit = 'Cannot load package ''%s.''  It contains unit ''%s,''' + 'which is
also contained in package ''%s''';
```

C++

```
SDuplicatePackageUnit = 'Cannot load package ''%s.''  It contains unit ''%s,''' + 'which is
also contained in package ''%s''';
```

File

SysConst

Description

This is constant SysConst.SDuplicatePackageUnit.

36.1.19 SysConst.SEndOfFile Constant

Pascal

```
SEndOfFile = 'Read beyond end of file';
```

C++

```
SEndOfFile = 'Read beyond end of file';
```

File

SysConst

Description

This is constant SysConst.SEndOfFile.

36.1.20 SysConst.sErrorLoadingPackage Constant

Pascal

```
sErrorLoadingPackage = 'Can''t load package %s.'+sLineBreak+'%s';
```

C++

```
sErrorLoadingPackage = 'Can''t load package %s.'+sLineBreak+'%s';
```

File

SysConst

Description

This is constant SysConst.sErrorLoadingPackage.

36.1.21 SysConst.SException Constant

Pascal

```
SException = 'Exception %s in module %s at %p.' + sLineBreak + '%s%s' + sLineBreak;
```

C++

```
SException = 'Exception %s in module %s at %p.' + sLineBreak + '%s%s' + sLineBreak;
```

File

SysConst

Description

This is constant SysConst.SException.

36.1.22 SysConst.SExceptTitle Constant

Pascal

```
SExceptTitle = 'Application Error';
```

C++

```
SExceptTitle = 'Application Error';
```

File

SysConst

Description

This is constant SysConst.SExceptTitle.

36.1.23 SysConst.SExternalException Constant

Pascal

```
SExternalException = 'External exception %x';
```

C++

```
SExternalException = 'External exception %x';
```

File

SysConst

Description

This is constant SysConst.SExternalException.

36.1.24 SysConst.SFileNotFound Constant

Pascal

```
SFileNotFound = 'File not found';
```

C++

```
SFileNotFound = 'File not found';
```

File

SysConst

Description

This is constant SysConst.SFileNotFound.

36.1.25 SysConst.SFormatTooLong Constant

Pascal

```
SFormatTooLong = 'Format string too long';
```

C++

```
SFormatTooLong = 'Format string too long';
```

File

SysConst

Description

This is constant SysConst.SFormatTooLong.

36.1.26 SysConst.SInOutError Constant

Pascal

```
SInOutError = 'I/O error %d';
```

C++

```
SInOutError = 'I/O error %d';
```

File

SysConst

Description

This is constant SysConst.SInOutError.

36.1.27 SysConst.SIntfCastError Constant

Pascal

```
SIntfCastError = 'Interface not supported';
```

C++

```
SIntfCastError = 'Interface not supported';
```

File

SysConst

Description

This is constant SysConst.SIntfCastError.

36.1.28 SysConst.SIntOverflow Constant

Pascal

```
SIntOverflow = 'Integer overflow';
```

C++

```
SIntOverflow = 'Integer overflow';
```

File

SysConst

Description

This is constant SysConst.SIntOverflow.

36.1.29 SysConst.SInvalidBoolean Constant

Pascal

```
SInvalidBoolean = '''%s'' is not a valid boolean value';
```

C++

```
SInvalidBoolean = '''%s'' is not a valid boolean value';
```

File

SysConst

Description

This is constant SysConst.SInvalidBoolean.

36.1.30 SysConst.SInvalidCast Constant

Pascal

```
SInvalidCast = 'Invalid class typecast';
```

C++

```
SInvalidCast = 'Invalid class typecast';
```

File

SysConst

Description

This is constant SysConst.SInvalidCast.

36.1.31 SysConst.SInvalidCharCount Constant

Pascal

```
SInvalidCharCount = 'Invalid count (%d)';
```

C++

```
SInvalidCharCount = 'Invalid count (%d)';
```

File

SysConst

Description

This is constant SysConst.SInvalidCharCount.

36.1.32 SysConst.SInvalidCodePage Constant

Pascal

```
SInvalidCodePage = 'Invalid code page';
```

C++

```
SInvalidCodePage = 'Invalid code page';
```

File

SysConst

Description

This is constant SysConst.SInvalidCodePage.

36.1.33 SysConst.SInvalidCurrency Constant

Pascal

```
SInvalidCurrency = '''%s'' is not a valid currency value';
```

C++

```
SInvalidCurrency = '''%s'' is not a valid currency value';
```

File

SysConst

Description

This is constant SysConst.SInvalidCurrency.

36.1.34 SysConst.SInvalidDate Constant

Pascal

```
SInvalidDate = '''%s'' is not a valid date';
```

C++

```
SInvalidDate = '''%s'' is not a valid date';
```

File

SysConst

Description

This is constant SysConst.SInvalidDate.

36.1.35 SysConst.SInvalidDateTime Constant

Pascal

```
SInvalidDateTime = '''%s'' is not a valid date and time';
```

C++

```
SInvalidDateTime = '''%s'' is not a valid date and time';
```

File

SysConst

Description

This is constant SysConst.SInvalidDateTime.

36.1.36 SysConst.SInvalidDateTimeFloat Constant

Pascal

```
SInvalidDateTimeFloat = '''%g'' is not a valid date and time';
```

C++

```
SInvalidDateTimeFloat = '''%g'' is not a valid date and time';
```

File

SysConst

Description

This is constant SysConst.SInvalidDateTimeFloat.

36.1.37 SysConst.SInvalidDestinationArray Constant

Pascal

```
SInvalidDestinationArray = 'Invalid destination array';
```

C++

```
SInvalidDestinationArray = 'Invalid destination array';
```

File

SysConst

Description

This is constant SysConst.SInvalidDestinationArray.

36.1.38 SysConst.SInvalidDestinationIndex Constant

Pascal

```
SInvalidDestinationIndex = 'Invalid destination index (%d)';
```

C++

```
SInvalidDestinationIndex = 'Invalid destination index (%d)';
```

File

SysConst

Description

This is constant SysConst.SInvalidDestinationIndex.

36.1.39 SysConst.SInvalidFilename Constant

Pascal

```
SInvalidFilename = 'Invalid filename';
```

C++

```
SInvalidFilename = 'Invalid filename';
```

File

SysConst

Description

This is constant SysConst.SInvalidFilename.

36.1.40 SysConst.SInvalidFloat Constant

Pascal

```
SInvalidFloat = '''%s'' is not a valid floating point value';
```

C++

```
SInvalidFloat = '''%s'' is not a valid floating point value';
```

File

SysConst

Description

This is constant SysConst.SInvalidFloat.

36.1.41 SysConst.SInvalidFormat Constant

Pascal

```
SInvalidFormat = 'Format ''%s'' invalid or incompatible with argument';
```

C++

```
SInvalidFormat = 'Format ''%s'' invalid or incompatible with argument';
```

File

SysConst

Description

This is constant SysConst.SInvalidFormat.

36.1.42 SysConst.SInvalidGUID Constant

Pascal

```
SInvalidGUID = '''%s'' is not a valid GUID value';
```

C++

```
SInvalidGUID = '''%s'' is not a valid GUID value';
```

File

SysConst

Description

This is constant SysConst.SInvalidGUID.

36.1.43 SysConst.SInvalidInput Constant

Pascal

```
SInvalidInput = 'Invalid numeric input';
```

C++

```
SInvalidInput = 'Invalid numeric input';
```

File

SysConst

Description

This is constant SysConst.SInvalidInput.

36.1.44 SysConst.SInvalidInteger Constant

Pascal

```
SInvalidInteger = '''%s'' is not a valid integer value';
```

C++

```
SInvalidInteger = '''%s'' is not a valid integer value';
```

File

SysConst

Description

This is constant SysConst.SInvalidInteger.

36.1.45 SysConst.SInvalidOp Constant

Pascal

```
SInvalidOp = 'Invalid floating point operation';
```

C++

```
SInvalidOp = 'Invalid floating point operation';
```

File

SysConst

Description

This is constant SysConst.SInvalidOp.

36.1.46 SysConst.SInvalidPackageFile Constant

Pascal

```
SInvalidPackageFile = 'Invalid package file ''%s''';
```

C++

```
SInvalidPackageFile = 'Invalid package file ''%s''';
```

File

SysConst

Description

This is constant SysConst.SInvalidPackageFile.

36.1.47 SysConst.SInvalidPackageHandle Constant

Pascal

```
SInvalidPackageHandle = 'Invalid package handle';
```

C++

```
SInvalidPackageHandle = 'Invalid package handle';
```

File

SysConst

Description

This is constant SysConst.SInvalidPackageHandle.

36.1.48 SysConst.SInvalidPointer Constant

Pascal

```
SInvalidPointer = 'Invalid pointer operation';
```

C++

```
SInvalidPointer = 'Invalid pointer operation';
```

File

SysConst

Description

This is constant SysConst.SInvalidPointer.

36.1.49 SysConst.SInvalidSourceArray Constant

Pascal

```
SInvalidSourceArray = 'Invalid source array';
```

C++

```
SInvalidSourceArray = 'Invalid source array';
```

File

SysConst

Description

This is constant SysConst.SInvalidSourceArray.

36.1.50 SysConst.SInvalidTime Constant

Pascal

```
SInvalidTime = '''%s'' is not a valid time';
```

C++

```
SInvalidTime = '''%s'' is not a valid time';
```

File

SysConst

Description

This is constant SysConst.SInvalidTime.

36.1.51 SysConst.SInvalidTimeStamp Constant

Pascal

```
SInvalidTimeStamp = '''%d.%d'' is not a valid timestamp';
```

C++

```
SInvalidTimeStamp = '''%d.%d'' is not a valid timestamp';
```

File

SysConst

Description

This is constant SysConst.SInvalidTimeStamp.

36.1.52 SysConst.SInvalidVarCast Constant

Pascal

```
SInvalidVarCast = 'Invalid variant type conversion';
```

C++

```
SInvalidVarCast = 'Invalid variant type conversion';
```

File

SysConst

Description

This is constant SysConst.SInvalidVarCast.

36.1.53 SysConst.SInvalidVarNullOp Constant

Pascal

```
SInvalidVarNullOp = 'Invalid NULL variant operation';
```

C++

```
SInvalidVarNullOp = 'Invalid NULL variant operation';
```

File

SysConst

Description

This is constant SysConst.SInvalidVarNullOp.

36.1.54 SysConst.SInvalidVarOp Constant

Pascal

```
SInvalidVarOp = 'Invalid variant operation';
```

C++

```
SInvalidVarOp = 'Invalid variant operation';
```

File

SysConst

Description

This is constant SysConst.SInvalidVarOp.

36.1.55 SysConst.SInvalidVarOpWithHResult Constant

Pascal

```
SInvalidVarOpWithHResult = 'Invalid variant operation ($%.8x)' deprecated;
```

C++

```
SInvalidVarOpWithHResult = 'Invalid variant operation ($%.8x)' deprecated;
```

File

SysConst

Description

This is constant SysConst.SInvalidVarOpWithHResult.

36.1.56 SysConst.SInvalidVarOpWithHResultWithPrefix Constant

Pascal

```
SInvalidVarOpWithHResultWithPrefix = 'Invalid variant operation (%s%.8x)'#10'%s';
```

C++

```
SInvalidVarOpWithHResultWithPrefix = 'Invalid variant operation (%s%.8x)'#10'%s';
```

File

SysConst

Description

This is constant SysConst.SInvalidVarOpWithHResultWithPrefix.

36.1.57 SysConst.SLongDayNameFri Constant

Pascal

```
SLongDayNameFri = 'Friday';
```

C++

```
SLongDayNameFri = 'Friday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameFri.

36.1.58 SysConst.SLongDayNameMon Constant

Pascal

```
SLongDayNameMon = 'Monday';
```

C++

```
SLongDayNameMon = 'Monday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameMon.

36.1.59 SysConst.SLongDayNameSat Constant

Pascal

```
SLongDayNameSat = 'Saturday';
```

C++

```
SLongDayNameSat = 'Saturday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameSat.

36.1.60 SysConst.SLongDayNameSun Constant

Pascal

```
SLongDayNameSun = 'Sunday';
```

C++

```
SLongDayNameSun = 'Sunday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameSun.

36.1.61 SysConst.SLongDayNameThu Constant

Pascal

```
SLongDayNameThu = 'Thursday';
```

C++

```
SLongDayNameThu = 'Thursday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameThu.

36.1.62 SysConst.SLongDayNameTue Constant

Pascal

```
SLongDayNameTue = 'Tuesday';
```

C++

```
SLongDayNameTue = 'Tuesday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameTue.

36.1.63 SysConst.SLongDayNameWed Constant

Pascal

```
SLongDayNameWed = 'Wednesday';
```

C++

```
SLongDayNameWed = 'Wednesday';
```

File

SysConst

Description

This is constant SysConst.SLongDayNameWed.

36.1.64 SysConst.SLongMonthNameApr Constant

Pascal

```
SLongMonthNameApr = 'April';
```

C++

```
SLongMonthNameApr = 'April';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameApr.

36.1.65 SysConst.SLongMonthNameAug Constant

Pascal

```
SLongMonthNameAug = 'August';
```

C++

```
SLongMonthNameAug = 'August';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameAug.

36.1.66 SysConst.SLongMonthNameDec Constant

Pascal

```
SLongMonthNameDec = 'December';
```

C++

```
SLongMonthNameDec = 'December';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameDec.

36.1.67 SysConst.SLongMonthNameFeb Constant

Pascal

```
SLongMonthNameFeb = 'February';
```

C++

```
SLongMonthNameFeb = 'February';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameFeb.

36.1.68 SysConst.SLongMonthNameJan Constant

Pascal

```
SLongMonthNameJan = 'January';
```

C++

```
SLongMonthNameJan = 'January';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameJan.

36.1.69 SysConst.SLongMonthNameJul Constant

Pascal

```
SLongMonthNameJul = 'July';
```

C++

```
SLongMonthNameJul = 'July';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameJul.

36.1.70 SysConst.SLongMonthNameJun Constant

Pascal

```
SLongMonthNameJun = 'June';
```

C++

```
SLongMonthNameJun = 'June';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameJun.

36.1.71 SysConst.SLongMonthNameMar Constant

Pascal

```
SLongMonthNameMar = 'March';
```

C++

```
SLongMonthNameMar = 'March';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameMar.

36.1.72 SysConst.SLongMonthNameMay Constant

Pascal

```
SLongMonthNameMay = 'May';
```

C++

```
SLongMonthNameMay = 'May';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameMay.

36.1.73 SysConst.SLongMonthNameNov Constant

Pascal

```
SLongMonthNameNov = 'November';
```

C++

```
SLongMonthNameNov = 'November';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameNov.

36.1.74 SysConst.SLongMonthNameOct Constant

Pascal

```
SLongMonthNameOct = 'October';
```

C++

```
SLongMonthNameOct = 'October';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameOct.

36.1.75 SysConst.SLongMonthNameSep Constant

Pascal

```
SLongMonthNameSep = 'September';
```

C++

```
SLongMonthNameSep = 'September';
```

File

SysConst

Description

This is constant SysConst.SLongMonthNameSep.

36.1.76 SysConst.SModuleAccessViolation Constant

Pascal

```
SModuleAccessViolation = 'Access violation at address %p in module ''%s''. %s of address %p';
```

C++

```
SModuleAccessViolation = 'Access violation at address %p in module ''%s''. %s of address %p';
```

File

SysConst

Description

This is constant SysConst.SModuleAccessViolation.

36.1.77 SysConst.SMonitorLockException Constant

Pascal

```
SMonitorLockException = 'Object lock not owned';
```

C++

```
SMonitorLockException = 'Object lock not owned';
```

File

SysConst

Description

This is constant SysConst.SMonitorLockException.

36.1.78 SysConst.SNL Constant

Pascal

```
SNL = 'Application is not licensed to use this feature';
```

C++

```
SNL = 'Application is not licensed to use this feature';
```

File

SysConst

Description

This is constant SysConst.SNL.

36.1.79 SysConst.SNoMonitorSupportException Constant

Pascal

```
SNoMonitorSupportException = 'Monitor support function not initialized';
```

C++

```
SNoMonitorSupportException = 'Monitor support function not initialized';
```

File

SysConst

Description

This is constant SysConst.SNoMonitorSupportException.

36.1.80 SysConst.SOperationAborted Constant

Pascal

```
SOperationAborted = 'Operation aborted';
```

C++

```
SOperationAborted = 'Operation aborted';
```

File

SysConst

Description

This is constant SysConst.SOperationAborted.

36.1.81 SysConst.SOSError Constant

Pascal

```
SOSError = 'System Error.  Code: %d.'+sLineBreak+'%s';
```

C++

```
SOSError = 'System Error.  Code: %d.'+sLineBreak+'%s';
```

File

SysConst

Description

This is constant SysConst.SOSError.

36.1.82 SysConst.SOutOfMemory Constant

Pascal

```
SOutOfMemory = 'Out of memory';
```

C++

```
SOutOfMemory = 'Out of memory';
```

File

SysConst

Description

This is constant SysConst.SOutOfMemory.

36.1.83 SysConst.SOverflow Constant

Pascal

```
SOverflow = 'Floating point overflow';
```

C++

```
SOverflow = 'Floating point overflow';
```

File

SysConst

Description

This is constant SysConst.SOverflow.

36.1.84 SysConst.SPrivilege Constant

Pascal

```
SPrivilege = 'Privileged instruction';
```

C++

```
SPrivilege = 'Privileged instruction';
```

File

SysConst

Description

This is constant SysConst.SPrivilege.

36.1.85 SysConst.SQuit Constant

Pascal

```
SQuit = 'Quit key hit';
```

C++

```
SQuit = 'Quit key hit';
```

File

SysConst

Description

This is constant SysConst.SQuit.

36.1.86 SysConst.SRangeError Constant

Pascal

```
SRangeError = 'Range check error';
```

C++

```
SRangeError = 'Range check error';
```

File

SysConst

Description

This is constant SysConst.SRangeError.

36.1.87 SysConst.SReadAccess Constant

Pascal

```
SReadAccess = 'Read';
```

C++

```
SReadAccess = 'Read';
```

File

SysConst

Description

This is constant SysConst.SReadAccess.

36.1.88 SysConst.SResultTooLong Constant

Pascal

```
SResultTooLong = 'Format result longer than 4096 characters';
```

C++

```
SResultTooLong = 'Format result longer than 4096 characters';
```

File

SysConst

Description

This is constant SysConst.SResultTooLong.

36.1.89 SysConst.SSafecallException Constant

Pascal

```
SSafecallException = 'Exception in safecall method';
```

C++

```
SSafecallException = 'Exception in safecall method';
```

File

SysConst

Description

This is constant SysConst.SSafecallException.

36.1.90 SysConst.SShortDayNameFri Constant

Pascal

```
SShortDayNameFri = 'Fri';
```

C++

```
SShortDayNameFri = 'Fri';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameFri.

36.1.91 SysConst.SShortDayNameMon Constant

Pascal

```
SShortDayNameMon = 'Mon';
```

C++

```
SShortDayNameMon = 'Mon';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameMon.

36.1.92 SysConst.SShortDayNameSat Constant

Pascal

```
SShortDayNameSat = 'Sat';
```

C++

```
SShortDayNameSat = 'Sat';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameSat.

36.1.93 SysConst.SShortDayNameSun Constant

Pascal

```
SShortDayNameSun = 'Sun';
```

C++

```
SShortDayNameSun = 'Sun';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameSun.

36.1.94 SysConst.SShortDayNameThu Constant

Pascal

```
SShortDayNameThu = 'Thu';
```

C++

```
SShortDayNameThu = 'Thu';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameThu.

36.1.95 SysConst.SShortDayNameTue Constant

Pascal

```
SShortDayNameTue = 'Tue';
```

C++

```
SShortDayNameTue = 'Tue';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameTue.

36.1.96 SysConst.SShortDayNameWed Constant

Pascal

```
SShortDayNameWed = 'Wed';
```

C++

```
SShortDayNameWed = 'Wed';
```

File

SysConst

Description

This is constant SysConst.SShortDayNameWed.

36.1.97 SysConst.SShortMonthNameApr Constant

Pascal

```
SShortMonthNameApr = 'Apr';
```

C++

```
SShortMonthNameApr = 'Apr';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameApr.

36.1.98 SysConst.SShortMonthNameAug Constant

Pascal

```
SShortMonthNameAug = 'Aug';
```

C++

```
SShortMonthNameAug = 'Aug';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameAug.

36.1.99 SysConst.SShortMonthNameDec Constant

Pascal

```
SShortMonthNameDec = 'Dec';
```

C++

```
SShortMonthNameDec = 'Dec';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameDec.

36.1.100 SysConst.SShortMonthNameFeb Constant

Pascal

```
SShortMonthNameFeb = 'Feb';
```

C++

```
SShortMonthNameFeb = 'Feb';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameFeb.

36.1.101 SysConst.SShortMonthNameJan Constant

Pascal

```
SShortMonthNameJan = 'Jan';
```

C++

```
SShortMonthNameJan = 'Jan';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameJan.

36.1.102 SysConst.SShortMonthNameJul Constant

Pascal

```
SShortMonthNameJul = 'Jul';
```

C++

```
SShortMonthNameJul = 'Jul';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameJul.

36.1.103 SysConst.SShortMonthNameJun Constant

Pascal

```
SShortMonthNameJun = 'Jun';
```

C++

```
SShortMonthNameJun = 'Jun';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameJun.

36.1.104 SysConst.SShortMonthNameMar Constant

Pascal

```
SShortMonthNameMar = 'Mar';
```

C++

```
SShortMonthNameMar = 'Mar';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameMar.

36.1.105 SysConst.SShortMonthNameMay Constant

Pascal

```
SShortMonthNameMay = 'May';
```

C++

```
SShortMonthNameMay = 'May';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameMay.

36.1.106 SysConst.SShortMonthNameNov Constant

Pascal

```
SShortMonthNameNov = 'Nov';
```

C++

```
SShortMonthNameNov = 'Nov';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameNov.

36.1.107 SysConst.SShortMonthNameOct Constant

Pascal

```
SShortMonthNameOct = 'Oct';
```

C++

```
SShortMonthNameOct = 'Oct';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameOct.

36.1.108 SysConst.SShortMonthNameSep Constant

Pascal

```
SShortMonthNameSep = 'Sep';
```

C++

```
SShortMonthNameSep = 'Sep';
```

File

SysConst

Description

This is constant SysConst.SShortMonthNameSep.

36.1.109 SysConst.SStackOverflow Constant

Pascal

```
SStackOverflow = 'Stack overflow';
```

C++

```
SStackOverflow = 'Stack overflow';
```

File

SysConst

Description

This is constant SysConst.SStackOverflow.

36.1.110 SysConst.STimeEncodeError Constant

Pascal

```
STimeEncodeError = 'Invalid argument to time encode';
```

C++

```
STimeEncodeError = 'Invalid argument to time encode';
```

File

SysConst

Description

This is constant SysConst.STimeEncodeError.

36.1.111 SysConst.STooManyOpenFiles Constant

Pascal

```
STooManyOpenFiles = 'Too many open files';
```

C++

```
STooManyOpenFiles = 'Too many open files';
```

File

SysConst

Description

This is constant SysConst.STooManyOpenFiles.

36.1.112 SysConst.SUnderflow Constant

Pascal

```
SUnderflow = 'Floating point underflow';
```

C++

```
SUnderflow = 'Floating point underflow';
```

File

SysConst

Description

This is constant SysConst.SUnderflow.

36.1.113 SysConst.SUnknown Constant

Pascal

```
SUnknown = '<unknown>';
```

C++

```
SUnknown = '<unknown>';
```

File

SysConst

Description

This is constant SysConst.SUnknown.

36.1.114 SysConst.sUnknownFromType Constant

Pascal

```
sUnknownFromType = 'Cannot convert from the specified type';
```

C++

```
sUnknownFromType = 'Cannot convert from the specified type';
```

File

SysConst

Description

This is constant SysConst.sUnknownFromType.

36.1.115 SysConst.sUnknownToType Constant

Pascal

```
sUnknownToType = 'Cannot convert to the specified type';
```

C++

```
sUnknownToType = 'Cannot convert to the specified type';
```

File

SysConst

Description

This is constant SysConst.sUnknownToType.

36.1.116 SysConst.SUnkOSError Constant

Pascal

```
SUnkOSError = 'A call to an OS function failed';
```

C++

```
SUnkOSError = 'A call to an OS function failed';
```

File

SysConst

Description

This is constant SysConst.SUnkOSError.

36.1.117 SysConst.SUnkWin32Error Constant

Pascal

```
SUnkWin32Error = 'A Win32 API function failed' deprecated 'use SUnkOSError';
```

C++

```
SUnkWin32Error = 'A Win32 API function failed' deprecated 'use SUnkOSError';
```

File

SysConst

Description

This is constant SysConst.SUnkWin32Error.

36.1.118 SysConst.SVarArrayBounds Constant

Pascal

```
SVarArrayBounds = 'Variant or safe array index out of bounds';
```

C++

```
SVarArrayBounds = 'Variant or safe array index out of bounds';
```

File

SysConst

Description

This is constant SysConst.SVarArrayBounds.

36.1.119 SysConst.SVarArrayCreate Constant

Pascal

```
SVarArrayCreate = 'Error creating variant or safe array';
```

C++

```
SVarArrayCreate = 'Error creating variant or safe array';
```

File

SysConst

Description

This is constant SysConst.SVarArrayCreate.

36.1.120 SysConst.SVarArrayLocked Constant

Pascal

```
SVarArrayLocked = 'Variant or safe array is locked';
```

C++

```
SVarArrayLocked = 'Variant or safe array is locked';
```

File

SysConst

Description

This is constant SysConst.SVarArrayLocked.

36.1.121 SysConst.SVarArrayWithHResult Constant

Pascal

```
SVarArrayWithHResult = 'Unexpected variant or safe array error: %s%.8x';
```

C++

```
SVarArrayWithHResult = 'Unexpected variant or safe array error: %s%.8x';
```

File

SysConst

Description

This is constant SysConst.SVarArrayWithHResult.

36.1.122 SysConst.SVarBadType Constant

Pascal

```
SVarBadType = 'Invalid variant type';
```

C++

```
SVarBadType = 'Invalid variant type';
```

File

SysConst

Description

This is constant SysConst.SVarBadType.

36.1.123 SysConst.SVarDataCastToRecursing Constant

Pascal

```
SVarDataCastToRecursing = 'Recursion while doing a VarDataCastTo';
```

C++

```
SVarDataCastToRecursing = 'Recursion while doing a VarDataCastTo';
```

File

SysConst

Description

This is constant SysConst.SVarDataCastToRecursing.

36.1.124 SysConst.SVarDataClearRecursing Constant

Pascal

```
SVarDataClearRecursing = 'Recursion while doing a VarDataClear';
```

C++

```
SVarDataClearRecursing = 'Recursion while doing a VarDataClear';
```

File

SysConst

Description

This is constant SysConst.SVarDataClearRecursing.

36.1.125 SysConst.SVarDataCopyNoIndRecursing Constant

Pascal

```
SVarDataCopyNoIndRecursing = 'Recursion while doing a VarDataCopyNoInd';
```

C++

```
SVarDataCopyNoIndRecursing = 'Recursion while doing a VarDataCopyNoInd';
```

File

SysConst

Description

This is constant SysConst.SVarDataCopyNoIndRecursing.

36.1.126 SysConst.SVarDataCopyRecursing Constant

Pascal

```
SVarDataCopyRecursing = 'Recursion while doing a VarDataCopy';
```

C++

```
SVarDataCopyRecursing = 'Recursion while doing a VarDataCopy';
```

File

SysConst

Description

This is constant SysConst.SVarDataCopyRecursing.

36.1.127 SysConst.SVarDataInitRecursing Constant

Pascal

```
SVarDataInitRecursing = 'Recursion while doing a VarDataInit';
```

C++

```
SVarDataInitRecursing = 'Recursion while doing a VarDataInit';
```

File

SysConst

Description

This is constant SysConst.SVarDataInitRecursing.

36.1.128 SysConst.SVarInvalid Constant

Pascal

```
SVarInvalid = 'Invalid argument';
```

C++

```
SVarInvalid = 'Invalid argument';
```

File

SysConst

Description

This is constant SysConst.SVarInvalid.

36.1.129 SysConst.SVarIsEmpty Constant

Pascal

```
SVarIsEmpty = 'Variant is empty';
```

C++

```
SVarIsEmpty = 'Variant is empty';
```

File

SysConst

Description

This is constant SysConst.SVarIsEmpty.

36.1.130 SysConst.SVarNotArray Constant

Pascal

```
SVarNotArray = 'Variant is not an array' deprecated;
```

C++

```
SVarNotArray = 'Variant is not an array' deprecated;
```

File

SysConst

Description

This is constant SysConst.SVarNotArray.

36.1.131 SysConst.SVarNotImplemented Constant

Pascal

```
SVarNotImplemented = 'Operation not supported';
```

C++

```
SVarNotImplemented = 'Operation not supported';
```

File

SysConst

Description

This is constant SysConst.SVarNotImplemented.

36.1.132 SysConst.SVarOutOfMemory Constant

Pascal

```
SVarOutOfMemory = 'Variant operation ran out memory';
```

C++

```
SVarOutOfMemory = 'Variant operation ran out memory';
```

File

SysConst

Description

This is constant SysConst.SVarOutOfMemory.

36.1.133 SysConst.SVarOverflow Constant

Pascal

```
SVarOverflow = 'Variant overflow';
```

C++

```
SVarOverflow = 'Variant overflow';
```

File

SysConst

Description

This is constant SysConst.SVarOverflow.

36.1.134 SysConst.SVarTypeAlreadyUsed Constant

Pascal

```
SVarTypeAlreadyUsed = 'Custom variant type ($%.4x) already used by %s' deprecated;
```

C++

```
SVarTypeAlreadyUsed = 'Custom variant type ($%.4x) already used by %s' deprecated;
```

File

SysConst

Description

This is constant SysConst.SVarTypeAlreadyUsed.

36.1.135 SysConst.SVarTypeAlreadyUsedWithPrefix Constant

Pascal

```
SVarTypeAlreadyUsedWithPrefix = 'Custom variant type (%s%.4x) already used by %s';
```

C++

```
SVarTypeAlreadyUsedWithPrefix = 'Custom variant type (%s%.4x) already used by %s';
```

File

SysConst

Description

This is constant SysConst.SVarTypeAlreadyUsedWithPrefix.

36.1.136 SysConst.SVarTypeConvertOverflow Constant

Pascal

```
SVarTypeConvertOverflow = 'Overflow while converting variant of type (%s) into type (%s)';
```

C++

```
SVarTypeConvertOverflow = 'Overflow while converting variant of type (%s) into type (%s)';
```

File

SysConst

Description

This is constant SysConst.SVarTypeConvertOverflow.

36.1.137 SysConst.SVarTypeCouldNotConvert Constant

Pascal

```
SVarTypeCouldNotConvert = 'Could not convert variant of type (%s) into type (%s)';
```

C++

```
SVarTypeCouldNotConvert = 'Could not convert variant of type (%s) into type (%s)';
```

File

SysConst

Description

This is constant SysConst.SVarTypeCouldNotConvert.

36.1.138 SysConst.SVarTypeNotUsable Constant

Pascal

```
SVarTypeNotUsable = 'Custom variant type ($%.4x) is not usable' deprecated;
```

C++

```
SVarTypeNotUsable = 'Custom variant type ($%.4x) is not usable' deprecated;
```

File

SysConst

Description

This is constant SysConst.SVarTypeNotUsable.

36.1.139 SysConst.SVarTypeNotUsableWithPrefix Constant

Pascal

```
SVarTypeNotUsableWithPrefix = 'Custom variant type (%s%.4x) is not usable';
```

C++

```
SVarTypeNotUsableWithPrefix = 'Custom variant type (%s%.4x) is not usable';
```

File

SysConst

Description

This is constant SysConst.SVarTypeNotUsableWithPrefix.

36.1.140 SysConst.SVarTypeOutOfRange Constant

Pascal

```
SVarTypeOutOfRange = 'Custom variant type ($%.4x) is out of range' deprecated;
```

C++

```
SVarTypeOutOfRange = 'Custom variant type ($%.4x) is out of range' deprecated;
```

File

SysConst

Description

This is constant SysConst.SVarTypeOutOfRange.

36.1.141 SysConst.SVarTypeOutOfRangeWithPrefix Constant

Pascal

```
SVarTypeOutOfRangeWithPrefix = 'Custom variant type (%s%.4x) is out of range';
```

C++

```
SVarTypeOutOfRangeWithPrefix = 'Custom variant type (%s%.4x) is out of range';
```

File

SysConst

Description

This is constant SysConst.SVarTypeOutOfRangeWithPrefix.

36.1.142 SysConst.SVarTypeRangeCheck1 Constant

Pascal

```
SVarTypeRangeCheck1 = 'Range check error for variant of type (%s)';
```

C++

```
SVarTypeRangeCheck1 = 'Range check error for variant of type (%s)';
```

File

SysConst

Description

This is constant SysConst.SVarTypeRangeCheck1.

36.1.143 SysConst.SVarTypeRangeCheck2 Constant

Pascal

```
SVarTypeRangeCheck2 = 'Range check error while converting variant of type (%s) into type (%s)';
```

C++

```
SVarTypeRangeCheck2 = 'Range check error while converting variant of type (%s) into type (%s)';
```

File

SysConst

Description

This is constant SysConst.SVarTypeRangeCheck2.

36.1.144 SysConst.SVarTypeTooManyCustom Constant

Pascal

```
SVarTypeTooManyCustom = 'Too many custom variant types have been registered';
```

C++

```
SVarTypeTooManyCustom = 'Too many custom variant types have been registered';
```

File

SysConst

Description

This is constant SysConst.SVarTypeTooManyCustom.

36.1.145 SysConst.SVarTypeUnknown Constant

Pascal

```
SVarTypeUnknown = 'Unknown custom variant type ($%.4x)' deprecated;
```

C++

```
SVarTypeUnknown = 'Unknown custom variant type ($%.4x)' deprecated;
```

File

SysConst

Description

This is constant SysConst.SVarTypeUnknown.

36.1.146 SysConst.SVarUnexpected Constant

Pascal

```
SVarUnexpected = 'Unexpected variant error';
```

C++

```
SVarUnexpected = 'Unexpected variant error';
```

File

SysConst

Description

This is constant SysConst.SVarUnexpected.

36.1.147 SysConst.SWin32Error Constant

Pascal

```
SWin32Error = 'Win32 Error.  Code: %d.'#10'%s' deprecated 'Use SOSError';
```

C++

```
SWin32Error = 'Win32 Error.  Code: %d.'#10'%s' deprecated 'Use SOSError';
```

File

SysConst

Description

This is constant SysConst.SWin32Error.

36.1.148 SysConst.SWriteAccess Constant

Pascal

```
SWriteAccess = 'Write';
```

C++

```
SWriteAccess = 'Write';
```

File

SysConst

Description

This is constant SysConst.SWriteAccess.

36.1.149 SysConst.SZeroDivide Constant

Pascal

```
SZeroDivide = 'Floating point division by zero';
```

C++

```
SZeroDivide = 'Floating point division by zero';
```

File

SysConst

Description

This is constant SysConst.SZeroDivide.

37 SysInit Namespace

This is namespace SysInit.

Topics

Name	Description
Functions (see page 3156)	The following table lists functions in this documentation.
Variables (see page 3159)	The following table lists variables in this documentation.
Constants (see page 3163)	The following table lists constants in this documentation.

Constants

Name	Description
PtrToNil (see page 3163)	This is constant SysInit.PtrToNil.

Functions

	Name	Description
	_GetTls (see page 3156)	This is function SysInit._GetTls.
	_InitExe (see page 3156)	This is function SysInit._InitExe.
	_InitLib (see page 3157)	This is function SysInit._InitLib.
	_InitPkg (see page 3157)	This is function SysInit._InitPkg.
	_PackageLoad (see page 3157)	This is function SysInit._PackageLoad.
	_PackageUnload (see page 3158)	This is function SysInit._PackageUnload.
	VclExit (see page 3158)	This is function SysInit.VclExit.
	VclInit (see page 3158)	This is function SysInit.VclInit.

Variables

Name	Description
CoverageLibraryName (see page 3159)	This is variable SysInit.CoverageLibraryName.
DataMark (see page 3159)	This is variable SysInit.DataMark.
DllProc (see page 3160)	This is variable SysInit.DllProc.
DllProcEx (see page 3160)	This is variable SysInit.DllProcEx.
HInstance (see page 3160)	This is variable SysInit.HInstance.
ModuleIsCpp (see page 3161)	This is variable SysInit.ModuleIsCpp.
ModuleIsLib (see page 3161)	This is variable SysInit.ModuleIsLib.
ModuleIsPackage (see page 3161)	This is variable SysInit.ModuleIsPackage.
TlsIndex (see page 3162)	This is variable SysInit.TlsIndex.
TlsLast (see page 3162)	This is variable SysInit.TlsLast.

37.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	_GetTls (see page 3156)	This is function SysInit._GetTls.
	_InitExe (see page 3156)	This is function SysInit._InitExe.
	_InitLib (see page 3157)	This is function SysInit._InitLib.
	_InitPkg (see page 3157)	This is function SysInit._InitPkg.
	_PackageLoad (see page 3157)	This is function SysInit._PackageLoad.
	_PackageUnload (see page 3158)	This is function SysInit._PackageUnload.
	VclExit (see page 3158)	This is function SysInit.VclExit.
	VclInit (see page 3158)	This is function SysInit.VclInit.

37.1.1 SysInit._GetTls Function

Pascal

```
function _GetTls: Pointer;
```

C++

```
void * _GetTls();
```

File

SysInit

Description

This is function SysInit._GetTls.

37.1.2 SysInit._InitExe Function

Pascal

```
procedure _InitExe(InitTable: Pointer);
```

C++

```
_InitExe(void * InitTable);
```

File

SysInit

Description

This is function SysInit._InitExe.

37.1.3 SysInit._InitLib Function

Pascal

```
procedure _InitLib;
```

C++

```
_InitLib();
```

File

SysInit

Description

This is function SysInit._InitLib.

37.1.4 SysInit._InitPkg Function

Pascal

```
function _InitPkg(Hinst: Integer; Reason: Integer; Resvd: Pointer): LongBool; stdcall;
```

C++

```
__stdcall LongBool _InitPkg(int Hinst, int Reason, void * Resvd);
```

File

SysInit

Description

This is function SysInit._InitPkg.

37.1.5 SysInit._PackageLoad Function

Pascal

```
procedure _PackageLoad(const Table: PackageInfo);
```

C++

```
_PackageLoad(const PackageInfo Table);
```

File

SysInit

Description

This is function SysInit._PackageLoad.

37.1.6 SysInit._PackageUnload Function

Pascal

```
procedure _PackageUnload(const Table: PackageInfo);
```

C++

```
_PackageUnload(const PackageInfo Table);
```

File

SysInit

Description

This is function SysInit._PackageUnload.

37.1.7 SysInit.VclExit Function

Pascal

```
procedure VclExit; cdecl;
```

C++

```
__cdecl VclExit();
```

File

SysInit

Description

This is function SysInit.VclExit.

37.1.8 SysInit.VclInit Function

Pascal

```
procedure VclInit(isDLL: Boolean; isPkg: Boolean; hInst: LongInt; isGui: Boolean); cdecl;
```

C++

```
__cdecl VclInit(Boolean isDLL, Boolean isPkg, LongInt hInst, Boolean isGui);
```

File

SysInit

Description

This is function SysInit.VclInit.

37.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CoverageLibraryName (see page 3159)	This is variable SysInit.CoverageLibraryName.
DataMark (see page 3159)	This is variable SysInit.DataMark.
DllProc (see page 3160)	This is variable SysInit.DllProc.
DllProcEx (see page 3160)	This is variable SysInit.DllProcEx.
HInstance (see page 3160)	This is variable SysInit.HInstance.
ModuleIsCpp (see page 3161)	This is variable SysInit.ModuleIsCpp.
ModuleIsLib (see page 3161)	This is variable SysInit.ModuleIsLib.
ModuleIsPackage (see page 3161)	This is variable SysInit.ModuleIsPackage.
TlsIndex (see page 3162)	This is variable SysInit.TlsIndex.
TlsLast (see page 3162)	This is variable SysInit.TlsLast.

37.2.1 SysInit.CoverageLibraryName Variable

Pascal

```
CoverageLibraryName: array [0..128] of AnsiChar = '*';
```

C++

```
array [0..128] of AnsiChar CoverageLibraryName = '*';
```

File

SysInit

Description

This is variable SysInit.CoverageLibraryName.

37.2.2 SysInit.DataMark Variable

Pascal

```
DataMark: Integer = 0;
```

C++

```
int DataMark = 0;
```

File

SysInit

Description

This is variable SysInit.DataMark.

37.2.3 SysInit.DllProc Variable

Pascal

```
DllProc: TDLLProc;
```

C++

```
TDLLProc DllProc;
```

File

SysInit

Description

This is variable SysInit.DllProc.

37.2.4 SysInit.DllProcEx Variable

Pascal

```
DllProcEx: TDLLProcEx absolute DllProc;
```

C++

```
TDLLProcEx absolute DllProc DllProcEx;
```

File

SysInit

Description

This is variable SysInit.DllProcEx.

37.2.5 SysInit.HInstance Variable

Pascal

```
HInstance: LongWord;
```

C++

```
LongWord HInstance;
```

File

SysInit

Description

This is variable SysInit.HInstance.

37.2.6 SysInit.ModuleIsCpp Variable

Pascal

```
ModuleIsCpp: Boolean;
```

C++

```
Boolean ModuleIsCpp;
```

File

SysInit

Description

This is variable SysInit.ModuleIsCpp.

37.2.7 SysInit.ModuleIsLib Variable

Pascal

```
ModuleIsLib: Boolean;
```

C++

```
Boolean ModuleIsLib;
```

File

SysInit

Description

This is variable SysInit.ModuleIsLib.

37.2.8 SysInit.ModuleIsPackage Variable

Pascal

```
ModuleIsPackage: Boolean;
```

C++

```
Boolean ModuleIsPackage;
```

File

SysInit

Description

This is variable SysInit.ModuleIsPackage.

37.2.9 SysInit.TlsIndex Variable

Pascal

```
TlsIndex: Integer = -1;
```

C++

```
int TlsIndex = -1;
```

File

SysInit

Description

This is variable SysInit.TlsIndex.

37.2.10 SysInit.TlsLast Variable

Pascal

```
TlsLast: Byte;
```

C++

```
Byte TlsLast;
```

File

SysInit

Description

This is variable SysInit.TlsLast.

37.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
PtrToNil (see page 3163)	This is constant SysInit.PtrToNil.

37.3.1 SysInit.PtrToNil Constant

Pascal

```
PtrToNil: Pointer = nil;
```

C++

```
void * PtrToNil = nil;
```

File

SysInit

Description

This is constant SysInit.PtrToNil.

38 System Namespace

This is namespace System.

Topics

Name	Description
Classes (see page 3185)	The following table lists classes in this documentation.
Interfaces (see page 3497)	The following table lists interfaces in this documentation.
Functions (see page 3507)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 3794)	The following table lists structs, records, enums in this documentation.
Types (see page 3822)	The following table lists types in this documentation.
Variables (see page 3874)	The following table lists variables in this documentation.
Constants (see page 3909)	The following table lists constants in this documentation.
Macros (see page 3960)	The following table lists macros in this documentation.

Classes

	Name	Description
	AnsiStringBase (see page 3185)	System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.
	AnsiStringT (see page 3219)	System::AnsiStringT is the C++ analog for the Delphi long string type.
	Currency (see page 3242)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 3262)	This is class System::CurrencyBase.
	DelphiInterface (see page 3263)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 3268)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	DynArrayException (see page 3279)	This is class System::DynArrayException.
	DynArrayNullData (see page 3279)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 3279)	This is class System::DynArrayOutOfRange.
	OleVariant (see page 3281)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	SmallString (see page 3322)	This is class System::SmallString.
	SmallStringBase (see page 3324)	This is class System::SmallStringBase.
	sPointer (see page 3326)	This is class System::sPointer.
	TAggregatedObject (see page 3328)	This is class System::TAggregatedObject.
	TClassHelperBase (see page 3331)	This is class System.TClassHelperBase.
	TContainedObject (see page 3333)	This is class System::TContainedObject.
	TDateTime (see page 3335)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.

	TDateTimeBase (see page 3354)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 3355)	This is class System::TInterfacedObject.
	TMetaClass (see page 3360)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TMonitor (see page 3361)	This is class System.TMonitor.
	TObject (see page 3364)	System::TObject is the ultimate ancestor of all objects and components.
	UnicodeString (see page 3393)	System::UnicodeString is the C++ analog for the Delphi UnicodeString type.
	Variant (see page 3430)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	WideString (see page 3476)	System::WideString represents strings of 16-bit characters.

Constants

Name	Description
CompilerVersion (see page 3911)	Designates the version number of the Delphi compiler.
CPUi386 (see page 3911)	This is constant System.CPUi386.
CPUi486 (see page 3912)	This is constant System.CPUi486.
CPUPentium (see page 3912)	This is constant System.CPUPentium.
E_NOINTERFACE (see page 3912)	This is constant System.E_NOINTERFACE.
E_NOTIMPL (see page 3913)	This is constant System.E_NOTIMPL.
E_UNEXPECTED (see page 3913)	This is constant System.E_UNEXPECTED.
fmClosed (see page 3913)	This is constant System.fmClosed.
fmInOut (see page 3914)	This is constant System.fmInOut.
fmInput (see page 3914)	This is constant System.fmInput.
fmOutput (see page 3914)	This is constant System.fmOutput.
hfFieldSize (see page 3915)	This is constant System.hfFieldSize.
hfMonitorOffset (see page 3915)	This is constant System.hfMonitorOffset.
INFINITE (see page 3915)	This is constant System.INFINITE.
MaxInt (see page 3916)	The maximum value of the Integer data type.
MaxLongint (see page 3916)	The maximum value of the Longint data type.
NumSmallBlockTypes (see page 3916)	NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.
opAdd (see page 3917)	opAdd defines an addition operation.
opAnd (see page 3917)	opAnd defines a logical and operation.
opCmpEQ (see page 3918)	opCmpEQ defines an equality comparison operator.
opCmpGE (see page 3918)	opCmpGE defines a greater than or equal comparison operator.
opCmpGT (see page 3919)	opCmpGT defines a greater than comparison operator.
opCmpLE (see page 3919)	opCmpLE defines a less than or equal comparison operator.
opCmpLT (see page 3920)	opCmpLT defines a less than comparison operator.
opCmpNE (see page 3920)	opCmpNE defines an inequality comparison operator.
opCompare (see page 3921)	opCompare defines a comparison operation.
opDivide (see page 3921)	opDivide defines a divide operation.
opIntDivide (see page 3922)	opIntDivide defines an integer divide operation.
opModulus (see page 3922)	opModulus defines a modulus operation.
opMultiply (see page 3923)	opMultiply defines a multiply operation.
opNegate (see page 3923)	opNegate defines a negate operation.
opNot (see page 3924)	opNot defines a binary negation operation.
opOr (see page 3924)	opOr defines a logical or operation.
opShiftLeft (see page 3925)	opShiftLeft defines a bitwise shift left operation.
opShiftRight (see page 3925)	opShiftRight defines a bitwise shift right operation.
opSubtract (see page 3926)	opSubtract defines a subtraction operation.
opXor (see page 3926)	opXor defines a logical exclusive or operation.
RTLVersion (see page 3927)	Designates the version number of the Delphi runtime library.
S_FALSE (see page 3927)	This is constant System.S_FALSE.
S_OK (see page 3927)	This is constant System.S_OK.
sLineBreak (see page 3928)	Represents the character(s) used to generate a line feed.
tfCRLF (see page 3928)	This is constant System.tfCRLF.

varAny (see page 3928)	Represents a Variant (see page 3430) that can hold any value.
varArray (see page 3929)	Represents a Variant (see page 3430) that holds dynamic array data.
varBoolean (see page 3930)	Represents a Variant (see page 3430) that holds WordBool data.
varByRef (see page 3930)	Represents a Variant (see page 3430) that points to another variable.
varByte (see page 3931)	Represents a Variant (see page 3430) that holds byte data.
varCurrency (see page 3931)	Represents a Variant (see page 3430) that holds a monetary floating point value.
varDate (see page 3932)	Represents a Variant (see page 3430) that holds a TDateTime (see page 3335) value.
varDispatch (see page 3932)	Represents a Variant (see page 3430) that has been assigned an IDispatch (see page 3498) value.
varDouble (see page 3933)	Represents a Variant (see page 3430) that holds a floating point value.
varEmpty (see page 3933)	Represents a Variant (see page 3430) that has not yet been assigned a value.
varError (see page 3934)	Represents a Variant (see page 3430) that holds a 32 bit error code.
varInt64 (see page 3934)	Represents a Variant (see page 3430) that holds Int64 data.
varInteger (see page 3935)	Represents a Variant (see page 3430) that holds Integer data.
varLongWord (see page 3935)	Represents a Variant (see page 3430) that holds LongWord data.
varNull (see page 3936)	Represents a Variant (see page 3430) that holds a null value.
varOleStr (see page 3936)	Represents a Variant (see page 3430) that has been assigned a COM interface type string value.
varShortInt (see page 3937)	Represents a Variant (see page 3430) that holds ShortInt data.
varSingle (see page 3937)	Represents a Variant (see page 3430) that holds byte data.
varSmallint (see page 3938)	This is constant System.varSmallint.
varStrArg (see page 3938)	Represents a Variant (see page 3430) that has holds a COM compatible string value.
varString (see page 3938)	Represents a Variant (see page 3430) that holds string data.
varTypeMask (see page 3939)	Defines a mask for filtering out the meta data part of a Variant (see page 3430) data type.
varUInt64 (see page 3940)	This is constant System.varUInt64.
varUnknown (see page 3940)	Represents a Variant (see page 3430) that holds an unknown value.
varUString (see page 3940)	This is constant System.varUString.
varVariant (see page 3941)	Represents a Variant (see page 3430) data type.
varWord (see page 3941)	Represents a Variant (see page 3430) that holds Word data.
vmtAddRef (see page 3942)	This is constant System.vmtAddRef.
vmtAfterConstruction (see page 3942)	This is constant System.vmtAfterConstruction.
vmtAutoTable (see page 3942)	This is constant System.vmtAutoTable.
vmtBeforeDestruction (see page 3943)	This is constant System.vmtBeforeDestruction.
vmtClassName (see page 3943)	This is constant System.vmtClassName.
vmtCreateObject (see page 3943)	This is constant System.vmtCreateObject.
vmtDefaultHandler (see page 3944)	This is constant System.vmtDefaultHandler.
vmtDestroy (see page 3944)	This is constant System.vmtDestroy.
vmtDispatch (see page 3944)	This is constant System.vmtDispatch.
vmtDynamicTable (see page 3945)	This is constant System.vmtDynamicTable.
vmtEquals (see page 3945)	This is constant System.vmtEquals.
vmtFieldTable (see page 3945)	This is constant System.vmtFieldTable.
vmtFreeInstance (see page 3946)	This is constant System.vmtFreeInstance.
vmtGetHashCode (see page 3946)	This is constant System.vmtGetHashCode.
vmtInitTable (see page 3946)	This is constant System.vmtInitTable.
vmtInstanceSize (see page 3947)	This is constant System.vmtInstanceSize.
vmtIntfTable (see page 3947)	This is constant System.vmtIntfTable.
vmtMethodTable (see page 3947)	This is constant System.vmtMethodTable.
vmtNewInstance (see page 3948)	This is constant System.vmtNewInstance.
vmtParent (see page 3948)	This is constant System.vmtParent.
vmtQueryInterface (see page 3948)	This is constant System.vmtQueryInterface.
vmtRelease (see page 3949)	This is constant System.vmtRelease.
vmtSafeCallException (see page 3949)	This is constant System.vmtSafeCallException.

vmtSelfPtr (see page 3949)	This is constant System.vmtSelfPtr.
vmtToString (see page 3950)	This is constant System.vmtToString.
vmtTypeInfo (see page 3950)	This is constant System.vmtTypeInfo.
vtAnsiString (see page 3950)	vtAnsiString defines an AnsiString TVarData (see page 3813) VType value.
vtBoolean (see page 3951)	vtBoolean defines a Boolean TVarData (see page 3813) VType value.
vtChar (see page 3951)	vtChar defines a Char TVarData (see page 3813) VType value.
vtClass (see page 3952)	vtClass defines a TClass (see page 3856) TVarData (see page 3813) VType value.
vtCurrency (see page 3952)	vtCurrency defines a Currency (see page 3242) TVarData (see page 3813) VType value.
vtExtended (see page 3953)	vtExtended defines an Extended TVarData (see page 3813) VType value.
vtInt64 (see page 3953)	vtInt64 defines an Int64 TVarData (see page 3813) VType value.
vtInteger (see page 3954)	vtInteger defines an Integer TVarData (see page 3813) VType value.
vtInterface (see page 3954)	vtInterface defines an Interface pointer TVarData (see page 3813) VType value.
vtObject (see page 3955)	vtObject defines a TObject (see page 3364) TVarData (see page 3813) VType value.
vtPChar (see page 3955)	vtPChar defines a PChar TVarData (see page 3813) VType value.
vtPointer (see page 3956)	vtPointer defines a Pointer TVarData (see page 3813) VType value.
vtPWideChar (see page 3956)	vtPWideChar defines a PWideChar TVarData (see page 3813) VType value.
vtString (see page 3957)	vtString defines a Variant (see page 3430) TVarData (see page 3813) VType value.
vtUnicodeString (see page 3957)	This is constant System.vtUnicodeString.
vtVariant (see page 3957)	This is constant System.vtVariant.
vtWideChar (see page 3958)	vtWideChar defines a WideChar TVarData (see page 3813) VType value.
vtWideString (see page 3958)	vtWideString defines a WideString (see page 3476) TVarData (see page 3813) VType value.

Functions

	Name	Description
	__ArrayToPasStr (see page 3518)	This is function System.__ArrayToPasStr.
	__CLenToPasStr (see page 3518)	This is function System.__CLenToPasStr.
	__CToPasStr (see page 3518)	This is function System.__CToPasStr.
	__currMul (see page 3519)	This is function System::__currMul.
	__IOTest (see page 3519)	This is function System.__IOTest.
	__lldiv (see page 3519)	This is function System.__lldiv.
	__lldivo (see page 3520)	This is function System.__lldivo.
	__llmod (see page 3520)	This is function System.__llmod.
	__llmodo (see page 3520)	This is function System.__llmodo.
	__llmul (see page 3521)	This is function System.__llmul.
	__llmulo (see page 3521)	This is function System.__llmulo.
	__llshl (see page 3521)	This is function System.__llshl.
	__ludiv (see page 3522)	This is function System.__ludiv.
	__lumod (see page 3522)	This is function System.__lumod.
	__lushr (see page 3522)	This is function System.__lushr.
	__PasToCStr (see page 3523)	This is function System.__PasToCStr.
	_AbstractError (see page 3523)	This is function System._AbstractError.
	_AddRef (see page 3523)	This is function System._AddRef.
	_AddRefArray (see page 3524)	This is function System._AddRefArray.
	_AddRefRecord (see page 3524)	This is function System._AddRefRecord.
	_AfterConstruction (see page 3524)	This is function System._AfterConstruction.
	_Append (see page 3525)	This is function System._Append.
	_AsClass (see page 3525)	This is function System._AsClass.
	_Assert (see page 3525)	This is function System._Assert.
	_Assign (see page 3526)	This is function System._Assign.
	_AStrCmp (see page 3526)	This is function System._AStrCmp.

	_BeforeDestruction (see page 3526)	This is function System._BeforeDestruction.
	_BlockRead (see page 3527)	This is function System._BlockRead.
	_BlockWrite (see page 3527)	This is function System._BlockWrite.
	_BoundErr (see page 3527)	This is function System._BoundErr.
	_CallDynaClass (see page 3528)	This is function System._CallDynaClass.
	_CallDynaInst (see page 3528)	This is function System._CallDynaInst.
	_CheckAutoResult (see page 3528)	This is function System._CheckAutoResult.
	_ClassCreate (see page 3529)	This is function System._ClassCreate.
	_ClassDestroy (see page 3529)	This is function System._ClassDestroy.
	_Close (see page 3529)	This is function System._Close.
	_Copy (see page 3530)	This is function System._Copy.
	_CopyArray (see page 3530)	This is function System._CopyArray.
	_CopyObject (see page 3530)	This is function System._CopyObject.
	_CopyRecord (see page 3531)	This is function System._CopyRecord.
	_CVR_PROBE (see page 3531)	This is function System._CVR_PROBE.
	_CVR_STMTPROBE (see page 3531)	This is function System._CVR_STMTPROBE.
	_Delete (see page 3532)	This is function System._Delete.
	_Dispose (see page 3532)	This is function System._Dispose.
	_DoneExcept (see page 3532)	This is function System._DoneExcept.
	_DynArrayAddRef (see page 3533)	This is function System._DynArrayAddRef.
	_DynArrayAsg (see page 3533)	This is function System._DynArrayAsg.
	_DynArrayClear (see page 3533)	This is function System._DynArrayClear.
	_DynArrayCopy (see page 3534)	This is function System._DynArrayCopy.
	_DynArrayCopyRange (see page 3534)	This is function System._DynArrayCopyRange.
	_DynArrayHigh (see page 3534)	This is function System._DynArrayHigh.
	_DynArrayLength (see page 3535)	This is function System._DynArrayLength.
	_DynArraySetLength (see page 3535)	This is function System._DynArraySetLength.
	_EnsureAnsiString (see page 3535)	This is function System._EnsureAnsiString.
	_EnsureUnicodeString (see page 3536)	This is function System._EnsureUnicodeString.
	_EofFile (see page 3536)	This is function System._EofFile.
	_EofText (see page 3536)	This is function System._EofText.
	_Eoln (see page 3537)	This is function System._Eoln.
	_Erase (see page 3537)	This is function System._Erase.
	_Ext2Real (see page 3537)	This is function System._Ext2Real.
	_Fail (see page 3538)	This is function System._Fail.
	_FilePos (see page 3538)	This is function System._FilePos.
	_FileSize (see page 3538)	This is function System._FileSize.
	_FillChar (see page 3539)	This is function System._FillChar.
	_Finalize (see page 3539)	This is function System._Finalize.
	_FinalizeArray (see page 3539)	This is function System._FinalizeArray.
	_FinalizeRecord (see page 3540)	This is function System._FinalizeRecord.
	_FindDynaClass (see page 3540)	This is function System._FindDynaClass.
	_FindDynaInst (see page 3540)	This is function System._FindDynaInst.
	_Flush (see page 3541)	This is function System._Flush.
	_FreeMem (see page 3541)	This is function System._FreeMem.
	_FSafeDivide (see page 3541)	This is function System._FSafeDivide.
	_FSafeDivideR (see page 3542)	This is function System._FSafeDivideR.
	_GetHelperIntf (see page 3542)	This is function System._GetHelperIntf.
	_GetMem (see page 3542)	This is function System._GetMem.
	_Halt (see page 3543)	This is function System._Halt.
	_Halt0 (see page 3543)	This is function System._Halt0.
	_HandleAnyException (see page 3543)	This is function System._HandleAnyException.
	_HandleAutoException (see page 3544)	This is function System._HandleAutoException.
	_HandleFinally (see page 3544)	This is function System._HandleFinally.

	_HandleOnException (see page 3544)	This is function System._HandleOnException.
	_Initialize (see page 3545)	This is function System._Initialize.
	_InitializeArray (see page 3545)	This is function System._InitializeArray.
	_InitializeRecord (see page 3545)	This is function System._InitializeRecord.
	_InitImports (see page 3546)	This is function System._InitImports.
	_InitResStringImports (see page 3546)	This is function System._InitResStringImports.
	_InitResStrings (see page 3546)	This is function System._InitResStrings.
	_InitUnicodeStrings (see page 3547)	This is function System._InitUnicodeStrings.
	_InitWideStrings (see page 3547)	This is function System._InitWideStrings.
	_Insert (see page 3547)	This is function System._Insert.
	_InternalLStrFromUStr (see page 3548)	This is function System._InternalLStrFromUStr.
	_InternalUStrFromLStr (see page 3548)	This is function System._InternalUStrFromLStr.
	_IntfAddRef (see page 3548)	This is function System._IntfAddRef.
	_IntfCast (see page 3549)	This is function System._IntfCast.
	_IntfClear (see page 3549)	This is function System._IntfClear.
	_IntfCopy (see page 3549)	This is function System._IntfCopy.
	_IntfDispCall (see page 3550)	This is function System._IntfDispCall.
	_IntfVarCall (see page 3550)	This is function System._IntfVarCall.
	_IntOver (see page 3550)	This is function System._IntOver.
	_IsClass (see page 3551)	This is function System._IsClass.
	_LGetDir (see page 3551)	This is function System._LGetDir.
	_LStrAddRef (see page 3551)	This is function System._LStrAddRef.
	_LStrArrayClr (see page 3552)	This is function System._LStrArrayClr.
	_LStrAsg (see page 3552)	This is function System._LStrAsg.
	_LStrCat (see page 3552)	This is function System._LStrCat.
	_LStrCat3 (see page 3553)	This is function System._LStrCat3.
	_LStrCatN (see page 3553)	This is function System._LStrCatN.
	_LStrClr (see page 3553)	This is function System._LStrClr.
	_LStrCmp (see page 3554)	This is function System._LStrCmp.
	_LStrCopy (see page 3554)	This is function System._LStrCopy.
	_LStrDelete (see page 3554)	This is function System._LStrDelete.
	_LStrEqual (see page 3555)	This is function System._LStrEqual.
	_LStrFromArray (see page 3555)	This is function System._LStrFromArray.
	_LStrFromChar (see page 3555)	This is function System._LStrFromChar.
	_LStrFromPChar (see page 3556)	This is function System._LStrFromPChar.
	_LStrFromPCharLen (see page 3556)	This is function System._LStrFromPCharLen.
	_LStrFromPWChar (see page 3556)	This is function System._LStrFromPWChar.
	_LStrFromPWCharLen (see page 3557)	This is function System._LStrFromPWCharLen.
	_LStrFromString (see page 3557)	This is function System._LStrFromString.
	_LStrFromUStr (see page 3557)	This is function System._LStrFromUStr.
	_LStrFromWArray (see page 3558)	This is function System._LStrFromWArray.
	_LStrFromWChar (see page 3558)	This is function System._LStrFromWChar.
	_LStrFromWStr (see page 3558)	This is function System._LStrFromWStr.
	_LStrInsert (see page 3559)	This is function System._LStrInsert.
	_LStrLAsg (see page 3559)	This is function System._LStrLAsg.
	_LStrLen (see page 3559)	This is function System._LStrLen.
	_LStrPos (see page 3560)	This is function System._LStrPos.
	_LStrSetLength (see page 3560)	This is function System._LStrSetLength.
	_LStrToPChar (see page 3560)	This is function System._LStrToPChar.
	_LStrToString (see page 3561)	This is function System._LStrToString.
	_New (see page 3561)	This is function System._New.
	_NewAnsiString (see page 3561)	This is function System._NewAnsiString.
	_NewUnicodeString (see page 3562)	This is function System._NewUnicodeString.
	_NewWideString (see page 3562)	This is function System._NewWideString.

	_ObjCopy (see page 3562)	This is function System._ObjCopy.
	_ObjSetup (see page 3563)	This is function System._ObjSetup.
	_PackageLoad (see page 3563)	This is function System._PackageLoad.
	_PackageUnload (see page 3563)	This is function System._PackageUnload.
	_PCharLen (see page 3564)	This is function System._PCharLen.
	_Pos (see page 3564)	This is function System._Pos.
	_Pow10 (see page 3564)	This is function System._Pow10.
	_PStrCat (see page 3565)	This is function System._PStrCat.
	_PStrCmp (see page 3565)	This is function System._PStrCmp.
	_PStrCpy (see page 3565)	This is function System._PStrCpy.
	_PStrNCat (see page 3566)	This is function System._PStrNCat.
	_PStrNCpy (see page 3566)	This is function System._PStrNCpy.
	_PWCharLen (see page 3566)	This is function System._PWCharLen.
	_RaiseAgain (see page 3567)	This is function System._RaiseAgain.
	_RaiseExcept (see page 3567)	This is function System._RaiseExcept.
	_ReadChar (see page 3567)	This is function System._ReadChar.
	_ReadCString (see page 3568)	This is function System._ReadCString.
	_ReadExt (see page 3568)	This is function System._ReadExt.
	_ReadInt64 (see page 3568)	This is function System._ReadInt64.
	_ReadLn (see page 3569)	This is function System._ReadLn.
	_ReadLong (see page 3569)	This is function System._ReadLong.
	_ReadLString (see page 3569)	This is function System._ReadLString.
	_ReadRec (see page 3570)	This is function System._ReadRec.
	_ReadString (see page 3570)	This is function System._ReadString.
	_ReadUString (see page 3570)	This is function System._ReadUString.
	_ReadWChar (see page 3571)	This is function System._ReadWChar.
	_ReadWCString (see page 3571)	This is function System._ReadWCString.
	_ReadWString (see page 3571)	This is function System._ReadWString.
	_Real2Ext (see page 3572)	This is function System._Real2Ext.
	_ReallocMem (see page 3572)	This is function System._ReallocMem.
	_Rename (see page 3572)	This is function System._Rename.
	_ResetFile (see page 3573)	This is function System._ResetFile.
	_ResetText (see page 3573)	This is function System._ResetText.
	_RewritFile (see page 3573)	This is function System._RewritFile.
	_RewritText (see page 3574)	This is function System._RewritText.
	_ROUND (see page 3574)	This is function System._ROUND.
	_roundToInt64 (see page 3574)	This is function System::_roundToInt64.
	_Run0Error (see page 3575)	This is function System._Run0Error.
	_RunError (see page 3575)	This is function System._RunError.
	_Seek (see page 3575)	This is function System._Seek.
	_SeekEof (see page 3576)	This is function System._SeekEof.
	_SeekEoln (see page 3576)	This is function System._SeekEoln.
	_SetElem (see page 3576)	This is function System._SetElem.
	_SetEq (see page 3577)	This is function System._SetEq.
	_SetExpand (see page 3577)	This is function System._SetExpand.
	_SetIntersect (see page 3577)	This is function System._SetIntersect.
	_SetIntersect3 (see page 3578)	This is function System._SetIntersect3.
	_SetLe (see page 3578)	This is function System._SetLe.
	_SetLength (see page 3578)	This is function System._SetLength.
	_SetRange (see page 3579)	This is function System._SetRange.
	_SetString (see page 3579)	This is function System._SetString.
	_SetSub (see page 3579)	This is function System._SetSub.
	_SetSub3 (see page 3580)	This is function System._SetSub3.
	_SetTextBuf (see page 3580)	This is function System._SetTextBuf.

	_SetUnion (see page 3580)	This is function System._SetUnion.
	_SetUnion3 (see page 3581)	This is function System._SetUnion3.
	_SGetDir (see page 3581)	This is function System._SGetDir.
	_StartExe (see page 3581)	This is function System._StartExe.
	_StartLib (see page 3582)	This is function System._StartLib.
	_Str0Ext (see page 3582)	This is function System._Str0Ext.
	_Str0Int64 (see page 3582)	This is function System._Str0Int64.
	_Str0Long (see page 3583)	This is function System._Str0Long.
	_Str0UInt64 (see page 3583)	This is function System._Str0UInt64.
	_Str1Ext (see page 3583)	This is function System._Str1Ext.
	_Str2Ext (see page 3584)	This is function System._Str2Ext.
	_StrInt64 (see page 3584)	This is function System._StrInt64.
	_StrLong (see page 3584)	This is function System._StrLong.
	_StrUInt64 (see page 3585)	This is function System._StrUInt64.
	_TRUNC (see page 3585)	This is function System._TRUNC.
	_Truncate (see page 3585)	This is function System._Truncate.
	_TryFinallyExit (see page 3586)	This is function System._TryFinallyExit.
	_UGetDir (see page 3586)	This is function System._UGetDir.
	_UniqueStringA (see page 3586)	This is function System._UniqueStringA.
	_UniqueStringU (see page 3587)	This is function System._UniqueStringU.
	_UniqueStringW (see page 3587)	This is function System._UniqueStringW.
	_UStrAddRef (see page 3587)	This is function System._UStrAddRef.
	_UStrArrayClr (see page 3588)	This is function System._UStrArrayClr.
	_UStrAsg (see page 3588)	This is function System._UStrAsg.
	_UStrCat (see page 3588)	This is function System._UStrCat.
	_UStrCat3 (see page 3589)	This is function System._UStrCat3.
	_UStrCatN (see page 3589)	This is function System._UStrCatN.
	_UStrClr (see page 3589)	This is function System._UStrClr.
	_UStrCmp (see page 3590)	This is function System._UStrCmp.
	_UStrCopy (see page 3590)	This is function System._UStrCopy.
	_UStrDelete (see page 3590)	This is function System._UStrDelete.
	_UStrEqual (see page 3591)	This is function System._UStrEqual.
	_UStrFromArray (see page 3591)	This is function System._UStrFromArray.
	_UStrFromChar (see page 3591)	This is function System._UStrFromChar.
	_UStrFromLStr (see page 3592)	This is function System._UStrFromLStr.
	_UStrFromPChar (see page 3592)	This is function System._UStrFromPChar.
	_UStrFromPCharLen (see page 3592)	This is function System._UStrFromPCharLen.
	_UStrFromPWChar (see page 3593)	This is function System._UStrFromPWChar.
	_UStrFromPWCharLen (see page 3593)	This is function System._UStrFromPWCharLen.
	_UStrFromString (see page 3593)	This is function System._UStrFromString.
	_UStrFromWArray (see page 3594)	This is function System._UStrFromWArray.
	_UStrFromWChar (see page 3594)	This is function System._UStrFromWChar.
	_UStrFromWStr (see page 3594)	This is function System._UStrFromWStr.
	_UStrInsert (see page 3595)	This is function System._UStrInsert.
	_UStrLAsg (see page 3595)	This is function System._UStrLAsg.
	_UStrLen (see page 3595)	This is function System._UStrLen.
	_UStrSetLength (see page 3596)	This is function System._UStrSetLength.
	_UStrToPWChar (see page 3596)	This is function System._UStrToPWChar.
	_UStrToString (see page 3596)	This is function System._UStrToString.
	_ValExt (see page 3597)	This is function System._ValExt.
	_ValInt64 (see page 3597)	This is function System._ValInt64.
	_ValLong (see page 3597)	This is function System._ValLong.
	_WCharToString (see page 3598)	This is function System._WCharToString.
	_WGetDir (see page 3598)	This is function System._WGetDir.

	_Write0Bool (see page 3598)	This is function System._Write0Bool.
	_Write0Char (see page 3599)	This is function System._Write0Char.
	_Write0CString (see page 3599)	This is function System._Write0CString.
	_Write0Ext (see page 3599)	This is function System._Write0Ext.
	_Write0Int64 (see page 3600)	This is function System._Write0Int64.
	_Write0Long (see page 3600)	This is function System._Write0Long.
	_Write0LString (see page 3600)	This is function System._Write0LString.
	_Write0String (see page 3601)	This is function System._Write0String.
	_Write0UInt64 (see page 3601)	This is function System._Write0UInt64.
	_Write0UString (see page 3601)	This is function System._Write0UString.
	_Write0Variant (see page 3602)	This is function System._Write0Variant.
	_Write0WChar (see page 3602)	This is function System._Write0WChar.
	_Write0WCString (see page 3602)	This is function System._Write0WCString.
	_Write0WString (see page 3603)	This is function System._Write0WString.
	_Write1Ext (see page 3603)	This is function System._Write1Ext.
	_Write2Ext (see page 3603)	This is function System._Write2Ext.
	_WriteBool (see page 3604)	This is function System._WriteBool.
	_WriteChar (see page 3604)	This is function System._WriteChar.
	_WriteCString (see page 3604)	This is function System._WriteCString.
	_WriteInt64 (see page 3605)	This is function System._WriteInt64.
	_WriteLn (see page 3605)	This is function System._WriteLn.
	_WriteLong (see page 3605)	This is function System._WriteLong.
	_WriteLString (see page 3606)	This is function System._WriteLString.
	_WriteRec (see page 3606)	This is function System._WriteRec.
	_WriteString (see page 3606)	This is function System._WriteString.
	_WriteUInt64 (see page 3607)	This is function System._WriteUInt64.
	_WriteUString (see page 3607)	This is function System._WriteUString.
	_WriteVariant (see page 3607)	This is function System._WriteVariant.
	_WriteWChar (see page 3608)	This is function System._WriteWChar.
	_WriteWCString (see page 3608)	This is function System._WriteWCString.
	_WriteWString (see page 3608)	This is function System._WriteWString.
	_WStrAddRef (see page 3609)	This is function System._WStrAddRef.
	_WStrArrayClr (see page 3609)	This is function System._WStrArrayClr.
	_WStrAsg (see page 3609)	This is function System._WStrAsg.
	_WStrCat (see page 3610)	This is function System._WStrCat.
	_WStrCat3 (see page 3610)	This is function System._WStrCat3.
	_WStrCatN (see page 3610)	This is function System._WStrCatN.
	_WStrClr (see page 3611)	This is function System._WStrClr.
	_WStrCmp (see page 3611)	This is function System._WStrCmp.
	_WStrCopy (see page 3611)	This is function System._WStrCopy.
	_WStrDelete (see page 3612)	This is function System._WStrDelete.
	_WStrEqual (see page 3612)	This is function System._WStrEqual.
	_WStrFromArray (see page 3612)	This is function System._WStrFromArray.
	_WStrFromChar (see page 3613)	This is function System._WStrFromChar.
	_WStrFromLStr (see page 3613)	This is function System._WStrFromLStr.
	_WStrFromPChar (see page 3613)	This is function System._WStrFromPChar.
	_WStrFromPCharLen (see page 3614)	This is function System._WStrFromPCharLen.
	_WStrFromPWChar (see page 3614)	This is function System._WStrFromPWChar.
	_WStrFromPWCharLen (see page 3614)	This is function System._WStrFromPWCharLen.
	_WStrFromString (see page 3615)	This is function System._WStrFromString.
	_WStrFromUStr (see page 3615)	This is function System._WStrFromUStr.
	_WStrFromWArray (see page 3615)	This is function System._WStrFromWArray.
	_WStrFromWChar (see page 3616)	This is function System._WStrFromWChar.
	_WStrInsert (see page 3616)	This is function System._WStrInsert.

	_WStrLAsg (see page 3616)	This is function System._WStrLAsg.
	_WStrLCmp (see page 3617)	This is function System._WStrLCmp.
	_WStrLen (see page 3617)	This is function System._WStrLen.
	_WStrSetLength (see page 3617)	This is function System._WStrSetLength.
	_WStrToPWChar (see page 3618)	This is function System._WStrToPWChar.
	_WStrToString (see page 3618)	This is function System._WStrToString.
	+ (see page 3618)	This is function System::+.
	+ (see page 3619)	This is function System::+.
	Abs (see page 3619)	Returns an absolute value.
	AcquireExceptionObject (see page 3619)	Retains access to exception object.
	AddModuleUnloadProc (see page 3620)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	AddModuleUnloadProc (see page 3620)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	Addr (see page 3621)	Returns a pointer to a specified object.
	AllocMem (see page 3622)	AllocMem allocates a memory block and initializes each byte to zero.
	AnsiToUtf8 (see page 3624)	Converts a string encoded in Ansi to UTF-8.
	Append (see page 3624)	Prepares an existing file for adding text to the end.
	ArcTan (see page 3625)	Calculates the arctangent of a given number.
	Assert (see page 3627)	Tests whether a Boolean expression is true.
	Assert (see page 3627)	Tests whether a Boolean expression is true.
	Assigned (see page 3628)	Tests for a nil (unassigned) pointer or procedural variable.
	AssignFile (see page 3629)	Associates the name of an external file with a file variable.
	AttemptToUseSharedMemoryManager (see page 3631)	Attempts to use a shared memory manager.
	BeginThread (see page 3632)	Spawns a separate thread of execution.
	BlockRead (see page 3633)	Reads one or more records from an open file into a variable.
	BlockRead (see page 3633)	Reads one or more records from an open file into a variable.
	BlockWrite (see page 3634)	Writes one or more records from a variable to an open file.
	BlockWrite (see page 3634)	Writes one or more records from a variable to an open file.
	Break (see page 3636)	Causes the flow of control to exit a for, while, or repeat statement.
	ChDir (see page 3638)	Changes the current directory.
	ChDir (see page 3638)	Changes the current directory.
	CheckSafecallResult (see page 3640)	This is function System::CheckSafecallResult.
	Chr (see page 3640)	Returns the character for a specified ASCII value.
	Close (see page 3643)	Terminates the association between a file variable and an external file.
	CloseFile (see page 3643)	Terminates the association between file variable and an external disk file.
	CompareTo (see page 3645)	This is function System.CompareTo.
	CompToCurrency (see page 3645)	Converts a Comp value to a Currency (see page 3242) value.
	CompToDouble (see page 3646)	Converts a Comp value to a double value.
	Concat (see page 3646)	Concatenates two or more strings into one.
	Concat (see page 3646)	Concatenates two or more strings into one.
	Concat (see page 3646)	Concatenates two or more strings into one.
	Continue (see page 3647)	Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.
	Copy (see page 3648)	Returns a substring of a string or a segment of a dynamic array.
	Cos (see page 3650)	Calculates the cosine of an angle.
	CurrencyToComp (see page 3651)	Converts a Currency (see page 3242) value to a Comp value.
	Dec (see page 3652)	Decrements a variable by 1 or N.
	Dec (see page 3652)	Decrements a variable by 1 or N.
	Delete (see page 3653)	Removes a substring from a string.
	Dispose (see page 3654)	Releases memory allocated for a dynamic variable.
	DoubleToComp (see page 3656)	Converts a double value to a Comp.
	DynArrayClear (see page 3656)	This is function System.DynArrayClear.
	DynArrayDim (see page 3657)	This is function System.DynArrayDim.
	DynArraySetLength (see page 3657)	This is function System.DynArraySetLength.

	EndThread (see page 3657)	Terminates the execution of a thread.
	EnumModules (see page 3658)	Executes a callback for all the modules in an application.
	EnumModules (see page 3658)	Executes a callback for all the modules in an application.
	EnumResourceModules (see page 3658)	Executes a callback for all resource modules in an application.
	EnumResourceModules (see page 3658)	Executes a callback for all resource modules in an application.
	Eof (see page 3659)	Tests whether the file position is at the end of a file.
	Eof (see page 3659)	Tests whether the file position is at the end of a file.
	Eof (see page 3659)	Tests whether the file position is at the end of a file.
	Eoln (see page 3660)	Tests whether the file pointer is at the end of a line.
	Eoln (see page 3660)	Tests whether the file pointer is at the end of a line.
	Equals (see page 3661)	This is function System.Equals.
	Erase (see page 3661)	Deletes an external file.
	Error (see page 3662)	Error is used to generate a run-time exception.
	ExceptAddr (see page 3663)	Returns the address at which the current exception was raised.
	ExceptObject (see page 3664)	Returns current exception object.
	Exclude (see page 3664)	Removes an element from a Delphi set or removes an event handler in .NET applications.
	Exit (see page 3665)	Exits from the current procedure.
	Exp (see page 3667)	Returns the exponential of X.
	Exp (see page 3667)	Returns the exponential of X.
	FilePos (see page 3668)	Returns the current file position.
	FileSize (see page 3669)	Returns the number of records in a file.
	FillChar (see page 3670)	Fills contiguous bytes with a specified value.
	Finalize (see page 3672)	Uninitializes a dynamically allocated variable.
	Finalize (see page 3672)	Uninitializes a dynamically allocated variable.
	FindClassHInstance (see page 3672)	Returns the instance handle for the module in which a class type is defined.
	FindDynaInst (see page 3673)	This is function System::FindDynaInst.
	FindHInstance (see page 3673)	Returns the instance handle of the module that contains a specified address.
	FindResourceHInstance (see page 3674)	Returns the instance handle of the resource module associated with a specified HInstance.
	Flush (see page 3674)	Empties the buffer of a text file opened for output.
	FPower10 (see page 3675)	This is function System.FPower10.
	Frac (see page 3675)	Returns the fractional part of a real number.
	FreeMem (see page 3676)	FreeMem frees a memory block.
	FreeMem (see page 3676)	FreeMem frees a memory block.
	FreeMemory (see page 3678)	FreeMemory frees a memory block.
	Get8087CW (see page 3679)	Returns the value of the 8087 code word.
	GetCurrent (see page 3679)	This is function System.GetCurrent.
	GetDir (see page 3679)	Returns the current directory.
	GetEnumerator (see page 3681)	This is function System.GetEnumerator.
	GetHeapStatus (see page 3681)	Returns the current status of the memory manager.
	GetLastError (see page 3681)	Returns the last error reported by an operating system API call.
	GetMem (see page 3683)	GetMem allocates a memory block.
	GetMemory (see page 3684)	GetMemory allocates a memory block.
	GetMemoryManager (see page 3686)	Returns the entry points of the currently installed memory manager.
	GetMemoryManager (see page 3686)	Returns the entry points of the currently installed memory manager.
	GetMemoryManagerState (see page 3690)	Fetches state information for the Memory Manager.
	GetMemoryMap (see page 3691)	Fetches the memory map.
	GetMinimumBlockAlignment (see page 3691)	Gets the minimum memory block alignment.
	GetModuleFileName (see page 3692)	Returns the fully qualified name for a module, given its handle.
	GetVariantManager (see page 3692)	Returns the entry points of the routines that define variant behavior.
	Halt (see page 3693)	Initiates abnormal termination of a program.
	Halt (see page 3693)	Initiates abnormal termination of a program.
	Hi (see page 3694)	Returns the high-order byte of X as an unsigned value.
	High (see page 3694)	Returns the highest value in the range of an argument.

	Inc (see page 3696)	Increments an ordinal value by one or N.
	Inc (see page 3696)	Increments an ordinal value by one or N.
	Include (see page 3697)	Adds an element to a Delphi set or adds an event handler in .NET applications.
	Initialize (see page 3698)	Initializes a dynamically allocated variable.
	Initialize (see page 3698)	Initializes a dynamically allocated variable.
	Insert (see page 3698)	Inserts a substring into a string beginning at a specified point.
	Int (see page 3699)	Returns the integer part of a real number.
	IOResult (see page 3700)	Returns the status of the last I/O operation performed.
	IsMemoryManagerSet (see page 3701)	Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 3751) procedure.
	IsVariantManagerSet (see page 3701)	Indicates whether variant support is implemented in an application.
	Length (see page 3702)	Returns the number of characters in a string or elements in an array.
	Ln (see page 3703)	Returns the natural log of a real expression.
	Lo (see page 3704)	Returns the low order Byte of argument X.
	LoadResourceModule (see page 3705)	This is function System.LoadResourceModule.
	LoadResourceString (see page 3705)	This is function System::LoadResourceString.
	LoadResString (see page 3705)	This is function System.LoadResString.
	Low (see page 3706)	Returns the lowest value in a range.
	Mark (see page 3707)	This is function System.Mark.
	MemoryBarrier (see page 3707)	This is function System.MemoryBarrier.
	MkDir (see page 3708)	Creates a new subdirectory.
	MkDir (see page 3708)	Creates a new subdirectory.
	MonitorEnter (see page 3709)	This is function System.MonitorEnter.
	MonitorExit (see page 3709)	This is function System.MonitorExit.
	MonitorPulse (see page 3710)	This is function System.MonitorPulse.
	MonitorPulseAll (see page 3710)	This is function System.MonitorPulseAll.
	MonitorTryEnter (see page 3710)	This is function System.MonitorTryEnter.
	MonitorWait (see page 3711)	This is function System.MonitorWait.
	Move (see page 3711)	Copies bytes from a source to a destination.
	MoveChars (see page 3712)	This is function System.MoveChars.
	New (see page 3712)	Creates a new dynamic variable and sets P to point to it.
	Odd (see page 3714)	Returns true if argument is an odd number.
	OleStrToString (see page 3715)	Copies data received from a COM interface to a string.
	OleStrToStrVar (see page 3715)	Copies a string from its COM representation to an existing Delphi string.
	OleStrToStrVar (see page 3715)	Copies a string from its COM representation to an existing Delphi string.
	Ord (see page 3716)	Returns the ordinal value of an ordinal-type expression.
	ParamCount (see page 3716)	Returns the number of parameters passed on the command line.
	ParamStr (see page 3718)	Returns a specified parameter from the command-line.
	Pi (see page 3719)	Returns 3.1415926535897932385.
	Pos (see page 3720)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3720)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3720)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pred (see page 3721)	Returns the predecessor of the argument.
	Ptr (see page 3723)	Converts a specified address to a pointer.
	PUCS4Chars (see page 3724)	Converts a UCS4 string to a null-terminated array of UCS4 characters.
	RaiseList (see page 3724)	This is function System.RaiseList.
	Random (see page 3725)	Generates random numbers within a specified range.
	Random (see page 3725)	Generates random numbers within a specified range.
	Randomize (see page 3726)	Initializes the random number generator with a random value.
	Read (see page 3727)	Read reads data from a file.
	Read (see page 3727)	Read reads data from a file.
	Read (see page 3727)	Read reads data from a file.
	Read (see page 3727)	Read reads data from a file.

	ReadLn (see page 3728)	Reads a line of text from a file.
	ReadLn (see page 3728)	Reads a line of text from a file.
	ReadLn (see page 3728)	Reads a line of text from a file.
	ReadLn (see page 3728)	Reads a line of text from a file.
	ReallocMem (see page 3729)	ReallocMem reallocates a memory block.
	ReallocMemory (see page 3730)	ReallocMemory resizes a memory block.
	RegisterExpectedMemoryLeak (see page 3731)	Registers an expected memory leak.
	RegisterModule (see page 3731)	This is function System.RegisterModule.
	Release (see page 3732)	This is function System.Release.
	ReleaseExceptionObject (see page 3732)	Releases exception object acquired by AcquireExceptionObject (see page 3619).
	RemoveModuleUnloadProc (see page 3732)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	RemoveModuleUnloadProc (see page 3732)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	Rename (see page 3733)	Changes the name of an external file.
	Rename (see page 3733)	Changes the name of an external file.
	Reset (see page 3734)	Opens an existing file.
	Reset (see page 3734)	Opens an existing file.
	Reset (see page 3734)	Opens an existing file.
	Reset (see page 3734)	Opens an existing file.
	Rewrite (see page 3736)	Creates a new file and opens it.
	Rewrite (see page 3736)	Creates a new file and opens it.
	RmDir (see page 3738)	Deletes an empty subdirectory.
	RmDir (see page 3738)	Deletes an empty subdirectory.
	Round (see page 3739)	Returns the value of X rounded to the nearest whole number.
	RunError (see page 3740)	Stops execution and generates a runtime error.
	RunError (see page 3740)	Stops execution and generates a runtime error.
	Seek (see page 3741)	Moves the current position of a file to a specified component.
	SeekEof (see page 3742)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEof (see page 3742)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEoln (see page 3743)	Returns the end-of-line status of a file, ignoring whitespace.
	SeekEoln (see page 3743)	Returns the end-of-line status of a file, ignoring whitespace.
	Set8087CW (see page 3744)	Sets both the control word in the floating point unit and the variable NoErrMsg (see page 3901) declared in the system unit.
	SetCodePage (see page 3746)	This is function System.SetCodePage.
	SetInOutRes (see page 3746)	This is function System.SetInOutRes.
	SetLastError (see page 3747)	SetLastError sets the last API error code.
	SetLength (see page 3748)	Sets the length of a string or dynamic-array variable.
	SetLineBreakStyle (see page 3750)	Determines the end-of-line and end-of-file conventions for text file I/O.
	SetMemoryManager (see page 3751)	Sets entry points of the memory manager.
	SetMemoryManager (see page 3751)	Sets entry points of the memory manager.
	SetMinimumBlockAlignment (see page 3756)	Sets the minimum memory block alignment.
	SetMultiByteConversionCodePage (see page 3756)	SetMultiByteConversionCodePage overrides the default multi byte code conversion page.
	SetRaiseList (see page 3757)	This is function System.SetRaiseList.
	SetString (see page 3757)	Sets the contents and length of the given string.
	SetTextBuf (see page 3758)	Assigns an I/O buffer to a text file.
	SetTextBuf (see page 3758)	Assigns an I/O buffer to a text file.
	SetVariantManager (see page 3759)	Sets the entry points of routines that define variant behavior.
	ShareMemoryManager (see page 3759)	Shares the module's memory manager.
	Sin (see page 3760)	Returns the sine of the angle in radians.
	SizeOf (see page 3761)	Returns the number of bytes occupied by a variable or type.
	Slice (see page 3762)	Returns a sub-section of an array.
	Sqr (see page 3762)	Returns the square of a number.
	Sqr (see page 3762)	Returns the square of a number.

	Sqrt (see page 3763)	Returns the square root of X.
	Str (see page 3764)	Formats a string and returns it to a variable.
	Str (see page 3764)	Formats a string and returns it to a variable.
	StringCodePage (see page 3765)	This is function System.StringCodePage.
	StringCodePage (see page 3765)	This is function System.StringCodePage.
	StringElementSize (see page 3765)	This is function System.StringElementSize.
	StringElementSize (see page 3766)	This is function System.StringElementSize.
	StringOfChar (see page 3766)	Returns a string with a specified number of repeating characters.
	StringOfChar (see page 3766)	Returns a string with a specified number of repeating characters.
	StringRefCount (see page 3766)	This is function System.StringRefCount.
	StringRefCount (see page 3767)	This is function System.StringRefCount.
	StringToOleStr (see page 3767)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToOleStr (see page 3767)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToWideChar (see page 3768)	Returns a UNICODE string from an AnsiString.
	Succ (see page 3768)	Returns the successor of an argument.
	Swap (see page 3769)	Exchanges high order byte with the low order byte of an integer or word.
	SysAllocMem (see page 3769)	This is function System.SysAllocMem.
	SysFreeMem (see page 3770)	Frees the memory pointed to by a specified pointer.
	SysGetMem (see page 3770)	Allocates a specified number of bytes and returns a pointer to them.
	SysReallocMem (see page 3771)	Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.
	SysRegisterExpectedMemoryLeak (see page 3772)	This is function System.SysRegisterExpectedMemoryLeak.
	SysUnregisterExpectedMemoryLeak (see page 3772)	This is function System.SysUnregisterExpectedMemoryLeak.
	TextStart (see page 3772)	This is function System.TextStart.
	Trunc (see page 3773)	Truncates a real number to an integer.
	Truncate (see page 3774)	Deletes all the records after the current file position.
	UCS4StringToUnicodeString (see page 3775)	This is function System.UCS4StringToUnicodeString.
	UCS4StringToWideString (see page 3775)	Converts a string of 4-byte Unicode characters into a WideString (see page 3476) value.
	UnicodeStringToUCS4String (see page 3775)	This is function System.UnicodeStringToUCS4String.
	UnicodeToUtf8 (see page 3776)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3776)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3776)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3776)	Converts a string of Unicode characters into a UTF-8 string.
	UniqueString (see page 3777)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3777)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3777)	Ensures that a given string has a reference count of one.
	UnregisterExpectedMemoryLeak (see page 3777)	Unregisters an expected memory leak.
	UnregisterModule (see page 3778)	This is function System.UnregisterModule.
	UpCase (see page 3778)	Converts a character to uppercase.
	UpCase (see page 3778)	Converts a character to uppercase.
	UTF8Decode (see page 3779)	Converts a UTF8 string to a Unicode string (WideString (see page 3476)).
	UTF8Encode (see page 3780)	Converts a WideString (see page 3476) value to a UTF8 string.
	UTF8Encode (see page 3780)	Converts a WideString (see page 3476) value to a UTF8 string.
	UTF8Encode (see page 3780)	Converts a WideString (see page 3476) value to a UTF8 string.
	UTF8EncodeToShortString (see page 3780)	This is function System.UTF8EncodeToShortString.
	UTF8EncodeToShortString (see page 3780)	This is function System.UTF8EncodeToShortString.
	UTF8EncodeToShortString (see page 3781)	This is function System.UTF8EncodeToShortString.
	Utf8ToAnsi (see page 3781)	Converts a UTF8 string to a string of Ansi characters.
	UTF8ToString (see page 3782)	This is function System.UTF8ToString.
	UTF8ToString (see page 3782)	This is function System.UTF8ToString.
	UTF8ToString (see page 3782)	This is function System.UTF8ToString.
	UTF8ToString (see page 3783)	This is function System.UTF8ToString.
	Utf8ToUnicode (see page 3783)	Converts a string of UTF-8 characters to a Unicode string.
	Utf8ToUnicode (see page 3783)	Converts a string of UTF-8 characters to a Unicode string.

	UTF8ToUnicodeString (see page 3784)	This is function System.UTF8ToUnicodeString.
	UTF8ToUnicodeString (see page 3784)	This is function System.UTF8ToUnicodeString.
	UTF8ToUnicodeString (see page 3784)	This is function System.UTF8ToUnicodeString.
	UTF8ToWideString (see page 3785)	This is function System.UTF8ToWideString.
	Val (see page 3785)	Converts a string to a numeric representation.
	VarArrayRedim (see page 3786)	Resizes a Variant (see page 3430) array.
	VarClear (see page 3786)	Empties a Variant (see page 3430), so that it is unassigned.
	WideCharLenToString (see page 3787)	Converts Unicode characters to single or multi byte character data.
	WideCharLenToStrVar (see page 3788)	WideCharLenToStrVar converts Unicode characters to single or multi byte character data.
	WideCharLenToStrVar (see page 3788)	WideCharLenToStrVar converts Unicode characters to single or multi byte character data.
	WideCharToString (see page 3788)	Converts null-terminated Unicode string to single or multi byte character data.
	WideCharToStrVar (see page 3788)	Converts Unicode string to a single or multi byte character data.
	WideStringToUCS4String (see page 3789)	Converts a WideString (see page 3476) value to a string of 4-byte Unicode characters.
	Write (see page 3789)	Writes to either a typed file or a text file
	Write (see page 3789)	Writes to either a typed file or a text file
	Write (see page 3789)	Writes to either a typed file or a text file
	Write (see page 3789)	Writes to either a typed file or a text file
	WriteLn (see page 3792)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3792)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3792)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3792)	Writes to a text file and adds an end-of-line marker.
	YieldProcessor (see page 3793)	This is function System.YieldProcessor.

Interfaces

	Name	Description
	IComparable (see page 3497)	This is class System.IComparable.
	IDispatch (see page 3498)	This is class System.IDispatch.
	IEnumerable (see page 3500)	This is class System.IEnumerable.
	IEnumerator (see page 3501)	This is class System.IEnumerator.
	IInterface (see page 3503)	IInterface is the base class for all interfaces defined in Delphi code.
	IInvokable (see page 3505)	IInvokable is the base class for invokable interfaces.

Macros

Name	Description
USE (see page 3960)	This is macro System::USE.
USEADDITIONALFILES (see page 3960)	This is macro System::USEADDITIONALFILES.
USEASM (see page 3961)	This is macro System::USEASM.
USEDATAMODULE (see page 3961)	This is macro System::USEDATAMODULE.
USEDATAMODULENS (see page 3961)	This is macro System::USEDATAMODULENS.
USEDEF (see page 3962)	This is macro System::USEDEF.
USEFILE (see page 3962)	This is macro System::USEFILE.
USEFORM (see page 3963)	This is macro System::USEFORM.
USEFORMNS (see page 3963)	This is macro System::USEFORMNS.
USEFORMRES (see page 3963)	This is macro System::USEFORMRES.
USEIDL (see page 3964)	This is macro System::USEIDL.
USELIB (see page 3964)	This is macro System::USELIB.
USEOBJ (see page 3964)	This is macro System::USEOBJ.
USEPACKAGE (see page 3965)	This is macro System::USEPACKAGE.
USERC (see page 3965)	This is macro System::USERC.
USERES (see page 3965)	This is macro System::USERES.
USETLB (see page 3966)	This is macro System::USETLB.
USEUNIT (see page 3966)	This is macro System::USEUNIT.

Structs, Records, Enums

	Name	Description
	PackageInfoTable (see page 3795)	This is record System.PackageInfoTable.
	PackageUnitEntry (see page 3795)	This is record System.PackageUnitEntry.
	TCallDesc (see page 3795)	TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 3830) is a pointer to this descriptior.
	TChunkStatus (see page 3796)	TChunkStatus enumerates the possible states of a chunk of memory.
	TCVModInfo (see page 3797)	This is record System.TCVModInfo.
	TDispatchMessage (see page 3797)	This is record System.TDispatchMessage.
	TDispDesc (see page 3798)	This is record System.TDispDesc.
	TDynArrayTypeInfo (see page 3798)	This is record System.TDynArrayTypeInfo.
	TFileRec (see page 3799)	TFileRec is the internal format for typed and untyped files in the Delphi language.
	TGUID (see page 3800)	TGUID is a structured form of the value that uniquely identifies an interface.
	THeapBlock (see page 3802)	This is record System::THeapBlock.
	THeapStatus (see page 3802)	This is record System::THeapStatus.
	TInitContext (see page 3803)	This is record System.TInitContext.
	TInterfaceEntry (see page 3803)	TInterfaceTable (see page 3804) lists the interfaces that a class supports, and PInterfaceTable (see page 3839) points to this list.
	TInterfaceTable (see page 3804)	This is record System.TInterfaceTable.
	TLibModule (see page 3804)	This is record System::TLibModule.
	TMemoryManager (see page 3805)	This is record System::TMemoryManager.
	TMemoryManagerEx (see page 3805)	This is record System::TMemoryManagerEx.
	TMemoryManagerState (see page 3806)	This is record System::TMemoryManagerState.
	TMethod (see page 3806)	TMethod stores Code and Data fields to represent a method.
	TMinimumBlockAlignment (see page 3807)	TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.
	TModuleUnloadRec (see page 3808)	This is record System::TModuleUnloadRec.
	TMonitorSupport (see page 3808)	This is record System.TMonitorSupport.
	TResStringRec (see page 3809)	This is record System::TResStringRec.
	TRuntimeError (see page 3809)	This is record System.TRuntimeError.
	TSmallBlockTypeState (see page 3810)	This is record System::TSmallBlockTypeState.
	TTextLineBreakStyle (see page 3811)	TTextLineBreakStyle indicates the default set of characters used to divide lines in text.
	TTextRec (see page 3811)	TTextRec is the internal format for text files.
	TVarArray (see page 3812)	This is record System::TVarArray.
	TVarArrayBound (see page 3813)	This is record System::TVarArrayBound.
	TVarData (see page 3813)	TVarData represents Variant (see page 3430) information.
	TVariantManager (see page 3817)	This is record System::TVariantManager.
	TVarRec (see page 3819)	This is class System::TVarRec.
	TCallDesc (see page 3820)	This is type System::TCallDesc.
	TDispDesc (see page 3820)	This is type System::TDispDesc.

Types

Name	Description
CppLongInt (see page 3824)	This is type System.CppLongInt.
CppULongInt (see page 3825)	This is type System.CppULongInt.
GetPackageInfoTable (see page 3825)	This is type System.GetPackageInfoTable.
HGLOBAL (see page 3825)	This is type System.HGLOBAL.
HINST (see page 3826)	This is type System.HINST.
HMODULE (see page 3826)	This is type System.HMODULE.
HRESULT (see page 3826)	This is type System.HRESULT.
HRSRC (see page 3827)	This is type System.HRSRC.
Int16 (see page 3827)	This is type System.Int16.
Int32 (see page 3827)	This is type System.Int32.
Int8 (see page 3828)	This is type System.Int8.

IntegerArray (see page 3828)	This is type System.IntegerArray.
IUnknown (see page 3828)	IUnknown is a special base interface.
PackageInfo (see page 3829)	This is type System.PackageInfo.
PAnsiString (see page 3829)	PAnsiString is a pointer to an AnsiString variable.
PBoolean (see page 3829)	PBoolean is a pointer to a Boolean variable.
PByte (see page 3830)	PByte is a pointer to a Byte variable.
PCallDesc (see page 3830)	This is type System::PCallDesc.
PCardinal (see page 3831)	PCardinal is a pointer to a Cardinal variable.
PComp (see page 3831)	PComp is a pointer to a Comp variable.
PCurrency (see page 3831)	PCurrency is a pointer to a Currency (see page 3242) variable.
PCVModInfo (see page 3832)	This is type System.PCVModInfo.
PDate (see page 3832)	PDate is a pointer to a Date variable.
PDateTime (see page 3833)	PDateTime is a pointer to a TDateTime (see page 3335) variable.
PDispatch (see page 3833)	This is type System.PDispatch.
PDispDesc (see page 3833)	This is type System::PDispDesc.
PDouble (see page 3834)	PDouble is a pointer to a Double variable.
PDynArrayTypeInfo (see page 3834)	This is type System.PDynArrayTypeInfo.
PError (see page 3834)	This is type System.PError.
PExtended (see page 3835)	PExtended is a pointer to an Extended variable.
PGUID (see page 3835)	PGUID is a pointer to a TGUID (see page 3800) variable.
PInitContext (see page 3837)	This is type System.PInitContext.
PInt64 (see page 3837)	PInt64 is a pointer to an Int64 variable.
PInteger (see page 3837)	PInteger is a pointer to an Integer variable.
PIntegerArray (see page 3838)	PIntegerArray is a pointer to an IntegerArray (see page 3828) variable.
PInterfaceEntry (see page 3838)	PInterfaceEntry is a pointer to a TInterfaceEntry (see page 3803) variable.
PInterfaceTable (see page 3839)	PInterfaceTable is a pointer to a TInterfaceTable (see page 3804) variable.
PLibModule (see page 3839)	PLibModule is a pointer to a TLibModule (see page 3804) variable.
PLongint (see page 3839)	This is type System.PLongint.
PLongWord (see page 3840)	PLongWord is a pointer to a LongWord variable.
PMemoryManager (see page 3840)	This is type System::PMemoryManager.
PMemoryManagerEx (see page 3840)	This is type System::PMemoryManagerEx.
PModuleUnloadRec (see page 3841)	This is type System::PModuleUnloadRec.
PMonitor (see page 3841)	This is type System.PMonitor.
PMonitorSupport (see page 3841)	This is type System.PMonitorSupport.
PointerArray (see page 3842)	This is type System.PointerArray.
POleVariant (see page 3842)	This is type System.POleVariant.
PPAnsiChar (see page 3842)	This is type System.PPAnsiChar.
PPCharArray (see page 3843)	This is type System.PPCharArray.
PPDispatch (see page 3843)	This is type System.PPDispatch.
PPMonitor (see page 3843)	This is type System.PPMonitor.
PPointer (see page 3844)	PPointer is a pointer to a Pointer variable.
PPointerArray (see page 3844)	PPointerArray is a pointer to a PointerArray (see page 3842) variable.
PPUnknown (see page 3844)	This is type System.PPUnknown.
PPWideChar (see page 3845)	This is type System.PPWideChar.
PRawByteString (see page 3845)	This is type System.PRawByteString.
PResStringRec (see page 3845)	This is type System::PResStringRec.
PShortInt (see page 3846)	PShortInt is a pointer to a ShortInt variable.
PShortString (see page 3846)	PShortString is a pointer to a ShortString variable.
PSingle (see page 3846)	PSingle is a pointer to a Single variable.
PSmallBlockTypeState (see page 3847)	This is type System::PSmallBlockTypeState.
PSmallInt (see page 3847)	PSmallInt is a pointer to a SmallInt variable.
PTextBuf (see page 3848)	This is type System.PTextBuf.
PUCS4Char (see page 3848)	This is type System.PUCS4Char.
PUCS4CharArray (see page 3848)	This is type System.PUCS4CharArray.

PUInt64 (see page 3849)	This is type System.PUInt64.
PUnicodeString (see page 3849)	This is type System.PUnicodeString.
PUnitEntryTable (see page 3849)	This is type System.PUnitEntryTable.
PUnknown (see page 3850)	PUnknown is a pointer to an IUnknown (see page 3828) variable.
PUTF8String (see page 3850)	This is type System.PUTF8String.
PVarArray (see page 3850)	This is type System.PVarArray.
PVarArrayBoundArray (see page 3851)	This is type System.PVarArrayBoundArray.
PVarArrayCoorArray (see page 3851)	This is type System.PVarArrayCoorArray.
PVarData (see page 3851)	This is type System.PVarData.
PVariant (see page 3852)	PVariant is a pointer to a Variant (see page 3430) variable.
PVariantManager (see page 3852)	This is type System::PVariantManager.
PVarRec (see page 3852)	This is type System::PVarRec.
PWideString (see page 3853)	PWideString is a pointer to a WideString (see page 3476) variable.
PWord (see page 3853)	PWord is a pointer to a Word variable.
PWordBool (see page 3853)	PWordBool is a pointer to a WordBool variable.
RawByteString (see page 3854)	RawByteString enables the passing of string data of any code page without doing any codepage conversions.
ResourceString (see page 3854)	This is type System::ResourceString.
TAssertErrorProc (see page 3855)	This is type System.TAssertErrorProc.
TBooleanDynArray (see page 3855)	This is type System::TBooleanDynArray.
TBoundArray (see page 3855)	This is type System.TBoundArray.
TByteDynArray (see page 3856)	This is type System::TByteDynArray.
TCardinalDynArray (see page 3856)	This is type System::TCardinalDynArray.
TClass (see page 3856)	TClass defines the metaclass for System::TObject (see page 3364).
TClassHelperBaseClass (see page 3857)	This is type System.TClassHelperBaseClass.
TDate (see page 3857)	This is type System.TDate.
TDateTime (see page 3858)	TDateTime represents a date-and-time value in the Delphi language.
TDLLProc (see page 3859)	This is type System.TDLLProc.
TDLLProcEx (see page 3859)	This is type System.TDLLProcEx.
TDoubleDynArray (see page 3859)	This is type System::TDoubleDynArray.
TEnumModuleFunc (see page 3860)	This is type System.TEnumModuleFunc.
TEnumModuleFuncLW (see page 3860)	This is type System.TEnumModuleFuncLW.
TFileIOFunc (see page 3860)	This is type System.TFileIOFunc.
TInt64DynArray (see page 3861)	This is type System::TInt64DynArray.
TIntegerDynArray (see page 3861)	This is type System::TIntegerDynArray.
TInterfacedClass (see page 3861)	TInterfacedClass defines the metaclass for TInterfacedObject (see page 3355).
TLongWordDynArray (see page 3862)	This is type System::TLongWordDynArray.
TMemoryMap (see page 3862)	TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 3796) values.
TModuleUnloadProc (see page 3863)	TModuleUnloadProc dehines a procedure that can be called during package unload.
TModuleUnloadProcLW (see page 3863)	This is type System.TModuleUnloadProcLW.
TPCharArray (see page 3863)	This is type System.TPCharArray.
TResourceHandle (see page 3864)	This is type System.TResourceHandle.
TSafeCallErrorProc (see page 3864)	This is type System.TSafeCallErrorProc.
TShortIntDynArray (see page 3864)	This is type System::TShortIntDynArray.
TSingleDynArray (see page 3865)	This is type System::TSingleDynArray.
TSmallBlockTypeStates (see page 3865)	This is type System::TSmallBlockTypeStates.
TSmallIntDynArray (see page 3865)	This is type System::TSmallIntDynArray.
TStringDynArray (see page 3866)	This is type System::TStringDynArray.
TSystemThreadEndProc (see page 3866)	This is type System.TSystemThreadEndProc.
TSystemThreadFuncProc (see page 3866)	This is type System.TSystemThreadFuncProc.
TTextBuf (see page 3867)	This is type System.TTextBuf.
TTextIOFunc (see page 3867)	This is type System.TTextIOFunc.
TThreadFunc (see page 3867)	This is type System::TThreadFunc.

TTime (see page 3868)	This is type System.TTime.
TUCS4CharArray (see page 3868)	This is type System.TUCS4CharArray.
TVarArrayBoundArray (see page 3868)	This is type System.TVarArrayBoundArray.
TVarArrayCoorArray (see page 3869)	This is type System.TVarArrayCoorArray.
TVarOp (see page 3869)	TVarOp defines a Variant (see page 3430) operation.
TWideStringDynArray (see page 3870)	This is type System::TWideStringDynArray.
TWordDynArray (see page 3870)	This is type System::TWordDynArray.
UCS4Char (see page 3871)	UCS4Char is used for working with 4–byte Unicode characters.
UCS4String (see page 3871)	UCS4String is used for working with 4–byte Unicode characters.
UInt16 (see page 3872)	This is type System.UInt16.
UInt32 (see page 3872)	This is type System.UInt32.
UInt8 (see page 3872)	This is type System.UInt8.
UnitEntryTable (see page 3873)	This is type System.UnitEntryTable.
UTF8String (see page 3873)	UTF8String represents UTF-8 encoded Unicode strings.

Variables

Name	Description
AbstractErrorProc (see page 3875)	AbstractErrorProc defines a callback routine for abstract method call errors.
AllocMemCount (see page 3875)	Represents the total number of allocated memory blocks in a Delphi application.
AllocMemSize (see page 3877)	Represents the total size of allocated memory blocks.
AssertErrorProc (see page 3878)	Points to the assertion error-handler.
CmdLine (see page 3880)	Points to the command-line arguments specified when the application is invoked.
CmdShow (see page 3880)	Specifies the flags for displaying the application's main window.
CPUCount (see page 3881)	This is variable System.CPUCount.
DebugHook (see page 3881)	DebugHook is set if an application is running under the IDE debugger.
Default8087CW (see page 3881)	Specifies the Default 8087 control word.
DefaultSystemCodePage (see page 3883)	This is variable System.DefaultSystemCodePage.
DefaultTextLineBreakStyle (see page 3883)	Specifies the characters that are used by default to separate lines in text.
DefaultUnicodeCodePage (see page 3884)	This is variable System.DefaultUnicodeCodePage.
DispCallByIDProc (see page 3884)	This is variable System.DispCallByIDProc.
DLLProc (see page 3884)	Points to a procedure invoked by a DLL entry point.
envp (see page 3885)	This is variable System.envp.
ErrorAddr (see page 3885)	Contains the address of a statement causing a runtime error.
ErrorProc (see page 3886)	Points to the RTL runtime error handler.
ErrOutput (see page 3888)	ErrOutput specifies a write-only Text file associated with the process's error output file.
ExceptClsProc (see page 3888)	ExceptClsProc defines a pointer to a function called during exception handling.
ExceptionAcquired (see page 3889)	This is variable System.ExceptionAcquired.
ExceptionClass (see page 3889)	This is variable System.ExceptionClass.
ExceptObjProc (see page 3889)	ExceptObjProc defines a pointer to a function called during exception handling.
ExceptProc (see page 3890)	Points to the lowest-level exception handler.
ExitCode (see page 3891)	Contains the application's exit code.
ExitProc (see page 3891)	Points to a program's exit procedure (provided for backward compatibility).
ExitProcessProc (see page 3892)	Specifies the last procedure to execute before the application shuts down.
FileMode (see page 3892)	Indicates the access mode on typed and untyped files opened by the Reset (see page 3734) procedure.
HeapAllocFlags (see page 3893)	Indicates how the memory manager obtains memory from the operating system.
HPrevInst (see page 3894)	This is variable System.HPrevInst.
InitProc (see page 3894)	InitProc is the last installed initialization procedure.
Input (see page 3895)	Specifies a read-only Text file associated with the processes standard Input file.
IsConsole (see page 3896)	Indicates whether the module was compiled as a console application.
IsLibrary (see page 3896)	Indicates whether the module is a shared library.
IsMultiThread (see page 3897)	Indicates whether the application spawned additional threads using BeginThread (see page 3632) or TThread objects.
JITEnable (see page 3897)	Controls when the just-in-time debugger is called.

LibModuleList (see page 3898)	Lists module records for enumeration procedures.
MainInstance (see page 3898)	Indicates the instance handle for the main executable.
MainThreadID (see page 3899)	Indicates the instance handle for the current module's main thread of execution.
ModuleUnloadList (see page 3899)	This is variable System.ModuleUnloadList.
MonitorSupport (see page 3900)	This is variable System.MonitorSupport.
NeverSleepOnMMThreadContention (see page 3900)	Dictates memory manager behavior during a thread contention.
NoErrMsg (see page 3901)	Controls whether the application displays an error message when a runtime error occurs.
Output (see page 3901)	Specifies a write-only Text file associated with the process's standard output file.
RaiseExceptionProc (see page 3902)	Points to RaiseException Windows function.
RaiseExceptObjProc (see page 3902)	This is variable System.RaiseExceptObjProc.
RandSeed (see page 3902)	RandSeed stores the built-in random number generator's seed.
ReportMemoryLeaksOnShutdown (see page 3903)	Report memory leaks on shutdown.
RTLUnwindProc (see page 3903)	This is variable System.RTLUnwindProc.
SafeCallErrorProc (see page 3904)	SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.
SystemThreadEndProc (see page 3904)	This is variable System.SystemThreadEndProc.
SystemThreadFuncProc (see page 3905)	This is variable System.SystemThreadFuncProc.
Test8086 (see page 3905)	This is variable System.Test8086.
Test8087 (see page 3905)	This is variable System.Test8087.
TestFDIV (see page 3906)	This is variable System.TestFDIV.
UTF8CompareLocale (see page 3906)	This is variable System.UTF8CompareLocale.
VarAddRefProc (see page 3906)	This is variable System.VarAddRefProc.
VarClearProc (see page 3907)	This is variable System.VarClearProc.
VarCopyProc (see page 3907)	This is variable System.VarCopyProc.
VarToLStrProc (see page 3907)	This is variable System.VarToLStrProc.
VarToWStrProc (see page 3908)	This is variable System.VarToWStrProc.

38.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	AnsiStringBase (see page 3185)	System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.
	Currency (see page 3242)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 3262)	This is class System::CurrencyBase.
	DynArrayException (see page 3279)	This is class System::DynArrayException.
	DynArrayNullData (see page 3279)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 3279)	This is class System::DynArrayOutOfRange.
	OleVariant (see page 3281)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	TAggregatedObject (see page 3328)	This is class System::TAggregatedObject.
	TClassHelperBase (see page 3331)	This is class System.TClassHelperBase.
	TContainedObject (see page 3333)	This is class System::TContainedObject.
	TDateTime (see page 3335)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.
	TDateTimeBase (see page 3354)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 3355)	This is class System::TInterfacedObject.
	TMetaClass (see page 3360)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TObject (see page 3364)	System::TObject is the ultimate ancestor of all objects and components.
	UnicodeString (see page 3393)	System::UnicodeString is the C++ analog for the Delphi UnicodeString type.
	Variant (see page 3430)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	WideString (see page 3476)	System::WideString represents strings of 16-bit characters.

Records

	Name	Description
	TMonitor (see page 3361)	This is class System.TMonitor.

Templates

	Name	Description
	AnsiStringT (see page 3219)	System::AnsiStringT is the C++ analog for the Delphi long string type.
	DelphiInterface (see page 3263)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 3268)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	SmallString (see page 3322)	This is class System::SmallString.
	SmallStringBase (see page 3324)	This is class System::SmallStringBase.
	sPointer (see page 3326)	This is class System::sPointer.

38.1.1 AnsiStringBase Class

System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.

Class Hierarchy

System::AnsiStringBase

Pascal

```
AnsiStringBase = class;
```

C++

```
class AnsiStringBase;
```

File

dstring.h

Description

System::AnsiStringBase exists to provide a place for methods/members that are common to all instantiations of the template class AnsiStringT (see page 3219)<CodePage (see page 3199)>. AnsiString itself is a typedef that is equivalent to AnsiStringT (see page 3219)<0>. You should never deal directly with System::AnsiStringBase.

System::AnsiStringT (see page 3219) is a template class that you use when handling a Delphi AnsiString that has a code page specified with it.

Delphi uses several string types. One important long string type is commonly known as System::AnsiString. Support for this type includes the following features:

- strings can be as large as available memory
- efficient use of memory is ensured through shared references
- routines and operators evaluate strings based on the current locale

Despite its name, System::AnsiStringBase is not restricted to the ANSI character set, and can use any character set supported by the current locale definition, including multi-byte and Unicode character sets.

System::AnsiStringBase variables that have not been assigned an initial value contain a zero-length string.

To use the C++ streaming operators (**<<** and **>>**) with System::AnsiStringBase, you must `iostream` before including `system.hpp` and use `AnsiStringT::c_str()` to return the internal string representation. The following example demonstrates the usage of AnsiString with stream operators:

```
#include <iostream>
#include <system.hpp>
int main() {
  AnsiString HelloStr = "hello";
  std::cout << HelloStr.c_str();
}
```

Note: Delphi also supports System::AnsiString, but implements it as a primitive type rather than a class.

UnicodeString (see page 3393) has become the default string type. By default, variables declared as type String are System::UnicodeString (see page 3393).

System::AnsiStringBase::> (see page 3218)

System::AnsiStringBase::>= (see page 3218)

System::AnsiStringBase::< (see page 3216)

System::AnsiStringBase::<= (see page 3217)

System::AnsiStringBase::+ (see page 3216)

System::AnsiStringT::+= (see page 3240)

38.1.1.1 AnsiStringBase Members

The following tables list the members exposed by AnsiStringBase.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3193)	This is record System::AnsiStringBase::TStringFloatFormat.
	TStringMbcsByteType (see page 3193)	This is record System::AnsiStringBase::TStringMbcsByteType.

Structures

	Name	Description
	StrRec (see page 3192)	This is record System::AnsiStringBase::StrRec.

Protected Data Members

	Name	Description
	Data (see page 3194)	This is Data, a member of class AnsiStringBase.

Protected Methods

	Name	Description
	_AnsiCat (see page 3195)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3196)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiCompare (see page 3196)	Compares the System::AnsiStringBase::AnsiString to another specified string (case-sensitively).
	AnsiCompareIC (see page 3197)	Compares the System::AnsiStringBase::AnsiString to another specified string (case insensitively).
	AnsiStringBase (see page 3189)	This is the overview for the AnsiStringBase constructor overload.
	GetRec (see page 3204)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3211)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Protected Operators

	Name	Description
	!= (see page 3215)	Compares two strings.
	< (see page 3216)	Compares two strings.
	<= (see page 3217)	Compares two strings.
	= (see page 3217)	Assigns the string rhs to this System::AnsiStringBase::AnsiString.
	== (see page 3218)	Compares the System::AnsiStringBase::AnsiString with a specified string, returning true if they are the same.
	> (see page 3218)	Compares two strings.
	>= (see page 3218)	Compares two strings.

Public Methods

	Name	Description
	~AnsiStringBase (see page 3189)	This is ~AnsiStringBase, a member of class AnsiStringBase.
	AnsiLastChar (see page 3197)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiString.
	AnsiPos (see page 3197)	Returns the index at which the specified substring begins.
	BytesOf (see page 3198)	This is BytesOf, a member of class AnsiStringBase.

	ByteType (see page 3198)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase::AnsiString.
	cat_vprintf (see page 3199)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiString.
	CodePage (see page 3199)	Gets code page of a System::AnsiStringBase (see page 3185).
	CurrToStr (see page 3199)	Converts a currency value to its string representation.
	CurrToStrF (see page 3200)	Converts a currency value to its string representation using the indicated float format convention.
	Delete (see page 3200)	Removes a specified number of characters from the string.
	ElementSize (see page 3200)	Gets element size of data in a System::AnsiStringBase (see page 3185).
	EnsureAnsi (see page 3201)	This is EnsureAnsi, a member of class AnsiStringBase.
	FloatToStrF (see page 3201)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3202)	Formats output using a resourced format string.
	Format (see page 3202)	System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase::AnsiString, format, and a series of array arguments, args.
	FormatFloat (see page 3203)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3205)	System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase::AnsiString.
	IntToHex (see page 3205)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3206)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3206)	Returns true if the System::AnsiStringBase::AnsiString is empty.
	IsLeadByte (see page 3206)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3206)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3207)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3207)	This is LastChar, a member of class AnsiStringBase.
	LastDelimiter (see page 3207)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3208)	Returns the length of the System::AnsiStringBase::AnsiString.
	LoadStr (see page 3208)	This is the overview for the LoadStr method overload.
	LoadString (see page 3209)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3209)	Returns a lower-case version of System::AnsiStringBase::AnsiString.
	Pos (see page 3209)	Returns the index at which a specified substring begins.
	RefCount (see page 3210)	Gets reference count of System::AnsiStringBase (see page 3185).
	SetLength (see page 3210)	Changes the length of the System::AnsiStringBase::AnsiString.
	StringOfChar (see page 3210)	Returns a string with the specified number of characters.
	SubString (see page 3211)	Returns a specified substring of the System::AnsiStringBase::AnsiString.
	swap (see page 3211)	This is swap, a member of class AnsiStringBase.
	ToDouble (see page 3211)	Converts the string to a floating-point value.
	ToInt (see page 3212)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3212)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3212)	Returns a new System::AnsiStringBase::AnsiString without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3212)	Returns a new System::AnsiStringBase::AnsiString without leading spaces or control characters.
	TrimRight (see page 3213)	Returns a new System::AnsiStringBase::AnsiString without trailing spaces or control characters.
	Unique (see page 3213)	Makes the System::AnsiStringBase::AnsiString unique.
	UpperCase (see page 3213)	Returns an upper-case version of this System::AnsiStringBase::AnsiString.
	vprintf (see page 3214)	Sets the value of the System::AnsiStringBase::AnsiString given a format string and its arguments.
	WideChar (see page 3214)	Converts the System::AnsiStringBase::AnsiString to a wide-character array.
	WideCharBufSize (see page 3214)	Returns the size of the buffer required by the WideChar (see page 3214) function.

Public Operators

	Name	Description
	[] (see page 3216)	This is the overview for the [] operator overload.
	+ (see page 3216)	Concatenates two System::AnsiStringBase::AnsiString values.

38.1.1.2 AnsiStringBase::~AnsiStringBase Destructor

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~AnsiStringBase();
```

Description

This is ~AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3 AnsiStringBase Constructor

This is the overview for the AnsiStringBase constructor overload.

Overload List

	Name	Description
	AnsiStringBase::AnsiStringBase () (see page 3190)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (AnsiStringBase&) (see page 3190)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (char*, int) (see page 3190)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (char*, int, int) (see page 3191)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (char16_t*, int, int) (see page 3191)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (char32_t*, int, int) (see page 3191)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (double, int) (see page 3191)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (UnicodeString &, int) (see page 3190)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (wchar_t*, int, int) (see page 3192)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (wchar_t, int) (see page 3192)	This is AnsiStringBase, a member of class AnsiStringBase.
	AnsiStringBase::AnsiStringBase (WideString &, int) (see page 3190)	This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.1 AnsiStringBase::AnsiStringBase Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall AnsiStringBase();
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.2 AnsiStringBase::AnsiStringBase Constructor (AnsiStringBase&)

Pascal

```
constructor Create(const src: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringBase(const AnsiStringBase& src);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.3 AnsiStringBase::AnsiStringBase Constructor (UnicodeString &, int)

Pascal

```
constructor Create(const src: UnicodeString &; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const UnicodeString & src, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.4 AnsiStringBase::AnsiStringBase Constructor (WideString &, int)

Pascal

```
constructor Create(const src: WideString &; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const WideString & src, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.5 AnsiStringBase::AnsiStringBase Constructor (char*, int)

Pascal

```
constructor Create(const src: char*; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const char* src, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.6 AnsiStringBase::AnsiStringBase Constructor (char*, int, int)

Pascal

```
constructor Create(const src: char*; byteLen: Integer; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const char* src, int byteLen, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.7 AnsiStringBase::AnsiStringBase Constructor (char16_t*, int, int)

Pascal

```
constructor Create(const src: char16_t*; numChar16: Integer; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const char16_t* src, int numChar16, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.8 AnsiStringBase::AnsiStringBase Constructor (char32_t*, int, int)

Pascal

```
constructor Create(const src: char32_t*; numChar32: Integer; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const char32_t* src, int numChar32, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.9 AnsiStringBase::AnsiStringBase Constructor (double, int)

Pascal

```
constructor Create(src: double; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(double src, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.10 AnsiStringBase::AnsiStringBase Constructor (wchar_t, int)

Pascal

```
constructor Create(src: wchar_t; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(wchar_t src, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.3.11 AnsiStringBase::AnsiStringBase Constructor (wchar_t*, int, int)

Pascal

```
constructor Create(const src: wchar_t*; numwchar: Integer; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase(const wchar_t* src, int numwchar, int codePage);
```

Description

This is AnsiStringBase, a member of class AnsiStringBase.

38.1.1.4 AnsiStringBase Structures

The structures of the AnsiStringBase class are listed here.

Structures

	Name	Description
	StrRec (see page 3192)	This is record System::AnsiStringBase::StrRec.

38.1.1.4.1 System::AnsiStringBase::StrRec Structure

Pascal

```
StrRec = record
  codePage: unsigned short;
  elemSize: unsigned short;
  refCnt: Integer;
  length: Integer;
end;
```

C++

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

File

dstring.h

Description

This is record System::AnsiStringBase::StrRec.

38.1.1.5 AnsiStringBase Enumerations

The enumerations of the AnsiStringBase class are listed here.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3193)	This is record System::AnsiStringBase::TStringFloatFormat.
	TStringMbcsByteType (see page 3193)	This is record System::AnsiStringBase::TStringMbcsByteType.

38.1.1.5.1 System::AnsiStringBase::TStringFloatFormat Enumeration

Pascal

```
TStringFloatFormat = (
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
);
```

C++

```
enum TStringFloatFormat {
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
};
```

File

dstring.h

Description

This is record System::AnsiStringBase::TStringFloatFormat.

38.1.1.5.2 System::AnsiStringBase::TStringMbcsByteType Enumeration

Pascal

```
TStringMbcsByteType = (
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
);
```

C++

```
enum TStringMbcsByteType {
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
};
```

File

dstring.h

Description

This is record System::AnsiStringBase::TStringMbcsByteType.

38.1.1.6 AnsiStringBase Data Members

The data members of the AnsiStringBase class are listed here.

Protected Data Members

	Name	Description
	Data (see page 3194)	This is Data, a member of class AnsiStringBase.

38.1.1.6.1 AnsiStringBase::Data Data Member

Pascal

```
Data: char *;
```

C++

```
char * Data;
```

Description

This is Data, a member of class AnsiStringBase.

38.1.1.7 AnsiStringBase Methods

The methods of the AnsiStringBase class are listed here.

Protected Methods

	Name	Description
	_AnsiCat (see page 3195)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3196)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiCompare (see page 3196)	Compares the System::AnsiStringBase::AnsiString to another specified string (case-sensitively).
	AnsiCompareIC (see page 3197)	Compares the System::AnsiStringBase::AnsiString to another specified string (case insensitively).
	GetRec (see page 3204)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3211)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Public Methods

	Name	Description
	AnsiLastChar (see page 3197)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiString.
	AnsiPos (see page 3197)	Returns the index at which the specified substring begins.
	BytesOf (see page 3198)	This is BytesOf, a member of class AnsiStringBase.
	ByteType (see page 3198)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase::AnsiString.
	cat_vprintf (see page 3199)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiString.
	CodePage (see page 3199)	Gets code page of a System::AnsiStringBase (see page 3185).
	CurrToStr (see page 3199)	Converts a currency value to its string representation.
	CurrToStrF (see page 3200)	Converts a currency value to its string representation using the indicated float format convention.
	Delete (see page 3200)	Removes a specified number of characters from the string.

	ElementSize (see page 3200)	Gets element size of data in a System::AnsiStringBase (see page 3185).
	EnsureAnsi (see page 3201)	This is EnsureAnsi, a member of class AnsiStringBase.
	FloatToStrF (see page 3201)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3202)	Formats output using a resourced format string.
	Format (see page 3202)	System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase::AnsiString, format, and a series of array arguments, args.
	FormatFloat (see page 3203)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3205)	System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase::AnsiString.
	IntToHex (see page 3205)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3206)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3206)	Returns true if the System::AnsiStringBase::AnsiString is empty.
	IsLeadByte (see page 3206)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3206)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3207)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3207)	This is LastChar, a member of class AnsiStringBase.
	LastDelimiter (see page 3207)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3208)	Returns the length of the System::AnsiStringBase::AnsiString.
	LoadStr (see page 3208)	This is the overview for the LoadStr method overload.
	LoadString (see page 3209)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3209)	Returns a lower-case version of System::AnsiStringBase::AnsiString.
	Pos (see page 3209)	Returns the index at which a specified substring begins.
	RefCount (see page 3210)	Gets reference count of System::AnsiStringBase (see page 3185).
	SetLength (see page 3210)	Changes the length of the System::AnsiStringBase::AnsiString.
	StringOfChar (see page 3210)	Returns a string with the specified number of characters.
	SubString (see page 3211)	Returns a specified substring of the System::AnsiStringBase::AnsiString.
	swap (see page 3211)	This is swap, a member of class AnsiStringBase.
	ToDouble (see page 3211)	Converts the string to a floating-point value.
	ToInt (see page 3212)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3212)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3212)	Returns a new System::AnsiStringBase::AnsiString without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3212)	Returns a new System::AnsiStringBase::AnsiString without leading spaces or control characters.
	TrimRight (see page 3213)	Returns a new System::AnsiStringBase::AnsiString without trailing spaces or control characters.
	Unique (see page 3213)	Makes the System::AnsiStringBase::AnsiString unique.
	UpperCase (see page 3213)	Returns an upper-case version of this System::AnsiStringBase::AnsiString.
	vprintf (see page 3214)	Sets the value of the System::AnsiStringBase::AnsiString given a format string and its arguments.
	WideChar (see page 3214)	Converts the System::AnsiStringBase::AnsiString to a wide-character array.
	WideCharBufSize (see page 3214)	Returns the size of the buffer required by the WideChar (see page 3214) function.

38.1.1.7.1 _AnsiCat Method

This is the overview for the _AnsiCat method overload.

Overload List

	Name	Description
	AnsiStringBase::_AnsiCat (AnsiStringBase&, AnsiStringBase&) (see page 3196)	This is _AnsiCat, a member of class AnsiStringBase.

	AnsiStringBase::_AnsiCat (AnsiStringBase&, AnsiStringBase&, AnsiStringBase&) (see page 3196)	This is _AnsiCat, a member of class AnsiStringBase.

38.1.1.7.1.1 AnsiStringBase::_AnsiCat Method (AnsiStringBase&, AnsiStringBase&)

Pascal

```
procedure _AnsiCat(var dst: AnsiStringBase; const src: AnsiStringBase&); static;
```

C++

```
static __fastcall void _AnsiCat(AnsiStringBase& dst, const AnsiStringBase& src);
```

Description

This is _AnsiCat, a member of class AnsiStringBase.

38.1.1.7.1.2 AnsiStringBase::_AnsiCat Method (AnsiStringBase&, AnsiStringBase&, AnsiStringBase&)

Pascal

```
procedure _AnsiCat(var dst: AnsiStringBase; const src1: AnsiStringBase&; const src2:
AnsiStringBase&); static;
```

C++

```
static __fastcall void _AnsiCat(AnsiStringBase& dst, const AnsiStringBase& src1, const
AnsiStringBase& src2);
```

Description

This is _AnsiCat, a member of class AnsiStringBase.

38.1.1.7.2 AnsiStringBase::_AnsiFromPWChar Method

Pascal

```
procedure _AnsiFromPWChar(var dst: AnsiStringBase; const src: wchar_t*; len: Integer;
codePage: Integer); static;
```

C++

```
static __fastcall void _AnsiFromPWChar(AnsiStringBase& dst, const wchar_t* src, int len, int
codePage);
```

Description

This is _AnsiFromPWChar, a member of class AnsiStringBase.

38.1.1.7.3 AnsiStringBase::AnsiCompare Method

Compares the System::AnsiStringBase::AnsiString to another specified string (case-sensitively).

Pascal

```
function AnsiCompare(const rhs: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiCompare(const AnsiStringBase& rhs) const;
```

Description

Compares this System::AnsiStringBase::AnsiString to rhs, with case sensitivity. The compare operation is controlled by the current Windows locale and is not necessarily the same as using the System::AnsiStringBase::AnsiString comparison operators. System::AnsiStringBase::AnsiCompare is based on a locale-specific collating order. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

38.1.1.7.4 AnsiStringBase::AnsiCompareIC Method

Compares the System::AnsiStringBase::AnsiString to another specified string (case insensitively).

Pascal

```
function AnsiCompareIC(const rhs: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiCompareIC(const AnsiStringBase& rhs) const;
```

Description

System::AnsiStringBase::AnsiCompareIC compares this System::AnsiStringBase::AnsiString to rhs, without case sensitivity. The compare operation is controlled by the current Windows locale. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

38.1.1.7.5 AnsiStringBase::AnsiLastChar Method

Returns a pointer to the last full character in the System::AnsiStringBase::AnsiString.

Pascal

```
function AnsiLastChar: char*;
```

C++

```
__fastcall char* AnsiLastChar() const;
```

Description

Returns a pointer to the last full character in the System::AnsiStringBase::AnsiString. This function supports multibyte characters.

See Also

System::AnsiStringBase::ByteType (see page 3198)

38.1.1.7.6 AnsiStringBase::AnsiPos Method

Returns the index at which the specified substring begins.

Pascal

```
function AnsiPos(const subStr: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiPos(const AnsiStringBase& subStr) const;
```

Description

Returns the index in the System::AnsiStringBase::AnsiString at which the substring subStr begins, where 1 is the first character in the string, 2 is the second character, and so on. If the substring is not contained in the System::AnsiStringBase::AnsiString, Pos (see page 3209) returns 0. This member function is the same as Pos (see page 3209) but supports multibyte character strings.

Note: See ByteType (see page 3198) for more information about multibyte characters.

See Also

System::AnsiStringBase::ByteType (see page 3198)

38.1.1.7.7 AnsiStringBase::BytesOf Method

Pascal

```
function BytesOf: DynamicArray<System::Byte>;
```

C++

```
__fastcall DynamicArray<System::Byte> BytesOf() const;
```

Description

This is BytesOf, a member of class AnsiStringBase.

38.1.1.7.8 AnsiStringBase::ByteType Method

Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase::AnsiString.

Pascal

```
function ByteType(index: Integer): TStringMbcsByteType;
```

C++

```
__fastcall TStringMbcsByteType ByteType(int index) const;
```

Description

System::AnsiStringBase::ByteType indicates what kind of byte exists at the byte indicated by index (counting from 0) in the System::AnsiStringBase::AnsiString. These are the possible return values.

Constant	Meaning
mbSingleByte	Single byte character.
mbLeadByte	Lead byte of a multi-byte character.
mbTrailByte	Trailing byte of a multi-byte character.

Some locales, including all Western locales, do not use multi-byte characters. Under those locales, System::AnsiStringBase::ByteType always returns mbSingleByte.

38.1.1.7.9 AnsiStringBase::cat_vprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiString.

Pascal

```
function cat_vprintf(codePage: Integer; const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(int codePage, const char* format, va_list);
```

Description

Use cat_System::AnsiStringBase::cat_vprintf to append to the value of the System::AnsiStringBase::AnsiString given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the number of bytes appended to the System::AnsiStringBase::AnsiString.

See Also

System::AnsiStringBase::Format (see page 3202)

System::AnsiStringBase::cat_vprintf

System::AnsiStringBase::cat_printf

System::AnsiStringBase::cat_sprintf

arg

start

38.1.1.7.10 AnsiStringBase::CodePage Method

Gets code page of a System::AnsiStringBase (see page 3185).

Pascal

```
function CodePage: unsigned short;
```

C++

```
unsigned short CodePage() const;
```

Description

System::AnsiStringBase::CodePage gets the code page of a System::AnsiStringBase (see page 3185) instance. If the instance is empty, it returns the system default code page, System::DefaultSystemCodePage (see page 3883).

See Also

System::AnsiStringBase::GetRec (see page 3204)

38.1.1.7.11 AnsiStringBase::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase CurrToStr(Currency value, int codePage);
```

Description

System::AnsiStringBase::CurrToStr converts the currency value given by value to its string representation. The conversion using the sffGeneral floating-point conversion rules. For further details, see System::AnsiStringBase::CurrToStrF (see page 3200).

See Also

System::AnsiStringBase::CurrToStrF (see page 3200)

38.1.1.7.12 AnsiStringBase::CurrToStrF Method

Converts a currency value to its string representation using the indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase CurrToStrF(Currency value, TStringFloatFormat format, int
digits, int codePage);
```

Description

System::AnsiStringBase::CurrToStrF converts the currency value given by value to its string representation using the indicated float format convention. A call to System::AnsiStringBase::CurrToStrF corresponds to a call to FloatToStrF (see page 3201) with an implied precision of 19 digits.

38.1.1.7.13 AnsiStringBase::Delete Method

Removes a specified number of characters from the string.

Pascal

```
function Delete(index: Integer; count: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Delete(int index, int count);
```

Description

System::AnsiStringBase::Delete modifies the System::AnsiStringBase::AnsiString to remove count characters from the string beginning with the character at index, where 1 is the index of the first character. It returns the resulting modified string (*this).

If index is larger than the length of the System::AnsiStringBase::AnsiString or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, System::AnsiStringBase::Delete removes the rest of the string. If count is less than 0, no characters are deleted.

38.1.1.7.14 AnsiStringBase::ElementSize Method

Gets element size of data in a System::AnsiStringBase (see page 3185).

Pascal

```
function ElementSize: unsigned short;
```

C++

```
unsigned short ElementSize() const;
```

Description

System::AnsiStringBase::ElementSize gets the element size in bytes of the data in a System::AnsiStringBase (see page 3185) instance. If the instance is empty, this returns 1.

See Also

System::AnsiStringBase::data

System::AnsiStringBase::GetRec (see page 3204)

38.1.1.7.15 AnsiStringBase::EnsureAnsi Method

Pascal

```
function EnsureAnsi: AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& EnsureAnsi();
```

Description

This is EnsureAnsi, a member of class AnsiStringBase.

38.1.1.7.16 AnsiStringBase::FloatToStrF Method

Returns the string representation of a floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits, int codePage);
```

Description

The format parameter controls the format of the resulting string. The precision parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the digits parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).

sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3242) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3242) Format (see page 3202) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator and ThousandSeparator global variables.

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

38.1.1.7.17 AnsiStringBase::FmtLoadStr Method

Formats output using a resourced format string.

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer; codePage: Integer):
AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FmtLoadStr(int ident, const TVarRec * args, int size, int
codePage);
```

Description

System::AnsiStringBase::FmtLoadStr loads a string from a program's resource string table and uses that string, plus the args array, as a parameter to Format (see page 3202). Ident is the string resource ID of the desired format string.

See Also

System::AnsiStringBase::LoadString (see page 3209)

System::AnsiStringBase::LoadStr (see page 3208)

38.1.1.7.18 AnsiStringBase::Format Method

System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase::AnsiString, format, and a series of array arguments, args.

Pascal

```
function Format(const format: AnsiStringBase&; const args: TVarRec *; size: Integer; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase Format(const AnsiStringBase& format, const TVarRec * args,
int size, int codePage);
```

Description

Use System::AnsiStringBase::Format to obtain an System::AnsiStringBase::AnsiString whose value is the result of applying an

array of arguments (args) to a given a format string (format). The last parameter (size) is the index of the last element in args (one less than the number of arguments).

Note that System::AnsiStringBase::Format is a static method. The returned value is a newly allocated System::AnsiStringBase::AnsiString, even if the method is called from an existing System::AnsiStringBase::AnsiString instance.

For information on how System::AnsiStringBase::Format assembles a final string from its format string and arguments, see System::AnsiStringBase::Format Strings.

See Also

System::AnsiStringBase::printf

System::AnsiStringBase::sprintf

38.1.1.7.19 AnsiStringBase::FormatFloat Method

Formats the floating-point value given by value using the format string given by format.

Pascal

```
function FormatFloat(const format: AnsiStringBase&; const value: long double&; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FormatFloat(const AnsiStringBase& format, const long double&
value, int codePage);
```

Description

The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the DecimalSeparator global variable, whose default value is specified in the Number Format (see page 3202) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the ThousandSeparator global variable, whose default value is specified in the Number Format (see page 3202) of the International section in the Windows Control Panel.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 3201) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 3202) string-1234-12340.50

Format (see page 3202) string-	**1234**	**-1234**	**0.5**	**0**
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	
#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

38.1.1.7.20 GetRec Method

This is the overview for the GetRec method overload.

Overload List

	Name	**Description**
	AnsiStringBase::GetRec () (see page 3204)	Gets a struct describing a System::AnsiStringBase (see page 3185).
	AnsiStringBase::GetRec () (see page 3204)	Gets a struct describing a System::AnsiStringBase (see page 3185).

38.1.1.7.20.1 AnsiStringBase::GetRec Method ()

Gets a struct describing a System::AnsiStringBase (see page 3185).

Pascal

```
function GetRec: const StrRec&;
function GetRec: StrRec&;
```

C++

```
const StrRec& GetRec() const;
StrRec& GetRec();
```

Description

System::AnsiStringBase::GetRec gets a struct that describes the contents of a System::AnsiStringBase (see page 3185) instance. The struct has this format:

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

38.1.1.7.21 AnsiStringBase::Insert Method

System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase::AnsiString.

Pascal

```
function Insert(const str: AnsiStringBase&; index: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Insert(const AnsiStringBase& str, int index);
```

Description

System::AnsiStringBase::Insert inserts the string str into this System::AnsiStringBase::AnsiString beginning at the position index, where 1 is the first position in the string. It returns the resulting modified string (*this).

If index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to Length (see page 3208)(), turning the operation into an append.

If the str parameter is an empty string, System::AnsiStringBase::Insert does nothing.

System::AnsiStringBase::Insert throws an EOutOfMemory exception if the method is unable to allocate enough memory to accommodate the new, longer, string.

Note: The index parameter specifies the character, not the byte, when working with a multi-byte character system.

38.1.1.7.22 AnsiStringBase::IntToHex Method

Converts a number into a string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase IntToHex(int value, int digits, int codePage);
```

Description

Value is the number to convert. Digits indicates the minimum number of hexadecimal digits.

38.1.1.7.23 AnsiStringBase::IsDelimiter Method

Returns true if the specified character matches any character in the delimiters string.

Pascal

```
function IsDelimiter(const delimiters: AnsiStringBase&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const AnsiStringBase& delimiters, int index) const;
```

Description

System::AnsiStringBase::IsDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character contained in delimiters. If the byte is part of a multi-byte character or not in delimiters, System::AnsiStringBase::IsDelimiter returns false.

38.1.1.7.24 AnsiStringBase::IsEmpty Method

Returns true if the System::AnsiStringBase::AnsiString is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::AnsiStringBase::IsEmpty returns true if this System::AnsiStringBase::AnsiString is empty, false otherwise.

38.1.1.7.25 AnsiStringBase::IsLeadByte Method

Returns true if the specified byte is a lead byte.

Pascal

```
function IsLeadByte(index: Integer): bool;
```

C++

```
__fastcall bool IsLeadByte(int index) const;
```

Description

System::AnsiStringBase::IsLeadByte returns true if the byte indicated by index (counting from 0) is the lead byte in a multi-byte character. If the byte is a trailing byte, or not part of a multi-byte character, System::AnsiStringBase::IsLeadByte returns false.

38.1.1.7.26 AnsiStringBase::IsPathDelimiter Method

Returns true if the specified character is '\'.

Pascal

```
function IsPathDelimiter(index: Integer): bool;
```

C++

```
__fastcall bool IsPathDelimiter(int index) const;
```

Description

System::AnsiStringBase::IsPathDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character containing the path delimiter ('\' on Windows, '/' on Linux).

See Also

System::AnsiStringBase::ByteType (see page 3198)

38.1.1.7.27 AnsiStringBase::IsTrailByte Method

Returns true if the specified byte is of type mbTrailByte.

Pascal

```
function IsTrailByte(index: Integer): bool;
```

C++

```
__fastcall bool IsTrailByte(int index) const;
```

Description

System::AnsiStringBase::IsTrailByte returns true if the byte indicated by index (counting from 0) is the trailing byte in a multi-byte character. If the byte is a lead byte, or not part of a multi-byte character, System::AnsiStringBase::IsTrailByte returns false.

38.1.1.7.28 AnsiStringBase::LastChar Method

Pascal

```
function LastChar: char*;
```

C++

```
__fastcall char* LastChar() const;
```

Description

This is LastChar, a member of class AnsiStringBase.

38.1.1.7.29 AnsiStringBase::LastDelimiter Method

Returns the index of the rightmost character that matches any character in the delimiters string.

Pascal

```
function LastDelimiter(const delimiters: AnsiStringBase&): Integer;
```

C++

```
__fastcall int LastDelimiter(const AnsiStringBase& delimiters) const;
```

Description

System::AnsiStringBase::LastDelimiter returns the byte index in this System::AnsiStringBase::AnsiString of the rightmost whole character that matches any character in delimiters except NULL The System::AnsiStringBase::AnsiString may contain multibyte characters; delimiters must contain only single byte non-NULL characters.

See Also

System::AnsiStringBase::ByteType (see page 3198)

38.1.1.7.30 AnsiStringBase::Length Method

Returns the length of the System::AnsiStringBase::AnsiString.

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::AnsiStringBase::Length returns the number of bytes in this System::AnsiStringBase::AnsiString.

38.1.1.7.31 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	AnsiStringBase::LoadStr (HINSTANCE, int, int) (see page 3208)	Loads a string from the compiled resources of a specified module.
	AnsiStringBase::LoadStr (int, int) (see page 3208)	Loads a string from the compiled resources of a specified module.

38.1.1.7.31.1 AnsiStringBase::LoadStr Method (HINSTANCE, int, int)

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadStr(ident: Integer; codePage: Integer): AnsiStringBase; static;
function LoadStr(hInstance: HINSTANCE; ident: Integer; codePage: Integer): AnsiStringBase;
static;
```

C++

```
static __fastcall AnsiStringBase LoadStr(int ident, int codePage);
static __fastcall AnsiStringBase LoadStr(HINSTANCE hInstance, int ident, int codePage);
```

Description

System::AnsiStringBase::LoadStr loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource. If hInstance is not given, System::AnsiStringBase::LoadStr loads the string from the current module (executable or shared library)

If the string resource does not exist, System::AnsiStringBase::LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringBase::LoadString (see page 3209)

System::AnsiStringBase::FmtLoadStr (see page 3202)

38.1.1.7.32 AnsiStringBase::LoadString Method

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer; codePage: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& LoadString(HINSTANCE hInstance, int ident, int codePage);
```

Description

System::AnsiStringBase::LoadString loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource.

If the string resource does not exist, System::AnsiStringBase::LoadString returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringBase::LoadStr (see page 3208)

System::AnsiStringBase::FmtLoadStr (see page 3202)

38.1.1.7.33 AnsiStringBase::LowerCase Method

Returns a lower-case version of System::AnsiStringBase::AnsiString.

Pascal

```
function LowerCase(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase LowerCase(int codePage) const;
```

Description

System::AnsiStringBase::LowerCase returns a new System::AnsiStringBase::AnsiString that contains all characters in this string, converted to lower case. The conversion uses the current locale . The original System::AnsiStringBase::AnsiString remains unchanged.

38.1.1.7.34 AnsiStringBase::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: AnsiStringBase&): Integer;
```

C++

```
__fastcall int Pos(const AnsiStringBase& subStr) const;
```

Description

System::AnsiStringBase::Pos returns the index in the System::AnsiStringBase::AnsiString at which the substring subStr begins, where 1 is the index of the first character, 2 is the index of the second character, and so on. If the substring is not contained in the System::AnsiStringBase::AnsiString, System::AnsiStringBase::Pos returns 0.

38.1.1.7.35 AnsiStringBase::RefCount Method

Gets reference count of System::AnsiStringBase (see page 3185).

Pascal

```
function RefCount: Integer;
```

C++

```
int RefCount() const;
```

Description

System::AnsiStringBase::RefCount gets the reference count of a System::AnsiStringBase (see page 3185) instance. If the instance is empty, it returns 0.

See Also

System::AnsiStringBase::GetRec (see page 3204)

38.1.1.7.36 AnsiStringBase::SetLength Method

Changes the length of the System::AnsiStringBase::AnsiString.

Pascal

```
function SetLength(newLength: Integer; codePage: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& SetLength(int newLength, int codePage);
```

Description

System::AnsiStringBase::SetLength changes the string's length to newLength, truncating if necessary.

System::AnsiStringBase::SetLength reallocates the underlying array of characters that stores the value of the System::AnsiStringBase::AnsiString. Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate the System::AnsiStringBase::AnsiString, an EOutOfMemory exception is thrown. Following a call to System::AnsiStringBase::SetLength, the System::AnsiStringBase::AnsiString is guaranteed not to be a shared reference.

System::AnsiStringBase::SetLength returns the modified System::AnsiStringBase::AnsiString object (*this)

38.1.1.7.37 AnsiStringBase::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: char; count: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase StringOfChar(char ch, int count);
```

Description

System::AnsiStringBase::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::AnsiStringBase::AnsiString s = System::AnsiStringBase::AnsiString::System::AnsiStringBase::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

38.1.1.7.38 AnsiStringBase::SubString Method

Returns a specified substring of the System::AnsiStringBase::AnsiString.

Pascal

```
function SubString(index: Integer; count: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase SubString(int index, int count) const;
```

Description

System::AnsiStringBase::SubString returns a new System::AnsiStringBase::AnsiString that is a substring of this System::AnsiStringBase::AnsiString. The substring contains count characters beginning at index.

38.1.1.7.39 AnsiStringBase::swap Method

Pascal

```
function swap(var other: AnsiStringBase): AnsiStringBase&;
```

C++

```
AnsiStringBase& swap(AnsiStringBase& other);
```

Description

This is swap, a member of class AnsiStringBase.

38.1.1.7.40 AnsiStringBase::ThrowIfOutOfRange Method

Pascal

```
procedure ThrowIfOutOfRange(idx: Integer); cdecl;
```

C++

```
__cdecl void ThrowIfOutOfRange(int idx) const;
```

Description

This is ThrowIfOutOfRange, a member of class AnsiStringBase.

38.1.1.7.41 AnsiStringBase::ToDouble Method

Converts the string to a floating-point value.

Pascal

```
function ToDouble: double;
```

C++

```
__fastcall double ToDouble() const;
```

Description

System::AnsiStringBase::ToDouble converts the string to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks in the string are ignored. The DecimalSeparator global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, an EConvertError exception is thrown.

38.1.1.7.42 AnsiStringBase::ToInt Method

Converts a string to an integer, throwing an exception if the string is invalid.

Pascal

```
function ToInt: Integer;
```

C++

```
__fastcall int ToInt() const;
```

Description

System::AnsiStringBase::ToInt converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, an EConvertError exception is thrown.

See Also

System::AnsiStringBase::ToIntDef (see page 3212)

38.1.1.7.43 AnsiStringBase::ToIntDef Method

Converts the string to an integer, returning a default value if the string is invalid.

Pascal

```
function ToIntDef(defaultValue: Integer): Integer;
```

C++

```
__fastcall int ToIntDef(int defaultValue) const;
```

Description

System::AnsiStringBase::ToIntDef converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, the value given by defaultValue is returned.

See Also

System::AnsiStringBase::ToInt (see page 3212)

38.1.1.7.44 AnsiStringBase::Trim Method

Returns a new System::AnsiStringBase::AnsiString without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase Trim(int codePage) const;
```

Description

System::AnsiStringBase::Trim returns a new System::AnsiStringBase::AnsiString removing leading and trailing spaces and control characters. Use System::AnsiStringBase::Trim to remove blank space before and after the first printing character.

38.1.1.7.45 AnsiStringBase::TrimLeft Method

Returns a new System::AnsiStringBase::AnsiString without leading spaces or control characters.

Pascal

```
function TrimLeft(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase TrimLeft(int codePage) const;
```

Description

System::AnsiStringBase::TrimLeft returns a new System::AnsiStringBase::AnsiString removing leading spaces and control characters. Use System::AnsiStringBase::TrimLeft to remove blank space before the first printing character.

38.1.1.7.46 AnsiStringBase::TrimRight Method

Returns a new System::AnsiStringBase::AnsiString without trailing spaces or control characters.

Pascal

```
function TrimRight(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase TrimRight(int codePage) const;
```

Description

System::AnsiStringBase::TrimRight returns a new System::AnsiStringBase::AnsiString removing trailing spaces and control characters. Use the System::AnsiStringBase::TrimRight function to remove blank space after the last printing character.

38.1.1.7.47 AnsiStringBase::Unique Method

Makes the System::AnsiStringBase::AnsiString unique.

Pascal

```
function Unique: AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::AnsiStringBase::Unique sets the reference count on the string for the System::AnsiStringBase::AnsiString object to 1 so that it is the only object referencing that string.

38.1.1.7.48 AnsiStringBase::UpperCase Method

Returns an upper-case version of this System::AnsiStringBase::AnsiString.

Pascal

```
function UpperCase(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase UpperCase(int codePage) const;
```

Description

System::AnsiStringBase::UpperCase returns a new System::AnsiStringBase::AnsiString that contains all characters in this string, converted to upper case. The conversion uses the current locale . The original System::AnsiStringBase::AnsiString remains unchanged.

38.1.1.7.49 AnsiStringBase::vprintf Method

Sets the value of the System::AnsiStringBase::AnsiString given a format string and its arguments.

Pascal

```
function vprintf(codePage: Integer; const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(int codePage, const char* format, va_list);
```

Description

Use System::AnsiStringBase::vprintf to set to the value of the System::AnsiStringBase::AnsiString given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the length of the final formatted string.

See Also

System::AnsiStringBase::Format (see page 3202)

System::AnsiStringBase::sprintf

System::AnsiStringBase::printf

System::AnsiStringBase::cat_vprintf (see page 3199)

arg

start

38.1.1.7.50 AnsiStringBase::WideChar Method

Converts the System::AnsiStringBase::AnsiString to a wide-character array.

Pascal

```
function WideChar(var dest: wchar_t; destSize: Integer; codePage: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* WideChar(wchar_t* dest, int destSize, int codePage) const;
```

Description

System::AnsiStringBase::WideChar converts the System::AnsiStringBase::AnsiString to an array of wide characters, and returns the resulting wide-character array.

dest is a buffer the caller allocates to hold the return value. Use the System::AnsiStringBase::WideCharBufSize (see page 3214) method to determine the size needed to hold the entire string value.

destSize is the size, in bytes, of dest.

System::AnsiStringBase::WideChar returns a pointer to the wide-character array that is written to dest.

See Also

System::AnsiStringBase::WideCharBufSize (see page 3214)

38.1.1.7.51 AnsiStringBase::WideCharBufSize Method

Returns the size of the buffer required by the WideChar (see page 3214) function.

Pascal

```
function WideCharBufSize(codePage: Integer): Integer;
```

C++

```
__fastcall int WideCharBufSize(int codePage) const;
```

Description

System::AnsiStringBase::WideCharBufSize returns an integer value indicating the size of the buffer required by the WideChar (see page 3214) method in order to convert this string.

See Also

System::AnsiStringBase::WideChar (see page 3214)

38.1.1.8 AnsiStringBase Operators

The operators of the AnsiStringBase class are listed here.

Protected Operators

	Name	Description
	!= (see page 3215)	Compares two strings.
	< (see page 3216)	Compares two strings.
	<= (see page 3217)	Compares two strings.
	= (see page 3217)	Assigns the string rhs to this System::AnsiStringBase::AnsiString.
	== (see page 3218)	Compares the System::AnsiStringBase::AnsiString with a specified string, returning true if they are the same.
	> (see page 3218)	Compares two strings.
	>= (see page 3218)	Compares two strings.

Public Operators

	Name	Description
	[] (see page 3216)	This is the overview for the [] operator overload.
	+ (see page 3216)	Concatenates two System::AnsiStringBase::AnsiString values.

38.1.1.8.1 AnsiStringBase::!= Operator

Compares two strings.

Pascal

```
operator !=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator !=(const AnsiStringBase& rhs) const;
```

Description

Returns true if the strings are not the same, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::!= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.1.8.2 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	AnsiStringBase::[] (int) (see page 3216)	Returns the character at a specified index in the string.
	AnsiStringBase::[] (int) (see page 3216)	Returns the character at a specified index in the string.

38.1.1.8.2.1 AnsiStringBase::[] Operator (int)

Returns the character at a specified index in the string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall char operator [](const int idx) const;
__fastcall char& operator [](const int idx);
```

Description

This System::AnsiStringBase (see page 3185)::[] returns the byte in the string at index value idx. The System::AnsiStringBase (see page 3185)::[] assumes a base index of 1.

Note: If the string contains multi-byte characters, the System::AnsiStringBase (see page 3185)::[] may return a byte value that represents the wrong character and/or a partial character. For character-level access, use the SubString (see page 3211) method.

See Also

System::AnsiStringBase::substring

38.1.1.8.3 AnsiStringBase::+ Operator

Concatenates two System::AnsiStringBase::AnsiString values.

Pascal

```
operator +(const rhs: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringBase operator +(const AnsiStringBase& rhs) const;
```

Description

The friend function returns an System::AnsiStringBase::AnsiString that is the concatenation of strings lhs and rhs.

The method returns an System::AnsiStringBase::AnsiString that is the concatenation of this System::AnsiStringBase::AnsiString and rhs.

38.1.1.8.4 AnsiStringBase::< Operator

Compares two strings.

Pascal

```
operator <(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator <(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is less than rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::< performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.1.8.5 AnsiStringBase::<= Operator

Compares two strings.

Pascal

```
operator <=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator <=(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is less than or equal to rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::<= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.1.8.6 AnsiStringBase::= Operator

Assigns the string rhs to this System::AnsiStringBase::AnsiString.

Pascal

```
operator =(const rhs: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringBase& operator =(const AnsiStringBase& rhs);
```

Description

Use this System::AnsiStringBase (see page 3185)::= to assign the value of the System::AnsiStringBase::AnsiString from another System::AnsiStringBase::AnsiString.

38.1.1.8.7 AnsiStringBase::== Operator

Compares the System::AnsiStringBase::AnsiString with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator ==(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is the same as rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::== performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.1.8.8 AnsiStringBase::> Operator

Compares two strings.

Pascal

```
operator >(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator >(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is greater than rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::> performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.1.8.9 AnsiStringBase::>= Operator

Compares two strings.

Pascal

```
operator >=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator >=(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is greater than or equal to rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3185)::>= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3196) or AnsiCompareIC (see page 3197) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3196)

System::AnsiStringBase::AnsiCompareIC (see page 3197)

38.1.2 AnsiStringT Template

System::AnsiStringT is the C++ analog for the Delphi long string type.

Class Hierarchy

Pascal

```
AnsiStringT = class(AnsiStringBase);
```

C++

```
template <unsigned short CP>
class AnsiStringT : public AnsiStringBase;
```

File

dstring.h

Description

System::AnsiStringBase (see page 3185) exists to provide a place for methods/members that are common to all instantiations of the template class AnsiStringT<CodePage (see page 3230)>. AnsiString itself is a typedef that is equivalent to AnsiStringT<0>. You should never deal directly with System::AnsiStringBase (see page 3185).

System::AnsiStringT is a template class that you use when handling a Delphi AnsiString that has a code page specified with it.

Delphi uses several string types. One important long string type is commonly known as System::AnsiString. Support for this type includes the following features:

- strings can be as large as available memory
- efficient use of memory is ensured through shared references
- routines and operators evaluate strings based on the current locale

System::AnsiStringT is a template class that holds code for each specific code page. Despite its name, System::AnsiStringT is not restricted to the ANSI character set, and can use any character set supported by the current locale definition, including multi-byte or Unicode character sets.

System::AnsiStringT variables that have not been assigned an initial value contain a zero-length string.

To use the C++ streaming operators (**<<** and **>>**) with System::AnsiStringBase (see page 3185), you must `iostream` before including `system.hpp` and use `AnsiStringT::c_str` (see page 3229)() to return the internal string representation. The following example demonstrates the usage of AnsiString with stream operators:

```
#include <iostream>
#include <system.hpp>
int main() {
  AnsiString HelloStr = "hello";
  std::cout << HelloStr.c_str();
}
```

Note: Delphi also supports System::AnsiString, but implements it as a primitive type rather than a class. By default, variables declared as type String are System::UnicodeString (see page 3393).

See Also

How to Handle Delphi AnsiString Code Page Specification in C++

System::WideString (see page 3476)

System::AnsiStringBase::[] (see page 3216)

System::AnsiStringT::= (see page 3241)

System::AnsiStringT::== (see page 3241)

System::AnsiStringT::!= (see page 3240)

System::AnsiStringT::> (see page 3241)

System::AnsiStringT::>= (see page 3241)

System::AnsiStringT::< (see page 3240)

System::AnsiStringT::<= (see page 3241)

System::AnsiStringT::+ (see page 3240)

System::AnsiStringT::+= (see page 3240)

38.1.2.1 AnsiStringT Members

The following tables list the members exposed by AnsiStringT.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3193)	This is record System::AnsiStringBase::TStringFloatFormat.
	TStringMbcsByteType (see page 3193)	This is record System::AnsiStringBase::TStringMbcsByteType.

Structures

	Name	Description
	StrRec (see page 3192)	This is record System::AnsiStringBase::StrRec.

Protected Data Members

	Name	Description
	Data (see page 3194)	This is Data, a member of class AnsiStringBase.

Protected Methods

	Name	Description
	_AnsiCat (see page 3195)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3196)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiStringBase (see page 3189)	This is the overview for the AnsiStringBase constructor overload.
	GetRec (see page 3204)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3211)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Public Methods

	Name	Description
	~AnsiStringBase (see page 3189)	This is ~AnsiStringBase, a member of class AnsiStringBase.
	AnsiCompare (see page 3229)	This is AnsiCompare, a member of class AnsiStringT.
	AnsiCompareIC (see page 3229)	This is AnsiCompareIC, a member of class AnsiStringT.

	AnsiLastChar (see page 3197)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiString.
	AnsiPos (see page 3229)	This is AnsiPos, a member of class AnsiStringT.
	AnsiStringT (see page 3222)	This is the overview for the AnsiStringT constructor overload.
	BytesOf (see page 3198)	This is BytesOf, a member of class AnsiStringBase.
	ByteType (see page 3198)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase::AnsiString.
	c_str (see page 3229)	Returns the System::AnsiStringT::AnsiString converted to a null-terminated character array.
	cat_printf (see page 3230)	This is cat_printf, a member of class AnsiStringT.
	cat_sprintf (see page 3230)	This is cat_sprintf, a member of class AnsiStringT.
	cat_vprintf (see page 3230)	This is cat_vprintf, a member of class AnsiStringT.
	CodePage (see page 3230)	Gets code page of a System::AnsiStringBase.
	CurrToStr (see page 3231)	This is CurrToStr, a member of class AnsiStringT.
	CurrToStrF (see page 3231)	This is CurrToStrF, a member of class AnsiStringT.
	data (see page 3231)	Returns a pointer to the underlying string System::AnsiStringT::data.
	Delete (see page 3232)	Removes a specified number of characters from the string.
	ElementSize (see page 3232)	Gets element size of data in a System::AnsiStringBase.
	EnsureAnsi (see page 3232)	This is EnsureAnsi, a member of class AnsiStringT.
	FloatToStrF (see page 3233)	This is FloatToStrF, a member of class AnsiStringT.
	FmtLoadStr (see page 3233)	This is FmtLoadStr, a member of class AnsiStringT.
	Format (see page 3233)	This is Format, a member of class AnsiStringT.
	FormatFloat (see page 3233)	This is FormatFloat, a member of class AnsiStringT.
	Insert (see page 3234)	This is Insert, a member of class AnsiStringT.
	IntToHex (see page 3234)	This is IntToHex, a member of class AnsiStringT.
	IsDelimiter (see page 3234)	This is IsDelimiter, a member of class AnsiStringT.
	IsEmpty (see page 3206)	Returns true if the System::AnsiStringBase::AnsiString is empty.
	IsLeadByte (see page 3206)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3206)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3207)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3207)	This is LastChar, a member of class AnsiStringBase.
	LastDelimiter (see page 3234)	This is LastDelimiter, a member of class AnsiStringT.
	Length (see page 3208)	Returns the length of the System::AnsiStringBase::AnsiString.
	LoadStr (see page 3208)	This is the overview for the LoadStr method overload.
	LoadStr (see page 3234)	This is the overview for the LoadStr method overload.
	LoadString (see page 3235)	This is LoadString, a member of class AnsiStringT.
	LowerCase (see page 3235)	This is LowerCase, a member of class AnsiStringT.
	Pos (see page 3236)	This is Pos, a member of class AnsiStringT.
	printf (see page 3236)	This is printf, a member of class AnsiStringT.
	RefCount (see page 3236)	Gets reference count of System::AnsiStringBase.
	SetLength (see page 3236)	This is SetLength, a member of class AnsiStringT.
	sprintf (see page 3237)	This is sprintf, a member of class AnsiStringT.
	StringOfChar (see page 3237)	Returns a string with the specified number of characters.
	SubString (see page 3237)	Returns a specified substring of the System::AnsiStringBase::AnsiString.
	swap (see page 3237)	This is swap, a member of class AnsiStringT.
	ToDouble (see page 3211)	Converts the string to a floating-point value.
	ToInt (see page 3212)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3212)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3238)	This is Trim, a member of class AnsiStringT.
	TrimLeft (see page 3238)	This is TrimLeft, a member of class AnsiStringT.
	TrimRight (see page 3238)	This is TrimRight, a member of class AnsiStringT.
	Unique (see page 3238)	Makes the System::AnsiStringBase::AnsiString unique.
	UpperCase (see page 3238)	This is UpperCase, a member of class AnsiStringT.
	vprintf (see page 3239)	This is vprintf, a member of class AnsiStringT.
	WideChar (see page 3239)	This is WideChar, a member of class AnsiStringT.

	WideCharBufSize (see page 3239)	This is WideCharBufSize, a member of class AnsiStringT.

Public Operators

	Name	Description
	!= (see page 3240)	This is !=, a member of class AnsiStringT.
	[] (see page 3216)	This is the overview for the [] operator overload.
	+ (see page 3240)	This is +, a member of class AnsiStringT.
	+= (see page 3240)	This is +=, a member of class AnsiStringT.
	< (see page 3240)	This is <, a member of class AnsiStringT.
	<= (see page 3241)	This is <=, a member of class AnsiStringT.
	= (see page 3241)	This is =, a member of class AnsiStringT.
	== (see page 3241)	This is ==, a member of class AnsiStringT.
	> (see page 3241)	This is >, a member of class AnsiStringT.
	>= (see page 3241)	This is >=, a member of class AnsiStringT.

38.1.2.2 AnsiStringT Constructor

This is the overview for the AnsiStringT constructor overload.

Overload List

	Name	Description
	AnsiStringT::AnsiStringT () (see page 3223)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (__int64) (see page 3224)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (AnsiStringBase&) (see page 3223)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (AnsiStringT&) (see page 3223)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (AnsiStringT<OTHER_CP>&) (see page 3224)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (char) (see page 3224)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (char*) (see page 3225)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (char*, int) (see page 3225)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (char16_t*, int) (see page 3225)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (char32_t*, int) (see page 3225)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (double) (see page 3226)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (int) (see page 3226)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (long) (see page 3226)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (short) (see page 3226)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (UnicodeString &) (see page 3224)	This is AnsiStringT, a member of class AnsiStringT.

	AnsiStringT::AnsiStringT (unsigned __int64) (see page 3226)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (unsigned int) (see page 3227)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (unsigned long) (see page 3227)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (unsigned short) (see page 3227)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (wchar_t) (see page 3227)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (wchar_t*, int) (see page 3228)	This is AnsiStringT, a member of class AnsiStringT.
	AnsiStringT::AnsiStringT (WideString &) (see page 3224)	This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.1 AnsiStringT::AnsiStringT Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall AnsiStringT();
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.2 AnsiStringT::AnsiStringT Constructor (AnsiStringBase&)

Pascal

```
constructor Create(const src: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringT(const AnsiStringBase& src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.3 AnsiStringT::AnsiStringT Constructor (AnsiStringT&)

Pascal

```
constructor Create(const src: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT(const AnsiStringT& src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.4 AnsiStringT::AnsiStringT Constructor (AnsiStringT<OTHER_CP>&)

Pascal

```
constructor Create(const src: AnsiStringT<OTHER_CP>&);
```

C++

```
template <unsigned short OTHER_CP> AnsiStringT<CP>(const AnsiStringT<OTHER_CP>& src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.5 AnsiStringT::AnsiStringT Constructor (UnicodeString &)

Pascal

```
constructor Create(const src: UnicodeString &);
```

C++

```
__fastcall AnsiStringT(const UnicodeString & src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.6 AnsiStringT::AnsiStringT Constructor (WideString &)

Pascal

```
constructor Create(const src: WideString &);
```

C++

```
__fastcall AnsiStringT(const WideString & src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.7 AnsiStringT::AnsiStringT Constructor (__int64)

Pascal

```
constructor Create(src: __int64);
```

C++

```
__fastcall AnsiStringT(__int64 src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.8 AnsiStringT::AnsiStringT Constructor (char)

Pascal

```
constructor Create(src: char);
```

C++

```
__fastcall AnsiStringT(char src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.9 AnsiStringT::AnsiStringT Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall AnsiStringT(const char* src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.10 AnsiStringT::AnsiStringT Constructor (char*, int)

Pascal

```
constructor Create(const src: char*; byteLen: Integer);
```

C++

```
__fastcall AnsiStringT(const char* src, int byteLen);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.11 AnsiStringT::AnsiStringT Constructor (char16_t*, int)

Pascal

```
constructor Create(const src: char16_t*; numChar16: Integer = -1);
```

C++

```
__fastcall AnsiStringT(const char16_t* src, int numChar16 = -1);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.12 AnsiStringT::AnsiStringT Constructor (char32_t*, int)

Pascal

```
constructor Create(const src: char32_t*; numChar32: Integer = -1);
```

C++

```
__fastcall AnsiStringT(const char32_t* src, int numChar32 = -1);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.13 AnsiStringT::AnsiStringT Constructor (double)

Pascal

```
constructor Create(src: double);
```

C++

```
__fastcall AnsiStringT(double src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.14 AnsiStringT::AnsiStringT Constructor (int)

Pascal

```
constructor Create(src: Integer);
```

C++

```
__fastcall AnsiStringT(int src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.15 AnsiStringT::AnsiStringT Constructor (long)

Pascal

```
constructor Create(src: long);
```

C++

```
__fastcall AnsiStringT(long src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.16 AnsiStringT::AnsiStringT Constructor (short)

Pascal

```
constructor Create(src: short);
```

C++

```
__fastcall AnsiStringT(short src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.17 AnsiStringT::AnsiStringT Constructor (unsigned __int64)

Pascal

```
constructor Create(src: unsigned __int64);
```

C++

```
__fastcall AnsiStringT(unsigned __int64 src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.18 AnsiStringT::AnsiStringT Constructor (unsigned int)

Pascal

```
constructor Create(src: unsigned int);
```

C++

```
__fastcall AnsiStringT(unsigned int src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.19 AnsiStringT::AnsiStringT Constructor (unsigned long)

Pascal

```
constructor Create(src: unsigned long);
```

C++

```
__fastcall AnsiStringT(unsigned long src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.20 AnsiStringT::AnsiStringT Constructor (unsigned short)

Pascal

```
constructor Create(src: unsigned short);
```

C++

```
__fastcall AnsiStringT(unsigned short src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.21 AnsiStringT::AnsiStringT Constructor (wchar_t)

Pascal

```
constructor Create(src: wchar_t);
```

C++

```
__fastcall AnsiStringT(wchar_t src);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.2.22 AnsiStringT::AnsiStringT Constructor (wchar_t*, int)

Pascal

```
constructor Create(const src: wchar_t*; numwchar: Integer = -1);
```

C++

```
__fastcall AnsiStringT(const wchar_t* src, int numwchar = -1);
```

Description

This is AnsiStringT, a member of class AnsiStringT.

38.1.2.3 AnsiStringT Methods

The methods of the AnsiStringT class are listed here.

Public Methods

	Name	Description
	AnsiCompare (see page 3229)	This is AnsiCompare, a member of class AnsiStringT.
	AnsiCompareIC (see page 3229)	This is AnsiCompareIC, a member of class AnsiStringT.
	AnsiPos (see page 3229)	This is AnsiPos, a member of class AnsiStringT.
	c_str (see page 3229)	Returns the System::AnsiStringT::AnsiString converted to a null-terminated character array.
	cat_printf (see page 3230)	This is cat_printf, a member of class AnsiStringT.
	cat_sprintf (see page 3230)	This is cat_sprintf, a member of class AnsiStringT.
	cat_vprintf (see page 3230)	This is cat_vprintf, a member of class AnsiStringT.
	CodePage (see page 3230)	Gets code page of a System::AnsiStringBase.
	CurrToStr (see page 3231)	This is CurrToStr, a member of class AnsiStringT.
	CurrToStrF (see page 3231)	This is CurrToStrF, a member of class AnsiStringT.
	data (see page 3231)	Returns a pointer to the underlying string System::AnsiStringT::data.
	Delete (see page 3232)	Removes a specified number of characters from the string.
	ElementSize (see page 3232)	Gets element size of data in a System::AnsiStringBase.
	EnsureAnsi (see page 3232)	This is EnsureAnsi, a member of class AnsiStringT.
	FloatToStrF (see page 3233)	This is FloatToStrF, a member of class AnsiStringT.
	FmtLoadStr (see page 3233)	This is FmtLoadStr, a member of class AnsiStringT.
	Format (see page 3233)	This is Format, a member of class AnsiStringT.
	FormatFloat (see page 3233)	This is FormatFloat, a member of class AnsiStringT.
	Insert (see page 3234)	This is Insert, a member of class AnsiStringT.
	IntToHex (see page 3234)	This is IntToHex, a member of class AnsiStringT.
	IsDelimiter (see page 3234)	This is IsDelimiter, a member of class AnsiStringT.
	LastDelimiter (see page 3234)	This is LastDelimiter, a member of class AnsiStringT.
	LoadStr (see page 3234)	This is the overview for the LoadStr method overload.
	LoadString (see page 3235)	This is LoadString, a member of class AnsiStringT.
	LowerCase (see page 3235)	This is LowerCase, a member of class AnsiStringT.
	Pos (see page 3236)	This is Pos, a member of class AnsiStringT.
	printf (see page 3236)	This is printf, a member of class AnsiStringT.
	RefCount (see page 3236)	Gets reference count of System::AnsiStringBase.
	SetLength (see page 3236)	This is SetLength, a member of class AnsiStringT.
	sprintf (see page 3237)	This is sprintf, a member of class AnsiStringT.
	StringOfChar (see page 3237)	Returns a string with the specified number of characters.
	SubString (see page 3237)	Returns a specified substring of the System::AnsiStringBase::AnsiString.
	swap (see page 3237)	This is swap, a member of class AnsiStringT.
	Trim (see page 3238)	This is Trim, a member of class AnsiStringT.

	TrimLeft (see page 3238)	This is TrimLeft, a member of class AnsiStringT.
	TrimRight (see page 3238)	This is TrimRight, a member of class AnsiStringT.
	Unique (see page 3238)	Makes the System::AnsiStringBase::AnsiString unique.
	UpperCase (see page 3238)	This is UpperCase, a member of class AnsiStringT.
	vprintf (see page 3239)	This is vprintf, a member of class AnsiStringT.
	WideChar (see page 3239)	This is WideChar, a member of class AnsiStringT.
	WideCharBufSize (see page 3239)	This is WideCharBufSize, a member of class AnsiStringT.

38.1.2.3.1 AnsiStringT::AnsiCompare Method

Pascal

```
function AnsiCompare(const rhs: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiCompare(const AnsiStringT& rhs) const;
```

Description

This is AnsiCompare, a member of class AnsiStringT.

38.1.2.3.2 AnsiStringT::AnsiCompareIC Method

Pascal

```
function AnsiCompareIC(const rhs: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiCompareIC(const AnsiStringT& rhs) const;
```

Description

This is AnsiCompareIC, a member of class AnsiStringT.

38.1.2.3.3 AnsiStringT::AnsiPos Method

Pascal

```
function AnsiPos(const subStr: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiPos(const AnsiStringT& subStr) const;
```

Description

This is AnsiPos, a member of class AnsiStringT.

38.1.2.3.4 AnsiStringT::c_str Method

Returns the System::AnsiStringT::AnsiString converted to a null-terminated character array.

Pascal

```
function c_str: char*;
```

C++

```
__fastcall char* c_str() const;
```

Description

System::AnsiStringT::c_str returns a pointer to a null-terminated character array containing the same characters as the

System::AnsiStringT::AnsiString. If the AnsiString is unassigned, c_str returns an empty string ("").

Usually, the value returned by System::AnsiStringT::c_str points to the internal character array referenced by the data (see page 3231) property. This pointer is valid until the string is next modified (for example when the SetLength (see page 3236) method is called or the AnsiString goes out of scope). However, if the internal array is NULL, c_str() returns a pointer to a string literal.

The System::AnsiStringT::c_str method is intended primarily for reading the value of the AnsiString. To modify the string's value, use the [] operator or System::AnsiStringT::AnsiString methods such as Insert (see page 3234) and Delete (see page 3232).

38.1.2.3.5 AnsiStringT::cat_printf Method

Pascal

```
function cat_printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int cat_printf(const char* format, ...);
```

Description

This is cat_printf, a member of class AnsiStringT.

38.1.2.3.6 AnsiStringT::cat_sprintf Method

Pascal

```
function cat_sprintf(const format: char*; : ...): AnsiStringT&; cdecl;
```

C++

```
__cdecl AnsiStringT& cat_sprintf(const char* format, ...);
```

Description

This is cat_sprintf, a member of class AnsiStringT.

38.1.2.3.7 AnsiStringT::cat_vprintf Method

Pascal

```
function cat_vprintf(const format: char*; list: va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(const char* format, va_list list);
```

Description

This is cat_vprintf, a member of class AnsiStringT.

38.1.2.3.8 AnsiStringT::CodePage Method

Gets code page of a System::AnsiStringBase.

Pascal

```
function CodePage: unsigned short;
```

C++

```
unsigned short CodePage() const;
```

Description

System::AnsiStringBase::CodePage gets the code page of a System::AnsiStringBase instance. If the instance is empty, it returns the system default code page, System::DefaultSystemCodePage.

See Also

System::AnsiStringBase::GetRec (see page 3204)

38.1.2.3.9 AnsiStringT::CurrToStr Method

Pascal

```
function CurrToStr(value: Currency): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT CurrToStr(Currency value);
```

Description

This is CurrToStr, a member of class AnsiStringT.

38.1.2.3.10 AnsiStringT::CurrToStrF Method

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer):
AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT CurrToStrF(Currency value, TStringFloatFormat format, int
digits);
```

Description

This is CurrToStrF, a member of class AnsiStringT.

38.1.2.3.11 AnsiStringT::data Method

Returns a pointer to the underlying string System::AnsiStringT::data.

Pascal

```
function data: const void*;
```

C++

```
__fastcall const void* data() const;
```

Description

System::AnsiStringT::data returns a pointer to a null-terminated character array that the System::AnsiStringT::AnsiString uses to store its value. This is the same value as the one returned by the System::AnsiStringT::c_str (see page 3229) method, except that System::AnsiStringT::data returns a NULL pointer when the value is an empty string.

Note: Because System::AnsiStringT::data returns NULL instead of an empty string, it is useful for C++ functions that expect either a valid (non-empty) char* or NULL. The following example assumes that TCHAR mapping is not set to wchar_t:

```
AnsiString x;
    ShellExecute(0, static_cast<const char*>(x.data()), "File.txt", NULL, NULL, SW_SHOW);
```

If TCHAR mapping is set to wchar_t, ShellExecute becomes the wide version, ShellExecuteW. If you want to use the Ansi version of ShellExecute when TCHAR mapping is set to wchar_t, you should specify ShellExecuteA.

See Also

System::AnsiStringT::c_str (see page 3229)

TCHAR Mapping

38.1.2.3.12 AnsiStringT::Delete Method

Removes a specified number of characters from the string.

Pascal

```
function Delete(index: Integer; count: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Delete(int index, int count);
```

Description

System::AnsiStringBase::Delete modifies the System::AnsiStringBase::AnsiString to remove count characters from the string beginning with the character at index, where 1 is the index of the first character. It returns the resulting modified string (*this).

If index is larger than the length of the System::AnsiStringBase::AnsiString or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, System::AnsiStringBase::Delete removes the rest of the string. If count is less than 0, no characters are deleted.

38.1.2.3.13 AnsiStringT::ElementSize Method

Gets element size of data in a System::AnsiStringBase.

Pascal

```
function ElementSize: unsigned short;
```

C++

```
unsigned short ElementSize() const;
```

Description

System::AnsiStringBase::ElementSize gets the element size in bytes of the data in a System::AnsiStringBase instance. If the instance is empty, this returns 1.

See Also

System::AnsiStringBase::data

System::AnsiStringBase::GetRec (see page 3204)

38.1.2.3.14 AnsiStringT::EnsureAnsi Method

Pascal

```
function EnsureAnsi: AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& EnsureAnsi();
```

Description

This is EnsureAnsi, a member of class AnsiStringT.

38.1.2.3.15 AnsiStringT::FloatToStrF Method

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits);
```

Description

This is FloatToStrF, a member of class AnsiStringT.

38.1.2.3.16 AnsiStringT::FmtLoadStr Method

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT FmtLoadStr(int ident, const TVarRec * args, int size);
```

Description

This is FmtLoadStr, a member of class AnsiStringT.

38.1.2.3.17 AnsiStringT::Format Method

Pascal

```
function Format(const format: AnsiStringT&; const args: TVarRec *; size: Integer):
AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT Format(const AnsiStringT& format, const TVarRec * args, int
size);
```

Description

This is Format, a member of class AnsiStringT.

38.1.2.3.18 AnsiStringT::FormatFloat Method

Pascal

```
function FormatFloat(const format: AnsiStringT&; const value: long double&): AnsiStringT;
static;
```

C++

```
static __fastcall AnsiStringT FormatFloat(const AnsiStringT& format, const long double& value);
```

Description

This is FormatFloat, a member of class AnsiStringT.

38.1.2.3.19 AnsiStringT::Insert Method

Pascal

```
function Insert(const str: AnsiStringT&; index: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Insert(const AnsiStringT& str, int index);
```

Description

This is Insert, a member of class AnsiStringT.

38.1.2.3.20 AnsiStringT::IntToHex Method

Pascal

```
function IntToHex(value: Integer; digits: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT IntToHex(int value, int digits);
```

Description

This is IntToHex, a member of class AnsiStringT.

38.1.2.3.21 AnsiStringT::IsDelimiter Method

Pascal

```
function IsDelimiter(const delimiters: AnsiStringT&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const AnsiStringT& delimiters, int index) const;
```

Description

This is IsDelimiter, a member of class AnsiStringT.

38.1.2.3.22 AnsiStringT::LastDelimiter Method

Pascal

```
function LastDelimiter(const delimiters: AnsiStringT&): Integer;
```

C++

```
__fastcall int LastDelimiter(const AnsiStringT& delimiters) const;
```

Description

This is LastDelimiter, a member of class AnsiStringT.

38.1.2.3.23 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	AnsiStringT::LoadStr (HINSTANCE, int) (see page 3235)	This is LoadStr, a member of class AnsiStringT.
	AnsiStringT::LoadStr (int) (see page 3235)	This is LoadStr, a member of class AnsiStringT.

38.1.2.3.23.1 AnsiStringT::LoadStr Method (HINSTANCE, int)

Pascal

```
function LoadStr(hInstance: HINSTANCE; ident: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT LoadStr(HINSTANCE hInstance, int ident);
```

Description

This is LoadStr, a member of class AnsiStringT.

38.1.2.3.23.2 AnsiStringT::LoadStr Method (int)

Pascal

```
function LoadStr(ident: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT LoadStr(int ident);
```

Description

This is LoadStr, a member of class AnsiStringT.

38.1.2.3.24 AnsiStringT::LoadString Method

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& LoadString(HINSTANCE hInstance, int ident);
```

Description

This is LoadString, a member of class AnsiStringT.

38.1.2.3.25 AnsiStringT::LowerCase Method

Pascal

```
function LowerCase: AnsiStringT;
```

C++

```
__fastcall AnsiStringT LowerCase() const;
```

Description

This is LowerCase, a member of class AnsiStringT.

38.1.2.3.26 AnsiStringT::Pos Method

Pascal

```
function Pos(const subStr: AnsiStringT&): Integer;
```

C++

```
__fastcall int Pos(const AnsiStringT& subStr) const;
```

Description

This is Pos, a member of class AnsiStringT.

38.1.2.3.27 AnsiStringT::printf Method

Pascal

```
function printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int printf(const char* format, ...);
```

Description

This is printf, a member of class AnsiStringT.

38.1.2.3.28 AnsiStringT::RefCount Method

Gets reference count of System::AnsiStringBase.

Pascal

```
function RefCount: Integer;
```

C++

```
int RefCount() const;
```

Description

System::AnsiStringBase::RefCount gets the reference count of a System::AnsiStringBase instance. If the instance is empty, it returns 0.

See Also

System::AnsiStringBase::GetRec (see page 3204)

38.1.2.3.29 AnsiStringT::SetLength Method

Pascal

```
function SetLength(newLength: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& SetLength(int newLength);
```

Description

This is SetLength, a member of class AnsiStringT.

38.1.2.3.30 AnsiStringT::sprintf Method

Pascal

```
function sprintf(const format: char*; : ...): AnsiStringT&; cdecl;
```

C++

```
__cdecl AnsiStringT& sprintf(const char* format, ...);
```

Description

This is sprintf, a member of class AnsiStringT.

38.1.2.3.31 AnsiStringT::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: char; count: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT StringOfChar(char ch, int count);
```

Description

System::AnsiStringBase::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::AnsiStringBase::AnsiString s = System::AnsiStringBase::AnsiString::System::AnsiStringBase::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

38.1.2.3.32 AnsiStringT::SubString Method

Returns a specified substring of the System::AnsiStringBase::AnsiString.

Pascal

```
function SubString(index: Integer; count: Integer): AnsiStringT;
```

C++

```
__fastcall AnsiStringT SubString(int index, int count) const;
```

Description

System::AnsiStringBase::SubString returns a new System::AnsiStringBase::AnsiString that is a substring of this System::AnsiStringBase::AnsiString. The substring contains count characters beginning at index.

38.1.2.3.33 AnsiStringT::swap Method

Pascal

```
function swap(var other: AnsiStringT): AnsiStringT&;
```

C++

```
AnsiStringT& swap(AnsiStringT& other);
```

Description

This is swap, a member of class AnsiStringT.

38.1.2.3.34 AnsiStringT::Trim Method

Pascal

```
function Trim: AnsiStringT;
```

C++

```
__fastcall AnsiStringT Trim() const;
```

Description

This is Trim, a member of class AnsiStringT.

38.1.2.3.35 AnsiStringT::TrimLeft Method

Pascal

```
function TrimLeft: AnsiStringT;
```

C++

```
__fastcall AnsiStringT TrimLeft() const;
```

Description

This is TrimLeft, a member of class AnsiStringT.

38.1.2.3.36 AnsiStringT::TrimRight Method

Pascal

```
function TrimRight: AnsiStringT;
```

C++

```
__fastcall AnsiStringT TrimRight() const;
```

Description

This is TrimRight, a member of class AnsiStringT.

38.1.2.3.37 AnsiStringT::Unique Method

Makes the System::AnsiStringBase::AnsiString unique.

Pascal

```
function Unique: AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::AnsiStringBase::Unique sets the reference count on the string for the System::AnsiStringBase::AnsiString object to 1 so that it is the only object referencing that string.

38.1.2.3.38 AnsiStringT::UpperCase Method

Pascal

```
function UpperCase: AnsiStringT;
```

C++

```
__fastcall AnsiStringT UpperCase() const;
```

Description

This is UpperCase, a member of class AnsiStringT.

38.1.2.3.39 AnsiStringT::vprintf Method

Pascal

```
function vprintf(const format: char*; list: va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(const char* format, va_list list);
```

Description

This is vprintf, a member of class AnsiStringT.

38.1.2.3.40 AnsiStringT::WideChar Method

Pascal

```
function WideChar(var dest: wchar_t; destSize: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* WideChar(wchar_t* dest, int destSize) const;
```

Description

This is WideChar, a member of class AnsiStringT.

38.1.2.3.41 AnsiStringT::WideCharBufSize Method

Pascal

```
function WideCharBufSize: Integer;
```

C++

```
__fastcall int WideCharBufSize() const;
```

Description

This is WideCharBufSize, a member of class AnsiStringT.

38.1.2.4 AnsiStringT Operators

The operators of the AnsiStringT class are listed here.

Public Operators

	Name	Description
	!= (see page 3240)	This is !=, a member of class AnsiStringT.
	+ (see page 3240)	This is +, a member of class AnsiStringT.
	+= (see page 3240)	This is +=, a member of class AnsiStringT.
	< (see page 3240)	This is <, a member of class AnsiStringT.
	<= (see page 3241)	This is <=, a member of class AnsiStringT.

	= (see page 3241)	This is =, a member of class AnsiStringT.
	== (see page 3241)	This is ==, a member of class AnsiStringT.
	> (see page 3241)	This is >, a member of class AnsiStringT.
	>= (see page 3241)	This is >=, a member of class AnsiStringT.

38.1.2.4.1 AnsiStringT::!= Operator

Pascal

```
operator !=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator !=(const AnsiStringT& rhs) const;
```

Description

This is !=, a member of class AnsiStringT.

38.1.2.4.2 AnsiStringT::+ Operator

Pascal

```
operator +(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT operator +(const AnsiStringT& rhs) const;
```

Description

This is +, a member of class AnsiStringT.

38.1.2.4.3 AnsiStringT::+= Operator

Pascal

```
operator +=(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT& operator +=(const AnsiStringT& rhs);
```

Description

This is +=, a member of class AnsiStringT.

38.1.2.4.4 AnsiStringT::< Operator

Pascal

```
operator <(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator <(const AnsiStringT& rhs) const;
```

Description

This is <, a member of class AnsiStringT.

38.1.2.4.5 AnsiStringT::<= Operator

Pascal

```
operator <=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator <=(const AnsiStringT& rhs) const;
```

Description

This is <=, a member of class AnsiStringT.

38.1.2.4.6 AnsiStringT::= Operator

Pascal

```
operator =(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT& operator =(const AnsiStringT& rhs);
```

Description

This is =, a member of class AnsiStringT.

38.1.2.4.7 AnsiStringT::== Operator

Pascal

```
operator ==(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator ==(const AnsiStringT& rhs) const;
```

Description

This is ==, a member of class AnsiStringT.

38.1.2.4.8 AnsiStringT::> Operator

Pascal

```
operator >(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator >(const AnsiStringT& rhs) const;
```

Description

This is >, a member of class AnsiStringT.

38.1.2.4.9 AnsiStringT::>= Operator

Pascal

```
operator >=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator >=(const AnsiStringT& rhs) const;
```

Description

This is >=, a member of class AnsiStringT.

38.1.3 Currency Class

System::Currency is the C++ implementation of the Delphi System::Currency data type.

Class Hierarchy

Pascal

```
Currency = class(CurrencyBase);
```

C++

```
class Currency : public CurrencyBase;
```

File

syscurr.h

Description

System::Currency is a C++ class that implements a Delphi intrinsic type, also called System::Currency. Use System::Currency to hold monetary values.

Note: A System::Currency object is implemented as a 64-bit signed integer. Avoid operations that might cause integer overflow.

Note: Use only the operators defined by System::Currency. The compiler ignores any operators you overload yourself. Use the System::Currency constructors to create System::Currency objects from pointers to other System::Currency objects, and also from numeric and string values..

Note: To utilize the C++ streaming operators (<< and >>) with System::Currency, you must use #include <iostream> before #include <syscurr.h>. This occurs automatically if you include vcl.h, clx.h, or System.hpp. The following stream operators are defined:

```
ostream& operator << (ostream& os, const Currency& arg);
istream& operator >> (istream& is, Currency& arg);
```

See Also

System::CurrencyComp

System::CurrencyCurrencyBase

38.1.3.1 Currency Members

The following tables list the members exposed by Currency.

Public Data Members

	Name	Description
	Val (see page 3263)	This is Val, a member of class CurrencyBase.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 3260)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

Public Methods

	Name	Description
	Currency (see page 3244)	This is the overview for the Currency constructor overload.

Public Operators

	Name	Description
	- (see page 3245)	This is the overview for the - operator overload.
	-- (see page 3246)	This is the overview for the -- operator overload.
	! (see page 3247)	Returns a new System::Currency::Currency (see page 3242) object that is the logical negation of this System::Currency::Currency (see page 3242) object.
	!= (see page 3248)	This is the overview for the != operator overload.
	% (see page 3248)	Returns a new System::Currency::Currency (see page 3242) object with the value that is the remainder of this System::Currency::Currency (see page 3242) object divided by a specified integer.
	%= (see page 3249)	Assigns this System::Currency::Currency (see page 3242) object the remainder of its initial value divided by integer rhs.
	* (see page 3249)	This is the overview for the * operator overload.
	*= (see page 3250)	Assigns this System::Currency::Currency (see page 3242) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3242) object rhs.
	/ (see page 3250)	This is the overview for the / operator overload.
	/= (see page 3251)	Assigns this System::Currency::Currency (see page 3242) object the result of its initial value divided by the value of System::Currency::Currency (see page 3242) object rhs.
	+ (see page 3252)	This is the overview for the + operator overload.
	++ (see page 3253)	This is the overview for the ++ operator overload.
	+= (see page 3253)	Increments the value of this System::Currency::Currency (see page 3242) object by the value of rhs.
	< (see page 3254)	This is the overview for the < operator overload.
	<= (see page 3255)	This is the overview for the <= operator overload.
	-= (see page 3256)	Decrements the value of this System::Currency::Currency (see page 3242) object by the value of rhs.
	= (see page 3255)	This is the overview for the = operator overload.
	== (see page 3257)	This is the overview for the == operator overload.
	> (see page 3257)	This is the overview for the > operator overload.
	>= (see page 3258)	This is the overview for the >= operator overload.
	double (see page 3259)	Converts the System::Currency::Currency (see page 3242) object to a double value.
	int (see page 3259)	Converts the System::Currency::Currency (see page 3242) object to an integer value

	System::String (see page 3260)	This is System::String, a member of class Currency.

38.1.3.2 Currency Constructor

This is the overview for the Currency constructor overload.

Overload List

	Name	Description
	Currency::Currency () (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.
	Currency::Currency (Currency&) (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.
	Currency::Currency (CurrencyBase&) (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.
	Currency::Currency (double) (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.
	Currency::Currency (int) (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.
	Currency::Currency (System::String&) (see page 3244)	Creates and initializes a System::Currency::Currency (see page 3242) object.

38.1.3.2.1 Currency::Currency Constructor ()

Creates and initializes a System::Currency::Currency (see page 3242) object.

Pascal

```
constructor Create;
constructor Create(val: double);
constructor Create(val: Integer);
constructor Create(const src: CurrencyBase&);
constructor Create(const src: Currency&);
constructor Create(const src: System::String&);
```

C++

```
__fastcall Currency();
__fastcall Currency(double val);
__fastcall Currency(int val);
__fastcall Currency(const CurrencyBase& src);
__fastcall Currency(const Currency& src);
__fastcall Currency(const System::String& src);
```

Description

Use System::Currency::Currency (see page 3242) to instantiate a System::Currency::Currency (see page 3242) object.

When called with no parameters, the resulting object has a value of 0.

When called with a System::Currency::Currency (see page 3242) object as the src parameter, the resulting object is a copy of src (the copy constructor).

When called with a System::Currency::CurrencyBase (see page 3262) object as the src parameter, the resulting object has the same value as the src parameter. System::Currency::CurrencyBase (see page 3262) is the base class for the System::Currency::Currency (see page 3242) type. It has a single member, a public Val (see page 3785) field that represents the value of the object.

When called with an AnsiString object as the src parameter, the value of the resulting object is the parsed value of the AnsiString. The AnsiString must represent a numeric value within the range valid for System::Currency::Currency (see page 3242) (-922337203685477.5808 to 922337203685477.5807).

When called with a double (see page 3259) or integer as the val parameter, the value of the resulting object is the value of the val parameter.

38.1.3.3 Currency Operators

The operators of the Currency class are listed here.

Public Operators

	Name	Description
	- (see page 3245)	This is the overview for the - operator overload.
	-- (see page 3246)	This is the overview for the -- operator overload.
	! (see page 3247)	Returns a new System::Currency::Currency (see page 3242) object that is the logical negation of this System::Currency::Currency (see page 3242) object.
	!= (see page 3248)	This is the overview for the != operator overload.
	% (see page 3248)	Returns a new System::Currency::Currency (see page 3242) object with the value that is the remainder of this System::Currency::Currency (see page 3242) object divided by a specified integer.
	%= (see page 3249)	Assigns this System::Currency::Currency (see page 3242) object the remainder of its initial value divided by integer rhs.
	* (see page 3249)	This is the overview for the * operator overload.
	*= (see page 3250)	Assigns this System::Currency::Currency (see page 3242) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3242) object rhs.
	/ (see page 3250)	This is the overview for the / operator overload.
	/= (see page 3251)	Assigns this System::Currency::Currency (see page 3242) object the result of its initial value divided by the value of System::Currency::Currency (see page 3242) object rhs.
	+ (see page 3252)	This is the overview for the + operator overload.
	++ (see page 3253)	This is the overview for the ++ operator overload.
	+= (see page 3253)	Increments the value of this System::Currency::Currency (see page 3242) object by the value of rhs.
	< (see page 3254)	This is the overview for the < operator overload.
	<= (see page 3255)	This is the overview for the <= operator overload.
	= (see page 3255)	This is the overview for the = operator overload.
	-= (see page 3256)	Decrements the value of this System::Currency::Currency (see page 3242) object by the value of rhs.
	== (see page 3257)	This is the overview for the == operator overload.
	> (see page 3257)	This is the overview for the > operator overload.
	>= (see page 3258)	This is the overview for the >= operator overload.
	double (see page 3259)	Converts the System::Currency::Currency (see page 3242) object to a double value.
	int (see page 3259)	Converts the System::Currency::Currency (see page 3242) object to an integer value
	System::String (see page 3260)	This is System::String, a member of class Currency.

38.1.3.3.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	Currency::- () (see page 3246)	This is -, a member of class Currency.

	Currency::- (Currency&) (see page 3246)	This is -, a member of class Currency.
	Currency::- (double) (see page 3246)	This is -, a member of class Currency.
	Currency::- (int) (see page 3246)	This is -, a member of class Currency.

38.1.3.3.1.1 Currency::- Operator ()

Pascal

```
operator -;
```

C++

```
__fastcall Currency operator -() const;
```

Description

This is -, a member of class Currency.

38.1.3.3.1.2 Currency::- Operator (Currency&)

Pascal

```
operator -(const rhs: Currency&);
```

C++

```
__fastcall Currency operator -(const Currency& rhs) const;
```

Description

This is -, a member of class Currency.

38.1.3.3.1.3 Currency::- Operator (double)

Pascal

```
operator -(rhs: double);
```

C++

```
__fastcall Currency operator -(double rhs) const;
```

Description

This is -, a member of class Currency.

38.1.3.3.1.4 Currency::- Operator (int)

Pascal

```
operator -(rhs: Integer);
```

C++

```
__fastcall Currency operator -(int rhs) const;
```

Description

This is -, a member of class Currency.

38.1.3.3.2 -- Operator

This is the overview for the -- operator overload.

Overload List

	Name	Description
	Currency::-- () (see page 3247)	Decrements the value of the System::Currency::Currency (see page 3242) object by a specified integer value.
	Currency::-- (int) (see page 3247)	Decrements the value of the System::Currency::Currency (see page 3242) object by a specified integer value.

38.1.3.3.2.1 Currency::-- Operator ()

Decrements the value of the System::Currency::Currency (see page 3242) object by a specified integer value.

Pascal

```
operator --;
operator --(: Integer);
```

C++

```
Currency& operator --();
Currency operator --(int);
```

Description

Use the unary System::Currency (see page 3242)::-- to decrement the value of the System::Currency::Currency (see page 3242) object by 1.

Use the binary System::Currency (see page 3242)::-- to decrement the value by the integer specified as an operand.

See Also

System::Currency::++ (see page 3253)

System::Currency::-= (see page 3256)

System::Currency::operator_minus_binary

38.1.3.3.3 Currency::! Operator

Returns a new System::Currency::Currency (see page 3242) object that is the logical negation of this System::Currency::Currency (see page 3242) object.

Pascal

```
operator !;
```

C++

```
__fastcall Currency operator !() const;
```

Description

If the value of the System::Currency::Currency (see page 3242) object is nonzero, the System::Currency (see page 3242)::! returns 0. If the value of the System::Currency::Currency (see page 3242) object is 0, the System::Currency (see page 3242)::! returns 1.

See Also

System::Currency::!= (see page 3248)

System::Currency::operator_minus_unary

38.1.3.3.4 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	Currency::!= (Currency&) (see page 3248)	Tests for inequality between the System::Currency::Currency (see page 3242) object's value and a specified value.
	Currency::!= (double) (see page 3248)	Tests for inequality between the System::Currency::Currency (see page 3242) object's value and a specified value.
	Currency::!= (int) (see page 3248)	Tests for inequality between the System::Currency::Currency (see page 3242) object's value and a specified value.

38.1.3.3.4.1 Currency::!= Operator (Currency&)

Tests for inequality between the System::Currency::Currency (see page 3242) object's value and a specified value.

Pascal

```
operator !=(const rhs: Currency&);
operator !=(rhs: Integer);
operator !=(rhs: double);
```

C++

```
__fastcall bool operator !=(const Currency& rhs) const;
__fastcall bool operator !=(int rhs) const;
__fastcall bool operator !=(double rhs) const;
```

Description

The System::Currency (see page 3242)::!= compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. If the values differ, the System::Currency (see page 3242)::!= returns true. If the values are the same, the System::Currency (see page 3242)::!= returns false.

See Also

System::Currency::= (see page 3256)

System::Currency::> (see page 3258)

System::Currency::>= (see page 3258)

System::Currency::< (see page 3254)

System::Currency::<= (see page 3255)

38.1.3.3.5 Currency::% Operator

Returns a new System::Currency::Currency (see page 3242) object with the value that is the remainder of this System::Currency::Currency (see page 3242) object divided by a specified integer.

Pascal

```
operator %(rhs: Integer);
```

C++

```
__fastcall Currency operator %(int rhs) const;
```

Description

Use the System::Currency (see page 3242)::% to obtain the remainder from dividing the value of this System::Currency::Currency (see page 3242) object by the integer specified by the rhs operand.

See Also

System::Currency::%= (see page 3249)

System::Currency::/ (see page 3251)

38.1.3.3.6 Currency::%= Operator

Assigns this System::Currency::Currency (see page 3242) object the remainder of its initial value divided by integer rhs.

Pascal

```
operator %=(rhs: Integer);
```

C++

```
__fastcall Currency& operator %=(int rhs);
```

Description

Use the System::Currency (see page 3242)::%= to obtain the remainder from dividing this System::Currency::Currency (see page 3242) object's value by the Value of the System::Currency::Currency (see page 3242) object specified by rhs.

See Also

System::Currency::= (see page 3256)

System::Currency::/= (see page 3251)

System::Currency::% (see page 3248)

38.1.3.3.7 * Operator

This is the overview for the * operator overload.

Overload List

	Name	Description
	Currency::* (Currency&) (see page 3249)	Multiplies the value of the System::Currency::Currency (see page 3242) object by a specified value.
	Currency::* (double) (see page 3249)	Multiplies the value of the System::Currency::Currency (see page 3242) object by a specified value.
	Currency::* (int) (see page 3249)	Multiplies the value of the System::Currency::Currency (see page 3242) object by a specified value.

38.1.3.3.7.1 Currency::* Operator (Currency&)

Multiplies the value of the System::Currency::Currency (see page 3242) object by a specified value.

Pascal

```
operator *(const rhs: Currency&);
operator *(rhs: Integer);
operator *(rhs: double);
```

C++

```
__fastcall Currency operator *(const Currency& rhs) const;
__fastcall Currency operator *(int rhs) const;
__fastcall Currency operator *(double rhs) const;
```

Description

Use the System::Currency (see page 3242)::* to multiply the value of the System::Currency::Currency (see page 3242) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency (see page 3242)::*s:

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

multiples the values of integer lhs and System::Currency::Currency (see page 3242) object rhs and returns a new System::Currency::Currency (see page 3242) object with the resulting value.

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

multiples the values of double (see page 3259) lhs and System::Currency::Currency (see page 3242) object rhs and returns a new System::Currency::Currency (see page 3242) object with the resulting value.

See Also

System::Currency::*= (see page 3250)

System::Currency::/ (see page 3251)

38.1.3.3.8 Currency::*= Operator

Assigns this System::Currency::Currency (see page 3242) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3242) object rhs.

Pascal

```
operator *=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator *=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3242)::*= to multiply this System::Currency::Currency (see page 3242) object's value by the Value of the System::Currency::Currency (see page 3242) object specified by rhs.

See Also

System::Currency::= (see page 3256)

System::Currency::/= (see page 3251)

System::Currency::* (see page 3249)

38.1.3.3.9 / Operator

This is the overview for the / operator overload.

Overload List

	Name	Description
	Currency::/ (Currency&) (see page 3251)	Divides the value of the System::Currency::Currency (see page 3242) object by a specified value.

	Currency::/ (double) (see page 3251)	Divides the value of the System::Currency::Currency (see page 3242) object by a specified value.
	Currency::/ (int) (see page 3251)	Divides the value of the System::Currency::Currency (see page 3242) object by a specified value.

38.1.3.3.9.1 Currency::/ Operator (Currency&)

Divides the value of the System::Currency::Currency (see page 3242) object by a specified value.

Pascal

```
operator /(const rhs: Currency&);
operator /(rhs: Integer);
operator /(rhs: double);
```

C++

```
__fastcall Currency operator /(const Currency& rhs) const;
__fastcall Currency operator /(int rhs) const;
__fastcall Currency operator /(double rhs) const;
```

Description

Use the System::Currency (see page 3242)::/ to divide the value of the System::Currency::Currency (see page 3242) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency::operator_slashs:

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

divides the value of int (see page 3259) lhs by the value of System::Currency::Currency (see page 3242) object rhs and returns a new System::Currency::Currency (see page 3242) object with the resulting value.

```
friend Currency __fastcalloperator /(double lhs, const Currency& rhs);
```

divides the value of double (see page 3259) lhs by the value of System::Currency::Currency (see page 3242) object rhs and returns a System::Currency::Currency (see page 3242) object with the resulting value.

See Also

System::Currency::/= (see page 3251)

System::Currency::* (see page 3249)

System::Currency::% (see page 3248)

38.1.3.3.10 Currency::/= Operator

Assigns this System::Currency::Currency (see page 3242) object the result of its initial value divided by the value of System::Currency::Currency (see page 3242) object rhs.

Pascal

```
operator /=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator /=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3242)::/= to divide this System::Currency::Currency (see page 3242) object's value by the Value of the System::Currency::Currency (see page 3242) object specified by rhs.

See Also

System::Currency::= (see page 3256)

System::Currency::*= (see page 3250)

System::Currency::/ (see page 3251)

38.1.3.3.11 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	Currency::+ (Currency&) (see page 3252)	Adds a specified value to the System::Currency::Currency (see page 3242) object.
	Currency::+ (double) (see page 3252)	Adds a specified value to the System::Currency::Currency (see page 3242) object.
	Currency::+ (int) (see page 3252)	Adds a specified value to the System::Currency::Currency (see page 3242) object.

38.1.3.3.11.1 Currency::+ Operator (Currency&)

Adds a specified value to the System::Currency::Currency (see page 3242) object.

Pascal

```
operator +(const rhs: Currency&);
operator +(rhs: Integer);
operator +(rhs: double);
```

C++

```
__fastcall Currency operator +(const Currency& rhs) const;
__fastcall Currency operator +(int rhs) const;
__fastcall Currency operator +(double rhs) const;
```

Description

Use the System::Currency (see page 3242)::+ to add the value specified by the rhs operand to the System::Currency::Currency (see page 3242) object. If the rhs operand is another System::Currency::Currency (see page 3242) object, the System::Currency (see page 3242)::+ adds its value to the System::Currency::Currency (see page 3242) object. If it is an integer or double (see page 3259) value, the System::Currency (see page 3242)::+ adds that value to the value of the System::Currency::Currency (see page 3242) object.

Note that there are two related friend System::Currency (see page 3242)::+s:

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 3242) object that is the sum of int (see page 3259) lhs and System::Currency::Currency (see page 3242) object rhs.

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 3242) object that is the sum of double (see page 3259) lhs and System::Currency::Currency (see page 3242) object rhs.

See Also

System::Currency::+= (see page 3253)

System::Currency::++ (see page 3253)

System::Currency::operator_minus_binary

38.1.3.3.12 ++ Operator

This is the overview for the ++ operator overload.

Overload List

	Name	Description
	Currency::++ () (see page 3253)	Increments the value of the System::Currency::Currency (see page 3242) object by a specified integer value.
	Currency::++ (int) (see page 3253)	Increments the value of the System::Currency::Currency (see page 3242) object by a specified integer value.

38.1.3.3.12.1 Currency::++ Operator ()

Increments the value of the System::Currency::Currency (see page 3242) object by a specified integer value.

Pascal

```
operator ++;
operator ++(: Integer);
```

C++

```
Currency& operator ++();
Currency operator ++(int);
```

Description

Use the unary System::Currency (see page 3242)::++ to increment the value of the System::Currency::Currency (see page 3242) object by 1.

Use the binary System::Currency (see page 3242)::++ to increment the value by the integer specified as an operand.

See Also

System::Currency::-- (see page 3247)

System::Currency::+= (see page 3253)

System::Currency::+ (see page 3252)

38.1.3.3.13 Currency::+= Operator

Increments the value of this System::Currency::Currency (see page 3242) object by the value of rhs.

Pascal

```
operator +=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator +=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3242)::+= to add the value of another System::Currency::Currency (see page 3242) object to this one.

See Also

System::Currency::= (see page 3256)

System::Currency::-= (see page 3256)

System::Currency::+ (see page 3252)

System::Currency::++ (see page 3253)

38.1.3.3.14 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	Currency::< (Currency&) (see page 3254)	Tests whether this System::Currency::Currency (see page 3242) value is less than a specified value.
	Currency::< (double) (see page 3254)	Tests whether this System::Currency::Currency (see page 3242) value is less than a specified value.
	Currency::< (int) (see page 3254)	Tests whether this System::Currency::Currency (see page 3242) value is less than a specified value.

38.1.3.3.14.1 Currency::< Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3242) value is less than a specified value.

Pascal

```
operator <(const rhs: Currency&);
operator <(rhs: Integer);
operator <(rhs: double);
```

C++

```
__fastcall bool operator <(const Currency& rhs) const;
__fastcall bool operator <(int rhs) const;
__fastcall bool operator <(double rhs) const;
```

Description

The < System::Currency (see page 3242)::< compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3242) object has the lesser value, false otherwise.

See Also

System::Currency::!= (see page 3248)

System::Currency::> (see page 3258)

System::Currency::>= (see page 3258)

System::Currency::== (see page 3257)

System::Currency::<= (see page 3255)

38.1.3.3.15 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	Currency::<= (Currency&) (see page 3255)	Tests whether this System::Currency::Currency (see page 3242) value is less than or equal to a specified value.
	Currency::<= (double) (see page 3255)	Tests whether this System::Currency::Currency (see page 3242) value is less than or equal to a specified value.
	Currency::<= (int) (see page 3255)	Tests whether this System::Currency::Currency (see page 3242) value is less than or equal to a specified value.

38.1.3.3.15.1 Currency::<= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3242) value is less than or equal to a specified value.

Pascal

```
operator <=(const rhs: Currency&);
operator <=(rhs: Integer);
operator <=(rhs: double);
```

C++

```
__fastcall bool operator <=(const Currency& rhs) const;
__fastcall bool operator <=(int rhs) const;
__fastcall bool operator <=(double rhs) const;
```

Description

The <= System::Currency (see page 3242)::<= compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3242) object has a value less than or equal to that of rhs, false otherwise.

See Also

System::Currency::!= (see page 3248)

System::Currency::> (see page 3258)

System::Currency::>= (see page 3258)

System::Currency::< (see page 3254)

System::Currency::== (see page 3257)

38.1.3.3.16 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	Currency::= (Currency&) (see page 3256)	Assigns the value of the System::Currency::Currency (see page 3242) object.

	Currency::= (CurrencyBase&) (see page 3256)	Assigns the value of the System::Currency::Currency (see page 3242) object.
	Currency::= (double) (see page 3256)	Assigns the value of the System::Currency::Currency (see page 3242) object.
	Currency::= (int) (see page 3256)	Assigns the value of the System::Currency::Currency (see page 3242) object.

38.1.3.3.16.1 Currency::= Operator (Currency&)

Assigns the value of the System::Currency::Currency (see page 3242) object.

Pascal

```
operator =(rhs: double);
operator =(rhs: Integer);
operator =(const rhs: CurrencyBase&);
operator =(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator =(double rhs);
__fastcall Currency& operator =(int rhs);
__fastcall Currency& operator =(const CurrencyBase& rhs);
__fastcall Currency& operator =(const Currency& rhs);
```

Description

The assignment System::Currency (see page 3242)::= assigns the value of the rhs operand to the System::Currency::Currency (see page 3242) object. The assignment System::Currency (see page 3242)::= can take

a double (see page 3259) or integer value, which is assigned to the System::Currency::Currency (see page 3242) object.

a System::Currency::CurrencyBase (see page 3262) or System::Currency::Currency (see page 3242) object, whose value is assigned to the System::Currency::Currency (see page 3242) object.

38.1.3.3.17 Currency::-= Operator

Decrements the value of this System::Currency::Currency (see page 3242) object by the value of rhs.

Pascal

```
operator -=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator -=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3242)::-= to subtract the value of another System::Currency::Currency (see page 3242) object from this one.

See Also

System::Currency::= (see page 3256)

System::Currency::+= (see page 3253)

System::Currency::operator_minus_binary

System::Currency::-- (see page 3247)

38.1.3.3.18 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	Currency::== (Currency&) (see page 3257)	Tests for equality between the System::Currency::Currency (see page 3242) object's value and a specified value.
	Currency::== (double) (see page 3257)	Tests for equality between the System::Currency::Currency (see page 3242) object's value and a specified value.
	Currency::== (int) (see page 3257)	Tests for equality between the System::Currency::Currency (see page 3242) object's value and a specified value.

38.1.3.3.18.1 Currency::== Operator (Currency&)

Tests for equality between the System::Currency::Currency (see page 3242) object's value and a specified value.

Pascal

```
operator ==(const rhs: Currency&);
operator ==(rhs: Integer);
operator ==(rhs: double);
```

C++

```
__fastcall bool operator ==(const Currency& rhs) const;
__fastcall bool operator ==(int rhs) const;
__fastcall bool operator ==(double rhs) const;
```

Description

The == System::Currency (see page 3242)::== compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. If the two values are the same, the System::Currency (see page 3242)::== returns true. If the values differ, the System::Currency (see page 3242)::== returns false.

See Also

System::Currency::!= (see page 3248)

System::Currency::> (see page 3258)

System::Currency::>= (see page 3258)

System::Currency::< (see page 3254)

System::Currency::<= (see page 3255)

38.1.3.3.19 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	Currency::> (Currency&) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than a specified value.

	Currency::> (double) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than a specified value.
	Currency::> (int) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than a specified value.

38.1.3.3.19.1 Currency::> Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3242) value is greater than a specified value.

Pascal

```
operator >(const rhs: Currency&);
operator >(rhs: Integer);
operator >(rhs: double);
```

C++

```
__fastcall bool operator >(const Currency& rhs) const;
__fastcall bool operator >(int rhs) const;
__fastcall bool operator >(double rhs) const;
```

Description

The System::Currency (see page 3242)::> compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3242) object has a greater value than rhs, false otherwise.

See Also

System::Currency::!= (see page 3248)

System::Currency::== (see page 3257)

System::Currency::>= (see page 3258)

System::Currency::< (see page 3254)

System::Currency::<= (see page 3255)

38.1.3.3.20 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	Currency::>= (Currency&) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than or equal to a specified value.
	Currency::>= (double) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than or equal to a specified value.
	Currency::>= (int) (see page 3258)	Tests whether this System::Currency::Currency (see page 3242) value is greater than or equal to a specified value.

38.1.3.3.20.1 Currency::>= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3242) value is greater than or equal to a specified value.

Pascal

```
operator >=(const rhs: Currency&);
operator >=(rhs: Integer);
operator >=(rhs: double);
```

C++

```
__fastcall bool operator >=(const Currency& rhs) const;
__fastcall bool operator >=(int rhs) const;
__fastcall bool operator >=(double rhs) const;
```

Description

The >= System::Currency (see page 3242)::>= compares the value of the System::Currency::Currency (see page 3242) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3242) object's value is greater than or equal to the value of rhs, false otherwise.

See Also

System::Currency::!= (see page 3248)

System::Currency::> (see page 3258)

System::Currency::== (see page 3257)

System::Currency::< (see page 3254)

System::Currency::<= (see page 3255)

38.1.3.3.21 Currency::double Operator

Converts the System::Currency::Currency (see page 3242) object to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

double is a conversion System::Currency::double that converts a System::Currency::Currency (see page 3242) object to a double.

See Also

System::Currency::int (see page 3259)

System::Currency::AnsiString

38.1.3.3.22 Currency::int Operator

Converts the System::Currency::Currency (see page 3242) object to an integer value

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

int is a conversion System::Currency::int that converts a System::Currency::Currency (see page 3242) object to an int.

See Also

System::Currency::double (see page 3259)

System::Currency::AnsiString

38.1.3.3.23 Currency::System::String Operator

Pascal

```
operator System::String;
```

C++

```
__fastcall operator System::String() const;
```

Description

This is System::String, a member of class Currency.

38.1.3.4 Currency Friends

The friends of the Currency class are listed here.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 3260)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 3261)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 3262)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

38.1.3.4.1 friend Currency __fastcall operator -(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).

38.1.3.4.2 friend Currency __fastcall operator -(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).

38.1.3.4.3 friend Currency __fastcall operator *(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).

38.1.3.4.4 friend Currency __fastcall operator *(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).

38.1.3.4.5 friend Currency __fastcall operator /(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).

38.1.3.4.6 friend Currency __fastcall operator /(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).

38.1.3.4.7 friend Currency __fastcall operator +(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).

38.1.3.4.8 friend Currency __fastcall operator +(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

38.1.4 CurrencyBase Class

Class Hierarchy

Pascal

```
CurrencyBase = class;
```

C++

```
class CurrencyBase;
```

File

syscurr.h

Description

This is class System::CurrencyBase.

38.1.4.1 CurrencyBase Members

The following tables list the members exposed by CurrencyBase.

Public Data Members

	Name	Description
	Val (see page 3263)	This is Val, a member of class CurrencyBase.

38.1.4.2 CurrencyBase Data Members

The data members of the CurrencyBase class are listed here.

Public Data Members

	Name	Description
	Val (see page 3263)	This is Val, a member of class CurrencyBase.

38.1.4.2.1 CurrencyBase::Val Data Member

Pascal

```
Val: __int64;
```

C++

```
__int64 Val;
```

Description

This is Val, a member of class CurrencyBase.

38.1.5 DelphiInterface Template

System::DelphiInterface is a C++ implementation of the Delphi interface.

Class Hierarchy

Pascal

```
DelphiInterface = class;
```

C++

```
template <class T>
class DelphiInterface;
```

File

systobj.h

Description

A Delphi interface is an abstract collection of properties, methods, and events with no implementation. It resembles a C++ class with only pure virtual methods. However a Delphi interface type supports built-in reference counting.

System::DelphiInterface is a C++ template that defines types compatible with Delphi interfaces, System::DelphiInterface defines reference counting logic in its initialization constructor, copy constructor, assignment operator, and destructor.

Note: Other operators that provide access to the underlying interface pointer do not handle reference counting. You may need to explicitly call AddRef or Release (see page 3266) to ensure proper reference counting.

System::DelphiInterface is a template:

```
template <class T> class RTL_DELPHIRETURN DelphiInterface;
```

where the T parameter is an underlying interface class or COM interface. In the object framework, the resulting System::DelphiInterface class is usually given a name such as _di_IUnknown, where IUnknown (see page 3828) is the name of the corresponding interface. Such interfaces are documented under the interface name (such as IFormDesigner).

TVariant

38.1.5.1 DelphiInterface Members

The following tables list the members exposed by DelphiInterface.

Public Methods

	Name	Description
	~DelphiInterface (see page 3264)	Frees an instance of System::DelphiInterface::DelphiInterface (see page 3263).
	DelphiInterface (see page 3265)	This is the overview for the DelphiInterface constructor overload.
	Release (see page 3266)	This is Release, a member of class DelphiInterface.

Public Operators

	Name	Description
	! (see page 3266)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 3263) object represents a NULL interface.
	& (see page 3266)	Returns a pointer to the underlying interface pointer.
	* (see page 3267)	Returns the underlying interface pointer.
	= (see page 3267)	This is the overview for the = operator overload.
	-> (see page 3268)	This is ->, a member of class DelphiInterface.
	T* (see page 3268)	This is T*, a member of class DelphiInterface.

38.1.5.2 DelphiInterface::~DelphiInterface Destructor

Frees an instance of System::DelphiInterface::DelphiInterface (see page 3263).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~DelphiInterface<T>();
```

Description

Before freeing the System::DelphiInterface::DelphiInterface (see page 3263) instance, System::DelphiInterface (see page 3263)::~DelphiInterface (see page 3263) calls the Release (see page 3266) method of the underlying interface.

38.1.5.3 DelphiInterface Constructor

This is the overview for the DelphiInterface constructor overload.

Overload List

	Name	Description
	DelphiInterface::DelphiInterface () (see page 3265)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3263).
	DelphiInterface::DelphiInterface (DelphiInterface<T> &) (see page 3265)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3263).
	DelphiInterface::DelphiInterface (T*) (see page 3265)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3263).

38.1.5.3.1 DelphiInterface::DelphiInterface Constructor ()

Creates an instance of System::DelphiInterface::DelphiInterface (see page 3263).

Pascal

```
constructor Create;
constructor Create(const rhs: DelphiInterface<T> &);
constructor Create(var rhs: T);
```

C++

```
__fastcall DelphiInterface<T>();
__fastcall DelphiInterface<T>(const DelphiInterface<T> & rhs);
__fastcall DelphiInterface<T>(T* rhs);
```

Description

The System::DelphiInterface::DelphiInterface (see page 3263) constructor is overloaded to create a System::DelphiInterface::DelphiInterface (see page 3263) in one of three ways:

When used with no parameters, System::DelphiInterface::DelphiInterface (see page 3263) creates a NULL interface.

When used with another System::DelphiInterface::DelphiInterface (see page 3263) object (the copy constructor), System::DelphiInterface::DelphiInterface (see page 3263) creates a new copy of the interface specified by rhs, incrementing the reference count of the underlying interface.

When used with an interface pointer of the underlying type, System::DelphiInterface::DelphiInterface (see page 3263) wraps the underlying interface specified by rhs and increments its reference count.

38.1.5.4 DelphiInterface Methods

The methods of the DelphiInterface class are listed here.

Public Methods

	Name	Description
	Release (see page 3266)	This is Release, a member of class DelphiInterface.

38.1.5.4.1 DelphiInterface::Release Method

Pascal

```
function Release: Integer;
```

C++

```
int Release();
```

Description

This is Release, a member of class DelphiInterface.

38.1.5.5 DelphiInterface Operators

The operators of the DelphiInterface class are listed here.

Public Operators

	Name	Description
	! (see page 3266)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 3263) object represents a NULL interface.
	& (see page 3266)	Returns a pointer to the underlying interface pointer.
	* (see page 3267)	Returns the underlying interface pointer.
	= (see page 3267)	This is the overview for the = operator overload.
	-> (see page 3268)	This is ->, a member of class DelphiInterface.
	T* (see page 3268)	This is T*, a member of class DelphiInterface.

38.1.5.5.1 DelphiInterface::! Operator

Indicates whether the System::DelphiInterface::DelphiInterface (see page 3263) object represents a NULL interface.

Pascal

```
operator !;
```

C++

```
bool operator !() const;
```

Description

The ! System::DelphiInterface (see page 3263)::! returns true if the System::DelphiInterface::DelphiInterface (see page 3263) object represents a NULL interface, and false otherwise.

38.1.5.5.2 DelphiInterface::& Operator

Returns a pointer to the underlying interface pointer.

Pascal

```
operator &;
```

C++

```
__fastcall T** operator &();
```

Description

Use the & System::DelphiInterface (see page 3263)::& to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 3263)::&, because it provides no reference counting support. For example, when using this System::DelphiInterface (see page 3263)::& to programmatically replace the underlying interface, you must first call Release (see page 3266) to decrement the reference count of the current interface and, depending on whether you are using this as an additional interface reference, you may need to increment the reference count on the interface being added.

38.1.5.5.3 DelphiInterface::* Operator

Returns the underlying interface pointer.

Pascal

```
operator *;
```

C++

```
__fastcall T& operator *();
```

Description

Use the & System::DelphiInterface (see page 3263)::* to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 3263)::*, because it provides no reference counting support. For example, you may need to increment the reference count on the returned value.

38.1.5.5.4 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	DelphiInterface::= (DelphiInterface<T>&) (see page 3267)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3263).
	DelphiInterface::= (T *) (see page 3267)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3263).

38.1.5.5.4.1 DelphiInterface::= Operator (DelphiInterface<T>&)

Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3263).

Pascal

```
operator =(var rhs: DelphiInterface<T>);
operator =(var rhs: T);
```

C++

```
__fastcall DelphiInterface<T>& operator =(DelphiInterface<T>& rhs);
__fastcall DelphiInterface<T>& operator =(T * rhs);
```

Description

The assignment System::DelphiInterface (see page 3263)::= assigns a value to the underlying interface from an interface pointer of the underlying type or from another System::DelphiInterface::DelphiInterface (see page 3263) object that wraps the same interface type.

This System::DelphiInterface (see page 3263)::= manages all reference counting issues. That is, it decrements the reference count on the current interface (if any) before making the assignment and increments the reference count on the newly assigned

interface (if any).

38.1.5.5.5 DelphiInterface::-> Operator

Pascal

```
operator ->;
```

C++

```
__fastcall T* operator ->() const;
```

Description

This is ->, a member of class DelphiInterface.

38.1.5.5.6 DelphiInterface::T* Operator

Pascal

```
operator T*;
```

C++

```
__fastcall operator T*() const;
```

Description

This is T*, a member of class DelphiInterface.

38.1.6 DynamicArray Template

System::DynamicArray is the C++ analog for the Delphi dynamic array type.

Class Hierarchy

Pascal

```
DynamicArray = class;
```

C++

```
template <class T>
class DynamicArray;
```

File

sysdyn.h

Description

A Dynamic Array is a resizable collection implemented as an array. The System::DynamicArray template is a C++ implementation of Delphi Dynamic Array types. The System::DynamicArray template uses a binary layout compatible with the Delphi Dynamic Array implementation.

```
template <class T> class DELPHIRETURN DynamicArray;
```

You must specify one template parameter:

Parameter	Usage
type	the type of the elements

Length (see page 3278) of dynamic arrays

The size of a System::DynamicArray can be set or obtained from the Length (see page 3278) property:

//C++ example

```
DynamicArray<int> arrayOfInt;
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

To free a System::DynamicArray, assign it a Length (see page 3278) of zero.

Accessing data

Access elements of a Dynamic Array via the subscript [] operator:

//C++ example

```
void InitArray(DynamicArray<char> &c_array)
{
  c_array[0] = 'A';
  c_array[1] = 'B';
  cout << "Third char is: " << c_array[2];
}
```

Bounds of dynamic arrays

The Low (see page 3278) and High (see page 3277) properties of System::DynamicArrays return the low and high bounds of the array respectively.

//C++ example

```
int TotalArray(const DynamicArray<int>& arrayOfInt)
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

Note: The Low (see page 3278) property always returns 0. The High (see page 3277) property returns Length (see page 3278)-1. So you may also traverse a dynamic array via the following construct:

for (int i=0; i<arrayOfInt. Length (see page 3278); i++)

Assigning, comparing and copying dynamic arrays

Dynamic Arrays are reference counted. When a System::DynamicArray is assigned to another, only the reference is assigned (and the reference count adjusted), the content of the source is not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To copy the contents of a System::DynamicArray, you must use the Copy (see page 3273) (or CopyRange (see page 3273)) methods.

//C++ example

```
void foo(DynamicArray<int> &i_array)
{
  DynamicArray<int> temp = i_array;
  assert(temp == i_array); // temp and i_array point to same chunk
                           // of data..
  i_array[0] = 20;
  assert(temp[0] == 20); // Temp 'sees' changes to i_array..
```

```
  temp = i_array.Copy(); // Temp gets its own copy of data
  temp[0] = 10;
  assert(temp[0] != i_array[0]); // Above assignment did not
                                 // modify i_array.
}
```

Multidimensional dynamic arrays

Dynamic arrays can be multidimensional. Multidimensional dynamic arrays don't have to be rectangular. The Length (see page 3278) property can be used to set each dimension. The following example illustrates.

//C++ example

```
typedef DynamicArray< DynamicArray < AnsiString > > T2DStringArray;
void foo(T2DStringArray &s_array)
{
  SetLength(s_array, 10);
for (int i=0; i<s_array.Length; i++)
  { // Set lengths of second dimensions.(NOTE: non-rectangular)
    SetLength(s_array[i], i+1);
for (int j=0; j<s_array[i].Length; j++)
    /* */ s_array[i][j] = itoa(i*10+j);
  }
}
```

C++ & Delphi System::DynamicArrays

A dynamic array declared in C++ code can be used in Delphi code and vice versa. The following examples illustrate passing a one-dimensional and two-dimensional array between C++ and Delphi.

C++ System::DynamicArray Example

Delphi System::DynamicArray Example

38.1.6.1 DynamicArray Members

The following tables list the members exposed by DynamicArray.

Protected Methods

	Name	Description
	AllocData (see page 3272)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 3274)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 3274)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 3275)	This is IncRefCount, a member of class DynamicArray.
	SetData (see page 3275)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	~DynamicArray (see page 3271)	Frees a DynamicArray (see page 3268) object.
	Copy (see page 3272)	This is the overview for the Copy method overload.
	CopyRange (see page 3273)	This is the overview for the CopyRange method overload.
	DimCount (see page 3274)	This is DimCount, a member of class DynamicArray.
	DynamicArray (see page 3271)	This is the overview for the DynamicArray constructor overload.
	get_high (see page 3274)	This is get_high, a member of class DynamicArray.
	get_length (see page 3275)	This is get_length, a member of class DynamicArray.
	get_low (see page 3275)	This is get_low, a member of class DynamicArray.
	set_length (see page 3275)	This is set_length, a member of class DynamicArray.

Public Operators

	Name	Description
	[] (see page 3276)	This is the overview for the [] operator overload.
	= (see page 3276)	Assigns data from another Dynamic Array.
	== (see page 3277)	Compares two Dynamic Arrays for equality.

Public Properties

	Name	Description
	High (see page 3277)	Indicates the high bounds of the array.
	Length (see page 3278)	Represents the number of elements in the DynamicArray (see page 3268).
	Low (see page 3278)	Indicates the low bound of a dynamic array.

38.1.6.2 DynamicArray::~DynamicArray Destructor

Frees a DynamicArray (see page 3268) object.

Pascal

```
destructor Destroy;
```

C++

```
~DynamicArray();
```

Description

Do not call the dynamic array destructor. To free a dynamically allocated DynamicArray (see page 3268), assign it a Length (see page 3278) of zero. DynamicArray (see page 3268) instances on the stack are freed when they go out of scope.

38.1.6.3 DynamicArray Constructor

This is the overview for the DynamicArray constructor overload.

Overload List

	Name	Description
	DynamicArray::DynamicArray () (see page 3271)	Creates and initializes a System::DynamicArray::DynamicArray (see page 3268) object.
	DynamicArray::DynamicArray (DynamicArray<T>&) (see page 3271)	Creates and initializes a System::DynamicArray::DynamicArray (see page 3268) object.

38.1.6.3.1 DynamicArray::DynamicArray Constructor ()

Creates and initializes a System::DynamicArray::DynamicArray (see page 3268) object.

Pascal

```
constructor Create;
constructor Create(const src: DynamicArray<T>&);
```

C++

```
DynamicArray();
DynamicArray(const DynamicArray<T>& src);
```

Description

When called with no parameters, the constructor creates an empty dynamic array. Otherwise, it copies another System::DynamicArray::DynamicArray (see page 3268).

38.1.6.4 DynamicArray Methods

The methods of the DynamicArray class are listed here.

Protected Methods

	Name	Description
	AllocData (see page 3272)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 3274)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 3274)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 3275)	This is IncRefCount, a member of class DynamicArray.
	SetData (see page 3275)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	Copy (see page 3272)	This is the overview for the Copy method overload.
	CopyRange (see page 3273)	This is the overview for the CopyRange method overload.
	DimCount (see page 3274)	This is DimCount, a member of class DynamicArray.
	get_high (see page 3274)	This is get_high, a member of class DynamicArray.
	get_length (see page 3275)	This is get_length, a member of class DynamicArray.
	get_low (see page 3275)	This is get_low, a member of class DynamicArray.
	set_length (see page 3275)	This is set_length, a member of class DynamicArray.

38.1.6.4.1 DynamicArray::AllocData Method

Pascal

```
function AllocData(count: Integer): T*; static;
```

C++

```
static T* AllocData(int count);
```

Description

This is AllocData, a member of class DynamicArray.

38.1.6.4.2 Copy Method

This is the overview for the Copy method overload.

Overload List

	Name	Description
	DynamicArray::Copy () (see page 3273)	Copies the contents of a DynamicArray (see page 3268) to the specified DynamicArray (see page 3268).
	DynamicArray::Copy (DynamicArray<T> &) (see page 3273)	Copies the contents of a DynamicArray (see page 3268) to the specified DynamicArray (see page 3268).

38.1.6.4.2.1 DynamicArray::Copy Method ()

Copies the contents of a DynamicArray (see page 3268) to the specified DynamicArray (see page 3268).

Pascal

```
function Copy: DynamicArray<T>;
procedure Copy(var dst: DynamicArray<T>);
```

C++

```
DynamicArray<T> Copy() const;
void Copy(DynamicArray<T> & dst) const;
```

Description

Use System::DynamicArray::Copy to make a copy of a dynamic array. Dynamic arrays are reference counted. Therefore assigning one to another simply copies the reference, not the data. The System::DynamicArray::Copy method, on the other hand, makes a separate copy of the dynamic array. The original contents of the destination array are discarded.

The following code copies the contents of i_array into temp; temp and i_array must be of the same DynamicArray (see page 3268) type.

```
temp = i_array.Copy();
```

See Also

CopyRange

38.1.6.4.3 CopyRange Method

This is the overview for the CopyRange method overload.

Overload List

	Name	Description
	DynamicArray::CopyRange (DynamicArray<T> &, int, int) (see page 3273)	Copies a range of the contents of a DynamicArray (see page 3268) within a specified range.
	DynamicArray::CopyRange (int, int) (see page 3273)	Copies a range of the contents of a DynamicArray (see page 3268) within a specified range.

38.1.6.4.3.1 DynamicArray::CopyRange Method (DynamicArray<T> &, int, int)

Copies a range of the contents of a DynamicArray (see page 3268) within a specified range.

Pascal

```
function CopyRange(startIndex: Integer; count: Integer): DynamicArray<T>;
procedure CopyRange(var dst: DynamicArray<T>; startIndex: Integer; count: Integer);
```

C++

```
DynamicArray<T> CopyRange(int startIndex, int count) const;
void CopyRange(DynamicArray<T> & dst, int startIndex, int count) const;
```

Description

Use the System::DynamicArray::CopyRange method to copy a subrange of a dynamic array. The System::DynamicArray::CopyRange method is similar to the Copy (see page 3273) method except that you can specify the startIndex and the number of items to copy from the source object. The size of the destination array will be truncated or expanded to accommodate what has been copied.

newArray = array.System::DynamicArray::CopyRange(3, 5);

See Also

Copy

38.1.6.4.4 DynamicArray::DecRefCount Method

Pascal

```
procedure DecRefCount;
```

C++

```
void DecRefCount();
```

Description

This is DecRefCount, a member of class DynamicArray.

38.1.6.4.5 DynamicArray::DimCount Method

Pascal

```
function DimCount: Integer; static;
```

C++

```
static int DimCount();
```

Description

This is DimCount, a member of class DynamicArray.

38.1.6.4.6 DynamicArray::FreeData Method

Pascal

```
procedure FreeData;
```

C++

```
void FreeData();
```

Description

This is FreeData, a member of class DynamicArray.

38.1.6.4.7 DynamicArray::get_high Method

Pascal

```
function get_high: Integer;
```

C++

```
int get_high() const;
```

Description

This is get_high, a member of class DynamicArray.

38.1.6.4.8 DynamicArray::get_length Method

Pascal

```
function get_length: Integer;
```

C++

```
int get_length() const;
```

Description

This is get_length, a member of class DynamicArray.

38.1.6.4.9 DynamicArray::get_low Method

Pascal

```
function get_low: Integer;
```

C++

```
int get_low() const;
```

Description

This is get_low, a member of class DynamicArray.

38.1.6.4.10 DynamicArray::IncRefCount Method

Pascal

```
procedure IncRefCount;
```

C++

```
void IncRefCount();
```

Description

This is IncRefCount, a member of class DynamicArray.

38.1.6.4.11 DynamicArray::set_length Method

Pascal

```
procedure set_length(l: Integer);
```

C++

```
void set_length(int l);
```

Description

This is set_length, a member of class DynamicArray.

38.1.6.4.12 DynamicArray::SetData Method

Pascal

```
procedure SetData(var t: T);
```

C++

```
void SetData(T* t);
```

Description

This is SetData, a member of class DynamicArray.

38.1.6.5 DynamicArray Operators

The operators of the DynamicArray class are listed here.

Public Operators

	Name	Description
	[] (see page 3276)	This is the overview for the [] operator overload.
	= (see page 3276)	Assigns data from another Dynamic Array.
	== (see page 3277)	Compares two Dynamic Arrays for equality.

38.1.6.5.1 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	DynamicArray::[] (int) (see page 3276)	Provides access to the data held by the dynamic array.
	DynamicArray::[] (int) (see page 3276)	Provides access to the data held by the dynamic array.

38.1.6.5.1.1 DynamicArray::[] Operator (int)

Provides access to the data held by the dynamic array.

Pascal

```
operator [](index: Integer);
operator [](index: Integer);
```

C++

```
T& operator [](int index);
T operator [](int index) const;
```

Description

The const version of the System::DynamicArray (see page 3268)::[] returns a copy of the data at the specified subscript. The non-const version returns a reference to the data, allowing you to modify the data.

cout << i_array[0]=10;

38.1.6.5.2 DynamicArray::= Operator

Assigns data from another Dynamic Array.

Pascal

```
operator =(const src: DynamicArray<T>&);
```

C++

```
DynamicArray& operator =(const DynamicArray<T>& src);
```

Description

Dynamic Arrays are reference counted. When a DynamicArray (see page 3268) is assigned to another, only the reference is assigned (and the reference count adjusted), the contents of the source are not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To create a separate copy of the contents of a DynamicArray (see page 3268), use the Copy (see page 3273) (or CopyRange (see page 3273)) method.

Copy

38.1.6.5.3 DynamicArray::== Operator

Compares two Dynamic Arrays for equality.

Pascal

```
operator ==(const other: DynamicArray<T> &);
```

C++

```
bool operator ==(const DynamicArray<T> & other) const;
```

Description

The == System::DynamicArray (see page 3268)::== determines whether two dynamic arrays refer to the same memory. It does not compare the contents of the arrays.

38.1.6.6 DynamicArray Properties

The properties of the DynamicArray class are listed here.

Public Properties

	Name	Description
R	High (see page 3277)	Indicates the high bounds of the array.
	Length (see page 3278)	Represents the number of elements in the DynamicArray (see page 3268).
R	Low (see page 3278)	Indicates the low bound of a dynamic array.

38.1.6.6.1 DynamicArray::High Property

Indicates the high bounds of the array.

Pascal

```
property High: Integer;
```

C++

```
__property int High;
```

Description

Reading the High property returns Length (see page 3278)-1.

The following function returns the sum of the contents of an integer type DynamicArray (see page 3268).

int TotalArray(const DynamicArray (see page 3268)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
```

```
return total;
}
```

See Also

Length

Low

38.1.6.6.2 DynamicArray::Length Property

Represents the number of elements in the DynamicArray (see page 3268).

Pascal

```
property Length: Integer;
```

C++

```
__property int Length;
```

Description

Use the Length property to set or get the length of the dynamic array. The following code sets the length of a DynamicArray (see page 3268) to 10.

DynamicArray (see page 3268)<int> arrayOfInt;

```
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

SetLength (see page 3748)(arrayOfInt, 10);

To free a dynamic array, simply set its Length to 0:

arrayOfInt.Length = 0;

See Also

High

38.1.6.6.3 DynamicArray::Low Property

Indicates the low bound of a dynamic array.

Pascal

```
property Low: Integer;
```

C++

```
__property int Low;
```

Description

The Low property always returns 0. The following function returns the sum of the contents of an integer type DynamicArray (see page 3268).

int TotalArray(const DynamicArray (see page 3268)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

38.1.7 DynArrayException Class

Class Hierarchy

Pascal

```
DynArrayException = class;
```

C++

```
class DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayException.

38.1.8 DynArrayNullData Class

Class Hierarchy

Pascal

```
DynArrayNullData = class(DynArrayException);
```

C++

```
class DynArrayNullData : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayNullData.

38.1.9 DynArrayOutOfRange Class

Class Hierarchy

Pascal

```
DynArrayOutOfRange = class(DynArrayException);
```

C++

```
class DynArrayOutOfRange : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayOutOfRange.

38.1.9.1 DynArrayOutOfRange Members

The following tables list the members exposed by DynArrayOutOfRange.

Public Data Members

	Name	Description
	m_Count (see page 3280)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 3281)	This is m_Index, a member of class DynArrayOutOfRange.

Public Methods

	Name	Description
	DynArrayOutOfRange (see page 3280)	This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

38.1.9.2 DynArrayOutOfRange::DynArrayOutOfRange Constructor

Pascal

```
constructor Create(index: Integer; count: Integer);
```

C++

```
DynArrayOutOfRange(int index, int count);
```

Description

This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

38.1.9.3 DynArrayOutOfRange Data Members

The data members of the DynArrayOutOfRange class are listed here.

Public Data Members

	Name	Description
	m_Count (see page 3280)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 3281)	This is m_Index, a member of class DynArrayOutOfRange.

38.1.9.3.1 DynArrayOutOfRange::m_Count Data Member

Pascal

```
m_Count: Integer;
```

C++

```
int m_Count;
```

Description

This is m_Count, a member of class DynArrayOutOfRange.

38.1.9.3.2 DynArrayOutOfRange::m_Index Data Member

Pascal

```
m_Index: Integer;
```

C++

```
int m_Index;
```

Description

This is m_Index, a member of class DynArrayOutOfRange.

38.1.10 OleVariant Class

System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.

Class Hierarchy

Pascal

```
OleVariant = class(Variant);
```

C++

```
class OleVariant : protected Variant;
```

File

sysvari.h

Description

System::OleVariant is a special descendant of the Variant (see page 3430) class that is used to represent COM interfaces or data that is passed over a COM interface. System::OleVariant inherits from Variant (see page 3430) as a protected class so that it can prevent operations on AnsiString (see page 3468) objects, which are not compatible with COM.

The syntax for using System::OleVariant is the same as that for using the Variant (see page 3430) class. Like the Variant (see page 3430) class, System::OleVariant has the following characteristics:

System::OleVariants can contain integer values, real values, string values, boolean values, date-and-time values, and Automation objects. In addition, System::OleVariants can contain arrays of varying size and dimension with elements of any of these types.

The special System::OleVariant value Unassigned is used to indicate that a System::OleVariant has not yet been assigned a value, and the special System::OleVariant value Null is used to indicate unknown or missing data.

A System::OleVariant can be combined with other System::OleVariants and it can be constructed from any of the following data types. The compiler automatically performs the necessary type conversions.

shortWordBool

intByte

floatVariant

doubleWideString

Currencywchar_t*

TDateTimeOle2::IDispatch (see page 3498)*

boolOle2::IUnknown (see page 3828)*

When an System::OleVariant contains an Automation object, the System::OleVariant can be used to get and set properties of the object, and to invoke methods on the object.

System::OleVariant variables are always initialized to be Unassigned when they are first created. This is true whether a System::OleVariant variable is global, local, or part of a structure such as an array.

Note that while System::OleVariants offer great flexibility, they also consume more memory than regular variables, and operations on System::OleVariants are substantially slower than operations on statically typed values.

Note: Use only the operators declared within System::OleVariant. The compiler will ignore any operators you overload yourself.

Note: For binary operators, if one operand is of type System::OleVariant, the other operand is automatically converted to type System::OleVariant.

System::Variant (see page 3430)

TVariantT

38.1.10.1 OleVariant Members

The following tables list the members exposed by OleVariant.

Public Data Members

	Name	Description
	TVarData::Reserved1 (see page 3298)	This is TVarData::Reserved1, a member of class OleVariant.
	TVarData::Reserved2 (see page 3298)	This is TVarData::Reserved2, a member of class OleVariant.
	TVarData::Reserved3 (see page 3298)	This is TVarData::Reserved3, a member of class OleVariant.
	TVarData::VArray (see page 3298)	This is TVarData::VArray, a member of class OleVariant.
	TVarData::VBoolean (see page 3299)	This is TVarData::VBoolean, a member of class OleVariant.
	TVarData::VByte (see page 3299)	This is TVarData::VByte, a member of class OleVariant.
	TVarData::VCurrency (see page 3299)	This is TVarData::VCurrency, a member of class OleVariant.
	TVarData::VDate (see page 3299)	This is TVarData::VDate, a member of class OleVariant.
	TVarData::VDispatch (see page 3299)	This is TVarData::VDispatch, a member of class OleVariant.
	TVarData::VDouble (see page 3300)	This is TVarData::VDouble, a member of class OleVariant.
	TVarData::VError (see page 3300)	This is TVarData::VError, a member of class OleVariant.
	TVarData::VInteger (see page 3300)	This is TVarData::VInteger, a member of class OleVariant.
	TVarData::VOleStr (see page 3300)	This is TVarData::VOleStr, a member of class OleVariant.
	TVarData::VPointer (see page 3301)	This is TVarData::VPointer, a member of class OleVariant.
	TVarData::VSingle (see page 3301)	This is TVarData::VSingle, a member of class OleVariant.
	TVarData::VSmallint (see page 3301)	This is TVarData::VSmallint, a member of class OleVariant.
	TVarData::VType (see page 3301)	This is TVarData::VType, a member of class OleVariant.
	TVarData::VUnknown (see page 3301)	This is TVarData::VUnknown, a member of class OleVariant.
	Variant::- (see page 3302)	This is Variant::-, a member of class OleVariant.
	Variant::! (see page 3302)	This is Variant::!, a member of class OleVariant.
	Variant::%= (see page 3302)	This is Variant::%=, a member of class OleVariant.
	Variant::&= (see page 3302)	This is Variant::&=, a member of class OleVariant.

	Variant::*= (see page 3303)	This is Variant::*=, a member of class OleVariant.
	Variant::/= (see page 3303)	This is Variant::/=, a member of class OleVariant.
	Variant::^= (see page 3303)	This is Variant::^=, a member of class OleVariant.
	Variant::__int64 (see page 3303)	This is Variant::__int64, a member of class OleVariant.
	Variant::|= (see page 3303)	This is Variant::|=, a member of class OleVariant.
	Variant::+= (see page 3304)	This is Variant::+=, a member of class OleVariant.
	Variant::<<= (see page 3304)	This is Variant::<<=, a member of class OleVariant.
	Variant::-= (see page 3304)	This is Variant::-=, a member of class OleVariant.
	Variant::>>= (see page 3304)	This is Variant::>>=, a member of class OleVariant.
	Variant::AnsiString (see page 3305)	This is Variant::AnsiString, a member of class OleVariant.
	Variant::ArrayDimCount (see page 3305)	This is Variant::ArrayDimCount, a member of class OleVariant.
	Variant::ArrayHighBound (see page 3305)	This is Variant::ArrayHighBound, a member of class OleVariant.
	Variant::ArrayLock (see page 3305)	This is Variant::ArrayLock, a member of class OleVariant.
	Variant::ArrayLowBound (see page 3305)	This is Variant::ArrayLowBound, a member of class OleVariant.
	Variant::ArrayRedim (see page 3306)	This is Variant::ArrayRedim, a member of class OleVariant.
	Variant::ArrayUnlock (see page 3306)	This is Variant::ArrayUnlock, a member of class OleVariant.
	Variant::AsType (see page 3306)	This is Variant::AsType, a member of class OleVariant.
	Variant::bool (see page 3306)	This is Variant::bool, a member of class OleVariant.
	Variant::Byte* (see page 3307)	This is Variant::Byte*, a member of class OleVariant.
	Variant::ChangeType (see page 3307)	This is Variant::ChangeType, a member of class OleVariant.
	Variant::char (see page 3307)	This is Variant::char, a member of class OleVariant.
	Variant::Clear (see page 3307)	This is Variant::Clear, a member of class OleVariant.
	Variant::Currency (see page 3307)	This is Variant::Currency, a member of class OleVariant.
	Variant::Currency* (see page 3308)	This is Variant::Currency*, a member of class OleVariant.
	Variant::double (see page 3308)	This is Variant::double, a member of class OleVariant.
	Variant::double* (see page 3308)	This is Variant::double*, a member of class OleVariant.
	Variant::float (see page 3308)	This is Variant::float, a member of class OleVariant.
	Variant::float* (see page 3309)	This is Variant::float*, a member of class OleVariant.
	Variant::GetElement (see page 3309)	This is Variant::GetElement, a member of class OleVariant.
	Variant::GetError (see page 3309)	This is Variant::GetError, a member of class OleVariant.
	Variant::IDispatch* (see page 3309)	This is Variant::IDispatch*, a member of class OleVariant.
	Variant::IInterface* (see page 3309)	This is Variant::IInterface*, a member of class OleVariant.
	Variant::int (see page 3310)	This is Variant::int, a member of class OleVariant.
	Variant::int* (see page 3310)	This is Variant::int*, a member of class OleVariant.
	Variant::IsArray (see page 3310)	This is Variant::IsArray, a member of class OleVariant.
	Variant::IsEmpty (see page 3310)	This is Variant::IsEmpty, a member of class OleVariant.
	Variant::IsNull (see page 3311)	This is Variant::IsNull, a member of class OleVariant.
	Variant::IUnknown* (see page 3311)	This is Variant::IUnknown*, a member of class OleVariant.
	Variant::long (see page 3311)	This is Variant::long, a member of class OleVariant.
	Variant::long* (see page 3311)	This is Variant::long*, a member of class OleVariant.
	Variant::PutElement (see page 3311)	This is Variant::PutElement, a member of class OleVariant.
	Variant::SetError (see page 3312)	This is Variant::SetError, a member of class OleVariant.
	Variant::short (see page 3312)	This is Variant::short, a member of class OleVariant.
	Variant::short* (see page 3312)	This is Variant::short*, a member of class OleVariant.
	Variant::signed char (see page 3312)	This is Variant::signed char, a member of class OleVariant.
	Variant::signed char* (see page 3313)	This is Variant::signed char*, a member of class OleVariant.
	Variant::TDateTime (see page 3313)	This is Variant::TDateTime, a member of class OleVariant.
	Variant::TDateTime* (see page 3313)	This is Variant::TDateTime*, a member of class OleVariant.
	Variant::Type (see page 3313)	This is Variant::Type, a member of class OleVariant.
	Variant::UnicodeString (see page 3313)	This is Variant::UnicodeString, a member of class OleVariant.
	Variant::unsigned char (see page 3314)	This is Variant::unsigned char, a member of class OleVariant.
	Variant::unsigned int (see page 3314)	This is Variant::unsigned int, a member of class OleVariant.
	Variant::unsigned int* (see page 3314)	This is Variant::unsigned int*, a member of class OleVariant.
	Variant::unsigned long (see page 3314)	This is Variant::unsigned long, a member of class OleVariant.

	Variant::unsigned short (see page 3315)	This is Variant::unsigned short, a member of class OleVariant.
	Variant::unsigned short* (see page 3315)	This is Variant::unsigned short*, a member of class OleVariant.
	Variant::WideString (see page 3315)	This is Variant::WideString, a member of class OleVariant.

Public Methods

	Name	Description
	~OleVariant (see page 3286)	Frees an instance of System::OleVariant::OleVariant (see page 3281).
	~Variant (see page 3433)	Frees a System::Variant::Variant (see page 3430) object.
	ArrayDimCount (see page 3437)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 3438)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 3438)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 3438)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 3439)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 3439)	Unlocks a variant array that was previously locked by ArrayLock (see page 3438).
	AsType (see page 3439)	Casts a System::Variant::Variant (see page 3430) object to the type specified by the argument VarType.
	ChangeType (see page 3439)	Changes the data type of a System::Variant::Variant (see page 3430) object once it has been instantiated.
	Clear (see page 3440)	System::Variant::Clears the value of the System::Variant::Variant (see page 3430).
	Empty (see page 3440)	This is Empty, a member of class Variant.
	GetBaseVariant (see page 3440)	Returns the Variant (see page 3430) that is assigned as the value of this Variant (see page 3430) when Type (see page 3444) is varVariant (see page 3941).
	GetElement (see page 3441)	This is the overview for the GetElement method overload.
	GetError (see page 3441)	Converts the System::Variant::Variant (see page 3430) to a varError (see page 3934) type and returns the integer value.
	IsArray (see page 3442)	Queries the VType of the base class TVarData (see page 3813) for the varArray (see page 3929) bit.
	IsEmpty (see page 3442)	Queries the VType of the base class TVarData (see page 3813).
	IsNull (see page 3442)	Queries the VType of the base class TVarData (see page 3813) for the varNull (see page 3936) bit.
	NoParam (see page 3443)	This is NoParam, a member of class Variant.
	OleVariant (see page 3286)	This is the overview for the OleVariant constructor overload.
	PutElement (see page 3443)	This is the overview for the PutElement method overload.
	Sanitized (see page 3444)	This is Sanitized, a member of class Variant.
	SetError (see page 3444)	Converts the System::Variant::Variant (see page 3430) to a varError (see page 3934) type and assigns the integer err as the value of the varError (see page 3934).
	Type (see page 3444)	This is Type, a member of class Variant.
	Variant (see page 3434)	This is the overview for the Variant constructor overload.

Public Operators

	Name	Description
	- (see page 3446)	This is the overview for the - operator overload.
	! (see page 3447)	Returns a new System::Variant::Variant (see page 3430) that is the logical negation of this System::Variant::Variant (see page 3430).
	!= (see page 3315)	This is the overview for the != operator overload.
	!= (see page 3448)	This is the overview for the != operator overload.
	% (see page 3448)	This is the overview for the % operator overload.
	%= (see page 3449)	Returns this System::Variant::Variant (see page 3430) as the remainder from dividing its original value and the System::Variant::Variant (see page 3430) specified by rhs.
	& (see page 3449)	This is the overview for the & operator overload.
	&= (see page 3450)	Returns this System::Variant::Variant (see page 3430) after performing a bitwise and operation.
	* (see page 3450)	This is the overview for the * operator overload.

	*= (see page 3451)	Multiplies this System::Variant::Variant (see page 3430) by the System::Variant::Variant (see page 3430) specified by rhs.
	/ (see page 3452)	This is the overview for the / operator overload.
	/= (see page 3452)	Divides this System::Variant::Variant (see page 3430) by the System::Variant::Variant (see page 3430) rhs.
	^ (see page 3453)	This is the overview for the ^ operator overload.
	^= (see page 3453)	Returns this System::Variant::Variant (see page 3430) after performing a bitwise xor operation.
	__int64 (see page 3454)	This is __int64, a member of class Variant.
	| (see page 3454)	This is the overview for the | operator overload.
	|= (see page 3454)	Returns this System::Variant::Variant (see page 3430) after performing a bitwise or operation.
	+ (see page 3455)	This is the overview for the + operator overload.
	+= (see page 3455)	Adds the System::Variant::Variant (see page 3430) specified by rhs to this System::Variant::Variant (see page 3430) object.
	< (see page 3316)	This is the overview for the < operator overload.
	< (see page 3456)	This is the overview for the < operator overload.
	<< (see page 3456)	This is the overview for the << operator overload.
	<<= (see page 3458)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 3430).
	<= (see page 3317)	This is the overview for the <= operator overload.
	<= (see page 3458)	This is the overview for the <= operator overload.
	-= (see page 3463)	Subtracts the System::Variant::Variant (see page 3430) specified by rhs from this System::Variant::Variant (see page 3430) object.
	= (see page 3317)	This is the overview for the = operator overload.
	= (see page 3459)	This is the overview for the = operator overload.
	== (see page 3320)	This is the overview for the == operator overload.
	== (see page 3463)	This is the overview for the == operator overload.
	> (see page 3320)	This is the overview for the > operator overload.
	> (see page 3464)	This is the overview for the > operator overload.
	>= (see page 3321)	This is the overview for the >= operator overload.
	>= (see page 3465)	This is the overview for the >= operator overload.
	>> (see page 3467)	This is the overview for the >> operator overload.
	>>= (see page 3468)	This is >>=, a member of class Variant.
	AnsiString (see page 3468)	Converts the System::Variant::Variant (see page 3430) to an AnsiString object.
	bool (see page 3468)	Converts the System::Variant::Variant (see page 3430) to a boolean value.
	char (see page 3468)	This is char, a member of class Variant.
	Currency (see page 3469)	Converts the System::Variant::Variant (see page 3430) to a Currency object.
	Currency* (see page 3469)	This is Currency*, a member of class Variant.
	double (see page 3469)	Converts the System::Variant::Variant (see page 3430) to a double value.
	double* (see page 3470)	This is double*, a member of class Variant.
	float (see page 3470)	Converts the System::Variant::Variant (see page 3430) to a float value.
	float* (see page 3470)	This is float*, a member of class Variant.
	IDispatch* (see page 3470)	This is IDispatch*, a member of class Variant.
	IInterface* (see page 3471)	This is IInterface*, a member of class Variant.
	int (see page 3471)	Converts the System::Variant::Variant (see page 3430) to an integer value.
	int* (see page 3471)	This is int*, a member of class Variant.
	IUnknown* (see page 3471)	This is IUnknown*, a member of class Variant.
	long (see page 3472)	This is long, a member of class Variant.
	long* (see page 3472)	This is long*, a member of class Variant.
	short (see page 3472)	Converts the System::Variant::Variant (see page 3430) to a short value.
	short* (see page 3472)	This is short*, a member of class Variant.
	signed char (see page 3473)	This is signed char, a member of class Variant.
	signed char* (see page 3473)	This is signed char*, a member of class Variant.
	TDateTime (see page 3473)	Converts the System::Variant::Variant (see page 3430) to a TDateTime object.
	TDateTime* (see page 3473)	This is TDateTime*, a member of class Variant.

	UnicodeString (see page 3474)	This is UnicodeString, a member of class Variant.
	unsigned char (see page 3474)	This is unsigned char, a member of class Variant.
	unsigned char* (see page 3474)	This is unsigned char*, a member of class Variant.
	unsigned int (see page 3474)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 3474)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 3475)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 3475)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 3475)	This is unsigned short, a member of class Variant.
	unsigned short* (see page 3475)	This is unsigned short*, a member of class Variant.
	WideString (see page 3476)	This is WideString, a member of class Variant.

38.1.10.2 OleVariant::~OleVariant Destructor

Frees an instance of System::OleVariant::OleVariant (see page 3281).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~OleVariant();
```

Description

~System::OleVariant::OleVariant (see page 3281) is the destructor for System::OleVariant::OleVariant (see page 3281).

38.1.10.3 OleVariant Constructor

This is the overview for the OleVariant constructor overload.

Overload List

	Name	Description
	OleVariant::OleVariant () (see page 3288)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (__int64) (see page 3291)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (__int64*) (see page 3291)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (AnsiString&) (see page 3288)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (bool) (see page 3291)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (char) (see page 3291)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (char*) (see page 3292)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Currency) (see page 3288)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Currency*) (see page 3288)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (double) (see page 3292)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (double*) (see page 3292)	This is OleVariant, a member of class OleVariant.

	OleVariant::OleVariant (float) (see page 3292)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (float*) (see page 3293)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IDispatch* const) (see page 3289)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IInterface* const) (see page 3289)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int) (see page 3293)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int*) (see page 3293)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int*, int, Word) (see page 3293)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IUnknown* const) (see page 3289)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (long*) (see page 3293)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (OleVariant&) (see page 3289)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (OleVariant*, int) (see page 3289)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (short) (see page 3294)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (short*) (see page 3294)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (signed char*) (see page 3294)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (TDateTime) (see page 3290)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (TDateTime*) (see page 3290)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (UnicodeString&) (see page 3290)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned char) (see page 3294)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned char*) (see page 3295)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned int) (see page 3295)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned int*) (see page 3295)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned long*) (see page 3295)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned short) (see page 3295)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned short*) (see page 3296)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Variant&) (see page 3290)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (wchar_t* const, bool) (see page 3296)	This is OleVariant, a member of class OleVariant.

	OleVariant::OleVariant (WideString&) (see page 3291)	This is OleVariant, a member of class OleVariant.

38.1.10.3.1 OleVariant::OleVariant Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall OleVariant();
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.2 OleVariant::OleVariant Constructor (AnsiString&)

Pascal

```
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall OleVariant(const AnsiString& src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.3 OleVariant::OleVariant Constructor (Currency)

Pascal

```
constructor Create(const src: Currency);
```

C++

```
__fastcall OleVariant(const Currency src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.4 OleVariant::OleVariant Constructor (Currency*)

Pascal

```
constructor Create(var src: Currency);
```

C++

```
__fastcall OleVariant(Currency* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.5 OleVariant::OleVariant Constructor (IDispatch* const)

Pascal

```
constructor Create(src: IDispatch* const);
```

C++

```
__fastcall OleVariant(IDispatch* const src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.6 OleVariant::OleVariant Constructor (IInterface* const)

Pascal

```
constructor Create(src: IInterface* const);
```

C++

```
__fastcall OleVariant(IInterface* const src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.7 OleVariant::OleVariant Constructor (IUnknown* const)

Pascal

```
constructor Create(src: IUnknown* const);
```

C++

```
__fastcall OleVariant(IUnknown* const src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.8 OleVariant::OleVariant Constructor (OleVariant&)

Pascal

```
constructor Create(const src: OleVariant&);
```

C++

```
__fastcall OleVariant(const OleVariant& src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.9 OleVariant::OleVariant Constructor (OleVariant*, int)

Pascal

```
constructor Create(const values: OleVariant*; const valuesSize: Integer);
```

C++

```
__fastcall OleVariant(const OleVariant* values, const int valuesSize);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.10 OleVariant::OleVariant Constructor (TDateTime)

Pascal

```
constructor Create(const src: TDateTime);
```

C++

```
__fastcall OleVariant(const TDateTime src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.11 OleVariant::OleVariant Constructor (TDateTime*)

Pascal

```
constructor Create(var src: TDateTime);
```

C++

```
__fastcall OleVariant(TDateTime* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.12 OleVariant::OleVariant Constructor (UnicodeString&)

Pascal

```
constructor Create(const src: UnicodeString&);
```

C++

```
__fastcall OleVariant(const UnicodeString& src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.13 OleVariant::OleVariant Constructor (Variant&)

Pascal

```
constructor Create(const src: Variant&);
```

C++

```
__fastcall OleVariant(const Variant& src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.14 OleVariant::OleVariant Constructor (WideString&)

Pascal

```
constructor Create(const src: WideString&);
```

C++

```
__fastcall OleVariant(const WideString& src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.15 OleVariant::OleVariant Constructor (__int64)

Pascal

```
constructor Create(const src: __int64);
```

C++

```
__fastcall OleVariant(const __int64 src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.16 OleVariant::OleVariant Constructor (__int64*)

Pascal

```
constructor Create(var src: __int64);
```

C++

```
__fastcall OleVariant(__int64* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.17 OleVariant::OleVariant Constructor (bool)

Pascal

```
constructor Create(const src: bool);
```

C++

```
__fastcall OleVariant(const bool src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.18 OleVariant::OleVariant Constructor (char)

Pascal

```
constructor Create(const src: char);
```

C++

```
__fastcall OleVariant(const char src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.19 OleVariant::OleVariant Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall OleVariant(const char* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.20 OleVariant::OleVariant Constructor (double)

Pascal

```
constructor Create(const src: double);
```

C++

```
__fastcall OleVariant(const double src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.21 OleVariant::OleVariant Constructor (double*)

Pascal

```
constructor Create(var src: double);
```

C++

```
__fastcall OleVariant(double* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.22 OleVariant::OleVariant Constructor (float)

Pascal

```
constructor Create(const src: float);
```

C++

```
__fastcall OleVariant(const float src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.23 OleVariant::OleVariant Constructor (float*)

Pascal

```
constructor Create(var src: float);
```

C++

```
__fastcall OleVariant(float* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.24 OleVariant::OleVariant Constructor (int)

Pascal

```
constructor Create(const src: Integer);
```

C++

```
__fastcall OleVariant(const int src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.25 OleVariant::OleVariant Constructor (int*)

Pascal

```
constructor Create(var src: Integer);
```

C++

```
__fastcall OleVariant(int* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.26 OleVariant::OleVariant Constructor (int*, int, Word)

Pascal

```
constructor Create(const bounds: int*; const boundsSize: Integer; varType: Word);
```

C++

```
__fastcall OleVariant(const int* bounds, const int boundsSize, Word varType);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.27 OleVariant::OleVariant Constructor (long*)

Pascal

```
constructor Create(var src: long);
```

C++

```
__fastcall OleVariant(long* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.28 OleVariant::OleVariant Constructor (short)

Pascal

```
constructor Create(const src: short);
```

C++

```
__fastcall OleVariant(const short src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.29 OleVariant::OleVariant Constructor (short*)

Pascal

```
constructor Create(var src: short);
```

C++

```
__fastcall OleVariant(short* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.30 OleVariant::OleVariant Constructor (signed char*)

Pascal

```
constructor Create(var src: signed char);
```

C++

```
__fastcall OleVariant(signed char* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.31 OleVariant::OleVariant Constructor (unsigned char)

Pascal

```
constructor Create(const src: unsigned char);
```

C++

```
__fastcall OleVariant(const unsigned char src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.32 OleVariant::OleVariant Constructor (unsigned char*)

Pascal

```
constructor Create(var src: unsigned char);
```

C++

```
__fastcall OleVariant(unsigned char* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.33 OleVariant::OleVariant Constructor (unsigned int)

Pascal

```
constructor Create(const src: unsigned int);
```

C++

```
__fastcall OleVariant(const unsigned int src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.34 OleVariant::OleVariant Constructor (unsigned int*)

Pascal

```
constructor Create(var src: unsigned int);
```

C++

```
__fastcall OleVariant(unsigned int* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.35 OleVariant::OleVariant Constructor (unsigned long*)

Pascal

```
constructor Create(var src: unsigned long);
```

C++

```
__fastcall OleVariant(unsigned long* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.36 OleVariant::OleVariant Constructor (unsigned short)

Pascal

```
constructor Create(const src: unsigned short);
```

C++

```
__fastcall OleVariant(const unsigned short src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.37 OleVariant::OleVariant Constructor (unsigned short*)

Pascal

```
constructor Create(var src: unsigned short);
```

C++

```
__fastcall OleVariant(unsigned short* src);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.3.38 OleVariant::OleVariant Constructor (wchar_t* const, bool)

Pascal

```
constructor Create(src: wchar_t* const; isBSTR: bool = true);
```

C++

```
__fastcall OleVariant(wchar_t* const src, bool isBSTR = true);
```

Description

This is OleVariant, a member of class OleVariant.

38.1.10.4 OleVariant Data Members

The data members of the OleVariant class are listed here.

Public Data Members

	Name	Description
	TVarData::Reserved1 (see page 3298)	This is TVarData::Reserved1, a member of class OleVariant.
	TVarData::Reserved2 (see page 3298)	This is TVarData::Reserved2, a member of class OleVariant.
	TVarData::Reserved3 (see page 3298)	This is TVarData::Reserved3, a member of class OleVariant.
	TVarData::VArray (see page 3298)	This is TVarData::VArray, a member of class OleVariant.
	TVarData::VBoolean (see page 3299)	This is TVarData::VBoolean, a member of class OleVariant.
	TVarData::VByte (see page 3299)	This is TVarData::VByte, a member of class OleVariant.
	TVarData::VCurrency (see page 3299)	This is TVarData::VCurrency, a member of class OleVariant.
	TVarData::VDate (see page 3299)	This is TVarData::VDate, a member of class OleVariant.
	TVarData::VDispatch (see page 3299)	This is TVarData::VDispatch, a member of class OleVariant.
	TVarData::VDouble (see page 3300)	This is TVarData::VDouble, a member of class OleVariant.
	TVarData::VError (see page 3300)	This is TVarData::VError, a member of class OleVariant.
	TVarData::VInteger (see page 3300)	This is TVarData::VInteger, a member of class OleVariant.
	TVarData::VOleStr (see page 3300)	This is TVarData::VOleStr, a member of class OleVariant.
	TVarData::VPointer (see page 3301)	This is TVarData::VPointer, a member of class OleVariant.
	TVarData::VSingle (see page 3301)	This is TVarData::VSingle, a member of class OleVariant.
	TVarData::VSmallint (see page 3301)	This is TVarData::VSmallint, a member of class OleVariant.
	TVarData::VType (see page 3301)	This is TVarData::VType, a member of class OleVariant.
	TVarData::VUnknown (see page 3301)	This is TVarData::VUnknown, a member of class OleVariant.
	Variant::- (see page 3302)	This is Variant::-, a member of class OleVariant.
	Variant::! (see page 3302)	This is Variant::!, a member of class OleVariant.

	Variant::%= (see page 3302)	This is Variant::%=, a member of class OleVariant.
	Variant::&= (see page 3302)	This is Variant::&=, a member of class OleVariant.
	Variant::*= (see page 3303)	This is Variant::*=, a member of class OleVariant.
	Variant::/= (see page 3303)	This is Variant::/=, a member of class OleVariant.
	Variant::^= (see page 3303)	This is Variant::^=, a member of class OleVariant.
	Variant::__int64 (see page 3303)	This is Variant::__int64, a member of class OleVariant.
	Variant::|= (see page 3303)	This is Variant::|=, a member of class OleVariant.
	Variant::+= (see page 3304)	This is Variant::+=, a member of class OleVariant.
	Variant::<<= (see page 3304)	This is Variant::<<=, a member of class OleVariant.
	Variant::-= (see page 3304)	This is Variant::-=, a member of class OleVariant.
	Variant::>>= (see page 3304)	This is Variant::>>=, a member of class OleVariant.
	Variant::AnsiString (see page 3305)	This is Variant::AnsiString, a member of class OleVariant.
	Variant::ArrayDimCount (see page 3305)	This is Variant::ArrayDimCount, a member of class OleVariant.
