Enabling Mouse

30.1.5.2.22 TComboBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
```

```
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

30.1.5.2.23 TComboBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

SetIme

SetImeCompositionWindow

30.1.5.2.24 TComboBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

Imes

30.1.5.2.25 TComboBox.ItemHeight Property

Specifies the height, in pixels, of the items in the drop-down list.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Read ItemHeight to determine the height of the items in the drop-down list.

The effect of setting ItemHeight varies, depending on the type of combo box and the style. For example, TComboBox lets you set the item height only when Style is set to csOwnerDrawFixed or csOwnerDrawVariable. If Style is csOwnerDrawVariable, ItemHeight is the default height for drawing list items, but this value can be overridden by an OnMeasureItem event handler.

TComboBoxEx does not let you change the value of ItemHeight.

Note: Combo boxes that do not support changes to ItemHeight do not raise an exception when you attempt to change ItemHeight; they simply ignore the attempt.

Items (see page 2308)

OnMeasureItem (see page 2338)

Style (see page 2337)

30.1.5.2.26 TComboBox.ItemIndex Property

Specifies the index of the selected item.

Pascal

```
property ItemIndex;
```

C++

```
__property ItemIndex;
```

Description

Read ItemIndex to determine which item is selected. The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1. If the list control supports multiple selected items, ItemIndex is the index of the selected item that has focus.

Set ItemIndex programmatically to select an item by passing in the index value.

Note: To implement the ItemIndex property in a TCustomListControl descendant, override the protected GetItemIndex and SetItemIndex methods.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
           mtInformation, TMsgDlgButtons() << mbOK, 0);
}
/*
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
selects an item and clicks the button, the selected item in
the list box is moved to the top of the list box:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->MultiSelect = false;
```

```
  Button1->Caption = "Move to Top";
  for (int i = 1; i <= 10; i++)
    ListBox1->Items->Add("Item " + IntToStr(i));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ListBox1->ItemIndex >= 0 && ListBox1->ItemIndex <= 9)
    ListBox1->Items->Move(ListBox1->ItemIndex, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
             mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
{
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
clicks the button, the selected item in the list box is
moved to the top of the list box:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (ListBox1.ItemIndex in [0..9]) then
    ListBox1.Items.Move(ListBox1.ItemIndex, 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  ListBox1.MultiSelect := False;
  Button1.Caption := 'Move to Top';
  for I := 1 to 10 do
    ListBox1.Items.Add('Item ' + IntToStr(I));
end;
```

See Also

GetItemIndex

SetItemIndex

30.1.5.2.27 TComboBox.Items Property

Provides access to the list of items (strings) in the list portion of the combo box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Read Items to access the list of items that appears in the combo box. Use the methods of Items to add, insert, delete and move items. Set the value of Items to copy the items from another string list.

C++ Examples:

```
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
  ComboBox1->Items->AddObject("vsIcon", reinterpret_cast<TObject *>(vsIcon));
```

```
  ComboBox1->Items->AddObject("vsList", reinterpret_cast<TObject *>(vsList));
  ComboBox1->Items->AddObject("vsReport", reinterpret_cast<TObject *>(vsReport));
  ComboBox1->Items->AddObject("vsSmallIcon", reinterpret_cast<TObject *>(vsSmallIcon));
  // Display first item in the Combo Box
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
}
```

Delphi Examples:

```
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
    for I := 0 to ImageList1.Count - 1 do
    begin
      ListItem := Items.Add;
      Listitem.Caption := 'Image' + IntToStr(I);
      ListItem.ImageIndex := I;
      Listitem.SubItems.Add(Col2Array[I]);
    end;
    // Create two columns to show during viewing as vsReport
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 1';
    NewColumn.Width := 200;
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 2';
    NewColumn.Width := 200;
    // Add View styles and constants to the Combo Box
    ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
    ComboBox1.Items.AddObject('vsList', TObject(vsList));
    ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
    ComboBox1.Items.AddObject(
      'vsSmallIcon', TObject(vsSmallIcon));
    // Display first item in the Combo Box
    ComboBox1.ItemIndex := 0;
```

```
  end;
end;

procedure TComboForm.ComboBox1Click(Sender: TObject);
begin
  with ComboBox1 do
    ListView1.ViewStyle := TViewStyle(Items.Objects[ItemIndex]);

end;
```

Assign

30.1.5.2.28 TComboBox.MaxLength Property

Specifies the maximum number of characters the user can type into the edit portion of the combo box.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that the user can enter into the edit portion of the combo box. A value of 0 indicates that there is no application-defined limit on the length.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Text

30.1.5.2.29 TComboBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.5.2.30 TComboBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.5.2.31 TComboBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.5.2.32 TComboBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.5.2.33 TComboBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

30.1.5.2.34 TComboBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.5.2.35 TComboBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Paste1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }
  /*
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  */
  void __fastcall TForm1::AddButtonClick(TObject *Sender)
  {
      // The owner (PopupMenu1) will cleanup this menu item.
      TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
      int index = PopupMenu1->Items->Count;
      PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
      NewItem->Caption = "Menu Item " + IntToStr(index);
      NewItem->Tag = index;
      NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler

```

```
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    PopupMenu1.AutoPopup := True;
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

  type
    TForm1 = class(TForm)
      AddButton: TButton;

30.1.5.2.36 TComboBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
```

```
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.5.2.37 TComboBox.Sorted Property

Determines whether the list portion of the combo box is alphabetized.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Set Sorted to true to sort the items in the Items list alphabetically. New items added to the list while Sorted is true are inserted in

the correct alphabetical position.

When Sorted is changed from false to true, the original order of the items is lost. Setting Sorted back to false does not restore the original order.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

30.1.5.2.38 TComboBox.Style Property

Determines the display style of the combo box.

Pascal

```
property Style: TComboBoxStyle;
```

C++

```
__property TComboBoxStyle Style;
```

Description

Set Style to specify how the list and edit region of the combo box should appear.

When Style is csOwnerDrawFixed or csOwnerDrawVariable, the OnDrawItem event occurs when the list items need to be drawn. If Style is csOwnerDrawVariable, an OnMeasureItem event occurs as well.

30.1.5.2.39 TComboBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

30.1.5.2.40 TComboBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.5.2.41 TComboBox.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                       //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

Caption

Lines (see page 2451)

30.1.5.2.42 TComboBox.TextHint Property

Specifies the text that is displayed as a text watermark in the edit box of the combo box control.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to get or set the watermark text that is shown in the edit box of the combo box control.

The disabled watermark is displayed as long as you do not modify the Text property of the combo box.

Note: This feature is only available in Vista.

See Also

TCustomComboBox (see page 2322)

30.1.5.2.43 TComboBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
```

```
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.

30.1.5.3 TComboBox Events

The events of the TComboBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 2228)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 2230)	Occurs when the user clicks the control.
	OnCloseUp (see page 2232)	Occurs when the drop-down list closes up due to some user action.
	OnContextPopup (see page 2233)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2233)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2234)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2237)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2240)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnDropDown (see page 2240)	Occurs when the user opens the drop-down list.
	OnEndDock (see page 2242)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2242)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2243)	Occurs when a control receives the input focus.
	OnExit (see page 2246)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2250)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2253)	Occurs when a key is pressed.
	OnKeyUp (see page 2254)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2256)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnMouseEnter (see page 2257)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2257)	Occurs when the user moves the mouse outside of a control.
	OnSelect (see page 2257)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 2257)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2258)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.5.3.1 TComboBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
```

```
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)

OnCloseUp (see page 2320)

30.1.5.3.2 TComboBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
  property OnClick;
```

C++

```
  __property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;

30.1.5.3.3 TComboBox.OnCloseUp Event

Occurs when the drop-down list closes up due to some user action.

Pascal

```
property OnCloseUp: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCloseUp;
```

Description

Write an OnCloseUp event handler to implement special processing that needs to occur when the drop-down list closes up. For example, an OnCloseUp event handler can check whether the user changed the selected item while the list was dropped down and respond accordingly.

OnDropDown (see page 2320)

DroppedDown (see page 2306)

30.1.5.3.4 TComboBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

30.1.5.3.5 TComboBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

30.1.5.3.6 TComboBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

30.1.5.3.7 TComboBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{

30.1.5.3.8 TComboBox.OnDrawItem Event

Occurs when an item in an owner-draw combo box needs to be displayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Write an OnDrawItem event handler to draw the items in the drop-down list of an owner-draw combo box. An OnDrawItem event handler can add graphic elements to the list items, or replace the list item text by graphics.

Draw the items on the Canvas using the coordinates provided by the Rect parameter. OnDrawItem occurs only if Style is set to csOwnerDrawFixed or csOwnerDrawVariable.

If an OnDrawItem event handler is not provided, the combo box fills the Rect parameter with the current brush and writes the text value of the item specified by the Index parameter.

Canvas (see page 2305)

Items (see page 2308)

OnMeasureItem (see page 2338)

Style (see page 2337)

30.1.5.3.9 TComboBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

30.1.5.3.11 TComboBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
```

```
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

30.1.5.3.12 TComboBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/

}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;

30.1.5.3.13 TComboBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

ActiveControl

30.1.5.3.14 TComboBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

30.1.5.3.15 TComboBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII

character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

30.1.5.3.17 TComboBox.OnMeasureItem Event

Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

When Style is set to csOwnerDrawVariable, the OnMeasureItem event precedes OnDrawItem. Write an OnMeasureItem event handler to specify the height, in pixels, needed to draw an item in the drop-down list.

See Also

ItemHeight (see page 2307)

Items (see page 2308)

OnDrawItem (see page 2338)

Style (see page 2337)

30.1.5.3.18 TComboBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.5.3.19 TComboBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.5.3.20 TComboBox.OnSelect Event

Occurs when the user selects a string in the drop-down list.

Pascal

```
property OnSelect: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnSelect;
```

Description

Write an OnSelect event handler to respond when the user changes the selected item in the drop-down list. OnSelect occurs after the selection has changed and the Text property reflects the new item.

See Also

AutoComplete (see page 2332)

ItemIndex

Text

30.1.5.3.21 TComboBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

30.1.5.3.22 TComboBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.6 TCustomButton Class

Base class for a push button control.

Class Hierarchy

Pascal

```
TCustomButton = class(TButtonControl);
```

C++

```
class TCustomButton : public TButtonControl;
```

File

StdCtrls

Description

Use TCustomButton as a base class for a standard push button on a form.

See Also

TButton (see page 2035)

30.1.6.1 TCustomButton Members

The following tables list the members exposed by TCustomButton.

Enumerations

	Name	Description
	TButtonStyle (see page 2261)	Style (see page 2275) of TButton (see page 2035).

Protected Methods

	Name	Description
	ActionChange (see page 2262)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2263)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2264)	Creates the underlying window.
	GetActionLinkClass (see page 2264)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2112)	Returns whether the button control is checked.
	Loaded (see page 2264)	Initializes the control after it is loaded from a stream.
	Notification (see page 2265)	Responds to notifications that components are being created or destroyed.
	SetButtonStyle (see page 2265)	Sets the Style (see page 2275) property for a button.

	SetChecked (see page 2112)	Sets the Checked (see page 2113) property.
	UpdateImageList (see page 2266)	Rebuilds the image list associated with the button.
	UpdateImages (see page 2266)	Updates the image list associated with the button.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	Checked (see page 2113)	Specifies whether the button control is checked.
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.
	WordWrap (see page 2115)	Specifies whether the button text wraps to fit the width of the control.

Public Events

	Name	Description
	OnDropDownClick (see page 2276)	Down arrow part of Vista style split button is clicked.

Public Methods

	Name	Description
	Click (see page 2263)	Simulates a mouse click, as if the user had clicked the button.
	Create (see page 2260)	Creates and initializes a button instance.
	Destroy (see page 2261)	Destroys an instance of TWinControl.
	UseRightToLeftAlignment (see page 2266)	Specifies whether the control's alignment is in a right-to-left mode.

Public Properties

	Name	Description
	Cancel (see page 2267)	Determines whether the button's OnClick event handler executes when the Escape key is pressed.
	CommandLinkHint (see page 2267)	Text displayed as hint below button caption for Command Link.
	Default (see page 2268)	Determines whether the button's OnClick event handler executes when the Enter key is pressed.
	DisabledImageIndex (see page 2269)	Image index for disabled button state.
	DropDownMenu (see page 2269)	Split button drop down menu.
	ElevationRequired (see page 2270)	Put shield icon on button indicating elevated access rights required.
	HotImageIndex (see page 2270)	Image index for hot button state.
	ImageAlignment (see page 2271)	Alignment of image on button.
	ImageIndex (see page 2271)	Image index for normal button state.
	ImageMargins (see page 2272)	Margins of image on button.
	Images (see page 2272)	List of images for a button.
	ModalResult (see page 2273)	Determines whether and how the button closes its (modal) parent form.
	PressedImageIndex (see page 2274)	Image index for pressed button state.
	SelectedImageIndex (see page 2274)	Image index for selected button state.
	Style (see page 2275)	Style of a button.
	TabStop (see page 2275)	Determines if the user can tab to a control.

30.1.6.2 TCustomButton.Create Constructor

Creates and initializes a button instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomButton(TComponent * AOwner);
```

Description

Use Create to programmatically instantiate a button. Buttons added in the form designer are created automatically.

AOwner is the component that is responsible for freeing the button instance. It becomes the value of the Owner property.

See Also

Owner

30.1.6.3 TCustomButton.Destroy Destructor

Destroys an instance of TWinControl.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomButton();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TWinControl reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

Destroy

30.1.6.4 TCustomButton Enumerations

The enumerations of the TCustomButton class are listed here.

Enumerations

	Name	Description
	TButtonStyle (see page 2261)	Style (see page 2275) of TButton (see page 2035).

30.1.6.4.1 StdCtrls.TCustomButton.TButtonStyle Enumeration

Style (see page 2275) of TButton (see page 2035).

Pascal

```
TButtonStyle = (
  bsPushButton,
  bsCommandLink,
  bsSplitButton
);
```

C++

```
enum TButtonStyle {
  bsPushButton,
  bsCommandLink,
  bsSplitButton
};
```

File

StdCtrls

Description

TButtonStyle indicates a TButton (see page 2035)'s style, which is the value of its Style (see page 2275) property. Following are the possible values of TButtonStyle:

Value	Meaning
bsPushButton	The button is a standard push button.
bsCommandLink	Command Link style button. Display the text in CommandLinkHint (see page 2267) as a hint below the button caption. Windows Vista only.
bsSplitButton	Make the button a Vista style split button, which has a drop down menu. Windows Vista only.

See Also

TButton (see page 2035)

CommandLinkHint (see page 2267)

Style (see page 2275)

30.1.6.5 TCustomButton Methods

The methods of the TCustomButton class are listed here.

Protected Methods

	Name	Description
	ActionChange (see page 2262)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2263)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2264)	Creates the underlying window.
	GetActionLinkClass (see page 2264)	Returns the appropriate action link class that is associated with button controls.
	Loaded (see page 2264)	Initializes the control after it is loaded from a stream.
	Notification (see page 2265)	Responds to notifications that components are being created or destroyed.
	SetButtonStyle (see page 2265)	Sets the Style (see page 2275) property for a button.
	UpdateImageList (see page 2266)	Rebuilds the image list associated with the button.
	UpdateImages (see page 2266)	Updates the image list associated with the button.

Public Methods

	Name	Description
	Click (see page 2263)	Simulates a mouse click, as if the user had clicked the button.
	UseRightToLeftAlignment (see page 2266)	Specifies whether the control's alignment is in a right-to-left mode.

30.1.6.5.1 TCustomButton.ActionChange Method

Updates the button control to reflect changes in its associated action.

Pascal

```
procedure ActionChange(Sender: TObject; CheckDefaults: Boolean); override;
```

C++

```
virtual __fastcall ActionChange(TObject * Sender, Boolean CheckDefaults);
```

Description

ActionChange is called automatically when the associated action changes. It updates the button control to reflect the action's current Checked state. Then it calls the inherited method, which checks the associated properties for that client type.

The Sender parameter is the associated action. The CheckDefaults parameter specifies whether properties and event handlers should be changed if they differ from the default values. When CheckDefaults is true, properties and event handlers are only changed when the current values are the default values (that is, when the values have not been previously changed). When CheckDefaults is false, properties and event handlers are changed, regardless of their current values.

See Also

TCustomAction

30.1.6.5.2 TCustomButton.Click Method

Simulates a mouse click, as if the user had clicked the button.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Calling Click assigns the value of the button's ModalResult (see page 2273) property to the ModalResult (see page 2273) property of its parent form, and then generates an OnClick event.

See Also

ModalResult (see page 2273)

OnClick

30.1.6.5.3 TCustomButton.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

30.1.6.5.4 TCustomButton.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

30.1.6.5.5 TCustomButton.GetActionLinkClass Method

Returns the appropriate action link class that is associated with button controls.

Pascal

```
function GetActionLinkClass: TControlActionLinkClass; override;
```

C++

```
virtual __fastcall TControlActionLinkClass GetActionLinkClass();
```

Description

GetActionLinkClass is used to get the appropriate class type for the action link used with button controls. GetActionLinkClass is used internally to create action link objects for clients when a button control has an associated action. The action link is used to link the action to the button control client. Each Action link class type is designed to link specific actions to clients based upon the types of properties the client supports. For button controls, GetActionLinkClass returns the TButtonActionLink class type.

See Also

TButtonActionLink (see page 2106)

30.1.6.5.6 TCustomButton.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

30.1.6.5.7 TCustomButton.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu

Notification

30.1.6.5.8 TCustomButton.SetButtonStyle Method

Sets the Style (see page 2275) property for a button.

Pascal

```
procedure SetButtonStyle(ADefault: Boolean); virtual;
```

C++

```
virtual __fastcall SetButtonStyle(Boolean ADefault);
```

Description

The SetButtonStyle method is called to change the Style (see page 2275) property according to the button's state, whenever a button changes its focus state.

See Also

TButtonStyle (see page 2261)

Style (see page 2275)

30.1.6.5.9 TCustomButton.UpdateImageList Method

Rebuilds the image list associated with the button.

Pascal

```
procedure UpdateImageList; virtual;
```

C++

```
virtual __fastcall UpdateImageList();
```

Description

The UpdateImageList method is called to update the image list associated with the button control.

See Also

UpdateImages (see page 2266)

30.1.6.5.10 TCustomButton.UpdateImages Method

Updates the image list associated with the button.

Pascal

```
procedure UpdateImages; virtual;
```

C++

```
virtual __fastcall UpdateImages();
```

Description

The UpdateImages method is called to add images to the image list associated with the button control.

See Also

UpdateImageList (see page 2266)

AddImage

30.1.6.5.11 TCustomButton.UseRightToLeftAlignment Method

Specifies whether the control's alignment is in a right-to-left mode.

Pascal

```
function UseRightToLeftAlignment: Boolean; override;
```

C++

```
virtual __fastcall Boolean UseRightToLeftAlignment();
```

Description

For this class, UseRightToLeftAlignment always returns false. This is because the alignment of a button should never be reversed automatically when running in Middle Eastern locales.

See Also

ModalResult (see page 2273)

OnClick

30.1.6.6 TCustomButton Properties

The properties of the TCustomButton class are listed here.

Public Properties

	Name	Description
	Cancel (see page 2267)	Determines whether the button's OnClick event handler executes when the Escape key is pressed.
	CommandLinkHint (see page 2267)	Text displayed as hint below button caption for Command Link.
	Default (see page 2268)	Determines whether the button's OnClick event handler executes when the Enter key is pressed.
	DisabledImageIndex (see page 2269)	Image index for disabled button state.
	DropDownMenu (see page 2269)	Split button drop down menu.
	ElevationRequired (see page 2270)	Put shield icon on button indicating elevated access rights required.
	HotImageIndex (see page 2270)	Image index for hot button state.
	ImageAlignment (see page 2271)	Alignment of image on button.
	ImageIndex (see page 2271)	Image index for normal button state.
	ImageMargins (see page 2272)	Margins of image on button.
	Images (see page 2272)	List of images for a button.
	ModalResult (see page 2273)	Determines whether and how the button closes its (modal) parent form.
	PressedImageIndex (see page 2274)	Image index for pressed button state.
	SelectedImageIndex (see page 2274)	Image index for selected button state.
	Style (see page 2275)	Style of a button.
	TabStop (see page 2275)	Determines if the user can tab to a control.

30.1.6.6.1 TCustomButton.Cancel Property

Determines whether the button's OnClick event handler executes when the Escape key is pressed.

Pascal

```
property Cancel: Boolean;
```

C++

```
__property Boolean Cancel;
```

Description

If Cancel is true, the button's OnClick event handler executes when the user presses Esc. Although an application can have more than one Cancel button, the form calls the OnClick event handler only for the first visible button in the tab order.

See Also

Default (see page 2268)

OnClick

30.1.6.6.2 TCustomButton.CommandLinkHint Property

Text displayed as hint below button caption for Command Link.

Pascal

```
property CommandLinkHint: string;
```

C++

```
__property UnicodeString CommandLinkHint;
```

Description

CommandLinkHint is the text displayed as a hint below the button caption when the Style (see page 2275) property is **bsCommandLink** to specify a Command Link button.

This is available on Windows Vista only.

See Also

Style (see page 2275)

TButtonStyle (see page 2261)

30.1.6.6.3 TCustomButton.Default Property

Determines whether the button's OnClick event handler executes when the Enter key is pressed.

Pascal

```
property Default: Boolean;
```

C++

```
__property Boolean Default;
```

Description

If Default is true, the button's OnClick event handler executes when the user presses Enter.

Although an application can have more than one Default button, the form calls the OnClick event handler only for the first visible button in the tab order. Moreover, any button that has focus becomes the Default button temporarily; hence, if the user selects another button before pressing Enter, the selected button's OnClick event handler executes instead.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

Cancel (see page 2267)

OnClick

30.1.6.6.4 TCustomButton.DisabledImageIndex Property

Image index for disabled button state.

Pascal

```
property DisabledImageIndex: TImageIndex;
```

C++

```
__property TImageIndex DisabledImageIndex;
```

Description

DisabledImageIndex is an image index into the Images (see page 2272) property for the disabled button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

HotImageIndex (see page 2270)

ImageIndex (see page 2271)

Images (see page 2272)

PressedImageIndex (see page 2274)

SelectedImageIndex (see page 2274)

30.1.6.6.5 TCustomButton.DropDownMenu Property

Split button drop down menu.

Pascal

```
property DropDownMenu: TPopupMenu;
```

C++

```
__property TPopupMenu DropDownMenu;
```

Description

When the Style (see page 2275) property is **bsSplitButton**, the button is a Vista style split button with a drop down menu. DropDownMenu specifies the drop down menu for the down arrow button part. The OnDropDownClick (see page 2276) event also occurs when the down arrow button part is clicked.

This is available on Windows Vista only.

See Also

TPopupMenu

Style (see page 2275)

OnDropDownClick (see page 2276)

TButtonStyle (see page 2261)

30.1.6.6.6 TCustomButton.ElevationRequired Property

Put shield icon on button indicating elevated access rights required.

Pascal

```
property ElevationRequired: Boolean;
```

C++

```
__property Boolean ElevationRequired;
```

Description

When ElevationRequired is true, the button has a shield icon, indicating that elevated access rights are required. Vista UI guidelines specify that when there is a button that performs an operation requiring elevated access rights, it should have this shield icon.

This icon overrides any of the properties specifying a button image for various button states, as in ImageIndex (see page 2271).

This is available on Windows Vista only.

See Also

ImageIndex (see page 2271)

Images (see page 2272)

30.1.6.6.7 TCustomButton.HotImageIndex Property

Image index for hot button state.

Pascal

```
property HotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex HotImageIndex;
```

Description

HotImageIndex is an image index into the Images (see page 2272) property for the hot button state, i.e., the cursor hovering over the button. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

DisabledImageIndex (see page 2269)

ImageIndex (see page 2271)

Images (see page 2272)

PressedImageIndex (see page 2274)

SelectedImageIndex (see page 2274)

30.1.6.6.8 TCustomButton.ImageAlignment Property

Alignment of image on button.

Pascal

```
property ImageAlignment: TImageAlignment;
```

C++

```
__property TImageAlignment ImageAlignment;
```

Description

TImageAlignment (see page 3002) indicates the alignment of an image on a button. It is a TImageAlignment (see page 3002) type.

See Also

ImageMargins (see page 2272)

Images (see page 2272)

TImageAlignment (see page 3002)

30.1.6.6.9 TCustomButton.ImageIndex Property

Image index for normal button state.

Pascal

```
property ImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ImageIndex;
```

Description

ImageIndex is an image index into the Images (see page 2272) property for the normal button state. If the index value is -1, no image is used.

In Vista, a standard green arrow is used when the index is -1 and the Style (see page 2275) property is **bsCommandLink** for a Command Link button.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

DisabledImageIndex (see page 2269)

HotImageIndex (see page 2270)

Images (see page 2272)

PressedImageIndex (see page 2274)

SelectedImageIndex (see page 2274)

Style (see page 2275)

TButtonStyle (see page 2261)

30.1.6.6.10 TCustomButton.ImageMargins Property

Margins of image on button.

Pascal

```
property ImageMargins: TImageMargins;
```

C++

```
__property TImageMargins ImageMargins;
```

Description

A button image may be positioned using margins. ImageMargins holds aTImageMargins object containing the margins of an image on a button. The TImageMargins.OnChange event is triggered when a margin changes.

See Also

ImageAlignment (see page 2271)

TImageMargins (see page 2602)

Images (see page 2272)

OnChange (see page 2607)

30.1.6.6.11 TCustomButton.Images Property

List of images for a button.

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

Images is a TCustomImageList object listing the various images that can be placed on a button.

The button's image depends on the button state. These images are determined by the value of the image state properties that index ImageIndex (see page 2271): DisabledImageIndex (see page 2269), HotImageIndex (see page 2270), ImageIndex (see page 2271), PressedImageIndex (see page 2274), and SelectedImageIndex (see page 2274). When the ImageIndex (see page 2271) index is -1, it generally means that no image is used for the normal state. For the other state image indexes,

-1 means to use the same image as the normal state.

The ImageMargins (see page 2272) and ImageAlignment (see page 2271) properties orient the image inside the button. The image is not sized to fit the button, and the button is not stretched.

This is available only on Windows XP and Vista.

PressedImageIndex (see page 2274)

SelectedImageIndex (see page 2274)

30.1.6.6.12 TCustomButton.ModalResult Property

Determines whether and how the button closes its (modal) parent form.

Pascal

```
property ModalResult: TModalResult;
```

C++

```
__property TModalResult ModalResult;
```

Description

Setting the button component's ModalResult property is an easy way to make clicking the button close a modal form. When a button is clicked, the ModalResult property of its parent form is set to the same value as the button's ModalResult property.

For example, if a dialog box has OK and Cancel (see page 2267) buttons, their ModalResult properties could be set at design time to mrOk and mrCancel, respectively. At runtime, clicking the OK button then changes the dialog's ModalResult property to mrOk, and clicking the Cancel (see page 2267) button changes the dialog's ModalResult property to mrCancel. Unless further processing is required, no OnClick event handlers are required for the buttons.

The following constants are of TModalResult type and defined for the ModalResult property:

Constant	Value	Meaning
mrNone	0	None. Used as a default value before the user exits.
mrOk	idOK	The user exited with OK button.
mrCancel	idCancel	The user exited with the CANCEL button.
mrAbort	idAbort	The user exited with the ABORT button.
mrRetry	idRetry	The user exited with the RETRY button.
mrIgnore	idIgnore	The user exited with the IGNORE button.
mrYes	idYes	The user exited with the YES button.
mrNo	idNo	The user exited with the NO button.
mrAll	mrNo + 1	The user exited with the ALL button.

mrNoToAll	mrAll + 1	The user exited with the NO TO ALL button.
mrYesToAll	mrNoToAll + 1	The user exited with the YES TO ALL button.
mrClose	mrYesToAll + 1	The user exited with the CLOSE button.

TModalResult

30.1.6.6.13 TCustomButton.PressedImageIndex Property

Image index for pressed button state.

Pascal

```
property PressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex PressedImageIndex;
```

Description

PressedImageIndex is an image index into the Images (see page 2272) property for the pressed button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

DisabledImageIndex (see page 2269)

HotImageIndex (see page 2270)

ImageIndex (see page 2271)

Images (see page 2272)

SelectedImageIndex (see page 2274)

30.1.6.6.14 TCustomButton.SelectedImageIndex Property

Image index for selected button state.

Pascal

```
property SelectedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex SelectedImageIndex;
```

Description

SelectedImageIndex is an image index into the Images (see page 2272) property for the selected button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

DisabledImageIndex (see page 2269)

HotImageIndex (see page 2270)

ImageIndex (see page 2271)

Images (see page 2272)

PressedImageIndex (see page 2274)

30.1.6.6.15 TCustomButton.Style Property

Style of a button.

Pascal

```
property Style: TButtonStyle;
```

C++

```
__property TButtonStyle Style;
```

Description

Style indicates a button's style, which is a TButtonStyle (see page 2261) type.

See Also

TButtonStyle (see page 2261)

30.1.6.6.16 TCustomButton.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.6.7 TCustomButton Events

The events of the TCustomButton class are listed here.

Public Events

	Name	Description
	OnDropDownClick (see page 2276)	Down arrow part of Vista style split button is clicked.

30.1.6.7.1 TCustomButton.OnDropDownClick Event

Down arrow part of Vista style split button is clicked.

Pascal

```
property OnDropDownClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDownClick;
```

Description

OnDropDownClick occurs when the down arrow part of a Vista style split button is clicked. This only applies when the button's Style (see page 2275) property is **bsSplitButton**.

This is available on Windows Vista only.

See Also

DropDownMenu (see page 2269)

Style (see page 2275)

TButtonStyle (see page 2261)

30.1.7 TCustomCheckBox Class

TCustomCheckBox is the ancestor of all check-box components.

Class Hierarchy

Pascal

```
TCustomCheckBox = class(TButtonControl);
```

C++

```
class TCustomCheckBox : public TButtonControl;
```

File

StdCtrls

Description

TCustomCheckBox is an abstract class from which check-box components, including TCheckBox (see page 2116) and TDBCheckBox, descend. Check boxes present the user with options that can be selected (checked) or deselected (unchecked).

See Also

TCheckBox (see page 2116)

TDBCheckBox

30.1.7.1 TCustomCheckBox Members

The following tables list the members exposed by TCustomCheckBox.

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	Click (see page 2278)	Click generates an OnClick event.
	CreateParams (see page 2278)	Initializes a window-creation parameter record.
	CreateWnd (see page 2279)	Creates a Windows control corresponding to the check box.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2279)	Returns the value of the Checked (see page 2113) property.
	SetChecked (see page 2280)	Sets the value of the Checked (see page 2113) property.
	Toggle (see page 2280)	Changes the state of the check box.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	Alignment (see page 2281)	Controls the position of the check box's caption.
	AllowGrayed (see page 2281)	Determines whether check box can be in a "grayed" state.
	Checked (see page 2113)	Specifies whether the button control is checked.
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.
	State (see page 2282)	Indicates whether the check box is selected, deselected, or grayed.
	WordWrap (see page 2115)	Specifies whether the button text wraps to fit the width of the control.

Public Methods

	Name	Description
	Create (see page 2277)	Creates and initializes a TCustomCheckBox (see page 2276) instance.
	GetControlsAlignment (see page 2279)	Returns the alignment of the check box caption.

Published Properties

	Name	Description
	TabStop (see page 2282)	Determines if the user can tab to a control.

30.1.7.2 TCustomCheckBox.Create Constructor

Creates and initializes a TCustomCheckBox (see page 2276) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomCheckBox(TComponent * AOwner);
```

Description

Call Create to generate a check box at runtime. Check boxes placed on forms at design time, Create is called automatically.

AOwner is a component, typically the form, that is responsible for freeing the check box instance.

See Also

Owner

30.1.7.3 TCustomCheckBox Methods

The methods of the TCustomCheckBox class are listed here.

Protected Methods

	Name	Description
	Click (see page 2278)	Click generates an OnClick event.
	CreateParams (see page 2278)	Initializes a window-creation parameter record.
	CreateWnd (see page 2279)	Creates a Windows control corresponding to the check box.
	GetChecked (see page 2279)	Returns the value of the Checked (see page 2113) property.
	SetChecked (see page 2280)	Sets the value of the Checked (see page 2113) property.
	Toggle (see page 2280)	Changes the state of the check box.

Public Methods

	Name	Description
	GetControlsAlignment (see page 2279)	Returns the alignment of the check box caption.

30.1.7.3.1 TCustomCheckBox.Click Method

Click generates an OnClick event.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

The protected Click method is called automatically when the check box is clicked with the mouse. In addition to generating an OnClick event, it sends a message to the parent control's window to indicate that the state of the check box has changed.

See Also

OnClick

Parent

30.1.7.3.2 TCustomCheckBox.CreateParams Method

Initializes a window-creation parameter record.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2279) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. CreateParams fills in the parameter record that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

In TCustomCheckBox (see page 2276), CreateParams calls the inherited method, then makes specific adjustments for check boxes.

See Also

CreateWnd

CreateWindowHandle

30.1.7.3.3 TCustomCheckBox.CreateWnd Method

Creates a Windows control corresponding to the check box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the check box is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. In TCustomCheckBox (see page 2276), this method calls the inherited method to generate the underlying windows control, then sends a BM_SETCHECK message to set the check state of the control.

See Also

CreateParams (see page 2278)

30.1.7.3.4 TCustomCheckBox.GetChecked Method

Returns the value of the Checked (see page 2113) property.

Pascal

```
function GetChecked: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetChecked();
```

Description

GetChecked is the protected implementation of the Checked (see page 2113) property. Override this method and the SetChecked (see page 2280) method to change the Checked (see page 2113) property in descendant classes.

See Also

Checked (see page 2113)

SetChecked (see page 2280)

30.1.7.3.5 TCustomCheckBox.GetControlsAlignment Method

Returns the alignment of the check box caption.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

GetControlsAlignment indicates the alignment of the check box caption. Usually, the caption is right-justified, but if the UseRightToLeftAlignment method returns true and the check mark is on the left, then GetControlsAlignment indicates that the caption should be left-justified.

See Also

Caption

Alignment (see page 2281)

UseRightToLeftAlignment

30.1.7.3.6 TCustomCheckBox.SetChecked Method

Sets the value of the Checked (see page 2113) property.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked is the protected implementation of the Checked (see page 2113) property. Override this method and the GetChecked (see page 2279) method to change the Checked (see page 2113) property in descendant classes.

See Also

Checked (see page 2113)

GetChecked (see page 2279)

30.1.7.3.7 TCustomCheckBox.Toggle Method

Changes the state of the check box.

Pascal

```
procedure Toggle; virtual;
```

C++

```
virtual __fastcall Toggle();
```

Description

Use the Toggle method to select or deselect the check box programmatically. Toggle switches among the valid check-box states—from checked to unchecked to grayed, or from checked to unchecked.

See Also

AllowGrayed (see page 2281)

State (see page 2282)

30.1.7.4 TCustomCheckBox Properties

The properties of the TCustomCheckBox class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 2281)	Controls the position of the check box's caption.
	AllowGrayed (see page 2281)	Determines whether check box can be in a "grayed" state.
	State (see page 2282)	Indicates whether the check box is selected, deselected, or grayed.

Published Properties

	Name	Description
	TabStop (see page 2282)	Determines if the user can tab to a control.

30.1.7.4.1 TCustomCheckBox.Alignment Property

Controls the position of the check box's caption.

Pascal

```
property Alignment: TLeftRight;
```

C++

```
__property TLeftRight Alignment;
```

Description

If Alignment is set to taRightJustify, the caption appears to the right of the check box. If Alignment is set to taLeftJustify, the caption appears to the left of the check box.

30.1.7.4.2 TCustomCheckBox.AllowGrayed Property

Determines whether check box can be in a "grayed" state.

Pascal

```
property AllowGrayed: Boolean;
```

C++

```
__property Boolean AllowGrayed;
```

Description

If AllowGrayed is set to true, the check box has three possible states: checked, unchecked, and grayed. If AllowGrayed is set to false, the check box has only two possible states: checked and unchecked.

C++ Examples:

```
/*
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->AllowGrayed = true;
  CheckBox1->State = cbChecked;
}
```

Delphi Examples:

```
{
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  CheckBox1.AllowGrayed := True;
  CheckBox1.State := cbChecked;
end;
```

See Also

Checked (see page 2113)

State (see page 2282)

30.1.7.4.3 TCustomCheckBox.State Property

Indicates whether the check box is selected, deselected, or grayed.

Pascal

```
property State: TCheckBoxState;
```

C++

```
__property TCheckBoxState State;
```

Description

Use State to determine whether the check box is checked (cbChecked), unchecked (cbUnchecked), or grayed (cbGrayed).

C++ Examples:

```
/*
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->AllowGrayed = true;
  CheckBox1->State = cbChecked;
}
```

Delphi Examples:

```
{
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  CheckBox1.AllowGrayed := True;
  CheckBox1.State := cbChecked;
end;
```

See Also

AllowGrayed (see page 2281)

Checked (see page 2113)

30.1.7.4.4 TCustomCheckBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.8 TCustomCombo Class

TCustomCombo is the base class for all combo boxes.

Class Hierarchy

Pascal

```
TCustomCombo = class(TCustomListControl);
```

C++

```
class TCustomCombo : public TCustomListControl;
```

File

StdCtrls

Description

Use TCustomCombo as a base class when defining a control that represents a specialized combo box. A combo box is an edit box with a scrollable list attached to it; users can select an item from the list or type directly into the edit box. Combo boxes can present the list as a drop-down list or as a list box that is always visible.

Typically, combo box classes do not descend directly from TCustomCombo. Rather, they descend from one of TCustomCombo's descendants, TCustomComboBox (see page 2322) or TCustomComboBoxEx. Use TCustomCombo as a base class for a simple combo box, or TCustomComboBoxEx as a base class for a combo box that supports the extended combo box features such as images on the list entries.

Do not create instances of TCustomCombo. To put a combo box in a form, use a descendant of TCustomCombo, such as TComboBox (see page 2184) or TComboBoxEx.

See Also

TComboBox (see page 2184)

TComboBoxEx

TDBComboBox

TColorBox

TDriveComboBox

TFilterComboBox

TCustomComboBox (see page 2322)

TCustomComboBoxEx

30.1.8.1 TCustomCombo Members

The following tables list the members exposed by TCustomCombo.

Protected Events

	Name	Description
	OnChange (see page 2318)	Occurs when the user changes the text displayed in the edit region.
	OnCloseUp (see page 2320)	Occurs when the drop-down list closes up due to some user action.
	OnDropDown (see page 2320)	Occurs when the user opens the drop-down list.
	OnSelect (see page 2322)	Occurs when the user selects a string in the drop-down list.

Protected Fields

	Name	Description
	FDefEditProc (see page 2286)	Represents the address of the edit box procedure assigned by Windows.
	FDefListProc (see page 2287)	Represents the address of the list box procedure assigned by Windows.
	FDropHandle (see page 2287)	Represents the window handle for the entire combo box.
	FDroppingDown (see page 2287)	Specifies whether the list box is dropping down.
	FEditHandle (see page 2288)	Represents the window handle for the edit portion of the combo box.
	FEditInstance (see page 2288)	Represents the address of an internal routine associated with the edit control.
	FFocusChanged (see page 2288)	Specifies whether the combo box changed its focus state.
	FIsFocused (see page 2288)	Specifies whether the combo box is focused.
	FListHandle (see page 2289)	Represents the window handle for the list of items in the combo box.
	FListInstance (see page 2289)	Represents the address of an internal routine associated with the list box.
	FSaveIndex (see page 2289)	Represents the index of an item from the combo box.

Protected Methods

	Name	Description
V	AdjustDropDown (see page 2292)	Adjusts the size and position of the drop down list.
	Change (see page 2292)	Generates an OnChange (see page 2318) event.
	CloseUp (see page 2293)	Generates an OnCloseUp (see page 2320) event.
V	ComboWndProc (see page 2294)	Responds to Windows messages sent to the edit control or drop-down list.
V	CreateWnd (see page 2295)	Creates the Windows control that represents the combo box.
V	DestroyWindowHandle (see page 2296)	Destroys all of the windows controls that implement the combo box.
	DropDown (see page 2296)	Generates an OnDropDown (see page 2320) event.
V	EditWndProc (see page 2296)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	GetDroppedDown (see page 2297)	Returns the value of the DroppedDown (see page 2306) property.
A	GetItemCount (see page 2298)	Returns the value of the ItemCount (see page 2307) property.
A	GetItemHt (see page 2298)	Returns the value of the ItemHeight (see page 2307) property.
V	GetItemIndex (see page 2298)	Returns the value of the ItemIndex property.
A	GetItemsClass (see page 2299)	Indicates the class that implements the Items (see page 2308) property.
	GetSelLength (see page 2299)	Returns the value of the SelLength (see page 2311) property.
	GetSelStart (see page 2299)	Returns the value of the SelStart (see page 2314) property.
	ListWndProc (see page 2300)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
V	Loaded (see page 2300)	Initializes the combo box after its form is loaded into memory.
	Select (see page 2301)	Generates an OnSelect (see page 2322) event.
V	SetDropDownCount (see page 2301)	Sets the value of the DropDownCount (see page 2306) property.
	SetDroppedDown (see page 2302)	Sets the value of the DroppedDown (see page 2306) property.
V	SetItemHeight (see page 2302)	Sets the value of the ItemHeight (see page 2307) property.
V	SetItemIndex (see page 2302)	Sets the value of the ItemIndex property.
V	SetItems (see page 2303)	Sets the value of the Items (see page 2308) property.

	SetMaxLength (see page 2303)	Sets the value of the MaxLength (see page 2310) property.
	SetSelLength (see page 2303)	Sets the value of the SelLength (see page 2311) property.
	SetSelStart (see page 2304)	Sets the value of the SelStart (see page 2314) property.
V	WndProc (see page 2304)	Processes messages received by the combo box.

Protected Properties

	Name	Description
	DropDownCount (see page 2306)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 2307)	Returns the window handle for the edit portion of the combo box.
R	ItemCount (see page 2307)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 2307)	Specifies the height, in pixels, of the items in the drop-down list.
R	ListHandle (see page 2310)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 2310)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentColor (see page 2311)	Determines where a control looks for its color information.

Public Methods

	Name	Description
V	AddItem (see page 2291)	Adds an item to the drop-down list of items.
V	Clear (see page 2293)	Deletes all text from the edit box and all items from the Items (see page 2308) list.
V	ClearSelection (see page 2293)	Deselects any selected items in the drop-down list.
V	CopySelection (see page 2294)	Copies the selected item in the drop-down list to another list control.
V	Create (see page 2285)	Creates and initializes a TCustomCombo (see page 2283) instance.
V	DeleteSelected (see page 2295)	Deletes the selected item from the drop-down list.
V	Destroy (see page 2286)	Destroys the combo box and frees its memory.
V	Focused (see page 2297)	Indicates whether the combo box has input focus.
V	GetCount (see page 2297)	Returns the value of the ItemCount (see page 2307) property.
V	SelectAll (see page 2301)	Selects the entire block of text in the edit box.

Public Properties

	Name	Description
R	Canvas (see page 2305)	Provides access to the drawing surface of the combo box.
	DroppedDown (see page 2306)	Indicates whether the drop-down list is currently displayed.
	Items (see page 2308)	Provides access to the list of items (strings) in the list portion of the combo box.
	SelLength (see page 2311)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2314)	Specifies the position of the first selected character in the edit portion of the combo box.
	TabStop (see page 2317)	Determines if the user can tab to a control.

30.1.8.2 TCustomCombo.Create Constructor

Creates and initializes a TCustomCombo (see page 2283) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomCombo(TComponent * AOwner);
```

Description

Call Create to generate a combo box at runtime. Combo boxes placed on forms at design time are created automatically.

AOwner is a component (typically a form) that is responsible for freeing the combo box instance.

See Also

Owner

30.1.8.3 TCustomCombo.Destroy Destructor

Destroys the combo box and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomCombo();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the combo box is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

30.1.8.4 TCustomCombo Fields

The fields of the TCustomCombo class are listed here.

Protected Fields

	Name	Description
	FDefEditProc (see page 2286)	Represents the address of the edit box procedure assigned by Windows.
	FDefListProc (see page 2287)	Represents the address of the list box procedure assigned by Windows.
	FDropHandle (see page 2287)	Represents the window handle for the entire combo box.
	FDroppingDown (see page 2287)	Specifies whether the list box is dropping down.
	FEditHandle (see page 2288)	Represents the window handle for the edit portion of the combo box.
	FEditInstance (see page 2288)	Represents the address of an internal routine associated with the edit control.
	FFocusChanged (see page 2288)	Specifies whether the combo box changed its focus state.
	FIsFocused (see page 2288)	Specifies whether the combo box is focused.
	FListHandle (see page 2289)	Represents the window handle for the list of items in the combo box.
	FListInstance (see page 2289)	Represents the address of an internal routine associated with the list box.
	FSaveIndex (see page 2289)	Represents the index of an item from the combo box.

30.1.8.4.1 TCustomCombo.FDefEditProc Field

Represents the address of the edit box procedure assigned by Windows.

Pascal

```
FDefEditProc: TWindowProcPtr;
```

C++

```
TWindowProcPtr FDefEditProc;
```

Description

The FDefEditProc field is used to handle Windows messages sent to the edit box control inside the combo box, that cannot be handled directly by Delphi.

See Also

FDefListProc (see page 2287)

30.1.8.4.2 TCustomCombo.FDefListProc Field

Represents the address of the list box procedure assigned by Windows.

Pascal

```
FDefListProc: TWindowProcPtr;
```

C++

```
TWindowProcPtr FDefListProc;
```

Description

The FDefListProc field is used to handle Windows messages sent to the list box control inside the combo box, that cannot be handled directly by Delphi.

See Also

FDefEditProc (see page 2286)

30.1.8.4.3 TCustomCombo.FDropHandle Field

Represents the window handle for the entire combo box.

Pascal

```
FDropHandle: HWnd;
```

C++

```
HWnd FDropHandle;
```

Description

FDropHandle is the window handle for the combo box.

See Also

FListHandle (see page 2289)

FEditHandle (see page 2288)

30.1.8.4.4 TCustomCombo.FDroppingDown Field

Specifies whether the list box is dropping down.

Pascal

```
FDroppingDown: Boolean;
```

C++

```
Boolean FDroppingDown;
```

Description

FDroppingDown field is used when adjusting the drop-down list box size.

See Also

AdjustDropDown (see page 2292)

30.1.8.4.5 TCustomCombo.FEditHandle Field

Represents the window handle for the edit portion of the combo box.

Pascal

```
FEditHandle: HWnd;
```

C++

```
HWnd FEditHandle;
```

Description

FEditHandle is the window handle for the edit control portion of the combo box.

See Also

EditHandle (see page 2307)

30.1.8.4.6 TCustomCombo.FEditInstance Field

Represents the address of an internal routine associated with the edit control.

Pascal

```
FEditInstance: Pointer;
```

C++

```
void * FEditInstance;
```

Description

FEditInstance represents the address of a Windows message handling procedure associated with the edit control inside the combo box.

See Also

FListInstance (see page 2289)

30.1.8.4.7 TCustomCombo.FFocusChanged Field

Specifies whether the combo box changed its focus state.

Pascal

```
FFocusChanged: Boolean;
```

C++

```
Boolean FFocusChanged;
```

Description

FFocusChanged field specifies whether the control changed its focus state.

See Also

Focused (see page 2297)

30.1.8.4.8 TCustomCombo.FIsFocused Field

Specifies whether the combo box is focused.

Pascal

```
FIsFocused: Boolean;
```

C++

```
Boolean FIsFocused;
```

Description

FIsFocused field is set to True if the combo box is focused and to False otherwise.

See Also

Focused (see page 2297)

30.1.8.4.9 TCustomCombo.FListHandle Field

Represents the window handle for the list of items in the combo box.

Pascal

```
FListHandle: HWnd;
```

C++

```
HWnd FListHandle;
```

Description

FListHandle is the window handle for the drop-down list.

See Also

ListHandle (see page 2310)

30.1.8.4.10 TCustomCombo.FListInstance Field

Represents the address of an internal routine associated with the list box.

Pascal

```
FListInstance: Pointer;
```

C++

```
void * FListInstance;
```

Description

FListInstance represents the address of a Windows message handling procedure associated with the list box inside the combo box.

See Also

FEditInstance (see page 2288)

30.1.8.4.11 TCustomCombo.FSaveIndex Field

Represents the index of an item from the combo box.

Pascal

```
FSaveIndex: Integer;
```

C++

```
int FSaveIndex;
```

Description

FSaveIndex field is used to store the index of an item from the combo box.

See Also

ItemIndex

30.1.8.5 TCustomCombo Methods

The methods of the TCustomCombo class are listed here.

Protected Methods

	Name	Description
	AdjustDropDown (see page 2292)	Adjusts the size and position of the drop down list.
	Change (see page 2292)	Generates an OnChange (see page 2318) event.
	CloseUp (see page 2293)	Generates an OnCloseUp (see page 2320) event.
	ComboWndProc (see page 2294)	Responds to Windows messages sent to the edit control or drop-down list.
	CreateWnd (see page 2295)	Creates the Windows control that represents the combo box.
	DestroyWindowHandle (see page 2296)	Destroys all of the windows controls that implement the combo box.
	DropDown (see page 2296)	Generates an OnDropDown (see page 2320) event.
	EditWndProc (see page 2296)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	GetDroppedDown (see page 2297)	Returns the value of the DroppedDown (see page 2306) property.
	GetItemCount (see page 2298)	Returns the value of the ItemCount (see page 2307) property.
	GetItemHt (see page 2298)	Returns the value of the ItemHeight (see page 2307) property.
	GetItemIndex (see page 2298)	Returns the value of the ItemIndex property.
	GetItemsClass (see page 2299)	Indicates the class that implements the Items (see page 2308) property.
	GetSelLength (see page 2299)	Returns the value of the SelLength (see page 2311) property.
	GetSelStart (see page 2299)	Returns the value of the SelStart (see page 2314) property.
	ListWndProc (see page 2300)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
	Loaded (see page 2300)	Initializes the combo box after its form is loaded into memory.
	Select (see page 2301)	Generates an OnSelect (see page 2322) event.
	SetDropDownCount (see page 2301)	Sets the value of the DropDownCount (see page 2306) property.
	SetDroppedDown (see page 2302)	Sets the value of the DroppedDown (see page 2306) property.
	SetItemHeight (see page 2302)	Sets the value of the ItemHeight (see page 2307) property.
	SetItemIndex (see page 2302)	Sets the value of the ItemIndex property.
	SetItems (see page 2303)	Sets the value of the Items (see page 2308) property.
	SetMaxLength (see page 2303)	Sets the value of the MaxLength (see page 2310) property.
	SetSelLength (see page 2303)	Sets the value of the SelLength (see page 2311) property.
	SetSelStart (see page 2304)	Sets the value of the SelStart (see page 2314) property.
	WndProc (see page 2304)	Processes messages received by the combo box.

Public Methods

	Name	Description
	AddItem (see page 2291)	Adds an item to the drop-down list of items.
	Clear (see page 2293)	Deletes all text from the edit box and all items from the Items (see page 2308) list.
	ClearSelection (see page 2293)	Deselects any selected items in the drop-down list.
	CopySelection (see page 2294)	Copies the selected item in the drop-down list to another list control.
	DeleteSelected (see page 2295)	Deletes the selected item from the drop-down list.

	Focused (see page 2297)	Indicates whether the combo box has input focus.
	GetCount (see page 2297)	Returns the value of the ItemCount (see page 2307) property.
	SelectAll (see page 2301)	Selects the entire block of text in the edit box.

30.1.8.5.1 TCustomCombo.AddItem Method

Adds an item to the drop-down list of items.

Pascal

```
procedure AddItem(Item: String; AObject: TObject); override;
```

C++

```
virtual __fastcall AddItem(UnicodeString Item, TObject * AObject);
```

Description

Call AddItem to add a string, with an associated object, to the drop-down list.

Item is the string to add to the drop-down list.

AObject is an object associated with that string. It can be accessed using the Objects property of the TStrings object that implements the Items (see page 2308) property.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
```

```
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

See Also

Items (see page 2308)

Objects

30.1.8.5.2 TCustomCombo.AdjustDropDown Method

Adjusts the size and position of the drop down list.

Pascal

```
procedure AdjustDropDown; virtual;
```

C++

```
virtual __fastcall AdjustDropDown();
```

Description

TCustomCombo (see page 2283) calls AdjustDropDown when it drops down the drop-down list. This method adjusts the size and position of the drop-down list to reflect the values of the ItemHeight (see page 2307) and DropDownCount (see page 2306) properties.

See Also

ItemHeight (see page 2307)

DroppedDown (see page 2306)

DropDownCount (see page 2306)

30.1.8.5.3 TCustomCombo.Change Method

Generates an OnChange (see page 2318) event.

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

Change is called automatically in response to notifications that the text has changed. It responds by generating an OnChange (see page 2318) event. Override this method to add additional processing when the text changes, or to block the OnChange (see page 2318) event.

See Also

OnChange (see page 2318)

Changed

30.1.8.5.4 TCustomCombo.Clear Method

Deletes all text from the edit box and all items from the Items (see page 2308) list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call Clear to empty the combo box at runtime.

See Also

Items (see page 2308)

Text

30.1.8.5.5 TCustomCombo.ClearSelection Method

Deselects any selected items in the drop-down list.

Pascal

```
procedure ClearSelection; override;
```

C++

```
virtual __fastcall ClearSelection();
```

Description

ClearSelection checks whether an item in the drop-down list is currently selected. If so, it deselects the item (sets ItemIndex to –1), and changes the Text property to an empty string.

See Also

ItemIndex

Text

30.1.8.5.6 TCustomCombo.CloseUp Method

Generates an OnCloseUp (see page 2320) event.

Pascal

```
procedure CloseUp; dynamic;
```

C++

```
__fastcall CloseUp();
```

Description

CloseUp is called automatically when the DroppedDown (see page 2306) property changes to false. It generates an OnCloseUp (see page 2320) event.

Override CloseUp to implement additional class-specific responses when the drop-down list closes up or to suppress the event.

See Also

DroppedDown (see page 2306)

OnCloseUp (see page 2320)

30.1.8.5.7 TCustomCombo.ComboWndProc Method

Responds to Windows messages sent to the edit control or drop-down list.

Pascal

```
procedure ComboWndProc(var Message: TMessage; ComboWnd: HWnd; ComboProc: TWindowProcPtr);
virtual;
```

C++

```
virtual __fastcall ComboWndProc(TMessage Message, HWnd ComboWnd, TWindowProcPtr ComboProc);
```

Description

ComboWndProc handles the common processing of Windows messages sent to the edit region or list portion of the combo box. It is called by the EditWndProc (see page 2296) and ListWndProc (see page 2300) methods to take care of all processing that is not specific to the edit region or drop-down list.

The Message parameter describes the Windows message. The ComboWnd parameter is the windows handle for the edit region or list. The ComboProc parameter is a pointer to the default window procedure for the window that received the message. ComboWndProc provides default responses to focus events, mouse events, and key strokes.

Override ComboWndProc to change the way the combo box responds to Windows messages. When overriding ComboWndProc, be sure to call the parent class's method to process all unhandled messages.

Note: Do not confuse ComboWndProc with the WndProc (see page 2304) method. ComboWndProc responds to messages that are sent to the edit region or drop-down list. WndProc (see page 2304) responds to messages sent to the combo box itself.

See Also

WndProc (see page 2304)

EditWndProc (see page 2296)

ListWndProc (see page 2300)

30.1.8.5.8 TCustomCombo.CopySelection Method

Copies the selected item in the drop-down list to another list control.

Pascal

```
procedure CopySelection(Destination: TCustomListControl); override;
```

C++

```
virtual __fastcall CopySelection(TCustomListControl Destination);
```

Description

CopySelection checks whether an item is selected in the drop-down list, and if so, adds it to the control specified by Destination, along with its associated object.

See Also

Items (see page 2308)

ItemIndex

30.1.8.5.9 TCustomCombo.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo (see page 2283) overrides the inherited method to ensure that the newly-created window and the TCustomCombo (see page 2283) properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo (see page 2283) instance.

See Also

CreateHandle

30.1.8.5.10 TCustomCombo.DeleteSelected Method

Deletes the selected item from the drop-down list.

Pascal

```
procedure DeleteSelected; override;
```

C++

```
virtual __fastcall DeleteSelected();
```

Description

DeleteSelected deletes the item specified by the ItemIndex property from the drop-down list.

See Also

ItemIndex

Items (see page 2308)

30.1.8.5.11 TCustomCombo.DestroyWindowHandle Method

Destroys all of the windows controls that implement the combo box.

Pascal

```
procedure DestroyWindowHandle; override;
```

C++

```
virtual __fastcall DestroyWindowHandle();
```

Description

The DestroyWnd method calls DestroyWindowHandle to release the underlying Windows control. TCustomCombo (see page 2283) overrides the inherited method to reset the EditHandle (see page 2307) and ListHandle (see page 2310) properties once the underlying Windows controls are gone.

See Also

DestroyWnd

EditHandle (see page 2307)

ListHandle (see page 2310)

30.1.8.5.12 TCustomCombo.DropDown Method

Generates an OnDropDown (see page 2320) event.

Pascal

```
procedure DropDown; dynamic;
```

C++

```
__fastcall DropDown();
```

Description

DropDown is called automatically when the DroppedDown (see page 2306) property changes to true. It responds by generating an OnDropDown (see page 2320) event. To perform additional processing or block the OnDropDown (see page 2320) event, override DropDown.

See Also

OnDropDown (see page 2320)

DroppedDown (see page 2306)

30.1.8.5.13 TCustomCombo.EditWndProc Method

Responds to Windows messages that are sent to the edit control portion of the combo box.

Pascal

```
procedure EditWndProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall EditWndProc(TMessage Message);
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. EditWndProc is the

window procedure for the edit control portion of the combo box.

See Also

EditHandle (see page 2307)

WndProc (see page 2304)

ListWndProc (see page 2300)

ComboWndProc (see page 2294)

30.1.8.5.14 TCustomCombo.Focused Method

Indicates whether the combo box has input focus.

Pascal

```
function Focused: Boolean; override;
```

C++

```
virtual __fastcall Boolean Focused();
```

Description

Call Focused to determine whether the combo box is currently the recipient of keyboard input. When Focused returns true, the combo box is the active control and keystroke messages are sent to it. When Focused is false, the combo box is not active (although it may be selected).

See Also

ActiveControl

30.1.8.5.15 TCustomCombo.GetCount Method

Returns the value of the ItemCount (see page 2307) property.

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount returns the number of items in the drop-down list.

See Also

ItemCount (see page 2307)

30.1.8.5.16 TCustomCombo.GetDroppedDown Method

Returns the value of the DroppedDown (see page 2306) property.

Pascal

```
function GetDroppedDown: Boolean;
```

C++

```
__fastcall Boolean GetDroppedDown();
```

Description

GetDroppedDown is the read implementation of the DroppedDown (see page 2306) property. It returns true if the drop-down list is showing.

See Also

DroppedDown (see page 2306)

30.1.8.5.17 TCustomCombo.GetItemCount Method

Returns the value of the ItemCount (see page 2307) property.

Pascal

```
function GetItemCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemCount() = 0;
```

Description

GetItemCount is the protected read access method for the ItemCount (see page 2307) property. In TCustomCombo (see page 2283), this method is abstract (pure virtual), meaning it has no implementation. Descendant classes override this method to return the number of items in the drop-down list.

See Also

ItemCount (see page 2307)

30.1.8.5.18 TCustomCombo.GetItemHt Method

Returns the value of the ItemHeight (see page 2307) property.

Pascal

```
function GetItemHt: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemHt() = 0;
```

Description

GetItemHt is the protected read access method for the ItemHeight (see page 2307) property. In TCustomCombo (see page 2283), this method is abstract (pure virtual), meaning it has no implementation. Descendant classes override this method to return the height of items in the drop-down list.

See Also

ItemHeight (see page 2307)

30.1.8.5.19 TCustomCombo.GetItemIndex Method

Returns the value of the ItemIndex property.

Pascal

```
function GetItemIndex: Integer; override;
```

C++

```
virtual __fastcall int GetItemIndex();
```

Description

GetItemIndex is the read implementation of the ItemIndex property. It returns the index of the selected item in the drop-down list. The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1.

See Also

ItemIndex

30.1.8.5.20 TCustomCombo.GetItemsClass Method

Indicates the class that implements the Items (see page 2308) property.

Pascal

```
function GetItemsClass: TCustomComboBoxStringsClass; virtual; abstract;
```

C++

```
virtual __fastcall TCustomComboBoxStringsClass GetItemsClass() = 0;
```

Description

TCustomCombo (see page 2283) uses GetItemsClass internally to determine what class to instantiate when it implements the Items (see page 2308) property.

In TCustomCombo (see page 2283), GetItemsClass is abstract pure virtual, meaning it has no implementation. TCustomCombo (see page 2283) descendants override this method to indicate a TCustomComboBoxStrings (see page 2339) descendant that implements the Items (see page 2308) property.

See Also

Items (see page 2308)

30.1.8.5.21 TCustomCombo.GetSelLength Method

Returns the value of the SelLength (see page 2311) property.

Pascal

```
function GetSelLength: Integer;
```

C++

```
__fastcall int GetSelLength();
```

Description

GetSelLength is the read implementation of the SelLength (see page 2311) property. It returns the number of selected characters.

See Also

SelLength (see page 2311)

30.1.8.5.22 TCustomCombo.GetSelStart Method

Returns the value of the SelStart (see page 2314) property.

Pascal

```
function GetSelStart: Integer;
```

C++

```
__fastcall int GetSelStart();
```

Description

GetSelStart is the read implementation of the SelStart (see page 2314) property. It returns the position of the first selected character, or the position of the cursor if no characters are selected.

See Also

SelStart (see page 2314)

30.1.8.5.23 TCustomCombo.ListWndProc Method

Responds to Windows messages that are sent to the drop-down list portion of the combo box.

Pascal

```
procedure ListWndProc(var Message: TMessage);
```

C++

```
__fastcall ListWndProc(TMessage Message);
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. ListWndProc is the window procedure for the drop-down list.

See Also

ListHandle (see page 2310)

WndProc (see page 2304)

EditWndProc (see page 2296)

ComboWndProc (see page 2294)

30.1.8.5.24 TCustomCombo.Loaded Method

Initializes the combo box after its form is loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The component streaming system calls this method after it loads the combo box's form from a stream.

TCustomCombo (see page 2283) overrides the inherited method to select the item specified by the ItemIndex property once the form is fully loaded.

See Also

Loaded

ItemIndex

30.1.8.5.25 TCustomCombo.Select Method

Generates an OnSelect (see page 2322) event.

Pascal

```
procedure Select; dynamic;
```

C++

```
__fastcall Select();
```

Description

Select is called automatically when the selected item in the drop-down list changes. It responds by generating an OnSelect (see page 2322) event. To perform additional processing or block the OnSelect (see page 2322) event, override Select.

See Also

OnSelect (see page 2322)

ItemIndex

30.1.8.5.26 TCustomCombo.SelectAll Method

Selects the entire block of text in the edit box.

Pascal

```
procedure SelectAll; override;
```

C++

```
virtual __fastcall SelectAll();
```

Description

Use SelectAll to select the entire block of text in the edit box. To select only part of the text, use the SelStart (see page 2314) and SelLength (see page 2311) properties.

See Also

SelStart (see page 2314)

SelLength (see page 2311)

30.1.8.5.27 TCustomCombo.SetDropDownCount Method

Sets the value of the DropDownCount (see page 2306) property.

Pascal

```
procedure SetDropDownCount(const Value: Integer); virtual;
```

C++

```
virtual __fastcall SetDropDownCount(const int Value);
```

Description

SetDropDownCount is the protected write implementation of the DropDownCount (see page 2306) property.

See Also

DropDownCount (see page 2306)

30.1.8.5.28 TCustomCombo.SetDroppedDown Method

Sets the value of the DroppedDown (see page 2306) property.

Pascal

```
procedure SetDroppedDown(Value: Boolean);
```

C++

```
__fastcall SetDroppedDown(Boolean Value);
```

Description

SetDroppedDown is the protected write implementation of the DroppedDown (see page 2306) property.

See Also

DroppedDown (see page 2306)

30.1.8.5.29 TCustomCombo.SetItemHeight Method

Sets the value of the ItemHeight (see page 2307) property.

Pascal

```
procedure SetItemHeight(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetItemHeight(int Value);
```

Description

SetItemHeight is the protected write implementation of the ItemHeight (see page 2307) property. Although SetItemHeight never raises an exception, in some cases it does not change the value of the ItemHeight (see page 2307) property. ItemHeight (see page 2307) can only be changed for some TCustomCombo (see page 2283) descendants, and then only under specific circumstances.

For example, TComboBoxEx never allows the ItemHeight (see page 2307) property to change.

See Also

ItemHeight (see page 2307)

30.1.8.5.30 TCustomCombo.SetItemIndex Method

Sets the value of the ItemIndex property.

Pascal

```
procedure SetItemIndex(const Value: Integer); override;
```

C++

```
virtual __fastcall SetItemIndex(const int Value);
```

Description

SetItemIndex is the protected write implementation of the ItemIndex property. It selects an item in the drop-down list.

Value is the item to select, where 0 indicates the first item, 1 indicates the second item, and so on. A negative Value causes all items to be unselected.

See Also

ItemIndex

30.1.8.5.31 TCustomCombo.SetItems Method

Sets the value of the Items (see page 2308) property.

Pascal

```
procedure SetItems(const Value: TStrings); virtual;
```

C++

```
virtual __fastcall SetItems(const TStrings Value);
```

Description

SetItems is the protected write implementation for the Items (see page 2308) property. It copies the strings (and possibly their associated objects) from Value to the Items (see page 2308) property.

See Also

Items (see page 2308)

Assign

30.1.8.5.32 TCustomCombo.SetMaxLength Method

Sets the value of the MaxLength (see page 2310) property.

Pascal

```
procedure SetMaxLength(Value: Integer);
```

C++

```
__fastcall SetMaxLength(int Value);
```

Description

SetMaxLength is the protected write implementation of the MaxLength (see page 2310) property.

See Also

MaxLength (see page 2310)

30.1.8.5.33 TCustomCombo.SetSelLength Method

Sets the value of the SelLength (see page 2311) property.

Pascal

```
procedure SetSelLength(Value: Integer);
```

C++

```
__fastcall SetSelLength(int Value);
```

Description

SetSelLength is the protected write implementation of the SelLength (see page 2311) property.

See Also

SelLength (see page 2311)

30.1.8.5.34 TCustomCombo.SetSelStart Method

Sets the value of the SelStart (see page 2314) property.

Pascal

```
procedure SetSelStart(Value: Integer);
```

C++

```
__fastcall SetSelStart(int Value);
```

Description

SetSelStart is the protected write implementation of the SelStart (see page 2314) property.

See Also

SelStart (see page 2314)

30.1.8.5.35 TCustomCombo.WndProc Method

Processes messages received by the combo box.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method to received Windows messages that are sent to the combo box. Messages sent to the child windows of the combo box (for the edit region and the list portion) go to the EditWndProc (see page 2296) or ListWndProc (see page 2300) method instead. WndProc handles messages about changes to the system colors defined in the Windows control panel, and closes up the drop-down list when the Enter key or the Escape key is pressed. All other messages are passed to Dispatch for default processing.

See Also

ComboWndProc (see page 2294)

EditWndProc (see page 2296)

ListWndProc (see page 2300)

30.1.8.6 TCustomCombo Properties

The properties of the TCustomCombo class are listed here.

Protected Properties

	Name	Description
	DropDownCount (see page 2306)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 2307)	Returns the window handle for the edit portion of the combo box.
R	ItemCount (see page 2307)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 2307)	Specifies the height, in pixels, of the items in the drop-down list.
R	ListHandle (see page 2310)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 2310)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.

	ParentColor (see page 2311)	Determines where a control looks for its color information.

Public Properties

	Name	Description
R	Canvas (see page 2305)	Provides access to the drawing surface of the combo box.
	DroppedDown (see page 2306)	Indicates whether the drop-down list is currently displayed.
	Items (see page 2308)	Provides access to the list of items (strings) in the list portion of the combo box.
	SelLength (see page 2311)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2314)	Specifies the position of the first selected character in the edit portion of the combo box.
	TabStop (see page 2317)	Determines if the user can tab to a control.

30.1.8.6.1 TCustomCombo.Canvas Property

Provides access to the drawing surface of the combo box.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use Canvas as the drawing surface when customizing the way the combo box paints itself. For example, when using a TCustomCombo (see page 2283) descendant that allows applications to draw combo box items in an OnDrawItem even, the OnDrawItem event handler uses Canvas for painting the customized items.

C++ Examples:

```
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TComboBox *myComboBox;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TComboBox")
  {
    myComboBox = dynamic_cast<TComboBox *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myComboBox->Canvas->MoveTo(myComboBox->ClientRect.Left, myComboBox->ClientRect.Top);
    myComboBox->Canvas->LineTo(myComboBox->ClientRect.Right, myComboBox->ClientRect.Bottom);
    myComboBox = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TComboBox) then
```

```
begin
  myComboBox:= (ListBox1.Items.Objects[Index] as TComboBox);
  with myComboBox.ClientRect do
  begin // make sure we are using the TControl's canvas and not the form's!
    myComboBox.Canvas.MoveTo(Left, Top);
    myComboBox.Canvas.LineTo(Right, Bottom);
  end;
myComboBox:= nil;
end;
```

See Also

OnDrawItem (see page 2338)

30.1.8.6.2 TCustomCombo.DropDownCount Property

Specifies the maximum number of items displayed in the drop-down list.

Pascal

```
property DropDownCount: Integer;
```

C++

```
__property int DropDownCount;
```

Description

By default, the drop-down list is long enough to contain eight items without requiring the user to scroll to see them all. To make the drop-down list smaller or larger, specify a number larger or smaller than eight as the DropDownCount value.

If the DropDownCount value is larger than the number of items in the Items (see page 2308) property, the drop-down list will be just large enough to hold all the possible choices and no more. If the DropDownCount value is smaller then the number of item in the Items (see page 2308) property, the drop down list will display a scroll bar.

See Also

Items (see page 2308)

ItemCount (see page 2307)

30.1.8.6.3 TCustomCombo.DroppedDown Property

Indicates whether the drop-down list is currently displayed.

Pascal

```
property DroppedDown: Boolean;
```

C++

```
__property Boolean DroppedDown;
```

Description

Read (see page 3634) DroppedDown to determine whether the drop-down list is visible. Set DropDown (see page 2296) to drop the list down or close it up. DroppedDown is true when the drop-down list is open, and false when it is closed.

See Also

OnDropDown (see page 2320)

AutoDropDown (see page 2334)

30.1.8.6.4 TCustomCombo.EditHandle Property

Returns the window handle for the edit portion of the combo box.

Pascal

```
property EditHandle: HWnd;
```

C++

```
__property HWnd EditHandle;
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. EditHandle is the window handle of the edit control portion. (The Handle property and the ListHandle (see page 2310) property give the handles for the combo box itself and the drop-down list, respectively.)

Use EditHandle when making Windows API calls addressed to the edit portion of the combo box.

See Also

Handle

ListHandle (see page 2310)

30.1.8.6.5 TCustomCombo.ItemCount Property

Specifies the number of items in the drop-down list.

Pascal

```
property ItemCount: Integer;
```

C++

```
__property int ItemCount;
```

Description

Read (see page 3634) ItemCount to get the number of items in the drop-down list. ItemCount is the number of all items, not just those that are visible at one time.

See Also

Items (see page 2308)

DropDownCount (see page 2306)

30.1.8.6.6 TCustomCombo.ItemHeight Property

Specifies the height, in pixels, of the items in the drop-down list.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Read (see page 3634) ItemHeight to determine the height of the items in the drop-down list.

The effect of setting ItemHeight varies, depending on the type of combo box and the style. For example, TComboBox (see

page 2184) lets you set the item height only when Style is set to csOwnerDrawFixed or csOwnerDrawVariable. If Style is csOwnerDrawVariable, ItemHeight is the default height for drawing list items, but this value can be overridden by an OnMeasureItem event handler.

TComboBoxEx does not let you change the value of ItemHeight.

Note: Combo boxes that do not support changes to ItemHeight do not raise an exception when you attempt to change ItemHeight; they simply ignore the attempt.

See Also

Items (see page 2308)

OnMeasureItem (see page 2338)

Style (see page 2337)

30.1.8.6.7 TCustomCombo.Items Property

Provides access to the list of items (strings) in the list portion of the combo box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Read (see page 3634) Items to access the list of items that appears in the combo box. Use the methods of Items to add, insert, delete and move items. Set the value of Items to copy the items from another string list.

C++ Examples:

```
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
```

```
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
  ComboBox1->Items->AddObject("vsIcon", reinterpret_cast<TObject *>(vsIcon));
  ComboBox1->Items->AddObject("vsList", reinterpret_cast<TObject *>(vsList));
  ComboBox1->Items->AddObject("vsReport", reinterpret_cast<TObject *>(vsReport));
  ComboBox1->Items->AddObject("vsSmallIcon", reinterpret_cast<TObject *>(vsSmallIcon));
  // Display first item in the Combo Box
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
}
```

Delphi Examples:

```
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
    for I := 0 to ImageList1.Count - 1 do
    begin
      ListItem := Items.Add;
      Listitem.Caption := 'Image' + IntToStr(I);
      ListItem.ImageIndex := I;
      Listitem.SubItems.Add(Col2Array[I]);
    end;
    // Create two columns to show during viewing as vsReport
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 1';
    NewColumn.Width := 200;
```

```
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 2';
      NewColumn.Width := 200;
      // Add View styles and constants to the Combo Box
      ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
      ComboBox1.Items.AddObject('vsList', TObject(vsList));
      ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
      ComboBox1.Items.AddObject(
        'vsSmallIcon', TObject(vsSmallIcon));
      // Display first item in the Combo Box
      ComboBox1.ItemIndex := 0;
    end;
  end;

  procedure TComboForm.ComboBox1Click(Sender: TObject);
  begin
    with ComboBox1 do
      ListView1.ViewStyle := TViewStyle(Items.Objects[ItemIndex]);

  end;
```

Assign

30.1.8.6.8 TCustomCombo.ListHandle Property

Provides access to the window handle of the list of items in the combo box.

Pascal

```
property ListHandle: HWnd;
```

C++

```
__property HWnd ListHandle;
```

Description

A combo box is composed of several windows: the combo box itself, the edit control, and the drop-down list. ListHandle is the window handle of the drop-down list. (The Handle property and the EditHandle (see page 2307) property give the handles for the combo box itself and the edit portion, respectively.)

Use ListHandle when making Windows API calls addressed to the list portion of the combo box.

Note: ListHandle is only available when the combo box has a "simple" style (an edit box with a fixed list below rather than a drop-down list).

See Also

Handle

EditHandle (see page 2307)

30.1.8.6.9 TCustomCombo.MaxLength Property

Specifies the maximum number of characters the user can type into the edit portion of the combo box.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that the user can enter into the edit portion of the combo box. A value of 0 indicates that there is no application-defined limit on the length.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

See Also

Text

30.1.8.6.10 TCustomCombo.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

Color

Parent

ParentFont

ParentShowHint

30.1.8.6.11 TCustomCombo.SelLength Property

Specifies the length, in characters, of the selected text in the edit portion of the combo box.

Pascal

```
property SelLength: Integer;
```

C++

```
__property int SelLength;
```

Description

The selected portion of the text in the edit region of the combo box is the string of SelLength characters that starts at the character specified by the SelStart (see page 2314) property. The selected text appears highlighted in the edit region of the combo box.

To select a section of text in the edit region, first set the SelStart (see page 2314) property to position the cursor, and then set SelLength to the number of characters that should be selected. The SelText property is the substring that is selected.

Note: The SelLength property is only valid when the combo box has focus. When the combo box does not have focus, reading SelLength always yields a value of 0, and setting it has no effect.

C++ Examples:

```
/*
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
*/
void __fastcall TForm1::ComboBox1KeyPress(TObject *Sender, char &Key)
{
  // first, process the keystroke to obtain the current string
  // This code requires all items in list to be uppercase
  if (Key >= 'a' && Key <= 'z')
    Key -= 32; // Force Uppercase only!
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
  AnsiString TmpStr;
  bool BackSpace = (Key == (char)VK_BACK);
  if (BackSpace && pCB->SelLength)
    TmpStr = pCB->Text.SubString(1,pCB->SelStart)+
             pCB->Text.SubString(pCB->SelLength+pCB->SelStart+1,255);
  else if (BackSpace) // SelLength == 0
    TmpStr = pCB->Text.SubString(1,pCB->SelStart-1)+
             pCB->Text.SubString(pCB->SelStart+1,255);
  else //Key is a visible character
    TmpStr = pCB->Text.SubString(1,pCB->SelStart)+ Key +
             pCB->Text.SubString(pCB->SelLength+pCB->SelStart+1,255);
  if (TmpStr.IsEmpty())
    return;
  // set SelSt to the current insertion point
  int SelSt = pCB->SelStart;
  if (BackSpace && SelSt > 0)
    SelSt--;
  else if (!BackSpace)

SelText (see page 2335)

Text

30.1.8.6.12 TCustomCombo.SelStart Property

Specifies the position of the first selected character in the edit portion of the combo box.

Pascal

```
property SelStart: Integer;
```

C++

```
__property int SelStart;
```

Description

Read (see page 3634) SelStart to determine where the selection starts in the Text property. The first character is designated with 0, the second with 1, and so on. When SelLength (see page 2311) is 0, SelStart is the position of the cursor.

Set SelStart to position the cursor in the edit region of the combo box. Setting SelStart to 0 positions the cursor before the first

character, setting SelStart to 1 positions the cursor before the second character, and so on.

Note: Setting SelStart changes the SelLength (see page 2311) property to 0. When using SelStart and SelLength (see page 2311) to programmatically select a portion of the text in the edit region, set SelStart before setting SelLength (see page 2311).

Note: The SelStart property is only valid when the combo box has focus. When the combo box does not have focus, reading SelStart always yields a value of 0, and setting it has no effect.

C++ Examples:

```
/*
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the

  CharSetList->Sort();
  ComboBox1->Items = CharSetList;
}
```

Delphi Examples:

```
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off
default auto completion.
}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
  TmpStr: string;
begin
  { first, process the keystroke to obtain the current string }
  { This code requires all items in list to be uppercase}
  if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
  ct := (Sender as TComboBox).Items.Count;
  with (Sender as TComboBox) do
  begin
    SelSt := SelStart;
    if (Key = Chr(vk_Back)) and (SelLength <> 0) then
     TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
    else if Key = Chr(vk_Back) then {SelLength = 0}
     TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
    else {Key in ['A'..'Z', etc]}
     TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
    if TmpStr = '' then Exit;
    { update SelSt to the current insertion point }
    if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
    else if Key <> Chr(vk_Back) then Inc(SelSt);
    Key := #0; { indicate that key was handled }
    if SelSt = 0 then
    begin
      Text:= '';
```

```
        Exit;
      end;
     {Now that TmpStr is the currently typed string, see if we can locate a match }
      Found := False;
      for i := 1 to ct do
      begin
        if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
        begin
          Text := Items[i-1]; { update to the match that was found }
          ItemIndex := i-1;
          Found := True;
          Break;
        end;
      end;
      if Found then { select the untyped end of the string }

30.1.8.6.13 TCustomCombo.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.8.7 TCustomCombo Events

The events of the TCustomCombo class are listed here.

Protected Events

	Name	Description
	OnChange (see page 2318)	Occurs when the user changes the text displayed in the edit region.
	OnCloseUp (see page 2320)	Occurs when the drop-down list closes up due to some user action.
	OnDropDown (see page 2320)	Occurs when the user opens the drop-down list.
	OnSelect (see page 2322)	Occurs when the user selects a string in the drop-down list.

30.1.8.7.1 TCustomCombo.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3707) an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
  if (pCB)
    PageControl1->ActivePage = dynamic_cast<TTabSheet *>(pCB->Items->Objects[pCB->ItemIndex]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{

OnCloseUp (see page 2320)

30.1.8.7.2 TCustomCombo.OnCloseUp Event

Occurs when the drop-down list closes up due to some user action.

Pascal

```
property OnCloseUp: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCloseUp;
```

Description

Write (see page 3707) an OnCloseUp event handler to implement special processing that needs to occur when the drop-down list closes up. For example, an OnCloseUp event handler can check whether the user changed the selected item while the list was dropped down and respond accordingly.

See Also

OnDropDown (see page 2320)

DroppedDown (see page 2306)

30.1.8.7.3 TCustomCombo.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDown;
```

Description

Write (see page 3707) an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
```

```
      begin
        if (Screen.CustomForms[I].Visible) then
          Items.Add(Screen.CustomForms[I].Caption); { add form name }
      end;
      Items.EndUpdate; {reenable painting }
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ComboBox1.Sorted := True; { make sure the form names are sorted }
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Form2.Show;
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    Form3.Show;
  end;
```

30.1.8.7.4 TCustomCombo.OnSelect Event

Occurs when the user selects a string in the drop-down list.

Pascal

```
property OnSelect: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnSelect;
```

Description

Write (see page 3707) an OnSelect event handler to respond when the user changes the selected item in the drop-down list. OnSelect occurs after the selection has changed and the Text property reflects the new item.

30.1.9 TCustomComboBox Class

TCustomComboBox is the base class for combobox components.

Class Hierarchy

Pascal

```
TCustomComboBox = class(TCustomCombo);
```

C++

```
class TCustomComboBox : public TCustomCombo;
```

File

StdCtrls

Description

Use TCustomComboBox as a base class when defining a control that represents a specialized Windows combo box. A combo box is an edit box with a scrollable list attached to it; users can select an item from the list or type directly into the edit box. Combo boxes can present the list as a drop-down list or as a list box that is always visible.

Note: To create a combo box class that uses the extended combo box features such as images associated with entries, do not use TCustomComboBox. Instead, use the TCustomComboBoxEx class instead.

Do not create instances of TCustomComboBox. To put a combo box in a form, use a descendant of TCustomComboBox, such as TComboBox (see page 2184).

30.1.9.1 TCustomComboBox Members

The following tables list the members exposed by TCustomComboBox.

Protected Events

	Name	Description
	OnChange (see page 2318)	Occurs when the user changes the text displayed in the edit region.
	OnCloseUp (see page 2320)	Occurs when the drop-down list closes up due to some user action.
	OnDrawItem (see page 2338)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnDropDown (see page 2320)	Occurs when the user opens the drop-down list.
	OnMeasureItem (see page 2338)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnSelect (see page 2322)	Occurs when the user selects a string in the drop-down list.

Protected Fields

	Name	Description
	FDefEditProc (see page 2286)	Represents the address of the edit box procedure assigned by Windows.
	FDefListProc (see page 2287)	Represents the address of the list box procedure assigned by Windows.
	FDropHandle (see page 2287)	Represents the window handle for the entire combo box.
	FDroppingDown (see page 2287)	Specifies whether the list box is dropping down.

	FEditHandle (see page 2288)	Represents the window handle for the edit portion of the combo box.
	FEditInstance (see page 2288)	Represents the address of an internal routine associated with the edit control.
	FFocusChanged (see page 2288)	Specifies whether the combo box changed its focus state.
	FIsFocused (see page 2288)	Specifies whether the combo box is focused.
	FListHandle (see page 2289)	Represents the window handle for the list of items in the combo box.
	FListInstance (see page 2289)	Represents the address of an internal routine associated with the list box.
	FSaveIndex (see page 2289)	Represents the index of an item from the combo box.

Protected Methods

	Name	Description
V	AdjustDropDown (see page 2292)	Adjusts the size and position of the drop down list.
	Change (see page 2292)	Generates an OnChange (see page 2318) event.
	CloseUp (see page 2293)	Generates an OnCloseUp (see page 2320) event.
V	ComboWndProc (see page 2294)	Responds to Windows messages sent to the edit control or drop-down list.
V	CreateParams (see page 2326)	Initializes the window-creation parameter record.
V	CreateWnd (see page 2327)	Creates the Windows control that represents the combo box.
V	DestroyWindowHandle (see page 2296)	Destroys all of the windows controls that implement the combo box.
V	DestroyWnd (see page 2327)	Destroys the Windows control that represents the combo box.
V	DoSetTextHint (see page 2328)	Sets the value of TextHint (see page 2337).
V	DrawItem (see page 2328)	Generates an OnDrawItem (see page 2338) event.
	DropDown (see page 2296)	Generates an OnDropDown (see page 2320) event.
V	EditWndProc (see page 2296)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	GetDroppedDown (see page 2297)	Returns the value of the DroppedDown (see page 2306) property.
V	GetItemCount (see page 2328)	Returns the number of items in the Items (see page 2308) property list.
V	GetItemHt (see page 2329)	Returns the value of the ItemHeight (see page 2307) property.
V	GetItemIndex (see page 2298)	Returns the value of the ItemIndex property.
V	GetItemsClass (see page 2329)	Returns the class used to implement the Items (see page 2308) property.
	GetSelLength (see page 2299)	Returns the value of the SelLength (see page 2311) property.
	GetSelStart (see page 2299)	Returns the value of the SelStart (see page 2314) property.
	GetSelText (see page 2329)	Returns the value of the SelText (see page 2335) property.
V	KeyPress (see page 2329)	Responds to WM_CHAR messages sent to the combo box.
	ListWndProc (see page 2300)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
V	Loaded (see page 2300)	Initializes the combo box after its form is loaded into memory.
V	MeasureItem (see page 2330)	Generates an OnMeasureItem (see page 2338) event.
	Select (see page 2301)	Generates an OnSelect (see page 2322) event.
	SelectItem (see page 2330)	Selects a specified item from the drop-down list.
V	SetDropDownCount (see page 2301)	Sets the value of the DropDownCount (see page 2306) property.
	SetDroppedDown (see page 2302)	Sets the value of the DroppedDown (see page 2306) property.
V	SetItemHeight (see page 2302)	Sets the value of the ItemHeight (see page 2307) property.
V	SetItemIndex (see page 2302)	Sets the value of the ItemIndex property.
V	SetItems (see page 2303)	Sets the value of the Items (see page 2308) property.
	SetMaxLength (see page 2303)	Sets the value of the MaxLength (see page 2310) property.
	SetSelLength (see page 2303)	Sets the value of the SelLength (see page 2311) property.
	SetSelStart (see page 2304)	Sets the value of the SelStart (see page 2314) property.
V	SetStyle (see page 2331)	Sets the Style (see page 2337) property.
V	WndProc (see page 2331)	Processes messages received by the combo box.

Protected Properties

	Name	Description
	DropDownCount (see page 2306)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 2307)	Returns the window handle for the edit portion of the combo box.
R	ItemCount (see page 2307)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 2307)	Specifies the height, in pixels, of the items in the drop-down list.

R	ListHandle (see page 2310)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 2310)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentColor (see page 2311)	Determines where a control looks for its color information.
	Sorted (see page 2335)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 2337)	Determines the display style of the combo box.

Public Methods

	Name	Description
V	AddItem (see page 2291)	Adds an item to the drop-down list of items.
V	Clear (see page 2293)	Deletes all text from the edit box and all items from the Items (see page 2308) list.
V	ClearSelection (see page 2293)	Deselects any selected items in the drop-down list.
V	CopySelection (see page 2294)	Copies the selected item in the drop-down list to another list control.
V	Create (see page 2325)	Creates and initializes a TCustomComboBox (see page 2322) instance.
V	DeleteSelected (see page 2295)	Deletes the selected item from the drop-down list.
V	Destroy (see page 2326)	Destroys the combo box and frees its memory.
V	Focused (see page 2297)	Indicates whether the combo box has input focus.
V	GetCount (see page 2297)	Returns the value of the ItemCount (see page 2307) property.
V	SelectAll (see page 2301)	Selects the entire block of text in the edit box.

Public Properties

	Name	Description
	AutoCloseUp (see page 2332)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2332)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2333)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2334)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
R	Canvas (see page 2305)	Provides access to the drawing surface of the combo box.
	CharCase (see page 2334)	Determines the case of the text in the combo box.
	DroppedDown (see page 2306)	Indicates whether the drop-down list is currently displayed.
	Items (see page 2308)	Provides access to the list of items (strings) in the list portion of the combo box.
	SelLength (see page 2311)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2314)	Specifies the position of the first selected character in the edit portion of the combo box.
	SelText (see page 2335)	Represents the selected text in the edit region.
	TabStop (see page 2317)	Determines if the user can tab to a control.
	TextHint (see page 2337)	Specifies the text that is displayed as a text watermark in the edit box of the combo box control.

30.1.9.2 TCustomComboBox.Create Constructor

Creates and initializes a TCustomComboBox (see page 2322) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomComboBox(TComponent * AOwner);
```

Description

Call Create to generate a combo box at runtime. Combo boxes placed on forms at design time are created automatically.

AOwner is a component, typically the form, that is responsible for freeing the combo box instance.

See Also

Owner

30.1.9.3 TCustomComboBox.Destroy Destructor

Destroys the combo box and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomComboBox();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the combo box is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

30.1.9.4 TCustomComboBox Methods

The methods of the TCustomComboBox class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2326)	Initializes the window-creation parameter record.
	CreateWnd (see page 2327)	Creates the Windows control that represents the combo box.
	DestroyWnd (see page 2327)	Destroys the Windows control that represents the combo box.
	DoSetTextHint (see page 2328)	Sets the value of TextHint (see page 2337).
	DrawItem (see page 2328)	Generates an OnDrawItem (see page 2338) event.
	GetItemCount (see page 2328)	Returns the number of items in the Items (see page 2308) property list.
	GetItemHt (see page 2329)	Returns the value of the ItemHeight (see page 2307) property.
	GetItemsClass (see page 2329)	Returns the class used to implement the Items (see page 2308) property.
	GetSelText (see page 2329)	Returns the value of the SelText (see page 2335) property.
	KeyPress (see page 2329)	Responds to WM_CHAR messages sent to the combo box.
	MeasureItem (see page 2330)	Generates an OnMeasureItem (see page 2338) event.
	SelectItem (see page 2330)	Selects a specified item from the drop-down list.
	SetStyle (see page 2331)	Sets the Style (see page 2337) property.
	WndProc (see page 2331)	Processes messages received by the combo box.

30.1.9.4.1 TCustomComboBox.CreateParams Method

Initializes the window-creation parameter record.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2327) method calls CreateParams to initialize the parameters it uses to create the window for the combo box. CreateParams overrides the inherited method to implement the Style (see page 2337) property.

See Also

CreateWnd (see page 2327)

Style (see page 2337)

30.1.9.4.2 TCustomComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle

30.1.9.4.3 TCustomComboBox.DestroyWnd Method

Destroys the Windows control that represents the combo box.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. TCustomComboBox (see page 2322) calls DestroyWnd to destroy this Windows control when necessary.

DestroyWnd saves the contents of Items (see page 2308) list before calling the inherited DestroyWnd method. The saved list is used if the window is recreated.

See Also

CreateWnd (see page 2327)

30.1.9.4.4 TCustomComboBox.DoSetTextHint Method

Sets the value of TextHint (see page 2337).

Pascal

```
procedure DoSetTextHint; virtual;
```

C++

```
virtual __fastcall DoSetTextHint();
```

Description

DoSetTextHint is a protected method used to set the value of the TextHint (see page 2337) property.

See Also

TextHint (see page 2380)

30.1.9.4.5 TCustomComboBox.DrawItem Method

Generates an OnDrawItem (see page 2338) event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); virtual;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

When Style (see page 2337) is csOwnerDrawFixed or csOwnerDrawVariable, DrawItem is called whenever an item in the list needs to be drawn. If an OnDrawItem (see page 2338) event handler is assigned, DrawItem generates an OnDrawItem (see page 2338) event, passing the Index, Rect, and State parameters to the event handler. Otherwise, OnDrawItem (see page 2338) fills the rectangle passed in Rect and draws any text associated with the indexed item, ignoring the State parameter.

Override DrawItem to provide class-specific drawing code for the items in the list.

See Also

OnDrawItem (see page 2338)

Style (see page 2337)

30.1.9.4.6 TCustomComboBox.GetItemCount Method

Returns the number of items in the Items (see page 2308) property list.

Pascal

```
function GetItemCount: Integer; override;
```

C++

```
virtual __fastcall int GetItemCount();
```

Description

GetItemCount is used internally to quickly determine the number of items in the drop-down list of the combo box.

See Also

Items (see page 2308)

30.1.9.4.7 TCustomComboBox.GetItemHt Method

Returns the value of the ItemHeight (see page 2307) property.

Pascal

```
function GetItemHt: Integer; override;
```

C++

```
virtual __fastcall int GetItemHt();
```

Description

GetItemHt is the protected read implementation of the ItemHeight (see page 2307) property.

See Also

ItemHeight (see page 2307)

30.1.9.4.8 TCustomComboBox.GetItemsClass Method

Returns the class used to implement the Items (see page 2308) property.

Pascal

```
function GetItemsClass: TCustomComboBoxStringsClass; override;
```

C++

```
virtual __fastcall TCustomComboBoxStringsClass GetItemsClass();
```

Description

Combo box controls use GetItemsClass internally to determine what class to use when implementing the Items (see page 2308) property. This allows the TCustomCombo (see page 2283) base class to implement the Items (see page 2308) property for both TCustomComboBox (see page 2322) descendants and TCustomComboBoxEx descendants.

See Also

Items (see page 2308)

30.1.9.4.9 TCustomComboBox.GetSelText Method

Returns the value of the SelText (see page 2335) property.

Pascal

```
function GetSelText: string;
```

C++

```
__fastcall UnicodeString GetSelText();
```

Description

GetSelText is the protected read implementation of the SelText (see page 2335) property.

See Also

SelText (see page 2335)

30.1.9.4.10 TCustomComboBox.KeyPress Method

Responds to WM_CHAR messages sent to the combo box.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress processes standard keystroke messages for the combo box control. If the KeyPress method does not handle the keystroke, it calls the inherited method, which generates an OnKeyPress event.

Key is the character represented by the key that was pressed. If the KeyPress method changes Key to 0, no further processing occurs for the keystroke.

See Also

KeyDown

KeyUp

OnKeyPress

30.1.9.4.11 TCustomComboBox.MeasureItem Method

Generates an OnMeasureItem (see page 2338) event.

Pascal

```
procedure MeasureItem(Index: Integer; var Height: Integer); virtual;
```

C++

```
virtual __fastcall MeasureItem(int Index, int Height);
```

Description

MeasureItem is the protected implementation method for the OnMeasureItem (see page 2338) event. Override MeasureItem to provide class-specific code to specify the size of list items when Style (see page 2337) is csOwnerDrawVariable.

See Also

OnMeasureItem (see page 2338)

Style (see page 2337)

30.1.9.4.12 TCustomComboBox.SelectItem Method

Selects a specified item from the drop-down list.

Pascal

```
function SelectItem(const AnItem: string): Boolean;
```

C++

```
__fastcall Boolean SelectItem(const UnicodeString AnItem);
```

Description

SelectItem selects the first item in the drop-down list that matches the string specified by AnItem. If the list does not contain a string that matches AnItem, SelectItem does nothing.

See Also

Items (see page 2308)

ItemIndex

30.1.9.4.13 TCustomComboBox.SetStyle Method

Sets the Style (see page 2337) property.

Pascal

```
procedure SetStyle(Value: TComboBoxStyle); virtual;
```

C++

```
virtual __fastcall SetStyle(TComboBoxStyle Value);
```

Description

SetStyle is the protected implementation method for the Style (see page 2337) property. Override SetStyle to change the implementation of the Style (see page 2337) property.

See Also

Style (see page 2337)

30.1.9.4.14 TCustomComboBox.WndProc Method

Processes messages received by the combo box.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method to received Windows messages that are sent to the combo box. Messages sent to the child windows of the combo box (for the edit region and the list portion) go to the EditWndProc (see page 2296) or ListWndProc (see page 2300) method instead. WndProc handles messages about changes to the system colors defined in the Windows control panel, and closes up the drop-down list when the Enter key or the Escape key is pressed. All other messages are passed to Dispatch for default processing.

See Also

ComboWndProc (see page 2294)

System::TObject::Dispatch (see page 3369)

WndProc

EditWndProc (see page 2296)

ListWndProc (see page 2300)

30.1.9.5 TCustomComboBox Properties

The properties of the TCustomComboBox class are listed here.

Protected Properties

	Name	Description
	Sorted (see page 2335)	Determines whether the list portion of the combo box is alphabetized.

	Style (see page 2337)	Determines the display style of the combo box.

Public Properties

	Name	Description
	AutoCloseUp (see page 2332)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2332)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2333)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2334)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	CharCase (see page 2334)	Determines the case of the text in the combo box.
	SelText (see page 2335)	Represents the selected text in the edit region.
	TextHint (see page 2337)	Specifies the text that is displayed as a text watermark in the edit box of the combo box control.

30.1.9.5.1 TCustomComboBox.AutoCloseUp Property

Specifies whether the drop-down closes up automatically when the user selects an item.

Pascal

```
property AutoCloseUp: Boolean;
```

C++

```
__property Boolean AutoCloseUp;
```

Description

When AutoCloseUp is true, the drop-down closes up automatically when the user selects an item.

See Also

AutoDropDown (see page 2334)

30.1.9.5.2 TCustomComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay (see page 2333) milliseconds between the characters typed and the autocomplete operation.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

See Also

AutoCompleteDelay (see page 2333)

30.1.9.5.3 TCustomComboBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2332) is true.

See Also

AutoComplete (see page 2332)

30.1.9.5.4 TCustomComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown: Boolean;
```

C++

```
__property Boolean AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

AutoComplete (see page 2332)

OnDropDown (see page 2320)

DroppedDown (see page 2306)

30.1.9.5.5 TCustomComboBox.CharCase Property

Determines the case of the text in the combo box.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the combo box into upper or lower case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types into the combo box. Changing the CharCase property changes the actual text, not just its appearance; case information is lost and cannot be recaptured by changing CharCase back to ecNormal.

See Also

Text

30.1.9.5.6 TCustomComboBox.SelText Property

Represents the selected text in the edit region.

Pascal

```
property SelText: string;
```

C++

```
__property UnicodeString SelText;
```

Description

Read (see page 3634) SelText to obtain the text that is selected in the edit region of the combo box. When the combo box is the active control, SelText appears highlighted. Set SelText to replace the current selection with a different substring. If no text is selected when a value is assigned to SelText, the SelText string is inserted in the text at the cursor.

Note: The SelText property is only valid when the combo box has focus. When the combo box does not have focus, reading SelText always yields an empty string and setting it inserts the text at the cursor rather than replacing the selected text.

See Also

SelLength (see page 2311)

SelStart (see page 2314)

30.1.9.5.7 TCustomComboBox.Sorted Property

Determines whether the list portion of the combo box is alphabetized.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Set Sorted to true to sort the items in the Items (see page 2308) list alphabetically. New (see page 3619) items added to the list while Sorted is true are inserted in the correct alphabetical position.

When Sorted is changed from false to true, the original order of the items is lost. Setting Sorted back to false does not restore the original order.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
```

```
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

See Also

Items (see page 2308)

Using TDBListBox and TDBComboBox

30.1.9.5.8 TCustomComboBox.Style Property

Determines the display style of the combo box.

Pascal

```
property Style: TComboBoxStyle;
```

C++

```
__property TComboBoxStyle Style;
```

Description

Set Style to specify how the list and edit region of the combo box should appear.

When Style is csOwnerDrawFixed or csOwnerDrawVariable, the OnDrawItem (see page 2338) event occurs when the list items need to be drawn. If Style is csOwnerDrawVariable, an OnMeasureItem (see page 2338) event occurs as well.

See Also

Height

ItemHeight (see page 2307)

OnDrawItem (see page 2338)

OnMeasureItem (see page 2338)

30.1.9.5.9 TCustomComboBox.TextHint Property

Specifies the text that is displayed as a text watermark in the edit box of the combo box control.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to get or set the watermark text that is shown in the edit box of the combo box control.

The disabled watermark is displayed as long as you do not modify the Text property of the combo box.

Note: This feature is only available in Vista.

See Also

TCustomComboBox (see page 2322)

30.1.9.6 TCustomComboBox Events

The events of the TCustomComboBox class are listed here.

Protected Events

	Name	Description
	OnDrawItem (see page 2338)	Occurs when an item in an owner-draw combo box needs to be displayed.

	OnMeasureItem (see page 2338)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.

30.1.9.6.1 TCustomComboBox.OnDrawItem Event

Occurs when an item in an owner-draw combo box needs to be displayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Write (see page 3707) an OnDrawItem event handler to draw the items in the drop-down list of an owner-draw combo box. An OnDrawItem event handler can add graphic elements to the list items, or replace the list item text by graphics.

Draw the items on the Canvas (see page 2305) using the coordinates provided by the Rect parameter. OnDrawItem occurs only if Style (see page 2337) is set to csOwnerDrawFixed or csOwnerDrawVariable.

If an OnDrawItem event handler is not provided, the combo box fills the Rect parameter with the current brush and writes the text value of the item specified by the Index parameter.

See Also

Canvas (see page 2305)

Items (see page 2308)

OnMeasureItem (see page 2338)

Style (see page 2337)

30.1.9.6.2 TCustomComboBox.OnMeasureItem Event

Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

When Style (see page 2337) is set to csOwnerDrawVariable, the OnMeasureItem event precedes OnDrawItem (see page 2338). Write (see page 3707) an OnMeasureItem event handler to specify the height, in pixels, needed to draw an item in the drop-down list.

See Also

ItemHeight (see page 2307)

Items (see page 2308)

OnDrawItem (see page 2338)

Style (see page 2337)

30.1.10 TCustomComboBoxStrings Class

TCustomComboBoxStrings represents the strings in the drop-down list of a combo box.

Class Hierarchy

Pascal

```
TCustomComboBoxStrings = class(TStrings);
```

C++

```
class TCustomComboBoxStrings : public TStrings;
```

File

StdCtrls

Description

TCustomComboBoxStrings is the base class for objects that represent the items in the drop-down list of a combo box. Each type of combo box (TComboBox (see page 2184) or TComboBoxEx) uses its own TCustomComboBoxStrings descendant to manage the list of items.

Do not create instances of TCustomComboBoxStrings. This class is designed to work only with a combo box. TCustomCombo (see page 2283) creates the TCustomComboBoxStrings descendant it uses to implement its Items property.

See Also

TCustomCombo (see page 2283)

TComboBox (see page 2184)

TComboBoxEx

30.1.10.1 TCustomComboBoxStrings Members

The following tables list the members exposed by TCustomComboBoxStrings.

Protected Methods

	Name	Description
	Get (see page 2342)	Returns a string given its index.
	GetCount (see page 2342)	Returns the number of strings in the list
	GetObject (see page 2342)	Returns the object associated with the item at a specified index.
	PutObject (see page 2343)	Changes the object associated with the string at a specified index.
	SetUpdateState (see page 2344)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
	ComboBox (see page 2344)	Identifies the combo box whose items this object represents.

Public Methods

	Name	Description
	Clear (see page 2341)	Deletes all the strings from the list.
	Create (see page 2340)	Constructs an object and initializes its data before the object is first used.

	Delete (see page 2341)	Removes the item specified by the Index parameter.
	Destroy (see page 2340)	Destroys the TPersistent instance and frees its memory.
	IndexOf (see page 2343)	Returns the position of a string in the list.

30.1.10.2 TCustomComboBoxStrings.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TCustomComboBoxStrings();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3356)

System::TObject::Free (see page 3372)

30.1.10.3 TCustomComboBoxStrings.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomComboBoxStrings();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

System::TObject::Destroy (see page 3356)

30.1.10.4 TCustomComboBoxStrings Methods

The methods of the TCustomComboBoxStrings class are listed here.

Protected Methods

	Name	Description
	Get (see page 2342)	Returns a string given its index.
	GetCount (see page 2342)	Returns the number of strings in the list

	GetObject (see page 2342)	Returns the object associated with the item at a specified index.
	PutObject (see page 2343)	Changes the object associated with the string at a specified index.
	SetUpdateState (see page 2344)	Performs internal adjustments before or after a series of updates.

Public Methods

	Name	Description
	Clear (see page 2341)	Deletes all the strings from the list.
	Delete (see page 2341)	Removes the item specified by the Index parameter.
	IndexOf (see page 2343)	Returns the position of a string in the list.

30.1.10.4.1 TCustomComboBoxStrings.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the drop-down list of the combo box. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 2341)

Objects

Strings

30.1.10.4.2 TCustomComboBoxStrings.Delete Method

Removes the item specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single item from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string in the drop-down list, where 0 is the first string, 1 is the second string, and so on.

Add

AddObject

Clear (see page 2341)

IndexOf (see page 2343)

InsertObject

Objects

Strings

30.1.10.4.3 TCustomComboBoxStrings.Get Method

Returns a string given its index.

Pascal

```
function Get(Index: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString Get(int Index);
```

Description

Get is the protected read implementation of the Strings property. It fetches the specified string from the combo box identified by the ComboBox (see page 2344) property.

Index identifies the string to return, where 0 is the index of the first string, 1 is the index of the second string, and so on.

See Also

Strings

IndexOf (see page 2343)

ComboBox (see page 2344)

30.1.10.4.4 TCustomComboBoxStrings.GetCount Method

Returns the number of strings in the list

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count property. It fetches the number of items from the combo box identified by the ComboBox (see page 2344) property.

See Also

Count

ComboBox (see page 2344)

30.1.10.4.5 TCustomComboBoxStrings.GetObject Method

Returns the object associated with the item at a specified index.

Pascal

```
function GetObject(Index: Integer): TObject; override;
```

C++

```
virtual __fastcall TObject * GetObject(int Index);
```

Description

GetObject is the protected read implementation of the Objects property. It fetches the associated object for the identified item from the combo box identified by the ComboBox (see page 2344) property.

Index is the index of the item with which the object is associated.

See Also

Objects

ComboBox (see page 2344)

30.1.10.4.6 TCustomComboBoxStrings.IndexOf Method

Returns the position of a string in the list.

Pascal

```
function IndexOf(const S: string): Integer; override;
```

C++

```
virtual __fastcall int IndexOf(const UnicodeString S);
```

Description

Call IndexOf to obtain the position of the first occurrence of a string that matches S. The string must be an exact match (S can't be the prefix of a string in the combo box).

IndexOf returns the 0-based index of the string. Thus, if S matches the first string in the list, IndexOf returns 0, if S is the second string, IndexOf returns 1, and so on. If the string does not have a match in the string list, IndexOf returns -1.

See Also

IndexOfName

IndexOfObject

Strings

30.1.10.4.7 TCustomComboBoxStrings.PutObject Method

Changes the object associated with the string at a specified index.

Pascal

```
procedure PutObject(Index: Integer; AObject: TObject); override;
```

C++

```
virtual __fastcall PutObject(int Index, TObject * AObject);
```

Description

PutObject is the protected write implementation of the Objects property. It associates the object specified by AObject with the item identified by Index.

Index identifies an item in the drop-down list of the combo box, where 0 is the index of the first item, 1 is the index of the second item, and so on.

AObject is the object to associated with the specified item.

See Also

Objects

30.1.10.4.8 TCustomComboBoxStrings.SetUpdateState Method

Performs internal adjustments before or after a series of updates.

Pascal

```
procedure SetUpdateState(Updating: Boolean); override;
```

C++

```
virtual __fastcall SetUpdateState(Boolean Updating);
```

Description

SetUpdateState is called at the beginning or end of a series of updates. When the BeginUpdate method is first called and the TCustomComboBoxStrings (see page 2339) object is not already in the middle of an update, SetUpdateState is called with Updating set to true. When the EndUpdate method is called and it cancels out the last unmatched call to BeginUpdate, SetUpdateState is called with Updating set to false.

SetUpdateState refreshes the combo box when Updating is false, so that the combo box reflects the new set of strings.

See Also

BeginUpdate

EndUpdate

30.1.10.5 TCustomComboBoxStrings Properties

The properties of the TCustomComboBoxStrings class are listed here.

Protected Properties

	Name	Description
	ComboBox (see page 2344)	Identifies the combo box whose items this object represents.

30.1.10.5.1 TCustomComboBoxStrings.ComboBox Property

Identifies the combo box whose items this object represents.

Pascal

```
property ComboBox: TCustomCombo;
```

C++

```
__property TCustomCombo ComboBox;
```

Description

TCustomComboBoxStrings (see page 2339) uses ComboBox internally so that the strings in the list and the items in the drop-down list of the combo box remain synchronized.

See Also

Items (see page 2308)

30.1.11 TCustomEdit Class

TCustomEdit is the base class from which all edit-box and memo controls are derived.

Class Hierarchy

Pascal

```
TCustomEdit = class(TWinControl);
```

C++

```
class TCustomEdit : public TWinControl;
```

File

StdCtrls

Description

TCustomEdit encapsulates the behavior common to all components for editing text by introducing methods and properties that provide:

Basic text editing functions such as selecting text, modifying selected text, and case conversions.

Ability to respond to changes in the contents of the text.

Access control of the text for making it read-only or introducing a password character to hide the actual value.

Do not create instances of TCustomEdit. Use TCustomEdit as a base class when declaring control objects that permit the user to enter or modify text. Properties and methods of TCustomEdit provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TCustomMaskEdit

TCustomMemo (see page 2443)

TEdit (see page 2463)

30.1.11.1 TCustomEdit Members

The following tables list the members exposed by TCustomEdit.

Protected Events

	Name	Description
	OnChange (see page 2381)	Occurs when the text for the edit control may have changed.

Protected Methods

	Name	Description
	Change (see page 2348)	Generates an OnChange (see page 2381) event.
V	CreateParams (see page 2351)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2351)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2352)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2354)	Destroys the Windows control that corresponds to the edit control.

	DoSetMaxLength (see page 2354)	Sets the MaxLength (see page 2368) property.
	DoSetTextHint (see page 2355)	Sets the value of TextHint (see page 2380).
	GetSelLength (see page 2356)	Returns the SelLength (see page 2371) property.
	GetSelStart (see page 2356)	Returns the SelStart (see page 2374) property.
	GetSelText (see page 2356)	Returns the SelText (see page 2377) property.
	SetAlignment (see page 2361)	Sets the Alignment (see page 2365) property.
	SetAutoSize (see page 2361)	Sets the AutoSize (see page 2366) property.
	SetSelLength (see page 2361)	Sets the SelLength (see page 2371) property.
	SetSelStart (see page 2362)	Sets the SelStart (see page 2374) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2365)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2366)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2367)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2367)	Determines the case of the text within the edit control.
	HideSelection (see page 2368)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2368)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2369)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2369)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2370)	Determines where a control looks for its color information.
	PasswordChar (see page 2370)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Methods

	Name	Description
	Clear (see page 2348)	Deletes all text from the edit control.
	ClearSelection (see page 2349)	Removes the selected text from the edit control.
	ClearUndo (see page 2349)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2349)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2347)	Creates an instance of TCustomEdit (see page 2345).
	CutToClipboard (see page 2352)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2354)	Provides message handling for all messages that the control does not fully process itself.
	GetControlsAlignment (see page 2355)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2357)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2358)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2359)	Selects all text in the edit control.
	SetSelText (see page 2362)	Sets the SelText (see page 2377) property.
	SetSelTextBuf (see page 2363)	Replaces the selected text with a null-terminated string.
	Undo (see page 2364)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	Alignment (see page 2365)	Determines how the text is aligned within the text edit control.
R	CanUndo (see page 2367)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2369)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2371)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2371)	Specifies the number of characters (bytes) that are selected.

	SelStart (see page 2374)	Specifies the position of the first selected character in the text.
	SelText (see page 2377)	Specifies the selected portion of the edit control's text.
	Text (see page 2379)	Contains a text string associated with the control.
	TextHint (see page 2380)	A hint or message to be displayed when the Text (see page 2379) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2379)	Determines if the user can tab to a control.

30.1.11.2 TCustomEdit.Create Constructor

Creates an instance of TCustomEdit (see page 2345).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomEdit(TComponent * AOwner);
```

Description

Call Create to create and initialize an instance of TCustomEdit (see page 2345).

AOwner is another component, typically the form, that is responsible for freeing the edit control. It becomes the value of the Owner property.

Derived objects that override the Create method should call the inherited Create before performing any additional initialization.

See Also

Owner

30.1.11.3 TCustomEdit Methods

The methods of the TCustomEdit class are listed here.

Protected Methods

	Name	Description
	Change (see page 2348)	Generates an OnChange (see page 2381) event.
V	CreateParams (see page 2351)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2351)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2352)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2354)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2354)	Sets the MaxLength (see page 2368) property.
V	DoSetTextHint (see page 2355)	Sets the value of TextHint (see page 2380).
V	GetSelLength (see page 2356)	Returns the SelLength (see page 2371) property.
V	GetSelStart (see page 2356)	Returns the SelStart (see page 2374) property.
V	GetSelText (see page 2356)	Returns the SelText (see page 2377) property.
	SetAlignment (see page 2361)	Sets the Alignment (see page 2365) property.
V	SetAutoSize (see page 2361)	Sets the AutoSize (see page 2366) property.
V	SetSelLength (see page 2361)	Sets the SelLength (see page 2371) property.
V	SetSelStart (see page 2362)	Sets the SelStart (see page 2374) property.

Public Methods

	Name	Description
	Clear (see page 2348)	Deletes all text from the edit control.
	ClearSelection (see page 2349)	Removes the selected text from the edit control.
	ClearUndo (see page 2349)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2349)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	CutToClipboard (see page 2352)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2354)	Provides message handling for all messages that the control does not fully process itself.
	GetControlsAlignment (see page 2355)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2357)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2358)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2359)	Selects all text in the edit control.
	SetSelText (see page 2362)	Sets the SelText (see page 2377) property.
	SetSelTextBuf (see page 2363)	Replaces the selected text with a null-terminated string.
	Undo (see page 2364)	Backs out all changes in the undo buffer.

30.1.11.3.1 TCustomEdit.Change Method

Generates an OnChange (see page 2381) event.

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

Applications do not call the Change method directly. It is triggered automatically by Windows events. Change is exposed as a protected method so that derived classes can make additional responses when the text changes beyond invoking the OnChange (see page 2381) event handler. If Derived classes that override the Change method do not call the inherited method, the OnChange (see page 2381) event handler will not be called.

See Also

Handle

OnChange (see page 2381)

Text

30.1.11.3.2 TCustomEdit.Clear Method

Deletes all text from the edit control.

Pascal

```
procedure Clear; virtual;
```

C++

```
virtual __fastcall Clear();
```

Description

Use Clear to replace the Text (see page 2379) property with an empty string. Clear removes all text, not just the selected text.

To remove just the selected text, use ClearSelection (see page 2349).

See Also

ClearSelection (see page 2349)

Text

30.1.11.3.3 TCustomEdit.ClearSelection Method

Removes the selected text from the edit control.

Pascal

```
procedure ClearSelection;
```

C++

```
__fastcall ClearSelection();
```

Description

Use ClearSelection to delete the selected text from the edit control. If no text is selected, ClearSelection does nothing. If all of the text is selected, ClearSelection clears all text, like the Clear (see page 2348) method.

Note: Calling ClearSelection does the same thing as sending the edit control a WM_CLEAR message.

See Also

Clear (see page 2348)

CutToClipboard (see page 2352)

SelText (see page 2377)

SetSelTextBuf (see page 2363)

30.1.11.3.4 TCustomEdit.ClearUndo Method

Clears the undo buffer so that no changes to the text can be backed out.

Pascal

```
procedure ClearUndo;
```

C++

```
__fastcall ClearUndo();
```

Description

Use ClearUndo to commit changes to the Text (see page 2379) property. After calling ClearUndo, the CanUndo (see page 2367) property is false and the Undo (see page 2364) method does nothing.

See Also

Undo (see page 2364)

CanUndo (see page 2367)

Text

30.1.11.3.5 TCustomEdit.CopyToClipboard Method

Copies the selected text in the edit control to the Clipboard in CF_TEXT format.

Pascal

```
procedure CopyToClipboard;
```

C++

```
__fastcall CopyToClipboard();
```

Description

Use CopyToClipboard to replace the contents of the Clipboard with the selected text. CopyToClipboard does not clear the Clipboard if no text is selected. If no text is selected, CopyToClipboard does nothing.

Note: Calling CopyToClipboard does the same thing as sending the edit control a WM_COPY message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->SelectAll();
  RichEdit1->CopyToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("..\\overview.rtf");
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;
  RichEdit1.CopyToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
```

```
    // you may need to change this path to suit your environment
    Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
```

See Also

CutToClipboard (see page 2352)

GetSelTextBuf (see page 2357)

PasteFromClipboard (see page 2358)

SelText (see page 2377)

Displaying and Editing Text in a Memo Control

30.1.11.3.6 TCustomEdit.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2352) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 2351). TCustomEdit (see page 2345) overrides the inherited method to specify a scrollable single-line edit control that reflects the current values of the BorderStyle (see page 2367), HideSelection (see page 2368), PasswordChar (see page 2370), and ReadOnly (see page 2371) properties.

See Also

BorderStyle (see page 2367)

CreateWindowHandle (see page 2351)

CreateWnd (see page 2352)

HideSelection (see page 2368)

PasswordChar (see page 2370)

ReadOnly (see page 2371)

30.1.11.3.7 TCustomEdit.CreateWindowHandle Method

Creates a Windows control to represent the control.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

CreateWindowHandle calls the inherited CreateWindowHandle method after working around a Win95 bug involving setting the read-only style on machines with Far East locales.

See Also

CreateParams (see page 2351)

CreateWnd (see page 2352)

DestroyWnd (see page 2354)

CreateWindowHandle

30.1.11.3.8 TCustomEdit.CreateWnd Method

Creates a Windows control corresponding to the edit control.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called when the edit control is created, and whenever a change to the edit control requires the window to be recreated. After calling the inherited method, CreateWnd sends the newly created window messages to enforce the MaxLength (see page 2368) and PasswordChar (see page 2370) properties.

See Also

CreateParams (see page 2351)

CreateWindowHandle

DestroyWnd (see page 2354)

MaxLength (see page 2368)

PasswordChar (see page 2370)

CreateWnd

30.1.11.3.9 TCustomEdit.CutToClipboard Method

Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.

Pascal

```
procedure CutToClipboard;
```

C++

```
__fastcall CutToClipboard();
```

Description

Use CutToClipboard to replace the contents of the Clipboard with the selected text while clearing the selected text. If no text is selected, CutToClipboard does nothing.

Note: Calling CopyToClipboard (see page 2349) does the same thing as sending the edit control a WM_CUT message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // ensure that all the text is cut, not just the current selection
  RichEdit1->SelectAll();
  RichEdit1->CutToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;  { ensure that all the text is cut, not just the current selection }
  RichEdit1.CutToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
end;
```

See Also

ClearSelection (see page 2349)

CopyToClipboard (see page 2349)

GetSelTextBuf (see page 2357)

PasteFromClipboard (see page 2358)

SelText (see page 2377)

Displaying and Editing Text in a Memo Control

30.1.11.3.10 TCustomEdit.DefaultHandler Method

Provides message handling for all messages that the control does not fully process itself.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to change the default message handling for the edit control. The Message parameter can be cast to a TMessage type, to obtain the WParam, LParam, and Result of the message. If the Result of the message is non-zero, the message has already been handled. Set the Result field to a non-zero value to prevent further processing of the message by the inherited method.

Note: In Delphi, calling inherited in a message-handling method results in a call to the ancestor's DefaultHandler method if that ancestor does not specify a handler for the message being handled.

See Also

WindowProc

DefWndProc

TMessage

30.1.11.3.11 TCustomEdit.DestroyWnd Method

Destroys the Windows control that corresponds to the edit control.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

The Windows control for the edit box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. When this happens, DestroyWnd is called.

Before the window is destroyed, DestroyWnd saves a copy of any properties that are needed to recreate the window after it is destroyed.

See Also

CreateWnd (see page 2352)

30.1.11.3.12 TCustomEdit.DoSetMaxLength Method

Sets the MaxLength (see page 2368) property.

Pascal

```
procedure DoSetMaxLength(Value: Integer); virtual;
```

C++

```
virtual __fastcall DoSetMaxLength(int Value);
```

Description

DoSetMaxLength is the property access function for the MaxLength (see page 2368) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the MaxLength (see page 2368) property.

DoSetMaxLength sends an EM_LIMITTEXT message to the window of the edit control.

See Also

MaxLength (see page 2368)

30.1.11.3.13 TCustomEdit.DoSetTextHint Method

Sets the value of TextHint (see page 2380).

Pascal

```
procedure DoSetTextHint(const Value: string); virtual;
```

C++

```
virtual __fastcall DoSetTextHint(const UnicodeString Value);
```

Description

DoSetTextHint is a protected method used to set the value of the TextHint (see page 2380) property.

See Also

TextHint (see page 2380)

30.1.11.3.14 TCustomEdit.GetControlsAlignment Method

Indicates how text is aligned within the control.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the alignment of the control. For controls that do not have an Alignment property, GetControlsAlignment returns taLeftJustify.

Note: GetControlsAlignment returns the alignment of text before it is altered by the BiDiMode property. To check if the alignment should be reversed to reflect the BiDiMode property, call UseRightToLeftAlignment.

See Also

BiDiMode

Text

Caption

UseRightToLeftAlignment

30.1.11.3.15 TCustomEdit.GetSelLength Method

Returns the SelLength (see page 2371) property.

Pascal

```
function GetSelLength: Integer; virtual;
```

C++

```
virtual __fastcall int GetSelLength();
```

Description

GetSelLength is the property access function for the SelLength (see page 2371) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the SelLength (see page 2371) property.

GetSelLength sends an EM_GETSEL message to the window of the edit control and returns the difference between the starting position and the ending position.

See Also

SelLength (see page 2371)

SetSelLength (see page 2361)

30.1.11.3.16 TCustomEdit.GetSelStart Method

Returns the SelStart (see page 2374) property.

Pascal

```
function GetSelStart: Integer; virtual;
```

C++

```
virtual __fastcall int GetSelStart();
```

Description

GetSelStart is the property access method for the SelStart (see page 2374) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the SelStart (see page 2374) property.

GetSelStart sends an EM_GETSEL message to the window of the edit control and returns the starting position.

See Also

SelStart (see page 2374)

SetSelStart (see page 2362)

30.1.11.3.17 TCustomEdit.GetSelText Method

Returns the SelText (see page 2377) property.

Pascal

```
function GetSelText: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetSelText();
```

Description

GetSelText is the property access method for the SelText (see page 2377) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the SelText (see page 2377) property.

See Also

SelText (see page 2377)

30.1.11.3.18 TCustomEdit.GetSelTextBuf Method

Copies the selected text into a buffer and returns the number of characters copied.

Pascal

```
function GetSelTextBuf(Buffer: PChar; BufSize: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int GetSelTextBuf(const char * Buffer, int BufSize);
```

Description

Use GetSelTextBuf to copy the selected text into a character buffer. If there is no selection, the buffer receives an empty string. If the selection contains more than (BufSize - 1) characters, only the first (BufSize - 1) characters are copied. GetSelTextBuf returns the number of characters that were actually copied into the buffer.

C++ Examples:

```
/*
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
*/
Char *Buffer;

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->SelLength; //Get length of selected text in Edit1
  Size++;                      //Add room for null character
  static std::auto_ptr<Char> _BufferCleaner(Buffer = new Char[Size]);
  Edit1->GetSelTextBuf(Buffer, Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
}
//---------------------------------------------------------------------------
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->SelText;
}
```

Delphi Examples:

```
{
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  Buffer: PChar;
  Size: Integer;
begin
  Size := Edit1.SelLength; {Get length of selected text in Edit1}
  Inc(Size); {Add room for null character}
  GetMem(Buffer, Size); {Creates Buffer dynamic variable}
  Edit1.GetSelTextBuf(Buffer,Size); {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);{Converts Buffer into Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.SelText;
end;
```

See Also

SelLength (see page 2371)

SelText (see page 2377)

SetSelTextBuf (see page 2363)

30.1.11.3.19 TCustomEdit.PasteFromClipboard Method

Pastes the contents of the Clipboard into edit control, replacing the current selection.

Pascal

```
procedure PasteFromClipboard;
```

C++

```
__fastcall PasteFromClipboard();
```

Description

Use PasteFromClipboard to replace the selected text with the contents of the Clipboard, or, if no text is selected, to insert the contents of the Clipboard at the cursor. If the Clipboard is empty, or if it does not contain anything in CF_TEXT format, PasteFromClipboard does nothing.

Note: Calling PasteFromClipboard does the same thing as sending the edit control a WM_PASTE message.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  RichEdit1->SelectAll();
  RichEdit1->CopyToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("..\\overview.rtf");
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, the first
line of text is copied from the rich edit control and pasted
into the edit box.  Note that only the text is pasted. If
the rich edit control includes any formatting information
that is not pasted into the edit control.  If the
destination were a rich edit control, the formatting
information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;
  RichEdit1.CopyToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  // you may need to change this path to suit your environment
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
end;
```

Displaying and Editing Text in a Memo Control

30.1.11.3.20 TCustomEdit.SelectAll Method

Selects all text in the edit control.

Pascal

```
procedure SelectAll;
```

C++

```
__fastcall SelectAll();
```

Description

Use SelectAll to select all text in the edit control. To select only part of the text, use the SelStart (see page 2374) and SelLength (see page 2371) properties.

C++ Examples:

```
/*
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // ensure that all the text is cut, not just the current selection
  RichEdit1->SelectAll();
  RichEdit1->CutToClipboard();
  Edit1->Clear();
  Edit1->PasteFromClipboard();
  RichEdit1->SetFocus();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example uses an edit box, a rich edit control, and a
button on a form. When the user clicks the button, text is
cut from the rich edit control and pasted into the edit box.
Note that only the text is pasted. If the rich edit control
includes any formatting information that is not pasted into
the edit control.  If the destination where a rich edit
control, the formatting information would be copied as well.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  RichEdit1.SelectAll;  { ensure that all the text is cut, not just the current selection }
  RichEdit1.CutToClipboard;
  Edit1.Clear;
  Edit1.PasteFromClipboard;
  RichEdit1.SetFocus;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
end;
```

SelText (see page 2377)

Text

30.1.11.3.21 TCustomEdit.SetAlignment Method

Sets the Alignment (see page 2365) property.

Pascal

```
procedure SetAlignment(Value: TAlignment);
```

C++

```
__fastcall SetAlignment(TAlignment Value);
```

Description

SetAlignment is exposed as a protected method so derived classes can customize their implementation of the Alignment (see page 2365) property.

See Also

Alignment (see page 2365)

30.1.11.3.22 TCustomEdit.SetAutoSize Method

Sets the AutoSize (see page 2366) property.

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

SetAutoSize is the protected write implementation of the AutoSize (see page 2366) property.

TCustomEdit (see page 2345) overrides the inherited method to update the height of the edit control to reflect the current font when the value of AutoSize (see page 2366) changes to true.

See Also

AutoSize (see page 2366)

30.1.11.3.23 TCustomEdit.SetSelLength Method

Sets the SelLength (see page 2371) property.

Pascal

```
procedure SetSelLength(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetSelLength(int Value);
```

Description

SetSelLength is the property access method for the SelLength (see page 2371) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the SelLength (see page 2371) property.

SetSelLength sends an EM_SETSEL message to the window of the edit control, specifying a selection that begins at SelStart (see page 2374) and ends at SelStart (see page 2374) + Value.

See Also

GetSelLength (see page 2356)

SelLength (see page 2371)

SelStart (see page 2374)

30.1.11.3.24 TCustomEdit.SetSelStart Method

Sets the SelStart (see page 2374) property.

Pascal

```
procedure SetSelStart(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetSelStart(int Value);
```

Description

SetSelStart is the property access method for the SelStart (see page 2374) property. It is exposed as a protected method so that descendants of TCustomEdit (see page 2345) can customize the implementation of the SelStart (see page 2374) property.

SetSelLength (see page 2361) sends an EM_SETSEL message to the window of the edit control to position the cursor on the position indicated by Value.

See Also

GetSelStart (see page 2356)

SelStart (see page 2374)

30.1.11.3.25 TCustomEdit.SetSelText Method

Sets the SelText (see page 2377) property.

Pascal

```
procedure SetSelText(const Value: string);
```

C++

```
__fastcall SetSelText(const UnicodeString Value);
```

Description

SetSelText is the property access method for the SelText (see page 2377) property.

See Also

GetSelTextBuf (see page 2357)

SelText (see page 2377)

30.1.11.3.26 TCustomEdit.SetSelTextBuf Method

Replaces the selected text with a null-terminated string.

Pascal

```
procedure SetSelTextBuf(Buffer: PChar);
```

C++

```
__fastcall SetSelTextBuf(const char * Buffer);
```

Description

Use SetSelTextBuf to replace the current selection by the contents of the null-terminated string pointed to by Buffer. If no text is selected, the contents of Buffer are inserted at the cursor. SetSelTextBuf does the same thing as setting the SelText (see page 2377) property, except that it takes a pointer to a char type rather than a string.

C++ Examples:

```
/*
This example inserts the contents of temp_string at the
current location of the cursor.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
   const AnsiString Path = "../readme.txt";
   Memo1->Lines->LoadFromFile(Path);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  WideChar *temp_string = L"I am now here";
  Memo1->SetSelTextBuf(temp_string);
}
```

Delphi Examples:

```
{
This example inserts the contents of temp_string at the
current location of the cursor.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  temp_string: array[0..15] of Char;
begin
  temp_string := 'I am now here';
  Memo1.SetSelTextBuf(temp_string);
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'readme.txt';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
```

See Also

GetSelTextBuf (see page 2357)

PasteFromClipboard (see page 2358)

SelText (see page 2377)

SetTextBuf

30.1.11.3.27 TCustomEdit.Undo Method

Backs out all changes in the undo buffer.

Pascal

```
procedure Undo;
```

C++

```
__fastcall Undo();
```

Description

Call Undo to cancel all changes made to the Text (see page 2379) property since the last call to the ClearUndo (see page 2349) method. If ClearUndo (see page 2349) was never called, Undo rolls back all changes.

To determine whether there are any changes in the undo buffer, check the CanUndo (see page 2367) property.

See Also

ClearUndo (see page 2349)

CanUndo (see page 2367)

Text

30.1.11.4 TCustomEdit Properties

The properties of the TCustomEdit class are listed here.

Protected Properties

	Name	Description
	AutoSelect (see page 2365)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2366)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2367)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2367)	Determines the case of the text within the edit control.
	HideSelection (see page 2368)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2368)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2369)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2369)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2370)	Determines where a control looks for its color information.
	PasswordChar (see page 2370)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Properties

	Name	Description
	Alignment (see page 2365)	Determines how the text is aligned within the text edit control.
R	CanUndo (see page 2367)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2369)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2371)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2371)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2374)	Specifies the position of the first selected character in the text.
	SelText (see page 2377)	Specifies the selected portion of the edit control's text.

	Text (see page 2379)	Contains a text string associated with the control.
	TextHint (see page 2380)	A hint or message to be displayed when the Text (see page 2379) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2379)	Determines if the user can tab to a control.

30.1.11.4.1 TCustomEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

See Also

SetAlignment (see page 2361)

Text

Displaying and Editing Fields in an Edit Box

30.1.11.4.2 TCustomEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect: Boolean;
```

C++

```
__property Boolean AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

See Also

SelectAll (see page 2359)

SelLength (see page 2371)

SelStart (see page 2374)

SelText (see page 2377)

SetSelTextBuf (see page 2363)

30.1.11.4.3 TCustomEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

See Also

BorderStyle (see page 2367)

ClientHeight

ControlStyle

Height

30.1.11.4.4 TCustomEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

30.1.11.4.5 TCustomEdit.CanUndo Property

Indicates whether the edit control contains changes that can be backed out.

Pascal

```
property CanUndo: Boolean;
```

C++

```
__property Boolean CanUndo;
```

Description

Read (see page 3634) CanUndo to determine whether the user has made any changes to the text that can be undone by calling the Undo (see page 2364) method. This is useful when enabling or disabling menu items that correspond to these commands.

See Also

Undo (see page 2364)

ClearUndo (see page 2349)

Text

30.1.11.4.6 TCustomEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

See Also

Text

30.1.11.4.7 TCustomEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

See Also

SelLength (see page 2371)

SelStart (see page 2374)

SelText (see page 2377)

SetSelTextBuf (see page 2363)

30.1.11.4.8 TCustomEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

See Also

Text

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

30.1.11.4.9 TCustomEdit.Modified Property

Indicates whether the user edited the text of the edit control.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Use Modified to determine whether the user changed the Text (see page 2379) property of the edit control. Modified is only reset to **False** when you assign a value to the Text (see page 2379) property. In particular, it is not reset when the control receives focus.

See Also

Change (see page 2348)

OnChange (see page 2381)

SetTextBuf

Text

30.1.11.4.10 TCustomEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly: Boolean;
```

C++

```
__property Boolean NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

30.1.11.4.11 TCustomEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

See Also

Text

30.1.11.4.12 TCustomEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color

Parent

ParentFont

ParentShowHint

30.1.11.4.13 TCustomEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar: Char;
```

C++

```
__property Char PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text (see page 2379) property reflects the actual characters that are typed.

See Also

Text

30.1.11.4.14 TCustomEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

See Also

CopyToClipboard (see page 2349)

GetSelTextBuf (see page 2357)

30.1.11.4.15 TCustomEdit.SelLength Property

Specifies the number of characters (bytes) that are selected.

Pascal

```
property SelLength: Integer;
```

C++

```
__property int SelLength;
```

Description

Read (see page 3634) SelLength to determine the length, in bytes, of the selected text. This is the same as the number of characters, unless you are using a multi-byte character set. Set SelLength to change the selection to consist of the first SelLength bytes starting at SelStart (see page 2374).

Note: Setting SelLength to a value greater than the number of characters from SelStart (see page 2374) to the end of the text results in the selection of all characters from SelStart (see page 2374) to the end of the text. Reading SelLength immediately after setting it to a value greater than the number of available characters returns the number of characters actually selected, not the value that was just set.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection. Notice that the
"Match whole word only" and "Match case" work.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FindDialog1->Position = Point(RichEdit1->Left + RichEdit1->Width, RichEdit1->Top);
```

```
  FindDialog1->Execute();
}

void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  int FoundAt, StartPos, ToEnd;
  TSearchTypes mySearchTypes = TSearchTypes();
  // begin the search after the current selection
  // if there is one
  // otherwise, begin at the start of the text
  if (FindDialog1->Options.Contains(frMatchCase))
    mySearchTypes << stMatchCase;
  if (FindDialog1->Options.Contains(frWholeWord))
    mySearchTypes << stWholeWord;
  if (RichEdit1->SelLength)
    StartPos = RichEdit1->SelStart + RichEdit1->SelLength;
  else
    StartPos = 0;
  // ToEnd is the length from StartPos
  // to the end of the text in the rich edit control
  ToEnd = RichEdit1->Text.Length() - StartPos;
  FoundAt = RichEdit1->FindText(FindDialog1->FindText, StartPos, ToEnd, mySearchTypes);
  if (FoundAt != -1)
  {
    RichEdit1->SetFocus();
    RichEdit1->SelStart = FoundAt;
    RichEdit1->SelLength = FindDialog1->FindText.Length();
  }
  else Beep();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;

30.1.11.4.16 TCustomEdit.SelStart Property

Specifies the position of the first selected character in the text.

Pascal

```
property SelStart: Integer;
```

C++

```
__property int SelStart;
```

Description

Read (see page 3634) SelStart to determine the position of the first selected character, where 0 indicates the first character. If there is no selected text, SelStart indicates the position of the cursor. Set SelStart to remove the current selection and position the cursor just before the indicated character.

To select a particular range of the text, first set SelStart to position the cursor, and then set SelLength (see page 2371) to extend the selection.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
```

```
  TFindDialog.  Clicking the button will display a Find
  Dialog to the right of the edit control.  Filling in the
  "Find what" text and pressing the Find Next button will

SelLength (see page 2371)

SelText (see page 2377)

30.1.11.4.17 TCustomEdit.SelText Property

Specifies the selected portion of the edit control's text.

Pascal

```
property SelText: string;
```

C++

```
__property UnicodeString SelText;
```

Description

Read (see page 3634) SelText to determine the value of the selected text. Set SelText to replace the selected text with a new string. If there is no selection, but the edit control has focus, set SelText to insert a new string into the text at the cursor.

C++ Examples:

```
/*
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
*/
Char *Buffer;

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->SelLength; //Get length of selected text in Edit1
  Size++;                      //Add room for null character
  static std::auto_ptr<Char> _BufferCleaner(Buffer = new Char[Size]);
  Edit1->GetSelTextBuf(Buffer, Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
}
//---------------------------------------------------------------------------
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->SelText;
}
```

Delphi Examples:

```
{
This example copies selected text from one text edit to
another.  This example requires two text edits and two buttons.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Integer;
begin
  Size := Edit1.SelLength; {Get length of selected text in Edit1}
  Inc(Size); {Add room for null character}
  GetMem(Buffer, Size); {Creates Buffer dynamic variable}
  Edit1.GetSelTextBuf(Buffer,Size); {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);{Converts Buffer into Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.SelText;
end;
```

Text

30.1.11.4.18 TCustomEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.11.4.19 TCustomEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                       //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
```

```
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

Caption

Lines (see page 2451)

30.1.11.4.20 TCustomEdit.TextHint Property

A hint or message to be displayed when the Text (see page 2379) property is empty.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

30.1.11.5 TCustomEdit Events

The events of the TCustomEdit class are listed here.

Protected Events

	Name	Description
	OnChange (see page 2381)	Occurs when the text for the edit control may have changed.

30.1.11.5.1 TCustomEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3707) an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified (see page 2369) property to see if a change actually occurred. The Text (see page 2379) property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

30.1.12 TCustomGroupBox Class

TCustomGroupBox is the base class for all group-box components.

Class Hierarchy

Pascal

```
TCustomGroupBox = class(TCustomControl);
```

C++

```
class TCustomGroupBox : public TCustomControl;
```

File

StdCtrls

Description

Group boxes are visual components that act as containers for sets of related controls, such as radio buttons. Group boxes may also contain other group boxes. TCustomGroupBox is the class from which all group-box components—including TGroupBox (see page 2535), TRadioGroup, and TDBRadioGroup—descend.

See Also

TDBRadioGroup

TRadioGroup

TGroupBox (see page 2535)

TCustomControl

TControl

30.1.12.1 TCustomGroupBox Members

The following tables list the members exposed by TCustomGroupBox.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2382)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2383)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2383)	Renders the onscreen image of the group box.

Public Methods

	Name	Description
	Create (see page 2382)	Creates and initializes a TCustomGroupBox (see page 2381) instance.

30.1.12.2 TCustomGroupBox.Create Constructor

Creates and initializes a TCustomGroupBox (see page 2381) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomGroupBox(TComponent * AOwner);
```

Description

Call Create to instantiate a group box at runtime. Group boxes placed on forms at design time are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the group box. It becomes the value of the Owner property.

See Also

Owner

30.1.12.3 TCustomGroupBox Methods

The methods of the TCustomGroupBox class are listed here.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2382)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2383)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2383)	Renders the onscreen image of the group box.

30.1.12.3.1 TCustomGroupBox.AdjustClientRect Method

Adjusts the ClientRect property for idiosyncrasies of the window.

Pascal

```
procedure AdjustClientRect(var Rect: TRect); override;
```

C++

```
virtual __fastcall AdjustClientRect(TRect Rect);
```

Description

AdjustClientRect is called internally when the group box needs accurate information on where to place child controls within the client area. It indents the client rectangle slightly so that child controls are not placed on the frame (or caption) of the group box.

See Also

ClientRect

Caption

30.1.12.3.2 TCustomGroupBox.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a group box creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

Specify the parameter record as the value of the Params parameter. The TCreateParams type is a data structure holding information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TCustomGroupBox (see page 2381) adjusts the window style by turning off the CS_HREDRAW and CS_VREDRAW flags.

See Also

CreateWnd

CreateWindowHandle

30.1.12.3.3 TCustomGroupBox.Paint Method

Renders the onscreen image of the group box.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint draws a border around the group box and fills in the caption.

30.1.13 TCustomLabel Class

TCustomLabel is the base class for non-windowed controls that display text on a form.

Class Hierarchy

Pascal

```
TCustomLabel = class(TGraphicControl);
```

C++

```
class TCustomLabel : public TGraphicControl;
```

File

StdCtrls

Description

Use TCustomLabel as a base class when defining objects that display text that users can't edit. TCustomLabel introduces several new properties and methods to control the appearance of the text.

TCustomLabel is not a descendant of TWinControl, so it does not have its own window and can't receive direct input from the keyboard. To define an object that responds to direct keyboard input in addition to displaying text, use TCustomStaticText (see page 2457) as a base class.

Do not create instances of TCustomLabel. To put a label on a form, use a TLabel (see page 2607) object.

See Also

TCustomStaticText (see page 2457)

TLabel (see page 2607)

30.1.13.1 TCustomLabel Members

The following tables list the members exposed by TCustomLabel.

Protected Methods

	Name	Description
	AdjustBounds (see page 2385)	Resizes the label when the text changes.
	DoDrawText (see page 2386)	Renders the text in the client area.
V	GetLabelText (see page 2386)	Returns the value of the Caption (see page 2392) property.
V	Loaded (see page 2387)	Adjusts the size of the label when it is first loaded. .
V	Notification (see page 2387)	Responds to notifications when objects are about to be created or destroyed.
V	Paint (see page 2387)	Draws the image of the label.
V	SetAutoSize (see page 2388)	Sets the AutoSize (see page 2389) property.

Protected Properties

	Name	Description
	Alignment (see page 2388)	Controls the horizontal placement of the text within the label.
	AutoSize (see page 2389)	Determines whether the size of the label automatically resizes to accommodate the text.
	EllipsisPosition (see page 2395)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.

	FocusControl (see page 2395)	Designates a windowed control associated with the label.
	Layout (see page 2396)	Specifies the vertical placement of the text within the label.
	ShowAccelChar (see page 2396)	Determines how an ampersand in the label text is displayed.
	Transparent (see page 2397)	Specifies whether controls that sit below the label on a form can be seen through the label.
	WordWrap (see page 2397)	Specifies whether the label text wraps when it is too long for the width of the label.

Public Methods

	Name	Description
	Create (see page 2385)	Creates and initializes an instance of TCustomLabel (see page 2384).

Public Properties

	Name	Description
	Canvas (see page 2390)	Provides the drawing surface used by the graphic control.
	Caption (see page 2392)	Specifies a text string that identifies the control to the user.
	GlowSize (see page 2395)	Specifies the radius of the glow around the label.

30.1.13.2 TCustomLabel.Create Constructor

Creates and initializes an instance of TCustomLabel (see page 2384).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomLabel(TComponent * AOwner);
```

Description

Call Create to create an instance of TCustomLabel (see page 2384) at runtime. Labels placed on forms at design time are created automatically.

AOwner is a component, typically the form, that is responsible for freeing the label.

See Also

Owner

30.1.13.3 TCustomLabel Methods

The methods of the TCustomLabel class are listed here.

Protected Methods

	Name	Description
	AdjustBounds (see page 2385)	Resizes the label when the text changes.
	DoDrawText (see page 2386)	Renders the text in the client area.
	GetLabelText (see page 2386)	Returns the value of the Caption (see page 2392) property.
	Loaded (see page 2387)	Adjusts the size of the label when it is first loaded. .
	Notification (see page 2387)	Responds to notifications when objects are about to be created or destroyed.
	Paint (see page 2387)	Draws the image of the label.
	SetAutoSize (see page 2388)	Sets the AutoSize (see page 2389) property.

30.1.13.3.1 TCustomLabel.AdjustBounds Method

Resizes the label when the text changes.

Pascal

```
procedure AdjustBounds; dynamic;
```

C++

```
__fastcall AdjustBounds();
```

Description

When the text in the label or the font changes, AdjustBounds is implicitly called. It redraws the text in the client area, and then resizes the label if the AutoSize (see page 2389) property is true.

When WordWrap (see page 2397) is true, the width of the label is fixed. If AutoSize (see page 2389) is also true, changes to the text cause the label to change in height. When AutoSize (see page 2389) is true and WordWrap (see page 2397) is false, the height of the label is determined by the font, and changes to the text cause the label to change in width.

Override AdjustBounds to make additional adjustments when the text changes.

See Also

DoDrawText (see page 2386)

AutoSize (see page 2389)

30.1.13.3.2 TCustomLabel.DoDrawText Method

Renders the text in the client area.

Pascal

```
procedure DoDrawText(var Rect: TRect; Flags: Longint); dynamic;
```

C++

```
__fastcall DoDrawText(TRect Rect, Longint Flags);
```

Description

When the label needs to draw itself, DoDrawText is implicitly called. DoDrawText uses the Windows API function, DrawText, to render the caption in the client area.

The first parameter, Rect, specifies the boundaries of the text within the client area. The second parameter, Flags, specifies how the text is aligned within those boundaries, how tab characters are handled, etc. See the Microsoft Windows API DrawText function for all the possible values of Flags.

Override DoDrawText to render text differently.

See Also

Caption

AdjustBounds (see page 2385)

30.1.13.3.3 TCustomLabel.GetLabelText Method

Returns the value of the Caption (see page 2392) property.

Pascal

```
function GetLabelText: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetLabelText();
```

Description

Call GetLabelText to obtain the string that appears as the text of the label.

See Also

Caption

30.1.13.3.4 TCustomLabel.Loaded Method

Adjusts the size of the label when it is first loaded. .

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The protected Loaded method is called immediately after a saved version of the form that contains the label is loaded into memory. TCustomLabel (see page 2384) uses this method to adjust the size of the label to the text it contains if the AutoSize (see page 2389) property is true.

See Also

AutoSize (see page 2389)

30.1.13.3.5 TCustomLabel.Notification Method

Responds to notifications when objects are about to be created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification is called automatically when components are created or destroyed. After calling the inherited method, Notification checks whether the windowed control specified by the FocusControl (see page 2395) property is about to be destroyed. If the windowed control is going away, Notification sets the FocusControl (see page 2395) property to nil (Delphi) or NULL (C++).

See Also

FocusControl (see page 2395)

30.1.13.3.6 TCustomLabel.Paint Method

Draws the image of the label.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called automatically when the label receives a WM_PAINT message from its Parent. Paint writes the text returned by the GetLabelText (see page 2386) method.

See Also

GetLabelText (see page 2386)

30.1.13.3.7 TCustomLabel.SetAutoSize Method

Sets the AutoSize (see page 2389) property.

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

SetAutoSize is the protected access method for the AutoSize (see page 2389) property. It is exposed as a protected method so descendants can override it to change the implementation of the AutoSize (see page 2389) property.

See Also

AutoSize (see page 2389)

30.1.13.4 TCustomLabel Properties

The properties of the TCustomLabel class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 2388)	Controls the horizontal placement of the text within the label.
	AutoSize (see page 2389)	Determines whether the size of the label automatically resizes to accommodate the text.
	EllipsisPosition (see page 2395)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	FocusControl (see page 2395)	Designates a windowed control associated with the label.
	Layout (see page 2396)	Specifies the vertical placement of the text within the label.
	ShowAccelChar (see page 2396)	Determines how an ampersand in the label text is displayed.
	Transparent (see page 2397)	Specifies whether controls that sit below the label on a form can be seen through the label.
	WordWrap (see page 2397)	Specifies whether the label text wraps when it is too long for the width of the label.

Public Properties

	Name	Description
	Canvas (see page 2390)	Provides the drawing surface used by the graphic control.
	Caption (see page 2392)	Specifies a text string that identifies the control to the user.
	GlowSize (see page 2395)	Specifies the radius of the glow around the label.

30.1.13.4.1 TCustomLabel.Alignment Property

Controls the horizontal placement of the text within the label.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Set Alignment to specify how the text of the label is justified within the ClientRect of the label control.

The effect of the Alignment property is more obvious if the WordWrap (see page 2397) property is true and the label includes more than one line of text.

See Also

ClientRect

GetLabelText (see page 2386)

Layout (see page 2396)

WordWrap (see page 2397)

30.1.13.4.2 TCustomLabel.AutoSize Property

Determines whether the size of the label automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the label adjust its size automatically so the client area accommodates the height and width of the text. When AutoSize is false, the label is fixed in size. When AutoSize is true, the size of the label readjusts whenever the text changes. The size of the label is also readjusts when the Font property changes.

When WordWrap (see page 2397) is true, the width of the label is fixed. If AutoSize is also true, changes to the text cause the label to change in height. When AutoSize is true and WordWrap (see page 2397) is false, the font determines the height of the label, and changes to the text cause the label to change in width.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
```

```
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
```

See Also

BoundsRect

GetLabelText (see page 2386)

Font

WordWrap (see page 2397)

Layout (see page 2396)

30.1.13.4.3 TCustomLabel.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl instance does not have its own Windows screen object, it obtains its device context from its parent control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
```

```
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = dynamic_cast<TLabel *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
```

```
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

30.1.13.4.4 TCustomLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
```

```
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
```

```
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.13.4.5 TCustomLabel.EllipsisPosition Property

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
property EllipsisPosition: TEllipsisPosition;
```

C++

```
__property TEllipsisPosition EllipsisPosition;
```

Description

Set EllipsisPosition to determine how an ellipsis is placed in text that does not fit in its allocated rectangle. This is a TEllipsisPosition (see page 3001) constant and its value corresponds to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

See Also

WordWrap (see page 2397)

30.1.13.4.6 TCustomLabel.FocusControl Property

Designates a windowed control associated with the label.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Set FocusControl to the windowed control that should receive focus when the user presses the accelerator key specified by the label. Specify an accelerator key by preceding a character in the label text with an ampersand (&) and setting the ShowAccelChar (see page 2396) property to true.

See Also

ShowAccelChar (see page 2396)

GetLabelText (see page 2386)

30.1.13.4.7 TCustomLabel.GlowSize Property

Specifies the radius of the glow around the label.

Pascal

```
property GlowSize: Integer;
```

C++

```
__property int GlowSize;
```

Description

Set the value of GlowSize to specify the radius of the glow around the label.

Note: This is available only on Windows Vista with the Aero theme enabled.

See Also

Hint

Transparent (see page 2397)

Alignment (see page 2388)

30.1.13.4.8 TCustomLabel.Layout Property

Specifies the vertical placement of the text within the label.

Pascal

```
property Layout: TTextLayout;
```

C++

```
__property TTextLayout Layout;
```

Description

Set Layout to specify how the text of the label is placed within the ClientRect of the label control. Layout is the vertical analog to the Alignment (see page 2388) property.

See Also

Alignment (see page 2388)

ClientRect

30.1.13.4.9 TCustomLabel.ShowAccelChar Property

Determines how an ampersand in the label text is displayed.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

Set ShowAccelChar to true to allow the label to display an underlined accelerator key value. When ShowAccelChar is true, any character preceded by an ampersand (&) appears underlined. If the FocusControl (see page 2395) property is set, the windowed control specified by the FocusControl (see page 2395) property receives input focus when the user types that underlined character. To display an ampersand when ShowAccelChar is true, use two ampersands (&&) to stand for the single ampersand that is displayed.

Set ShowAccelChar to false to display the label text with all ampersands appearing as ampersands. When ShowAccelChar is false, the value of the FocusControl (see page 2395) property is not used.

C++ Examples:

```
/*
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
```

```
  label also includes an ampersand, but it does not appear as
  an accelerator character.
  */
  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Label1->ShowAccelChar = true;
    Label1->Caption = "An &Underlined character appears here";
    Label2->ShowAccelChar = false;
    Label2->Caption = "An ampersand (&) appears here";
  }
```

Delphi Examples:

```
  {
  This example uses two labels on a form. The first label has
  a caption with an accelerator character in it. The second
  label also includes an ampersand, but it does not appear as
  an accelerator character.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Label1.ShowAccelChar := True;
    Label1.Caption := 'An &Underlined character appears here';
    Label2.ShowAccelChar := False;
    Label2.Caption := 'An ampersand (&) appears here';
  end;
```

See Also

FocusControl (see page 2395)

GetLabelText (see page 2386)

30.1.13.4.10 TCustomLabel.Transparent Property

Specifies whether controls that sit below the label on a form can be seen through the label.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to prevent the label from obscuring other controls on the form. For example, if the label is used to add text to a graphic, set Transparent to true so that the label does not stand out as a separate object.

Writing text so that the background is transparent is slower than writing text when Transparent is false. If the label is not obscuring a complicated image, performance can be improved by setting the background color of the label to match the object beneath it and setting Transparent to false.

See Also

Color

ParentColor

30.1.13.4.11 TCustomLabel.WordWrap Property

Specifies whether the label text wraps when it is too long for the width of the label.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the label to display multiple line of text. When WordWrap is true, text that is too wide for the label control wraps at the right margin and continues in additional lines.

Set WordWrap to false to limit the label to a single line. When WordWrap is false, text that is too wide for the label appears truncated.

See Also

ClientWidth

GetLabelText (see page 2386)

30.1.14 TCustomListBox Class

TCustomListBox is the base class for listbox objects that are wrappers for list box controls.

Class Hierarchy

Pascal

```
TCustomListBox = class(TCustomMultiSelectListControl);
```

C++

```
class TCustomListBox : public TCustomMultiSelectListControl;
```

File

StdCtrls

Description

TCustomListBox encapsulates behavior common to all list box controls. List box objects are used to display a scrollable list from which users can select one or more items. Use a list box control to limit the user to selecting from a list of items. Items (see page 2429) can be added at design time or at runtime.

As a wrapper for a list box TCustomListBox introduces methods for:

Displaying, sorting, selecting, manipulating, and querying items in the list.

Creating owner-draw style list boxes that can display graphical images such as icons and bitmaps.

Creating multiple-column and multiple-selection lists.

By default, TCustomListBox is a standard list box that displays items as text strings. These items are contained in a TStrings object, and the methods of the TStrings object are used to add, insert or delete a string. The following code demonstrates adding a new string to the list box:

MyListBox.Items.Add('New (see page 3619) item'); //Delphi

MyListBox->Items (see page 2429)->Add("New (see page 3619) item"); // C++

Descendants of TCustomListBox inherit the basic functionality of TCustomListBox. Some descendants also have specialized behavior and can be linked to file, directory, drive, or database information. Use these list boxes to easily access and list this type of information.

A combo box is a list box with an edit control and an optional drop down style for the list. Use a combo box to allow users to type their selection into an edit box or to save space on a form by having the list drop down.

For lists of items that require a matrix or expandable tree-like structure, use list views or tree views. These controls allow the grouping of items under column headings or in expandable and contractible rows.

TStrings

30.1.14.1 TCustomListBox Members

The following tables list the members exposed by TCustomListBox.

Protected Events

	Name	Description
	OnData (see page 2438)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2439)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2439)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDrawItem (see page 2439)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnMeasureItem (see page 2442)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Protected Fields

	Name	Description
	FMoving (see page 2401)	Specifies whether the strings of the list box are changing their position.

Protected Methods

	Name	Description
V	CreateParams (see page 2404)	Initializes the window-creation parameter record passed in the Params parameter.
V	CreateWnd (see page 2405)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2406)	Deletes a string from the list box.
V	DestroyWnd (see page 2406)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2407)	Returns the index of a string in the list box.
	DoGetData (see page 2407)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2408)	Returns the object associated with an item in a virtual list box.
V	DragCanceled (see page 2408)	Sends a mouse message canceling the drag-and-drop operation.
V	DrawItem (see page 2408)	Generates an OnDrawItem (see page 2439) event.
	GetItemData (see page 2409)	Returns a 32-bit value associated with the specified item in a list box.
V	GetItemIndex (see page 2410)	Returns the value of the ItemIndex property.
V	GetSelCount (see page 2410)	Returns the number of selected items.
	GetSelected (see page 2410)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2411)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2411)	Associates an integer with a specified item in the list box.
V	KeyPress (see page 2415)	Responds when the user presses a key.
V	LoadRecreateItems (see page 2415)	Assigns new strings to the list.
V	MeasureItem (see page 2415)	Generates an OnMeasureItem (see page 2442) event.
	ResetContent (see page 2416)	Removes all of the items from a list box.
V	SaveRecreateItems (see page 2416)	Saves the items from a list box.
	SetItemData (see page 2417)	Sets the 32-bit value associated with the specified item in a list box.

	SetItemIndex (see page 2417)	Gives focus to the item with a specified index.
	SetMultiSelect (see page 2417)	Sets the MultiSelect property.
	WndProc (see page 2418)	Handles Windows messages.

Protected Properties

	Name	Description
	BorderStyle (see page 2423)	Determines whether the list box has a border.
	Columns (see page 2426)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	ExtendedSelect (see page 2427)	Determines if the user can select a sequential range of items in the list box.
	IntegralHeight (see page 2428)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2428)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 2431)	Determines where a control looks for its color information.
	Sorted (see page 2434)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2436)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 2437)	Specifies the size of the tabs in the list box.

Public Methods

	Name	Description
	AddItem (see page 2402)	Adds an item to the list box
	Clear (see page 2403)	Deletes all items from the list box.
	ClearSelection (see page 2403)	Deselects all selected items in the list box, if possible.
	CopySelection (see page 2404)	Copies the selected items to another list-type control
	Create (see page 2400)	Instantiates a list box control.
	DeleteSelected (see page 2406)	Deletes the selected items from the list box
	Destroy (see page 2401)	Destroys the instance of a list box control.
	GetCount (see page 2409)	Returns the value of the Count (see page 2427) property.
	ItemAtPos (see page 2411)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2413)	Returns the rectangle that surrounds the item specified in the Item parameter.
	SelectAll (see page 2416)	Selects the entire block of text in the list box.

Public Properties

	Name	Description
	AutoComplete (see page 2423)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2423)	Specifies the delay between a key press and an attempt to autocomplete the field.
R	Canvas (see page 2424)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2439) event of an owner-draw list box.
	Count (see page 2427)	Indicates the number of items in the list box.
	Items (see page 2429)	Contains the strings that appear in the list box.
	ScrollWidth (see page 2432)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	Selected (see page 2432)	Indicates whether a particular item is selected.
	TopIndex (see page 2437)	Specifies the index number of the item that appears at the top of the list box.

Published Properties

	Name	Description
	TabStop (see page 2436)	Determines if the user can tab to a control.

30.1.14.2 TCustomListBox.Create Constructor

Instantiates a list box control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a list box control at runtime. For list boxes created at design time, Create is called automatically.AOwner is the component that is responsible for freeing the list box. It becomes the value of the Owner property. If AOwner is nil, the caller is responsible for explicitly freeing the control.

See Also

Owner

30.1.14.3 TCustomListBox.Destroy Destructor

Destroys the instance of a list box control.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomListBox();
```

Description

Do not call Destroy directly in an application. Instead, an application should call Free. Free checks that the list box reference is not nil before it calls Destroy.

Destroy frees the memory associated with the objects for the Canvas (see page 2424) and Items (see page 2429) properties. Then it calls the inherited destructor to destroy the list box object.

See Also

System::TObject::Free (see page 3372)

30.1.14.4 TCustomListBox Fields

The fields of the TCustomListBox class are listed here.

Protected Fields

	Name	Description
	FMoving (see page 2401)	Specifies whether the strings of the list box are changing their position.

30.1.14.4.1 TCustomListBox.FMoving Field

Specifies whether the strings of the list box are changing their position.

Pascal

```
FMoving: Boolean;
```

C++

```
Boolean FMoving;
```

Description

FMoving is an internal field specifying whether the strings of the list box are moving inside the list box.

See Also

Move

30.1.14.5 TCustomListBox Methods

The methods of the TCustomListBox class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2404)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateWnd (see page 2405)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2406)	Deletes a string from the list box.
	DestroyWnd (see page 2406)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2407)	Returns the index of a string in the list box.
	DoGetData (see page 2407)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2408)	Returns the object associated with an item in a virtual list box.
	DragCanceled (see page 2408)	Sends a mouse message canceling the drag-and-drop operation.
	DrawItem (see page 2408)	Generates an OnDrawItem (see page 2439) event.
	GetItemData (see page 2409)	Returns a 32-bit value associated with the specified item in a list box.
	GetItemIndex (see page 2410)	Returns the value of the ItemIndex property.
	GetSelCount (see page 2410)	Returns the number of selected items.
	GetSelected (see page 2410)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2411)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2411)	Associates an integer with a specified item in the list box.
	KeyPress (see page 2415)	Responds when the user presses a key.
	LoadRecreateItems (see page 2415)	Assigns new strings to the list.
	MeasureItem (see page 2415)	Generates an OnMeasureItem (see page 2442) event.
	ResetContent (see page 2416)	Removes all of the items from a list box.
	SaveRecreateItems (see page 2416)	Saves the items from a list box.
	SetItemData (see page 2417)	Sets the 32-bit value associated with the specified item in a list box.
	SetItemIndex (see page 2417)	Gives focus to the item with a specified index.
	SetMultiSelect (see page 2417)	Sets the MultiSelect property.
	WndProc (see page 2418)	Handles Windows messages.

Public Methods

	Name	Description
	AddItem (see page 2402)	Adds an item to the list box
	Clear (see page 2403)	Deletes all items from the list box.
	ClearSelection (see page 2403)	Deselects all selected items in the list box, if possible.
	CopySelection (see page 2404)	Copies the selected items to another list-type control
	DeleteSelected (see page 2406)	Deletes the selected items from the list box
	GetCount (see page 2409)	Returns the value of the Count (see page 2427) property.
	ItemAtPos (see page 2411)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2413)	Returns the rectangle that surrounds the item specified in the Item parameter.
	SelectAll (see page 2416)	Selects the entire block of text in the list box.

30.1.14.5.1 TCustomListBox.AddItem Method

Adds an item to the list box

Pascal

```
procedure AddItem(Item: String; AObject: TObject); override;
```

C++

```
virtual __fastcall AddItem(UnicodeString Item, TObject * AObject);
```

Description

Call AddItem to add a new item to the end of the list.

Item is the text of the item to add.

AObject is the object associated with the new item.

See Also

AddObject

Items (see page 2429)

30.1.14.5.2 TCustomListBox.Clear Method

Deletes all items from the list box.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Use Clear to delete all of the items in the list box at once. Although the items in a standard list box are of type TStrings, use the Clear method of the list box rather than calling the Clear method of the Items (see page 2429) property. This allows descendants of TCustomListBox (see page 2398) to perform any other necessary clean-up in the Clear method, in addition to deleting the items from the Items (see page 2429) property. Thus, applications should use

```
ListBox1.Clear;
ListBox1->Clear();
```

rather than

```
ListBox1.Items.Clear;
ListBox1->Items->Clear();
```

See Also

Clear

Items (see page 2429)

30.1.14.5.3 TCustomListBox.ClearSelection Method

Deselects all selected items in the list box, if possible.

Pascal

```
procedure ClearSelection; override;
```

C++

```
virtual __fastcall ClearSelection();
```

Description

Use ClearSelection to deselect all the currently selected items in the list box. When the list box receives focus, after ClearSelection is called, the last item that was selected is the item that receives the current focus in the list box. Although this item receives focus, the item itself is not selected.

See Also

DeleteSelected (see page 2406)

ExtendedSelect (see page 2427)

MultiSelect

SelCount

Selected (see page 2432)

ItemIndex

30.1.14.5.4 TCustomListBox.CopySelection Method

Copies the selected items to another list-type control

Pascal

```
procedure CopySelection(Destination: TCustomListControl); override;
```

C++

```
virtual __fastcall CopySelection(TCustomListControl Destination);
```

Description

Call CopySelection to copy all the items selected in the list box to a combo box, list view, or another list box. If the destination control is not sorted, the selected items are added to the end of its list.

Destination is the list box, combo box, or list view to which the selected items are copied.

See Also

MoveSelection

ExtendedSelect (see page 2427)

MultiSelect

SelCount

Selected (see page 2432)

ItemIndex

30.1.14.5.5 TCustomListBox.CreateParams Method

Initializes the window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams is used to pass information, in its Params parameter, to CreateWindowHandle when the list box control is created.

TCustomListBox (see page 2398) overrides CreateParams to customize the representation of the window. It uses information from the list box Columns (see page 2426), ExtendedSelect (see page 2427), IntegralHeight (see page 2428), MultiSelect, Sorted (see page 2434) and Style (see page 2436) properties and sets WS_HSCROLL, WS_VSCROLL, LBS_HASSTRINGS and LBS_NOTIFY Windows styles for creation of the list box.

When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

See Also

Columns (see page 2426)

CreateWindowHandle

CreateWnd

ExtendedSelect (see page 2427)

IntegralHeight (see page 2428)

MultiSelect

Sorted (see page 2434)

Style (see page 2436)

30.1.14.5.6 TCustomListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams (see page 2404) to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns (see page 2426)

CreateHandle

CreateParams (see page 2404)

CreateWindowHandle

CreateWnd

ItemIndex

Items (see page 2429)

TabWidth (see page 2437)

TopIndex (see page 2437)

30.1.14.5.7 TCustomListBox.DeleteSelected Method

Deletes the selected items from the list box

Pascal

```
procedure DeleteSelected; override;
```

C++

```
virtual __fastcall DeleteSelected();
```

Description

Call DeleteSelected to delete the selected items from the list box.

See Also

ClearSelection

MoveSelection

CopySelection (see page 2404)

ExtendedSelect (see page 2427)

MultiSelect

SelCount

Selected (see page 2432)

ItemIndex

30.1.14.5.8 TCustomListBox.DeleteString Method

Deletes a string from the list box.

Pascal

```
procedure DeleteString(Index: Integer); dynamic;
```

C++

```
__fastcall DeleteString(int Index);
```

Description

DeleteString deletes the string, specified by the Index parameter, from the list box control.

30.1.14.5.9 TCustomListBox.DestroyWnd Method

Saves the list box items in a string list before freeing the underlying Windows control.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

DestroyWnd saves the list box text string items in the Items (see page 2429) property to internal storage in a TStringList object that it creates. It then calls the inherited DestroyWnd method to destroy the windowed control's window handle and free associated device contexts.

See Also

DestroyWnd

Items (see page 2429)

TStringList

30.1.14.5.10 TCustomListBox.DoFindData Method

Returns the index of a string in the list box.

Pascal

```
function DoFindData(const Data: String): Integer;
```

C++

```
__fastcall int DoFindData(const UnicodeString Data);
```

Description

This protected method is called automatically when the list box needs to indicate the index for an item.

If the list box is virtual (that is, if the value of the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw), DoFindData generates an OnDataFind (see page 2439) event so that the index can be provided dynamically. If the list box is not virtual (any other Style (see page 2436)), DoFindData locates the specified string from the Items (see page 2429) property and returns its index.

Data is the text of the item to locate.

See Also

OnDataFind (see page 2439)

Style (see page 2436)

Items (see page 2429)

30.1.14.5.11 TCustomListBox.DoGetData Method

Returns a string in the list box given its index.

Pascal

```
function DoGetData(const Index: Integer): String;
```

C++

```
__fastcall UnicodeString DoGetData(const int Index);
```

Description

This protected method is called automatically when a virtual list box needs to supply the text of an item. DoGetData is never called unless the list box is virtual (that is, unless the value of the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw).

DoGetData generates an OnData (see page 2438) event and returns the string that is supplied dynamically by the event handler.

See Also

OnData (see page 2438)

Style (see page 2436)

Items (see page 2429)

30.1.14.5.12 TCustomListBox.DoGetDataObject Method

Returns the object associated with an item in a virtual list box.

Pascal

```
function DoGetDataObject(const Index: Integer): TObject;
```

C++

```
__fastcall TObject * DoGetDataObject(const int Index);
```

Description

This protected method is called automatically when a virtual list box needs to supply the object associated with an item. DoGetDataObject is never called unless the list box is virtual (that is, unless the value of the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw).

DoGetDataObject generates an OnDataObject (see page 2439) event and returns the object that is supplied dynamically by the event handler.

See Also

OnDataObject (see page 2439)

Style (see page 2436)

Items (see page 2429)

30.1.14.5.13 TCustomListBox.DragCanceled Method

Sends a mouse message canceling the drag-and-drop operation.

Pascal

```
procedure DragCanceled; override;
```

C++

```
virtual __fastcall DragCanceled();
```

Description

DragCanceled is called in response to the cancellation of a drag-and-drop operation that had started. Users can cancel the operation by dropping the item over a component that does not accept the item, or by pressing Esc while dragging.

The OnEndDrag event occurs after the call to DragCanceled.

See Also

OnEndDrag

30.1.14.5.14 TCustomListBox.DrawItem Method

Generates an OnDrawItem (see page 2439) event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); virtual;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem (see page 2439) event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight (see page 2428)

MeasureItem (see page 2415)

OnDrawItem (see page 2439)

OnMeasureItem (see page 2442)

Style (see page 2436)

30.1.14.5.15 TCustomListBox.GetCount Method

Returns the value of the Count (see page 2427) property.

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count (see page 2427) property.

See Also

Count (see page 2427)

30.1.14.5.16 TCustomListBox.GetItemData Method

Returns a 32-bit value associated with the specified item in a list box.

Pascal

```
function GetItemData(Index: Integer): TCustomLongData; dynamic;
```

C++

```
__fastcall TCustomLongData GetItemData(int Index);
```

Description

GetItemData retrieves the data associated with a particular item in the list box. This value can be displayed as that list box item, or can be a value (such as a pointer) associated with the list box item.

See Also

SetItemData (see page 2417)

30.1.14.5.17 TCustomListBox.GetItemIndex Method

Returns the value of the ItemIndex property.

Pascal

```
function GetItemIndex: Integer; override;
```

C++

```
virtual __fastcall int GetItemIndex();
```

Description

GetItemIndex is the protected read implementation of the ItemIndex property. It returns the index of the first selected item in the list box.

The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1.

See Also

ItemIndex

30.1.14.5.18 TCustomListBox.GetSelCount Method

Returns the number of selected items.

Pascal

```
function GetSelCount: Integer; override;
```

C++

```
virtual __fastcall int GetSelCount();
```

Description

GetSelCount is the protected read implementation of the SelCount property.

See Also

SelCount

30.1.14.5.19 TCustomListBox.GetSelected Method

Indicates whether a particular item is selected.

Pascal

```
function GetSelected(Index: Integer): Boolean;
```

C++

```
__fastcall Boolean GetSelected(int Index);
```

Description

GetSelected is the protected read implementation of the Selected (see page 2432) property. It returns true if the item specified by Index is selected, false if it is not.

30.1.14.5.20 TCustomListBox.InternalGetItemData Method

Retrieves the data associated with an item in the list box.

Pascal

```
function InternalGetItemData(Index: Integer): TCustomLongData; dynamic;
```

C++

```
__fastcall TCustomLongData InternalGetItemData(int Index);
```

Description

InternalGetItemData is the low-level protected method for fetching the data associated with an item in the list box. It retrieves a reference pointer to the object associated with the specified item, as an integer.

Index is the index of the item whose data is to be fetched.

See Also

GetItemData (see page 2409)

30.1.14.5.21 TCustomListBox.InternalSetItemData Method

Associates an integer with a specified item in the list box.

Pascal

```
procedure InternalSetItemData(Index: Integer; AData: TCustomLongData); dynamic;
```

C++

```
__fastcall InternalSetItemData(int Index, TCustomLongData AData);
```

Description

InternalSetItemData is the low-level protected method for associating data with an item in the list box. It associates the item that has the index specified by Index with the integer specified by AData.

See Also

SetItemData (see page 2417)

30.1.14.5.22 TCustomListBox.ItemAtPos Method

Returns the index of the list box item indicated by the coordinates of a point on the control.

Pascal

```
function ItemAtPos(Pos: TPoint; Existing: Boolean): Integer;
```

C++

```
__fastcall int ItemAtPos(TPoint Pos, Boolean Existing);
```

Description

Use ItemAtPos to detect if an item exists at a particular point in the control.

The Pos (see page 3627) parameter is the point in the control in window coordinates. If Pos (see page 3627) is beyond the last item in the list box, the value of the Existing variable determines the returned value. If Existing is set to true, ItemAtPos returns -1, indicating that no item exists at that point. If Existing is set to false, ItemAtPos returns the index of the last item in the list box plus one.

C++ Examples:

```
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < ComponentCount; i++)
    ListBox1->Items->InsertObject(0,
                                  Components[i]->Name,
                                  dynamic_cast<TObject *>(Components[i]));
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  if (Button == mbRight)
  {
    TClass ClassRef;
    int Index = ListBox1->ItemAtPos(Point(X,Y), true);
    // only components that are controls have a position
    // make sure the component is a control
    for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
         ClassRef != NULL;
         ClassRef = ClassRef->ClassParent())
      if (String(ClassRef->ClassName()) == "TControl")
      {
        TControl *TheObject = dynamic_cast<TControl *>(ListBox1->Items->Objects[Index]);
        StatusBar1->SimpleText =
          TheObject->Name + " is at (" +
          IntToStr(TheObject->Left) + ", " +
          IntToStr(TheObject->Top) + ")";
        break;
      }
    if (ClassRef == NULL) // if it wasn't a control
      MessageBeep(0);
  }
}
```

Delphi Examples:

```
{
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Form1.ComponentCount-1 do
    ListBox1.Items.InsertObject(
      0, Form1.Components[I].Name,
      Form1.Components[I] as TObject);
end;

procedure TForm1.ListBox1MouseUp(
  Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X,Y: integer);
var
  APoint: TPoint;
  Index: integer;
  TheObject: TControl;
begin
  if Button = mbRight then
  begin
  APoint.X := X;
  APoint.Y := Y;
  Index := ListBox1.ItemAtPos(APoint, True);
  if (ListBox1.Items.Objects[Index] is TControl) then
  begin
    TheObject :=
      (ListBox1.Items.Objects[Index] as TControl);
    StatusBar1.SimpleText := TheObject.Name + ' is at (' +
                             IntToStr(TheObject.Left) + ', ' +
                             IntToStr(TheObject.Top) + ') ';
  end
  else
    Beep;
  end;
end;
```

ItemIndex

Items (see page 2429)

30.1.14.5.23 TCustomListBox.ItemRect Method

Returns the rectangle that surrounds the item specified in the Item parameter.

Pascal

```
function ItemRect(Index: Integer): TRect;
```

C++

```
__fastcall TRect ItemRect(int Index);
```

Description

Use ItemRect to get the coordinates of a particular item in the list box. For example, ItemRect is used internally by the ItemAtPos (see page 2411) method.

The Item parameter is the ItemIndex of the item whose position is queried.

C++ Examples:

```
/*
This example uses a list box on a form. When the user clicks
one of the items in the list box, a beep occurs if the mouse
```

```
is in the first half of the item. A similar technique can be
used to detect "hot" regions in an owner-draw list box:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Hello");
  ListBox1->Items->Add("New");
  ListBox1->Items->Add("World");
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  TRect ItemBounds;
  if (Button == mbLeft)
  {
    ItemBounds = ListBox1->ItemRect(ListBox1->ItemIndex);
    if (Y > ItemBounds.Top &&
        Y < ItemBounds.Bottom &&
        X > ItemBounds.Left &&
        X < (ItemBounds.Left + ItemBounds.Right)/2)
      MessageBeep(0);
  }
}
```

Delphi Examples:

```
{
This example uses a list box on a form. When the user clicks
one of the items in the list box, a beep occurs if the mouse
is in the first half of the item. A similar technique can be
used to detect "hot" regions in an owner-draw list box:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with ListBox1 do
  begin
    Items.Add('Hello');
    Items.Add('New');
    Items.Add('World');
  end;
end;

procedure TForm1.ListBox1MouseUp (Sender: TObject; Button: TMouseButton; Shift: TShiftState;
X, Y: Integer);
var
  ListBoxItem: TRect;
begin
  if Button = mbLeft then
  begin
    ListBoxItem := ListBox1.ItemRect(ListBox1.ItemIndex);
    if (Y > ListBoxItem.Top) and
       (Y < ListBoxItem.Bottom) and
       (X > ListBoxItem.Left) and
       (X < (ListBoxItem.Left + ListBoxItem.Right) div 2) then
      Beep;
  end;
 end;
```

30.1.14.5.24 TCustomListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete (see page 2423) property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress

30.1.14.5.25 TCustomListBox.LoadRecreateItems Method

Assigns new strings to the list.

Pascal

```
procedure LoadRecreateItems(RecreateItems: TStrings); virtual;
```

C++

```
virtual __fastcall LoadRecreateItems(TStrings RecreateItems);
```

Description

LoadRecreateItems is used to set the strings from the list to the strings of the `RecreateItems` parameter.

See Also

Items (see page 2429)

Assign

30.1.14.5.26 TCustomListBox.MeasureItem Method

Generates an OnMeasureItem (see page 2442) event.

Pascal

```
procedure MeasureItem(Index: Integer; var Height: Integer); virtual;
```

C++

```
virtual __fastcall MeasureItem(int Index, int Height);
```

Description

MeasureItem is called whenever a visual aspect of a variable owner-draw list box changes and the value of the Style (see page 2436) property is csOwnerDrawVariable.

Before drawing its items, a variable owner-draw list box calls MeasureItem once for each visible item, passing the index of the item to measure, and the default height of the item. Since Height is passed by reference (a var parameter), MeasureItem can

increase or reduce the height of each item as needed.

By default, the MeasureItem method does nothing except call any event handler attached to the OnMeasureItem (see page 2442) event. Override MeasureItem to change or add functionality to the default behavior.

See Also

DrawItem (see page 2408)

ItemHeight (see page 2428)

ItemIndex

OnDrawItem (see page 2439)

OnMeasureItem (see page 2442)

Style (see page 2436)

30.1.14.5.27 TCustomListBox.ResetContent Method

Removes all of the items from a list box.

Pascal

```
procedure ResetContent; dynamic;
```

C++

```
__fastcall ResetContent();
```

Description

ResetContent is used to remove the items from the list box. ResetContent is used, for example, by the Clear (see page 2403) method.

See Also

Clear (see page 2403)

30.1.14.5.28 TCustomListBox.SaveRecreateItems Method

Saves the items from a list box.

Pascal

```
procedure SaveRecreateItems(RecreateItems: TStrings); virtual;
```

C++

```
virtual __fastcall SaveRecreateItems(TStrings RecreateItems);
```

Description

SaveRecreateItems is used to save the values and the properties of the items in a TStrings variable.

See Also

Items (see page 2429)

Assign

30.1.14.5.29 TCustomListBox.SelectAll Method

Selects the entire block of text in the list box.

Pascal

```
procedure SelectAll; override;
```

C++

```
virtual __fastcall SelectAll();
```

Description

Use SelectAll to select the entire block of text in the list box. To select only part of the text, use the SelStart and SelLength properties.

30.1.14.5.30 TCustomListBox.SetItemData Method

Sets the 32-bit value associated with the specified item in a list box.

Pascal

```
procedure SetItemData(Index: Integer; AData: TCustomLongData); dynamic;
```

C++

```
__fastcall SetItemData(int Index, TCustomLongData AData);
```

Description

Use SetItemData to set the data associated with a particular item in a list box. This value can be displayed as that list box item, or it can be a value (such as a pointer) represented by the list box item.

See Also

GetItemData (see page 2409)

30.1.14.5.31 TCustomListBox.SetItemIndex Method

Gives focus to the item with a specified index.

Pascal

```
procedure SetItemIndex(const Value: Integer); override;
```

C++

```
virtual __fastcall SetItemIndex(const int Value);
```

Description

SetItemIndex is the protected write implementation for the ItemIndex property. Value is the index of the item that should receive focus.

See Also

ItemIndex

30.1.14.5.32 TCustomListBox.SetMultiSelect Method

Sets the MultiSelect property.

Pascal

```
procedure SetMultiSelect(Value: Boolean); override;
```

C++

```
virtual __fastcall SetMultiSelect(Boolean Value);
```

Description

SetMultiSelect is the protected write implementation for the MultiSelect property. Value is true if the list box should allow more than one item to be selected, false if only one item can be selected at a time.

See Also

MultiSelect

30.1.14.5.33 TCustomListBox.WndProc Method

Handles Windows messages.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc overrides the inherited WndProc to provide specialized responses to messages that allows the list box to handle auto drag mode itself. Then it calls the inherited WndProc to handle all other messages.

When overriding the WndProc method, be sure to call the inherited WndProc at the end to dispatch any other messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/

30.1.14.6 TCustomListBox Properties

The properties of the TCustomListBox class are listed here.

Protected Properties

	Name	Description
	BorderStyle (see page 2423)	Determines whether the list box has a border.
	Columns (see page 2426)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	ExtendedSelect (see page 2427)	Determines if the user can select a sequential range of items in the list box.
	IntegralHeight (see page 2428)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2428)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 2431)	Determines where a control looks for its color information.
	Sorted (see page 2434)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2436)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 2437)	Specifies the size of the tabs in the list box.

Public Properties

	Name	Description
	AutoComplete (see page 2423)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2423)	Specifies the delay between a key press and an attempt to autocomplete the field.
R	Canvas (see page 2424)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2439) event of an owner-draw list box.
	Count (see page 2427)	Indicates the number of items in the list box.
	Items (see page 2429)	Contains the strings that appear in the list box.
	ScrollWidth (see page 2432)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	Selected (see page 2432)	Indicates whether a particular item is selected.
	TopIndex (see page 2437)	Specifies the index number of the item that appears at the top of the list box.

Published Properties

	Name	Description
	TabStop (see page 2436)	Determines if the user can tab to a control.

30.1.14.6.1 TCustomListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

30.1.14.6.2 TCustomListBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2423) is true.

See Also

AutoComplete (see page 2423)

30.1.14.6.3 TCustomListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D

30.1.14.6.4 TCustomListBox.Canvas Property

Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2439) event of an owner-draw list box.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Canvas is only useful for applications that control the drawing of list box items, that is, for owner-draw list boxes. Canvas is used to draw graphical images that can be used as items in a list box.

By default a TControlCanvas object is created for the Canvas property in the list box constructor. To create an owner-draw list box that uses a canvas, set the Style (see page 2436) property accordingly.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);

}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
```

```
    ListBox1.Items.AddObject('Butterfly', bitmap2);
  end;

  procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
  TOwnerDrawState);
  var
    Bitmap: TBitmap;      { temporary variable for the item's bitmap }
    Offset: Integer;      { text offset width }
  begin
    Bitmap := TBitmap.Create;
    with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
    begin
      FillRect(Rect);       { clear the rectangle }
      Offset := 2;          { provide default offset }
      Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
      if Bitmap <> nil then
      begin
        BrushCopy(
          Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
          Bitmap,
          Bounds(0, 0, Bitmap.Width, Bitmap.Height),
          clRed);  {render bitmap}
        Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
      end;
      TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
  text }
    end;
  end;
  {
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  }
    if (ListBox1.Items.Objects[Index] is TListBox) then
    begin
      myListBox:= (ListBox1.Items.Objects[Index] as TListBox);
      with myListBox.ClientRect do
      begin // make sure we are using the TControl's canvas and not the form's!
        myListBox.Canvas.MoveTo(Left, Top);
        myListBox.Canvas.LineTo(Right, Bottom);
      end;
    myListBox:= nil;
    end;

TCanvas

TControlCanvas

30.1.14.6.5 TCustomListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
  property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 2428)

Width

30.1.14.6.6 TCustomListBox.Count Property

Indicates the number of items in the list box.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of items in the list box. You can only set Count when the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw, in which case you must set this property.

See Also

Style (see page 2436)

30.1.14.6.7 TCustomListBox.ExtendedSelect Property

Determines if the user can select a sequential range of items in the list box.

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

ExtendedSelect works with the MultiSelect property. If ExtendedSelect is true and MultiSelect is true, the user can select an item then hold down the Shift key and select another and all the items in between the two selected items also become selected.

If the user doesn't hold down the Shift or Ctrl key while selecting a second item, the first selected item becomes unselected— in other words, the user must use the Ctrl key to select multiple noncontiguous items, or the Shift key to select a range of items.

If ExtendedSelect is false and MultiSelect is true, the user can select multiple items without using the Shift or Ctrl key, but they can't select a range of items in one operation.

If MultiSelect is false, the setting of ExtendedSelect has no effect as the user will not be able to select more than one item at a time in the list box.

See Also

MultiSelect

30.1.14.6.8 TCustomListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style (see page 2436) property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight (see page 2428) property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style (see page 2436) property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 2428)

Items (see page 2429)

Style (see page 2436)

Using TDBListBox and TDBComboBox

30.1.14.6.9 TCustomListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style (see page 2436) property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight (see page 2428) property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style (see page 2436) property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

See Also

DrawItem (see page 2408)

Using TDBListBox and TDBComboBox

30.1.14.6.10 TCustomListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

TStrings

30.1.14.6.11 TCustomListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color

Parent

ParentFont

ParentShowHint

30.1.14.6.12 TCustomListBox.ScrollWidth Property

Specifies the width, in pixels, by which the list box can scroll horizontally.

Pascal

```
property ScrollWidth: Integer;
```

C++

```
__property int ScrollWidth;
```

Description

Use ScrollWidth to get or set the logical width of the list box. When ScrollWidth is greater than the client width of the list box, the list box gets a horizontal scroll bar. When ScrollWidth is less than or equal to ClientWidth, the horizontal scroll bar disappears.

See Also

Columns (see page 2426)

ClientWidth

30.1.14.6.13 TCustomListBox.Selected Property

Indicates whether a particular item is selected.

Pascal

```
property Selected [Index: Integer]: Boolean;
```

C++

```
__property Boolean Selected[int Index];
```

Description

Use Selected to query the state of a particular item in the list box. If the item specified by the Index parameter is selected in the list box, the value of the Selected property is true. If the specified item is not selected, Selected is false. Set Selected to change the currently selected item.

The Index parameter is the item referenced by its position in the list box, with the first item having an Index value of 0.

An item is selected when the user highlights it. More than one item in the list box can be selected by setting the MultiSelect

property to true. In this case, the Selected item is the one that has focus when the list box has input focus.

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          String("File " + FileListBox1->Items->Strings[i] + "not found").c_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(AnsiString(FileListBox1->Items->Strings[i]).c_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(int(statbuf.st_size)));
      fclose(F);
    }
  }
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);

SelCount

30.1.14.6.14 TCustomListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
```

```
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
}
```

Delphi Examples:

```
{
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

procedure TForm1.AddClick(Sender: TObject);
begin
  ListBox1.Items.Add(Edit1.Text);
end;

procedure TForm1.SortClick(Sender: TObject);
begin
  ListBox1.Sorted := True;
end;
```

Items (see page 2429)

Style (see page 2436)

30.1.14.6.15 TCustomListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

30.1.14.6.16 TCustomListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.14.6.17 TCustomListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

30.1.14.6.18 TCustomListBox.TopIndex Property

Specifies the index number of the item that appears at the top of the list box.

Pascal

```
property TopIndex: Integer;
```

C++

```
__property int TopIndex;
```

Description

Use TopIndex property to find or set the first item displayed at the top of the list box. TopIndex can be used, for example, to change the topmost item to a different item in the list.

C++ Examples:

```
/*
The following example uses a list box containing a list of
strings, a button, and an edit box on a form. When the user
runs the application and clicks the button, the third item
in the list becomes the first item, and the index value of
that item appears in the edit box. The index value displayed
is 2, indicating the third item in the list (the first item
in the list has an index value of 0):
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListBox1->TopIndex = 2;
  Edit1->Text = IntToStr(ListBox1->TopIndex);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int Number = 1; Number <= 20; Number++)
    ListBox1->Items->Add("Item " + IntToStr(Number));
}
```

Delphi Examples:

```
{
The following example uses a list box containing a list of
strings, a button, and an edit box on a form. When the user
runs the application and clicks the button, the third item
in the list becomes the first item, and the index value of
```

```
  that item appears in the edit box. The index value displayed
  is 2, indicating the third item in the list (the first item
  in the list has an index value of 0):
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    ListBox1.TopIndex := 2;
    Edit1.Text := IntToStr(ListBox1.TopIndex);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    Number: Integer;
  begin
    for Number := 1 to 20 do
      ListBox1.Items.Add('Item ' + IntToStr(Number));
  end;
```

30.1.14.7 TCustomListBox Events

The events of the TCustomListBox class are listed here.

Protected Events

	Name	Description
	OnData (see page 2438)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2439)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2439)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDrawItem (see page 2439)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnMeasureItem (see page 2442)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

30.1.14.7.1 TCustomListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataFind (see page 2439)

OnDataObject (see page 2439)

Style (see page 2436)

Count (see page 2427)

30.1.14.7.2 TCustomListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style (see page 2436) property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 2438)

OnDataObject (see page 2439)

Style (see page 2436)

Count (see page 2427)

30.1.14.7.3 TCustomListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

See Also

OnData (see page 2438)

OnDataFind (see page 2439)

Style (see page 2436)

Count (see page 2427)

30.1.14.7.4 TCustomListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style (see page 2436) values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight (see page 2428) property for fixed owner-draw list boxes or by the response to the OnMeasureItem (see page 2442) event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = (dynamic_cast<TListBox *>(Control))->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
      pBitmap,
      Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
```

```
  example, a list box with the lbOwnerDrawFixed style draws a
  bitmap to the left of each string.
  Select the TListBox and set the ItemHeight property to 32.
  Select the ImageList and set the Layout Height and Width to
  32.  Double click on the ImageList to load the images.  Be
  sure to load in the correct order, logo2, Sunflower,
  butterfly.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    MyList := TStringList.Create;
    bitmap0 := TBitmap.Create;
    bitmap1 := TBitmap.Create;
    bitmap2 := TBitmap.Create;
  //  MyList.Add('Animal');
  //  MyList.Add('Flowers');
  //  MyList.Add('Butterfly');
  //  ListBox1.Items.AddStrings(MyList);

    ImageList1.GetBitmap(0, bitmap0);
    ListBox1.Items.AddObject('Flowers', bitmap0);
    ImageList1.GetBitmap(1, bitmap1);
    ListBox1.Items.AddObject('Animal', bitmap1);
    ImageList1.GetBitmap(2, bitmap2);
    ListBox1.Items.AddObject('Butterfly', bitmap2);
  end;

  procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
  TOwnerDrawState);
  var
    Bitmap: TBitmap;      { temporary variable for the item's bitmap }
    Offset: Integer;      { text offset width }
  begin
    Bitmap := TBitmap.Create;
    with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
    begin
      FillRect(Rect);       { clear the rectangle }
      Offset := 2;          { provide default offset }
      Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
      if Bitmap <> nil then
      begin
        BrushCopy(
          Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
          Bitmap,
          Bounds(0, 0, Bitmap.Width, Bitmap.Height),
          clRed);  {render bitmap}
        Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
      end;
      TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
  text }
    end;
  end;
```

30.1.14.7.5 TCustomListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style (see page 2436) property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent (see page 3012) which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem (see page 2439) event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
      int &Height)
{
  Graphics::TBitmap *bitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (bitmap && bitmap->Height > Height)
    Height = bitmap->Height;
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
```

```
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}

#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Making these static keeps them around until the project terminates.
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);
  bitmap0->LoadFromFile("../littleB_64.bmp");
//  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Butterfly", bitmap0);
  ImageList1->GetBitmap(3, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1); // no bitmap, see if it leaves this height at
64.
  ImageList1->GetBitmap(4, bitmap2);
  ListBox1->Items->AddObject("Sunflower", bitmap2); // no bitmap, see if it leaves this height
at 64.

}
```

30.1.15 TCustomMemo Class

TCustomMemo is the base type for memo components, which are multiline edit boxes, including TMemo (see page 2737) and TDBMemo.

Class Hierarchy

Pascal

```
TCustomMemo = class(TCustomEdit);
```

C++

```
class TCustomMemo : public TCustomEdit;
```

File

StdCtrls

Description

TCustomMemo introduces new properties and methods to expand the capabilities of TCustomEdit (see page 2345) for handling multiline edit boxes.

Do not create instances of TCustomMemo. Use TCustomMemo as a base class when declaring control objects that implement a multiline edit control. Properties and methods of TCustomMemo provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TDBMemo

TMemo (see page 2737)

30.1.15.1 TCustomMemo Members

The following tables list the members exposed by TCustomMemo.

Protected Events

	Name	Description
	OnChange (see page 2381)	Occurs when the text for the edit control may have changed.

Protected Methods

	Name	Description
	Change (see page 2348)	Generates an OnChange (see page 2381) event.
V	CreateParams (see page 2447)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2447)	Creates a window based on the window-creation parameter record.
V	CreateWnd (see page 2352)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2354)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2354)	Sets the MaxLength (see page 2368) property.
V	DoSetTextHint (see page 2355)	Sets the value of TextHint (see page 2380).
V	GetCaretPos (see page 2448)	Returns the value of the CaretPos (see page 2450) property.
V	GetSelLength (see page 2356)	Returns the SelLength (see page 2371) property.
V	GetSelStart (see page 2356)	Returns the SelStart (see page 2374) property.
V	GetSelText (see page 2356)	Returns the SelText (see page 2377) property.
V	KeyPress (see page 2448)	Ensures that return characters are not entered into the text when WantReturns (see page 2454) is false.
V	Loaded (see page 2448)	Initializes the memo control when it is first loaded into memory.
	SetAlignment (see page 2361)	Sets the Alignment (see page 2365) property.
V	SetAutoSize (see page 2361)	Sets the AutoSize (see page 2366) property.
V	SetCaretPos (see page 2449)	Sets the CaretPos (see page 2450) property.
	SetLines (see page 2449)	Sets the Lines (see page 2451) property.
	SetScrollBars (see page 2449)	Sets the ScrollBars (see page 2452) property.
V	SetSelLength (see page 2361)	Sets the SelLength (see page 2371) property.
V	SetSelStart (see page 2362)	Sets the SelStart (see page 2374) property.
	SetWordWrap (see page 2450)	Sets the WordWrap (see page 2455) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2365)	Determines whether all the text in the edit control is automatically selected when the control gets focus.

	AutoSize (see page 2366)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BorderStyle (see page 2367)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2367)	Determines the case of the text within the edit control.
	HideSelection (see page 2368)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	MaxLength (see page 2368)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2369)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2369)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentColor (see page 2370)	Determines where a control looks for its color information.
	PasswordChar (see page 2370)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	ScrollBars (see page 2452)	Determines whether the memo control has scroll bars.
	WantReturns (see page 2454)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2454)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2455)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Public Methods

	Name	Description
V	Clear (see page 2348)	Deletes all text from the edit control.
	ClearSelection (see page 2349)	Removes the selected text from the edit control.
	ClearUndo (see page 2349)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2349)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
V	Create (see page 2446)	Creates and initializes an instance of TCustomMemo (see page 2443).
	CutToClipboard (see page 2352)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 2354)	Provides message handling for all messages that the control does not fully process itself.
V	Destroy (see page 2446)	Destroys an instance of TCustomMemo (see page 2443).
V	GetControlsAlignment (see page 2355)	Indicates how text is aligned within the control.
V	GetSelTextBuf (see page 2357)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2358)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2359)	Selects all text in the edit control.
	SetSelText (see page 2362)	Sets the SelText (see page 2377) property.
	SetSelTextBuf (see page 2363)	Replaces the selected text with a null-terminated string.
	Undo (see page 2364)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	Alignment (see page 2365)	Determines how the text is aligned within the text edit control.
R	CanUndo (see page 2367)	Indicates whether the edit control contains changes that can be backed out.
	CaretPos (see page 2450)	Indicates the position of the caret in the client area of the memo.
	Lines (see page 2451)	Contains the individual lines of text in the memo control.
	Modified (see page 2369)	Indicates whether the user edited the text of the edit control.
	ReadOnly (see page 2371)	Determines whether the user can change the text of the edit control.
	SelLength (see page 2371)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2374)	Specifies the position of the first selected character in the text.
	SelText (see page 2377)	Specifies the selected portion of the edit control's text.
	Text (see page 2379)	Contains a text string associated with the control.
	TextHint (see page 2380)	A hint or message to be displayed when the Text (see page 2379) property is empty.

Published Properties

	Name	Description
	TabStop (see page 2379)	Determines if the user can tab to a control.

30.1.15.2 TCustomMemo.Create Constructor

Creates and initializes an instance of TCustomMemo (see page 2443).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomMemo(TComponent * AOwner);
```

Description

Call Create to instantiate a TCustomMemo (see page 2443) object.

AOwner is the component, typically the form, that is responsible for freeing the memo object. This becomes the value of the Owner property.

Derived objects that override the Create method should call the inherited Create before making any additional initializations.

See Also

Owner

30.1.15.3 TCustomMemo.Destroy Destructor

Destroys an instance of TCustomMemo (see page 2443).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomMemo();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TCustomMemo (see page 2443) reference is not nil, and only then calls Destroy.

Destroy frees the TStrings object that implements the Lines (see page 2451) property before calling the inherited destructor.

See Also

System::TObject::Free (see page 3372)

Lines (see page 2451)

TStrings

30.1.15.4 TCustomMemo Methods

The methods of the TCustomMemo class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2447)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateWindowHandle (see page 2447)	Creates a window based on the window-creation parameter record.
	GetCaretPos (see page 2448)	Returns the value of the CaretPos (see page 2450) property.
	KeyPress (see page 2448)	Ensures that return characters are not entered into the text when WantReturns (see page 2454) is false.
	Loaded (see page 2448)	Initializes the memo control when it is first loaded into memory.
	SetCaretPos (see page 2449)	Sets the CaretPos (see page 2450) property.
	SetLines (see page 2449)	Sets the Lines (see page 2451) property.
	SetScrollBars (see page 2449)	Sets the ScrollBars (see page 2452) property.
	SetWordWrap (see page 2450)	Sets the WordWrap (see page 2455) property.

30.1.15.4.1 TCustomMemo.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 2352) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 2447). TCustomMemo (see page 2443) overrides the inherited method to specify a scrollable multiline edit control. The Params parameter is updated to reflect the current values of the Alignment (see page 2365), ScrollBars (see page 2452), and WordWrap (see page 2455) properties, in addition to the BorderStyle (see page 2367), HideSelection (see page 2368), PasswordChar (see page 2370), and ReadOnly (see page 2371) properties that the inherited method specifies.

See Also

Alignment (see page 2365)

BorderStyle (see page 2367)

CreateWindowHandle (see page 2447)

CreateWnd (see page 2352)

HideSelection (see page 2368)

PasswordChar (see page 2370)

ReadOnly (see page 2371)

ScrollBars (see page 2452)

WordWrap (see page 2455)

30.1.15.4.2 TCustomMemo.CreateWindowHandle Method

Creates a window based on the window-creation parameter record.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

The CreateWnd (see page 2352) method calls CreateWindowHandle to create the edit control window once it has been specified in the window-creation parameters. CreateWindowHandle creates the window by calling the CreateWindowEx API function, passing parameters from the record passed in the Params parameter. CreateWindowHandle overrides the inherited method to interpret the Caption in Params as the initial text rather than as the window caption.

See Also

CreateParams (see page 2447)

CreateWnd (see page 2352)

30.1.15.4.3 TCustomMemo.GetCaretPos Method

Returns the value of the CaretPos (see page 2450) property.

Pascal

```
function GetCaretPos: TPoint; virtual;
```

C++

```
virtual __fastcall TPoint GetCaretPos();
```

Description

CaretPos (see page 2450) represents the coordinates of the cursor. GetCaretPos is the protected implementation of the CaretPos (see page 2450) property. Override this method to change the way the caret position is computed.

See Also

CaretPos (see page 2450)

30.1.15.4.4 TCustomMemo.KeyPress Method

Ensures that return characters are not entered into the text when WantReturns (see page 2454) is false.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the user presses a key. After calling the inherited KeyPress, which calls the OnKeyPress event handler, KeyPress discards return characters when WantReturns (see page 2454) is false.

See Also

WantReturns (see page 2454)

30.1.15.4.5 TCustomMemo.Loaded Method

Initializes the memo control when it is first loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Loaded overrides the inherited method so that the Modified (see page 2369) property is set to false when the form containing the memo is first loaded into memory. Derived classes can override the Loaded method to perform additional initializations after the memo's form is loaded.

See Also

Modified (see page 2369)

30.1.15.4.6 TCustomMemo.SetCaretPos Method

Sets the CaretPos (see page 2450) property.

Pascal

```
procedure SetCaretPos(const Value: TPoint); virtual;
```

C++

```
virtual __fastcall SetCaretPos(const TPoint Value);
```

Description

SetCaretPos is the property write access method for the CaretPos (see page 2450) property. The CaretPos (see page 2450) property returns the coordinates of the cursor. SetCaretPos sets the cursor position to Value.

See Also

CaretPos (see page 2450)

30.1.15.4.7 TCustomMemo.SetLines Method

Sets the Lines (see page 2451) property.

Pascal

```
procedure SetLines(Value: TStrings);
```

C++

```
__fastcall SetLines(TStrings Value);
```

Description

SetLines is the protected write implementation for the Lines (see page 2451) property.

SetLines is exposed as a protected method so derived classes can customize their implementation of the Lines (see page 2451) property.

See Also

Lines (see page 2451)

30.1.15.4.8 TCustomMemo.SetScrollBars Method

Sets the ScrollBars (see page 2452) property.

Pascal

```
procedure SetScrollBars(Value: TScrollStyle);
```

C++

```
__fastcall SetScrollBars(TScrollStyle Value);
```

Description

SetScrollBars is the property access method for the ScrollBars (see page 2452) property.

SetScrollBars is exposed as a protected method so derived classes can customize their implementation of the ScrollBars (see page 2452) property.

See Also

ScrollBars (see page 2452)

30.1.15.4.9 TCustomMemo.SetWordWrap Method

Sets the WordWrap (see page 2455) property.

Pascal

```
procedure SetWordWrap(Value: Boolean);
```

C++

```
__fastcall SetWordWrap(Boolean Value);
```

Description

SetWordWrap is the property access method for the WordWrap (see page 2455) property.

See Also

WordWrap (see page 2455)

30.1.15.5 TCustomMemo Properties

The properties of the TCustomMemo class are listed here.

Protected Properties

	Name	Description
	ScrollBars (see page 2452)	Determines whether the memo control has scroll bars.
	WantReturns (see page 2454)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2454)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2455)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Public Properties

	Name	Description
	CaretPos (see page 2450)	Indicates the position of the caret in the client area of the memo.
	Lines (see page 2451)	Contains the individual lines of text in the memo control.

30.1.15.5.1 TCustomMemo.CaretPos Property

Indicates the position of the caret in the client area of the memo.

Pascal

```
property CaretPos: TPoint;
```

C++

```
__property TPoint CaretPos;
```

Description

Use CaretPos to determine the coordinates of the cursor. CaretPos defines a location onscreen, in characters, with the origin in the top left corner of the memo. X specifies the horizontal coordinate of the point, Y specifies the vertical coordinate.

To determine the position of the caret in terms of characters of text only (rather than X/Y location), use the SelStart (see page 2374) property.

See Also

ClientRect

ClientOrigin

SelStart (see page 2374)

30.1.15.5.2 TCustomMemo.Lines Property

Contains the individual lines of text in the memo control.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Use Lines to manipulate text in an memo control on a line-by-line basis. Lines is a TStrings object, so the TStrings methods may be used for Lines to perform manipulations such as counting the lines of text, adding new lines, deleting lines, or replacing lines with new text.

To work with all the text at once, use the Text (see page 2379) property. To manipulate individual lines of text, the Lines property works better.

Note: Although Lines is implemented as a TStrings descendant, it does not implement the support for associating objects with the strings in the list.

C++ Examples:

```
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
```

```
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.LoadFromFile('readme.txt');
  Caption:= Memo1.Lines[4];
end;
```

See Also

TStrings

SelText (see page 2377)

SetLines (see page 2449)

Text

WordWrap (see page 2455)

30.1.15.5.3 TCustomMemo.ScrollBars Property

Determines whether the memo control has scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give a multiline edit control horizontal or vertical scroll bars. ScrollBars can take one of the following values:

Value	Meaning
ssNone	The control has no scroll bars.
ssHorizontal	The control has a single scroll bar on the bottom edge.
ssVertical	The control has a single scroll bar on the right edge.
ssBoth	The control has a scroll bar on both the bottom and right edges.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
```

```
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
  // move text cursor to top of editend;
  RichEdit1.SelStart := 0;
end;

procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  RichEdit1.HideScrollbars := CheckBox1.Checked;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
const
  ScrollBarA: array[0..3] of TScrollStyle = (
    ssBoth,
    ssHorizontal,
    ssNone,
    ssVertical);
begin
  RichEdit1.ScrollBars :=
```

```
    ScrollBarA[RadioGroup1.ItemIndex];
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with RadioGroup1, Items do
  begin
    Caption := 'Scroll Bars';
    Clear;
    Add('ssBoth');
    Add('ssHorizontal');
    Add('ssNone');
    Add('ssVertical');
  end;
  with CheckBox1 do
  begin
    Caption := 'HideScrollBars';
    Checked := True;
  end;
  Button1.Caption := 'Loaded';
  RichEdit1.Text := 'Just a little text.';
  RichEdit1.WordWrap := False;
end;
```

See Also

SetScrollBars (see page 2449)

WordWrap (see page 2455)

Displaying and Editing Text in a Memo Control

30.1.15.5.4 TCustomMemo.WantReturns Property

Determines whether the user can insert return characters into the text.

Pascal

```
property WantReturns: Boolean;
```

C++

```
__property Boolean WantReturns;
```

Description

Set WantReturns to true to allow users to enter return characters into the text. Set WantReturns to false to allow the form to handle return characters instead.

For example, in a form with a default button (such as an OK button) and a memo control, if WantReturns is false, pressing Enter chooses the default button. If WantReturns is true, pressing Enter inserts a return character in the text.

Note: If WantReturns is false, users can still enter return characters into the text by pressing Ctrl+Enter.

See Also

Text

WantTabs (see page 2454)

WordWrap (see page 2455)

30.1.15.5.5 TCustomMemo.WantTabs Property

Determines whether the user can insert tab characters into the text.

Pascal

```
property WantTabs: Boolean;
```

C++

```
__property Boolean WantTabs;
```

Description

Set WantTabs to true to allow users to enter tab characters into the text. Set WantTabs to false if you want the tab character to select the next control on the form instead.

Note: If WantTabs is true, users can tab into the edit control, but they can't tab out.

See Also

Text

WantReturns (see page 2454)

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

30.1.15.5.6 TCustomMemo.WordWrap Property

Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to make the edit control wrap text at the right margin so it fits in the client area. The wrapping is cosmetic only. The text does not include any return characters that were not explicitly entered. Set WordWrap to false to have the edit control show a separate line only where return characters were explicitly entered into the text.

Note: There should be no use for a horizontal scroll bar if WordWrap is true.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
```

```
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
  // move text cursor to top of editend;
  RichEdit1.SelStart := 0;
end;

procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  RichEdit1.HideScrollbars := CheckBox1.Checked;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
const
  ScrollBarA: array[0..3] of TScrollStyle = (
    ssBoth,
    ssHorizontal,
    ssNone,
    ssVertical);
begin
  RichEdit1.ScrollBars :=
```

```
    ScrollBarA[RadioGroup1.ItemIndex];
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with RadioGroup1, Items do
  begin
    Caption := 'Scroll Bars';
    Clear;
    Add('ssBoth');
    Add('ssHorizontal');
    Add('ssNone');
    Add('ssVertical');
  end;
  with CheckBox1 do
  begin
    Caption := 'HideScrollBars';
    Checked := True;
  end;
  Button1.Caption := 'Loaded';
  RichEdit1.Text := 'Just a little text.';
  RichEdit1.WordWrap := False;
end;
```

Displaying and Editing Text in a Memo Control

30.1.16 TCustomStaticText Class

TCustomStaticText is the base class for TStaticText (see page 2945).

Class Hierarchy

Pascal

```
TCustomStaticText = class(TWinControl);
```

C++

```
class TCustomStaticText : public TWinControl;
```

File

StdCtrls

Description

TCustomStaticText is the base class for TStaticText (see page 2945), a windowed control that displays text on a form. This component functions like TLabel (see page 2607), except that it has a window handle.

TCustomStaticText cannot receive focus or contain other controls.

See Also

TLabel (see page 2607)

TStaticText (see page 2945)

30.1.16.1 TCustomStaticText Members

The following tables list the members exposed by TCustomStaticText.

Protected Methods

	Name	Description
	CreateParams (see page 2459)	Initializes a window-creation parameter data structure.
	Loaded (see page 2459)	Initializes the control after it is loaded from a stream.
	Notification (see page 2460)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2460)	Sets the value of the AutoSize property.

Protected Properties

	Name	Description
	Alignment (see page 2461)	Determines how text is aligned within the component.
	AutoSize (see page 2461)	Determines whether the component is automatically resized to accommodate its text.
	BorderStyle (see page 2462)	Determines the appearance of the control's border.
	FocusControl (see page 2462)	Links the component with another windowed control.
	ShowAccelChar (see page 2462)	Enables accelerator characters.
	Transparent (see page 2463)	Specifies whether the background of the image obscures objects below the image object.

Public Methods

	Name	Description
	Create (see page 2458)	Creates and initializes a TCustomStaticText (see page 2457) instance.

30.1.16.2 TCustomStaticText.Create Constructor

Creates and initializes a TCustomStaticText (see page 2457) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomStaticText(TComponent * AOwner);
```

Description

Create calls the inherited constructor, then initializes the TCustomStaticText (see page 2457) instance

See Also

AutoSize (see page 2461)

ControlStyle

ShowAccelChar (see page 2462)

30.1.16.3 TCustomStaticText Methods

The methods of the TCustomStaticText class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2459)	Initializes a window-creation parameter data structure.
	Loaded (see page 2459)	Initializes the control after it is loaded from a stream.
	Notification (see page 2460)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2460)	Sets the value of the AutoSize property.

30.1.16.3.1 TCustomStaticText.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

30.1.16.3.2 TCustomStaticText.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

30.1.16.3.3 TCustomStaticText.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu

Notification

30.1.16.3.4 TCustomStaticText.SetAutoSize Method

Sets the value of the AutoSize property.

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

SetAutoSize is a protected method in the TControl class and is used to set the value of the AutoSize property.

See Also

TControl

AutoSize

30.1.16.4 TCustomStaticText Properties

The properties of the TCustomStaticText class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 2461)	Determines how text is aligned within the component.
	AutoSize (see page 2461)	Determines whether the component is automatically resized to accommodate its text.
	BorderStyle (see page 2462)	Determines the appearance of the control's border.
	FocusControl (see page 2462)	Links the component with another windowed control.
	ShowAccelChar (see page 2462)	Enables accelerator characters.
	Transparent (see page 2463)	Specifies whether the background of the image obscures objects below the image object.

30.1.16.4.1 TCustomStaticText.Alignment Property

Determines how text is aligned within the component.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

The possible values of Alignment are

Value	Meaning
taLeftJustify	Text is aligned at the left of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is aligned at the right of the control.

See Also

Font

Caption

30.1.16.4.2 TCustomStaticText.AutoSize Property

Determines whether the component is automatically resized to accommodate its text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

If AutoSize is true, the component is automatically resized— at runtime and design time— whenever the font size or Caption text changes.

See Also

Caption

Font

30.1.16.4.3 TCustomStaticText.BorderStyle Property

Determines the appearance of the control's border.

Pascal

```
property BorderStyle: TStaticBorderStyle;
```

C++

```
__property TStaticBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify the appearance of the border, if any, that appears around the text.

30.1.16.4.4 TCustomStaticText.FocusControl Property

Links the component with another windowed control.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Use the FocusControl property to link the TCustomStaticText (see page 2457) instance with another windowed control. If the text of Caption includes an accelerator key, the component specified by FocusControl receives focus when the accelerator is pressed.

See Also

Caption

FocusControl (see page 2395)

TWinControl

30.1.16.4.5 TCustomStaticText.ShowAccelChar Property

Enables accelerator characters.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

If ShowAccelChar is true, an ampersand in the component's Caption text appears as an underline and makes the character after it into an accelerator key. If ShowAccelChar is false, ampersands appear as ampersands.

See Also

Caption

30.1.16.4.6 TCustomStaticText.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TCustomStaticText (see page 2457) object to show through the background of the image. Set Transparent to false to make the background of the image opaque.

30.1.17 TEdit Class

TEdit is a wrapper for a Windows single-line edit control.

Class Hierarchy

Pascal

```
TEdit = class(TCustomEdit);
```

C++

```
class TEdit : public TCustomEdit;
```

File

StdCtrls

Description

Use a TEdit object to put a standard Windows edit control on a form. Edit controls are used to retrieve text that users type. Edit controls can also display text to the user.

When only displaying text to the user, choose an edit control to allow users to select text and copy it to the Clipboard. Choose a label object if the selection capabilities of an edit control are not needed.

TEdit implements the generic behavior introduced in TCustomEdit (see page 2345). TEdit publishes many of the properties inherited from TCustomEdit (see page 2345), but does not introduce any new behavior. For specialized edit controls, use other descendant classes of TCustomEdit (see page 2345) or derive from it.

Edit Controls

30.1.17.1 TEdit Members

The following tables list the members exposed by TEdit.

Protected Methods

	Name	Description
	Change (see page 2348)	Generates an OnChange (see page 2381) event.
V	CreateParams (see page 2351)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2351)	Creates a Windows control to represent the control.
V	CreateWnd (see page 2352)	Creates a Windows control corresponding to the edit control.
V	DestroyWnd (see page 2354)	Destroys the Windows control that corresponds to the edit control.
V	DoSetMaxLength (see page 2354)	Sets the MaxLength (see page 2368) property.
V	DoSetTextHint (see page 2355)	Sets the value of TextHint (see page 2380).
V	GetSelLength (see page 2356)	Returns the SelLength (see page 2371) property.
V	GetSelStart (see page 2356)	Returns the SelStart (see page 2374) property.
V	GetSelText (see page 2356)	Returns the SelText (see page 2377) property.
	SetAlignment (see page 2361)	Sets the Alignment (see page 2365) property.
V	SetAutoSize (see page 2361)	Sets the AutoSize (see page 2366) property.
V	SetSelLength (see page 2361)	Sets the SelLength (see page 2371) property.
V	SetSelStart (see page 2362)	Sets the SelStart (see page 2374) property.

Public Methods

	Name	Description
V	Clear (see page 2348)	Deletes all text from the edit control.
	ClearSelection (see page 2349)	Removes the selected text from the edit control.
	ClearUndo (see page 2349)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2349)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
V	Create (see page 2347)	Creates an instance of TCustomEdit (see page 2345).
	CutToClipboard (see page 2352)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 2354)	Provides message handling for all messages that the control does not fully process itself.
V	GetControlsAlignment (see page 2355)	Indicates how text is aligned within the control.
V	GetSelTextBuf (see page 2357)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2358)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2359)	Selects all text in the edit control.
	SetSelText (see page 2362)	Sets the SelText (see page 2377) property.
	SetSelTextBuf (see page 2363)	Replaces the selected text with a null-terminated string.
	Undo (see page 2364)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
R	CanUndo (see page 2367)	Indicates whether the edit control contains changes that can be backed out.
	Modified (see page 2369)	Indicates whether the user edited the text of the edit control.

	SelLength (see page 2371)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2374)	Specifies the position of the first selected character in the text.
	SelText (see page 2377)	Specifies the selected portion of the edit control's text.

Published Events

	Name	Description
	OnChange (see page 2501)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2502)	Occurs when the user clicks the control.
	OnContextPopup (see page 2504)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2504)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2505)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2508)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2511)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2511)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2512)	Occurs when a control receives the input focus.
	OnExit (see page 2515)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2519)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2522)	Occurs when a key is pressed.
	OnKeyUp (see page 2523)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2525)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2526)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2528)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2529)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2529)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2531)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2533)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2534)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2467)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2471)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2471)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 2472)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2472)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 2473)	Specifies which edges of the control are beveled.
	BevelInner (see page 2474)	Specifies the cut of the inner bevel.
	BevelKind (see page 2474)	Specifies the control's bevel style.
	BevelOuter (see page 2474)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2475)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2475)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2476)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2476)	Determines the case of the text within the edit control.
	Color (see page 2476)	Specifies the background color of the control.
	Constraints (see page 2477)	Specifies the size constraints for the control.

	Ctl3D (see page 2478)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2478)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2480)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2481)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2481)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2482)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2483)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2484)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2484)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2485)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	MaxLength (see page 2486)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2486)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2486)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2487)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2487)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2488)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2488)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2488)	Determines where a control looks for its font information.
	ParentShowHint (see page 2489)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 2489)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 2490)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2495)	Determines whether the user can change the text of the edit control.
	ShowHint (see page 2495)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2497)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2497)	Determines if the user can tab to a control.
	Text (see page 2498)	Contains a text string associated with the control.
	TextHint (see page 2499)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 2499)	Determines whether the component appears onscreen.

30.1.17.2 TEdit Properties

The properties of the TEdit class are listed here.

Published Properties

	Name	Description
	Align (see page 2467)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2471)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2471)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 2472)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2472)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 2473)	Specifies which edges of the control are beveled.
	BevelInner (see page 2474)	Specifies the cut of the inner bevel.
	BevelKind (see page 2474)	Specifies the control's bevel style.
	BevelOuter (see page 2474)	Specifies the cut of the outer bevel.

	BevelWidth (see page 2475)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2475)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2476)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2476)	Determines the case of the text within the edit control.
	Color (see page 2476)	Specifies the background color of the control.
	Constraints (see page 2477)	Specifies the size constraints for the control.
	Ctl3D (see page 2478)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2478)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2480)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2481)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2481)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2482)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2483)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2484)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2484)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2485)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	MaxLength (see page 2486)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 2486)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 2486)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2487)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2487)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2488)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2488)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2488)	Determines where a control looks for its font information.
	ParentShowHint (see page 2489)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 2489)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 2490)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2495)	Determines whether the user can change the text of the edit control.
	ShowHint (see page 2495)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2497)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2497)	Determines if the user can tab to a control.
	Text (see page 2498)	Contains a text string associated with the control.
	TextHint (see page 2499)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 2499)	Determines whether the component appears onscreen.

30.1.17.2.1 TEdit.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
```

```
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
```

```
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane - a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

Anchors

30.1.17.2.2 TEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

SetAlignment (see page 2361)

Text

Displaying and Editing Fields in an Edit Box

30.1.17.2.3 TEdit.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.17.2.4 TEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect: Boolean;
```

C++

```
__property Boolean AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

See Also

SelectAll (see page 2359)

SelLength (see page 2371)

SelStart (see page 2374)

SelText (see page 2377)

SetSelTextBuf (see page 2363)

30.1.17.2.5 TEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

30.1.17.2.6 TEdit.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

30.1.17.2.7 TEdit.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

30.1.17.2.8 TEdit.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelOuter

BevelInner

BevelWidth

30.1.17.2.9 TEdit.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

30.1.17.2.10 TEdit.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

30.1.17.2.11 TEdit.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

30.1.17.2.12 TEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

30.1.17.2.13 TEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

30.1.17.2.14 TEdit.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

30.1.17.2.15 TEdit.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the

ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

30.1.17.2.16 TEdit.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D

BorderWidth

30.1.17.2.17 TEdit.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the

windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

30.1.17.2.18 TEdit.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.17.2.19 TEdit.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.17.2.20 TEdit.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
```

```
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

30.1.17.2.21 TEdit.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.17.2.22 TEdit.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

30.1.17.2.23 TEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

30.1.17.2.24 TEdit.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

30.1.17.2.25 TEdit.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

Imes

30.1.17.2.26 TEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

30.1.17.2.27 TEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly: Boolean;
```

C++

```
__property Boolean NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

30.1.17.2.28 TEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

30.1.17.2.29 TEdit.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.17.2.30 TEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.17.2.31 TEdit.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.17.2.32 TEdit.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.17.2.33 TEdit.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

30.1.17.2.34 TEdit.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.17.2.35 TEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar: Char;
```

C++

```
__property Char PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text property reflects the actual characters that are typed.

30.1.17.2.36 TEdit.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {

                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
```

```
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.

OnContextPopup

30.1.17.2.37 TEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

CopyToClipboard (see page 2349)

GetSelTextBuf (see page 2357)

30.1.17.2.38 TEdit.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.17.2.39 TEdit.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

30.1.17.2.40 TEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.17.2.41 TEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                       //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

Caption

Lines (see page 2451)

30.1.17.2.42 TEdit.TextHint Property

A hint or message to be displayed when the Text property is empty.

Pascal

```
property TextHint: string;
```

C++

```
__property UnicodeString TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

30.1.17.2.43 TEdit.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin

30.1.17.3 TEdit Events

The events of the TEdit class are listed here.

Published Events

	Name	Description
	OnChange (see page 2501)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2502)	Occurs when the user clicks the control.
	OnContextPopup (see page 2504)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2504)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2505)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2508)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2511)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2511)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2512)	Occurs when a control receives the input focus.
	OnExit (see page 2515)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2519)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2522)	Occurs when a key is pressed.
	OnKeyUp (see page 2523)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2525)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2526)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2528)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2529)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2529)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2531)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2533)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2534)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.17.3.1 TEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 2348)

Text

30.1.17.3.2 TEdit.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}
```

```
void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}

30.1.17.3.3 TEdit.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

30.1.17.3.4 TEdit.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

30.1.17.3.5 TEdit.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

30.1.17.3.6 TEdit.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
```

```
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';

DragKind

30.1.17.3.9 TEdit.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{

30.1.17.3.10 TEdit.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

        hostmask1 < 0 || hostmask1 > 255 ||
        hostmask2 < 0 || hostmask2 > 255)
      throw(Exception("Not a valid subnet mask."));

    // compute the subnet address using bit-wise AND
    int sub_net1 = net1 & netmask1;
    int sub_net2 = net2 & netmask2;
    int sub_host1 = host1 & hostmask1;
    int sub_host2 = host2 & hostmask2;

    // display the subnet address
    MaskEdit3->Text =
      String(sub_net1) + "." + String(sub_net2) + "." +
      String(sub_host1) + "." + String(sub_host2);
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var

ActiveControl

30.1.17.3.11 TEdit.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

30.1.17.3.12 TEdit.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII

character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

OnKeyDown

OnKeyPress

30.1.17.3.14 TEdit.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

30.1.17.3.15 TEdit.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
```

```
*/
int StartX, StartY; // Declare at the top of the form's unit

MouseCapture

30.1.17.3.16 TEdit.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.17.3.17 TEdit.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.17.3.18 TEdit.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
```

```
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);

MouseCapture

30.1.17.3.19 TEdit.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

30.1.17.3.20 TEdit.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.17.3.21 TEdit.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.18 TGroupBox Class

TGroupBox represents a Windows group box.

Class Hierarchy

Pascal

```
TGroupBox = class(TCustomGroupBox);
```

C++

```
class TGroupBox : public TCustomGroupBox;
```

File

StdCtrls

Description

The TGroupBox component represents a standard Windows group box, used to group related controls on a form. When another control component is placed within a group box, the group box becomes the parent of that component.

Grouping Controls

30.1.18.1 TGroupBox Members

The following tables list the members exposed by TGroupBox.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2382)	Adjusts the ClientRect property for idiosyncrasies of the window.
	CreateParams (see page 2383)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 2383)	Renders the onscreen image of the group box.

Public Methods

	Name	Description
	Create (see page 2382)	Creates and initializes a TCustomGroupBox (see page 2381) instance.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2566)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2566)	Occurs when an object with custom alignment is aligned.
	OnClick (see page 2567)	Occurs when the user clicks the control.
	OnContextPopup (see page 2569)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 2570)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 2570)	Occurs when another control is docked to the control.
	OnDockOver (see page 2572)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 2574)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2577)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2580)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2580)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2581)	Occurs when a control receives the input focus.
	OnExit (see page 2584)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 2588)	Returns the control's docking information.
	OnMouseActivate (see page 2590)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2591)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2593)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2594)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2594)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2596)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2598)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2599)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 2600)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 2537)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2541)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2541)	Specifies the bi-directional mode for the control.
	Caption (see page 2542)	Specifies a text string that identifies the control to the user.
	Color (see page 2544)	Specifies the background color of the control.
	Constraints (see page 2545)	Specifies the size constraints for the control.
	Ctl3D (see page 2546)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 2546)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 2547)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2549)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2550)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2550)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2551)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2552)	Controls the attributes of text written on or in the control.
	Padding (see page 2553)	Specifies the padding of a control.
	ParentBackground (see page 2553)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 2554)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2554)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2555)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2555)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2555)	Determines where a control looks for its font information.
	ParentShowHint (see page 2556)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2556)	Identifies the pop-up menu associated with the control.

	ShowHint (see page 2561)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2563)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2563)	Determines if the user can tab to a control.
	Visible (see page 2564)	Determines whether the component appears onscreen.

30.1.18.2 TGroupBox Properties

The properties of the TGroupBox class are listed here.

Published Properties

	Name	Description
	Align (see page 2537)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2541)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2541)	Specifies the bi-directional mode for the control.
	Caption (see page 2542)	Specifies a text string that identifies the control to the user.
	Color (see page 2544)	Specifies the background color of the control.
	Constraints (see page 2545)	Specifies the size constraints for the control.
	Ctl3D (see page 2546)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 2546)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 2547)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2549)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2550)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2550)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2551)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2552)	Controls the attributes of text written on or in the control.
	Padding (see page 2553)	Specifies the padding of a control.
	ParentBackground (see page 2553)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 2554)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2554)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2555)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2555)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2555)	Determines where a control looks for its font information.
	ParentShowHint (see page 2556)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2556)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2561)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2563)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2563)	Determines if the user can tab to a control.
	Visible (see page 2564)	Determines whether the component appears onscreen.

30.1.18.2.1 TGroupBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

Parent

Anchors

30.1.18.2.2 TGroupBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.18.2.3 TGroupBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.18.2.4 TGroupBox.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
```

```
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.18.2.5 TGroupBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

30.1.18.2.6 TGroupBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.18.2.7 TGroupBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

30.1.18.2.8 TGroupBox.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

30.1.18.2.9 TGroupBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,

{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;

30.1.18.2.11 TGroupBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.18.2.12 TGroupBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/

property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.18.2.14 TGroupBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

30.1.18.2.15 TGroupBox.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

30.1.18.2.16 TGroupBox.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has

no effect unless XP themes are enabled.

30.1.18.2.17 TGroupBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.18.2.18 TGroupBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.18.2.19 TGroupBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.18.2.20 TGroupBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.18.2.21 TGroupBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

30.1.18.2.22 TGroupBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.18.2.23 TGroupBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
```

```
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
```

```
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

OnContextPopup

30.1.18.2.24 TGroupBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

30.1.18.2.25 TGroupBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.18.2.26 TGroupBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.18.2.27 TGroupBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

30.1.18.3 TGroupBox Events

The events of the TGroupBox class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2566)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2566)	Occurs when an object with custom alignment is aligned.
	OnClick (see page 2567)	Occurs when the user clicks the control.
	OnContextPopup (see page 2569)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2570)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 2570)	Occurs when another control is docked to the control.
	OnDockOver (see page 2572)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 2574)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2577)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2580)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2580)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2581)	Occurs when a control receives the input focus.
	OnExit (see page 2584)	Occurs when the input focus shifts away from one control to another.

	OnGetSiteInfo (see page 2588)	Returns the control's docking information.
	OnMouseActivate (see page 2590)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2591)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2593)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2594)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2594)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2596)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2598)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2599)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 2600)	Occurs when the application tries to undock a control that is docked to the windowed control.

30.1.18.3.1 TGroupBox.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

TAlignInsertBeforeEvent

30.1.18.3.2 TGroupBox.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment

parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

30.1.18.3.3 TGroupBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
```

```
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

30.1.18.3.4 TGroupBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

30.1.18.3.5 TGroupBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

30.1.18.3.6 TGroupBox.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

DockSite

OnDockOver

30.1.18.3.7 TGroupBox.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

OnDockDrop

OnGetSiteInfo

TDragDockObject

30.1.18.3.8 TGroupBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
```

```
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,

OnStartDrag

TDragObject

30.1.18.3.9 TGroupBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
```

```
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type
  TForm1 = class(TForm)
```

```
    Panel1: TPanel;
    Label1: TLabel;
    procedure Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragDrop(Sender, Source: TObject; X, Y: Integer);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

30.1.18.3.11 TGroupBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;

30.1.18.3.12 TGroupBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
```

```
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------

30.1.18.3.13 TGroupBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
```

```
  where the third mask edit box is set to be read only.
  When the application runs, it initializes the mask edit boxes
  to contain the empty string, to use the Courier font and to
  use a particular mask, corresponding to IP address coding convetions.
  The mask edit boxes display the IP address, the subnet mask
  and the subnet address correspondingly. When the user exits the
  subnet mask edit box, the subnet address is automatically calculated
  using bit-wise AND operations and displayed in the third mask edit box.
  An additional test is made to assure that the values in the IP address
  and in the subnet mask are in the interval from 0 to 255 ,
  as this validation test cannot be accomplished
  using the edit mask property alone.
  */
  void __fastcall TForm1::FormCreate(TObject *Sender)

OnEnter

ActiveControl

30.1.18.3.14 TGroupBox.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
```

```
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
```

```
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

TDragDockObject

30.1.18.3.15 TGroupBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.18.3.16 TGroupBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
```

```
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

30.1.18.3.17 TGroupBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.18.3.18 TGroupBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.18.3.19 TGroupBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

Responding to a Mouse-up Action

30.1.18.3.21 TGroupBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.18.3.22 TGroupBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

OnDragDrop

30.1.18.3.23 TGroupBox.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
```

```
    //Make DockManager repaints it's clients.
  end;

  procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
    Source: TDragDockObject; X, Y: Integer; State: TDragState;
    var Accept: Boolean);
  var
    ARect: TRect;
  begin
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;

30.1.19 TImageMargins Class

Margins of image on button.

Class Hierarchy

Pascal

```
  TImageMargins = class(TPersistent);
```

C++

```
  class TImageMargins : public TPersistent;
```

File

StdCtrls

Description

A button image may be positioned using margins. TImageMargins defines the margins of an image on a TButton (see page 2035). The margin values are in the Bottom (see page 2605), Top (see page 2606), Left (see page 2605) and Right (see page 2606) properties.

The OnChange (see page 2607) event is triggered when a margin changes.

The TButton.ImageMargins property contains a TImageMargins instance.

See Also

Bottom (see page 2605)

ImageMargins (see page 2058)

Left (see page 2605)

Right (see page 2606)

Top (see page 2606)

OnChange (see page 2607)

30.1.19.1 TImageMargins Members

The following tables list the members exposed by TImageMargins.

Protected Methods

	Name	Description
	Change (see page 2604)	Called when the image margins change.

Public Events

	Name	Description
	OnChange (see page 2607)	Margin changed.

Public Methods

	Name	Description
	Assign (see page 2604)	Copies the contents of another, similar object.

Published Properties

	Name	Description
	Bottom (see page 2605)	Bottom margin of image on button.
	Left (see page 2605)	Left margin of image on button.
	Right (see page 2606)	Right margin of image on button.
	Top (see page 2606)	Top margin of image on button.

30.1.19.2 TImageMargins Methods

The methods of the TImageMargins class are listed here.

Protected Methods

	Name	Description
	Change (see page 2604)	Called when the image margins change.

Public Methods

	Name	Description
	Assign (see page 2604)	Copies the contents of another, similar object.

30.1.19.2.1 TImageMargins.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent calls the source object's AssignTo method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

See Also

AssignTo

EConvertError (see page 3919)

30.1.19.2.2 TImageMargins.Change Method

Called when the image margins change.

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

Override Change in a derived class to perform actions when the image margins change.

By default, Change calls the OnChange (see page 2607) event handler.

See Also

ImageMargins (see page 2058)

OnChange (see page 2607)

30.1.19.3 TImageMargins Properties

The properties of the TImageMargins class are listed here.

Published Properties

	Name	Description
	Bottom (see page 2605)	Bottom margin of image on button.
	Left (see page 2605)	Left margin of image on button.
	Right (see page 2606)	Right margin of image on button.
	Top (see page 2606)	Top margin of image on button.

30.1.19.3.1 TImageMargins.Bottom Property

Bottom margin of image on button.

Pascal

```
property Bottom: Integer;
```

C++

```
__property int Bottom;
```

Description

A button image may be positioned using margins. Bottom is the bottom margin of an image on a TButton (see page 2035).

See Also

ImageMargins (see page 2058)

Left (see page 2605)

Right (see page 2606)

Top (see page 2606)

30.1.19.3.2 TImageMargins.Left Property

Left margin of image on button.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

A button image may be positioned using margins. Left is the left margin of an image on a TButton (see page 2035).

See Also

Bottom (see page 2605)

ImageMargins (see page 2058)

Right (see page 2606)

Top (see page 2606)

30.1.19.3.3 TImageMargins.Right Property

Right margin of image on button.

Pascal

```
property Right: Integer;
```

C++

```
__property int Right;
```

Description

A button image may be positioned using margins. Right is the right margin of an image on a TButton (see page 2035).

See Also

Bottom (see page 2605)

ImageMargins (see page 2058)

Left (see page 2605)

Top (see page 2606)

30.1.19.3.4 TImageMargins.Top Property

Top margin of image on button.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

A button image may be positioned using margins. Top is the top margin of an image on a TButton (see page 2035).

See Also

Bottom (see page 2605)

ImageMargins (see page 2058)

Left (see page 2605)

Right (see page 2606)

30.1.19.4 TImageMargins Events

The events of the TImageMargins class are listed here.

Public Events

	Name	Description
	OnChange (see page 2607)	Margin changed.

30.1.19.4.1 TImageMargins.OnChange Event

Margin changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

OnChange occurs when a margin changes.

See Also

ImageMargins (see page 2058)

30.1.20 TLabel Class

TLabel is a nonwindowed control that displays text on a form.

Class Hierarchy

Pascal

```
TLabel = class(TCustomLabel);
```

C++

```
class TLabel : public TCustomLabel;
```

File

StdCtrls

Description

Use TLabel to add text that the user can't edit to a form. This text can be used to label another control, and can set focus to that control when the user types an accelerator key.

Because TLabel is not a descendant of TWinControl, it does not have its own window and can't receive direct input from the keyboard. To add an object to a form that can respond to keyboard input (other than setting focus to another object when an accelerator key is typed) in addition to displaying text, use TStaticText (see page 2945).

To add an object to a form that displays text that a user can scroll or edit, use TEdit (see page 2463).

See Also

TEdit (see page 2463)

TStaticText (see page 2945)

Labels

Display Controls

30.1.20.1 TLabel Members

The following tables list the members exposed by TLabel.

Protected Methods

	Name	Description
	AdjustBounds (see page 2385)	Resizes the label when the text changes.
	DoDrawText (see page 2386)	Renders the text in the client area.
V	GetLabelText (see page 2386)	Returns the value of the Caption (see page 2392) property.
V	Loaded (see page 2387)	Adjusts the size of the label when it is first loaded. .
V	Notification (see page 2387)	Responds to notifications when objects are about to be created or destroyed.
V	Paint (see page 2387)	Draws the image of the label.
V	SetAutoSize (see page 2388)	Sets the AutoSize (see page 2389) property.

Public Methods

	Name	Description
V	Create (see page 2385)	Creates and initializes an instance of TCustomLabel (see page 2384).

Public Properties

	Name	Description
	Canvas (see page 2390)	Provides the drawing surface used by the graphic control.

Published Events

	Name	Description
	OnClick (see page 2637)	Occurs when the user clicks the control.
	OnContextPopup (see page 2639)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2640)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2640)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2643)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2646)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2647)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2648)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2649)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2651)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2651)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2652)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2654)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2656)	Occurs when the user begins to drag a control with a DragKind of dkDock.

	OnStartDrag (see page 2657)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2610)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2613)	Controls the horizontal placement of the text within the label.
	Anchors (see page 2614)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2614)	Determines whether the size of the label automatically resizes to accommodate the text.
	BiDiMode (see page 2615)	Specifies the bi-directional mode for the control.
	Caption (see page 2616)	Specifies a text string that identifies the control to the user.
	Color (see page 2618)	Specifies the background color of the control.
	Constraints (see page 2619)	Specifies the size constraints for the control.
	DragCursor (see page 2620)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2620)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2621)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EllipsisPosition (see page 2622)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	Enabled (see page 2623)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2623)	Designates a windowed control associated with the label.
	Font (see page 2623)	Controls the attributes of text written on or in the control.
	GlowSize (see page 2624)	Specifies the radius of the glow around the label.
	Layout (see page 2625)	Specifies the vertical placement of the text within the label.
	ParentBiDiMode (see page 2625)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2626)	Determines where a control looks for its color information.
	ParentFont (see page 2626)	Determines where a control looks for its font information.
	ParentShowHint (see page 2627)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2627)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2632)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 2633)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Transparent (see page 2635)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Visible (see page 2635)	Determines whether the component appears onscreen.
	WordWrap (see page 2636)	Specifies whether the label text wraps when it is too long for the width of the label.

30.1.20.2 TLabel Properties

The properties of the TLabel class are listed here.

Published Properties

	Name	Description
	Align (see page 2610)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2613)	Controls the horizontal placement of the text within the label.
	Anchors (see page 2614)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2614)	Determines whether the size of the label automatically resizes to accommodate the text.
	BiDiMode (see page 2615)	Specifies the bi-directional mode for the control.
	Caption (see page 2616)	Specifies a text string that identifies the control to the user.
	Color (see page 2618)	Specifies the background color of the control.
	Constraints (see page 2619)	Specifies the size constraints for the control.
	DragCursor (see page 2620)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2620)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 2621)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EllipsisPosition (see page 2622)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	Enabled (see page 2623)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2623)	Designates a windowed control associated with the label.
	Font (see page 2623)	Controls the attributes of text written on or in the control.
	GlowSize (see page 2624)	Specifies the radius of the glow around the label.
	Layout (see page 2625)	Specifies the vertical placement of the text within the label.
	ParentBiDiMode (see page 2625)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2626)	Determines where a control looks for its color information.
	ParentFont (see page 2626)	Determines where a control looks for its font information.
	ParentShowHint (see page 2627)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2627)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2632)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 2633)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Transparent (see page 2635)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Visible (see page 2635)	Determines whether the component appears onscreen.
	WordWrap (see page 2636)	Specifies whether the label text wraps when it is too long for the width of the label.

30.1.20.2.1 TLabel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
```

```
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>

Anchors

30.1.20.2.2 TLabel.Alignment Property

Controls the horizontal placement of the text within the label.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Set Alignment to specify how the text of the label is justified within the ClientRect of the label control.

The effect of the Alignment property is more obvious if the WordWrap property is true and the label includes more than one line of text.

See Also

ClientRect

GetLabelText (see page 2386)

Layout (see page 2396)

WordWrap (see page 2397)

30.1.20.2.3 TLabel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

30.1.20.2.4 TLabel.AutoSize Property

Determines whether the size of the label automatically resizes to accommodate the text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to make the label adjust its size automatically so the client area accommodates the height and width of the text. When AutoSize is false, the label is fixed in size. When AutoSize is true, the size of the label readjusts whenever the text changes. The size of the label is also readjusts when the Font property changes.

When WordWrap is true, the width of the label is fixed. If AutoSize is also true, changes to the text cause the label to change in height. When AutoSize is true and WordWrap is false, the font determines the height of the label, and changes to the text cause the label to change in width.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
```

30.1.20.2.5 TLabel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.20.2.6 TLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
```

```
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.20.2.7 TLabel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

30.1.20.2.8 TLabel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.20.2.9 TLabel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.20.2.10 TLabel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.20.2.11 TLabel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
```

```
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;

30.1.20.2.12 TLabel.EllipsisPosition Property

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
property EllipsisPosition: TEllipsisPosition;
```

C++

```
__property TEllipsisPosition EllipsisPosition;
```

Description

Set EllipsisPosition to determine how an ellipsis is placed in text that does not fit in its allocated rectangle. This is a TEllipsisPosition constant and its value corresponds to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

See Also

WordWrap (see page 2397)

30.1.20.2.13 TLabel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.20.2.14 TLabel.FocusControl Property

Designates a windowed control associated with the label.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Set FocusControl to the windowed control that should receive focus when the user presses the accelerator key specified by the label. Specify an accelerator key by preceding a character in the label text with an ampersand (&) and setting the ShowAccelChar property to true.

See Also

ShowAccelChar (see page 2396)

30.1.20.2.15 TLabel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

30.1.20.2.16 TLabel.GlowSize Property

Specifies the radius of the glow around the label.

Pascal

```
property GlowSize: Integer;
```

C++

```
__property int GlowSize;
```

Description

Set the value of GlowSize to specify the radius of the glow around the label.

Note: This is available only on Windows Vista with the Aero theme enabled.

Specifies the vertical placement of the text within the label.

Pascal

```
property Layout: TTextLayout;
```

C++

```
__property TTextLayout Layout;
```

Description

Set Layout to specify how the text of the label is placed within the ClientRect of the label control. Layout is the vertical analog to the Alignment property.

See Also

Alignment (see page 2388)

ClientRect

30.1.20.2.18 TLabel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.20.2.19 TLabel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.20.2.20 TLabel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

30.1.20.2.21 TLabel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.20.2.22 TLabel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
```

```
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);

    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
```

```
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
```

```
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

30.1.20.2.23 TLabel.ShowAccelChar Property

Determines how an ampersand in the label text is displayed.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

Set ShowAccelChar to true to allow the label to display an underlined accelerator key value. When ShowAccelChar is true, any character preceded by an ampersand (&) appears underlined. If the FocusControl property is set, the windowed control specified by the FocusControl property receives input focus when the user types that underlined character. To display an ampersand when ShowAccelChar is true, use two ampersands (&&) to stand for the single ampersand that is displayed.

Set ShowAccelChar to false to display the label text with all ampersands appearing as ampersands. When ShowAccelChar is false, the value of the FocusControl property is not used.

C++ Examples:

```
/*
This example uses two labels on a form. The first label has
```

```
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label1->ShowAccelChar = true;
  Label1->Caption = "An &Underlined character appears here";
  Label2->ShowAccelChar = false;
  Label2->Caption = "An ampersand (&) appears here";
}
```

Delphi Examples:

```
{
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label1.ShowAccelChar := True;
  Label1.Caption := 'An &Underlined character appears here';
  Label2.ShowAccelChar := False;
  Label2.Caption := 'An ampersand (&) appears here';
end;
```

30.1.20.2.24 TLabel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
```

```
  to both controls. The last statement enables the Help Hints
  for the entire application.
  */
  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Edit1->Hint = "Enter your name";
    Edit1->ShowHint = true;

    char string[10];
    char index[3];
    for(int i = 1; i <= 10; i++)
    {
      strcpy(string, "Item");
      itoa(i, index, 10);
      strcat(string, index);
      ListBox1->Items->Add(string);
    }
    ListBox1->Hint = "Select an item";
    ListBox1->ShowHint = true;
    Application->ShowHint = true;
  }
  /*
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  */
```

Delphi Examples:

```
  {
  This example uses an edit box and a list box on a form.
  Items are added to the list box and a Help Hint is assigned
  to both controls. The last statement enables the Help Hints
  for the entire application.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    I: Integer;
  begin
    Edit1.Hint := 'Enter your name';
    Edit1.ShowHint := True;
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }

30.1.20.2.25 TLabel.Transparent Property

Specifies whether controls that sit below the label on a form can be seen through the label.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to prevent the label from obscuring other controls on the form. For example, if the label is used to add text to a graphic, set Transparent to true so that the label does not stand out as a separate object.

Writing text so that the background is transparent is slower than writing text when Transparent is false. If the label is not obscuring a complicated image, performance can be improved by setting the background color of the label to match the object beneath it and setting Transparent to false.

Color

ParentColor

30.1.20.2.26 TLabel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

30.1.20.2.27 TLabel.WordWrap Property

Specifies whether the label text wraps when it is too long for the width of the label.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the label to display multiple line of text. When WordWrap is true, text that is too wide for the label control wraps at the right margin and continues in additional lines.

Set WordWrap to false to limit the label to a single line. When WordWrap is false, text that is too wide for the label appears truncated.

30.1.20.3 TLabel Events

The events of the TLabel class are listed here.

Published Events

	Name	Description
	OnClick (see page 2637)	Occurs when the user clicks the control.
	OnContextPopup (see page 2639)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2640)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2640)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2643)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2646)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2647)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2648)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2649)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2651)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2651)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2652)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2654)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2656)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2657)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.20.3.1 TLabel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

30.1.20.3.2 TLabel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The

OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

OnClick

Responding to User Actions at Runtime

30.1.20.3.4 TLabel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{

30.1.20.3.5 TLabel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor

property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

30.1.20.3.7 TLabel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
```

```
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';

DragKind

30.1.20.3.8 TLabel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate

event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.20.3.9 TLabel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

30.1.20.3.10 TLabel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.20.3.11 TLabel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.20.3.12 TLabel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*

MouseCapture

30.1.20.3.13 TLabel.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
```

```
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);

OnMouseMove

Responding to a Mouse-up Action

30.1.20.3.14 TLabel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

30.1.20.3.15 TLabel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.21 TListBox Class

TListBox displays a collection of items in a scrollable list.

Class Hierarchy

Pascal

```
TListBox = class(TCustomListBox);
```

C++

```
class TListBox : public TCustomListBox;
```

File

StdCtrls

Description

Use TListBox to display a scrollable list of items that users can select, add, or delete. TListBox is a wrapper for the Windows listbox control. For specialized list boxes, use other descendant classes of TCustomListBox (see page 2398) or derive your own class from TCustomListBox (see page 2398).

TListBox implements the generic behavior introduced in TCustomListBox (see page 2398). TListBox publishes many of the properties inherited from TCustomListBox (see page 2398), but does not introduce any new behavior.

List Boxes and Check-list Boxes

30.1.21.1 TListBox Members

The following tables list the members exposed by TListBox.

Protected Fields

	Name	Description
	FMoving (see page 2401)	Specifies whether the strings of the list box are changing their position.

Protected Methods

	Name	Description
	CreateParams (see page 2404)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateWnd (see page 2405)	Creates a Windows control corresponding to the list box component.
	DeleteString (see page 2406)	Deletes a string from the list box.
	DestroyWnd (see page 2406)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoFindData (see page 2407)	Returns the index of a string in the list box.
	DoGetData (see page 2407)	Returns a string in the list box given its index.
	DoGetDataObject (see page 2408)	Returns the object associated with an item in a virtual list box.
	DragCanceled (see page 2408)	Sends a mouse message canceling the drag-and-drop operation.
	DrawItem (see page 2408)	Generates an OnDrawItem (see page 2439) event.
	GetItemData (see page 2409)	Returns a 32-bit value associated with the specified item in a list box.
	GetItemIndex (see page 2410)	Returns the value of the ItemIndex property.
	GetSelCount (see page 2410)	Returns the number of selected items.
	GetSelected (see page 2410)	Indicates whether a particular item is selected.
	InternalGetItemData (see page 2411)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2411)	Associates an integer with a specified item in the list box.
	KeyPress (see page 2415)	Responds when the user presses a key.
	LoadRecreateItems (see page 2415)	Assigns new strings to the list.
	MeasureItem (see page 2415)	Generates an OnMeasureItem (see page 2442) event.
	ResetContent (see page 2416)	Removes all of the items from a list box.
	SaveRecreateItems (see page 2416)	Saves the items from a list box.
	SetItemData (see page 2417)	Sets the 32-bit value associated with the specified item in a list box.
	SetItemIndex (see page 2417)	Gives focus to the item with a specified index.
	SetMultiSelect (see page 2417)	Sets the MultiSelect property.

	WndProc (see page 2418)	Handles Windows messages.

Public Methods

	Name	Description
	AddItem (see page 2402)	Adds an item to the list box
	Clear (see page 2403)	Deletes all items from the list box.
	ClearSelection (see page 2403)	Deselects all selected items in the list box, if possible.
	CopySelection (see page 2404)	Copies the selected items to another list-type control
	Create (see page 2400)	Instantiates a list box control.
	DeleteSelected (see page 2406)	Deletes the selected items from the list box
	Destroy (see page 2401)	Destroys the instance of a list box control.
	GetCount (see page 2409)	Returns the value of the Count (see page 2427) property.
	ItemAtPos (see page 2411)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 2413)	Returns the rectangle that surrounds the item specified in the Item parameter.
	SelectAll (see page 2416)	Selects the entire block of text in the list box.

Public Properties

	Name	Description
	Canvas (see page 2424)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 2439) event of an owner-draw list box.
	Count (see page 2427)	Indicates the number of items in the list box.
	Selected (see page 2432)	Indicates whether a particular item is selected.
	TopIndex (see page 2437)	Specifies the index number of the item that appears at the top of the list box.

Published Events

	Name	Description
	OnClick (see page 2699)	Occurs when the user clicks the control.
	OnContextPopup (see page 2701)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2701)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2702)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2702)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2703)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2703)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2706)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2709)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2711)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2712)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2713)	Occurs when a control receives the input focus.
	OnExit (see page 2715)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2719)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2723)	Occurs when a key is pressed.
	OnKeyUp (see page 2724)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2725)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2727)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2728)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2730)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2731)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2731)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 2733)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2735)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2736)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2662)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2665)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2666)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2666)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 2666)	Specifies which edges of the control are beveled.
	BevelInner (see page 2667)	Specifies the cut of the inner bevel.
	BevelKind (see page 2667)	Specifies the control's bevel style.
	BevelOuter (see page 2668)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2668)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2668)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2669)	Determines whether the list box has a border.
	Color (see page 2669)	Specifies the background color of the control.
	Columns (see page 2670)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2671)	Specifies the size constraints for the control.
	Ctl3D (see page 2671)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2672)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2674)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2674)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2674)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2676)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 2676)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 2677)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2678)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2678)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2679)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2680)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2680)	Contains the strings that appear in the list box.
	MultiSelect (see page 2683)	Specifies whether the user can select more than one item.
	ParentBiDiMode (see page 2684)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2684)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2685)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2685)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2685)	Determines where a control looks for its font information.
	ParentShowHint (see page 2686)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2686)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 2691)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 2692)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2693)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2695)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2695)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2696)	Determines if the user can tab to a control.

	TabWidth (see page 2696)	Specifies the size of the tabs in the list box.
	Visible (see page 2697)	Determines whether the component appears onscreen.

30.1.21.2 TListBox Properties

The properties of the TListBox class are listed here.

Published Properties

	Name	Description
	Align (see page 2662)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2665)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2666)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 2666)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 2666)	Specifies which edges of the control are beveled.
	BevelInner (see page 2667)	Specifies the cut of the inner bevel.
	BevelKind (see page 2667)	Specifies the control's bevel style.
	BevelOuter (see page 2668)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2668)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2668)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2669)	Determines whether the list box has a border.
	Color (see page 2669)	Specifies the background color of the control.
	Columns (see page 2670)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2671)	Specifies the size constraints for the control.
	Ctl3D (see page 2671)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2672)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2674)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2674)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2674)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2676)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 2676)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 2677)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2678)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2678)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2679)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2680)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2680)	Contains the strings that appear in the list box.
	MultiSelect (see page 2683)	Specifies whether the user can select more than one item.
	ParentBiDiMode (see page 2684)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2684)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2685)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2685)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2685)	Determines where a control looks for its font information.
	ParentShowHint (see page 2686)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2686)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 2691)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 2692)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2693)	Specifies whether the items in a list box are arranged alphabetically.

	Style (see page 2695)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2695)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2696)	Determines if the user can tab to a control.
	TabWidth (see page 2696)	Specifies the size of the tabs in the list box.
	Visible (see page 2697)	Determines whether the component appears onscreen.

30.1.21.2.1 TListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);
```

```
  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.

        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
```

```
  into resizable panes.  All objects on the form are created
  dynamically in the OnCreate event handler of the form. To
  run this example, add ExtCtrls and FileCtrl to the uses
  clause of the form's implementation section.
  Note that when creating a splitter dynamically at runtime,
  it is important to set its position to the appropriate side
  of the control it will resize.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    Split: TSplitter;
    Files: TFileListBox;
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane - a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

Parent

Anchors

30.1.21.2.2 TListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.21.2.3 TListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

30.1.21.2.4 TListBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2666) is true.

See Also

AutoComplete (see page 2666)

30.1.21.2.5 TListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

30.1.21.2.6 TListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

30.1.21.2.7 TListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

30.1.21.2.8 TListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

30.1.21.2.9 TListBox.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

30.1.21.2.10 TListBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.21.2.11 TListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D

30.1.21.2.12 TListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the

Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

30.1.21.2.13 TListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 2428)

Width

30.1.21.2.14 TListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

30.1.21.2.15 TListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

30.1.21.2.16 TListBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
```

```
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

30.1.21.2.17 TListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.21.2.18 TListBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.21.2.19 TListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then

30.1.21.2.20 TListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

Enabling Mouse

30.1.21.2.21 TListBox.ExtendedSelect Property

Makes list item multi-select operate with Shift and CTRL keys.

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

ExtendedSelect only has effect when the MultiSelect (see page 2683) is true.

When ExtendedSelect is true, the Shift key (in conjunction with the left mouse button, or arrow keys) is used to select a contiguous sequence of list items. And the Ctrl key is used (in conjunction with the left mouse buttton) to select non-contiguous list items.

When ExtendedSelect is false, Multi-Select operates very differently. The Shift and Ctrl keys are not recognised. List items are always selected individually in any sequence. Reselecting a selected list item will deselect it. Use the arrow and spacebar keys, or the left mouse button to make selections.

See Also

MultiSelect (see page 2683)

30.1.21.2.22 TListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
```

```
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

30.1.21.2.23 TListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

SetImeCompositionWindow

30.1.21.2.24 TListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

30.1.21.2.25 TListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 2428)

Items (see page 2429)

Using TDBListBox and TDBComboBox

30.1.21.2.26 TListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

Using TDBListBox and TDBComboBox

30.1.21.2.27 TListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
```

```
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/

TStrings

30.1.21.2.28 TListBox.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect;
```

C++

```
__property MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount property indicates the number of selected items. When MultiSelect is false, the user can only select one item, which is indicated by the ItemIndex property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl descendant, override the protected SetMultiSelect method.

C++ Examples:

```
/*
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
selects an item and clicks the button, the selected item in
the list box is moved to the top of the list box:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->MultiSelect = false;
  Button1->Caption = "Move to Top";
  for (int i = 1; i <= 10; i++)
    ListBox1->Items->Add("Item " + IntToStr(i));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ListBox1->ItemIndex >= 0 && ListBox1->ItemIndex <= 9)
    ListBox1->Items->Move(ListBox1->ItemIndex, 0);
}
```

Delphi Examples:

```
{
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
clicks the button, the selected item in the list box is
moved to the top of the list box:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (ListBox1.ItemIndex in [0..9]) then
    ListBox1.Items.Move(ListBox1.ItemIndex, 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  I: Integer;
begin
  ListBox1.MultiSelect := False;
  Button1.Caption := 'Move to Top';
  for I := 1 to 10 do
    ListBox1.Items.Add('Item ' + IntToStr(I));
end;
```

SelCount

ItemIndex

30.1.21.2.29 TListBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

30.1.21.2.30 TListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.21.2.31 TListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.21.2.32 TListBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.21.2.33 TListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own

Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

30.1.21.2.34 TListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.21.2.35 TListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

30.1.21.2.36 TListBox.ScrollWidth Property

Specifies the width, in pixels, by which the list box can scroll horizontally.

Pascal

```
property ScrollWidth: Integer;
```

C++

```
__property int ScrollWidth;
```

Description

Use ScrollWidth to get or set the logical width of the list box. When ScrollWidth is greater than the client width of the list box, the list box gets a horizontal scroll bar. When ScrollWidth is less than or equal to ClientWidth, the horizontal scroll bar disappears.

Columns (see page 2426)

ClientWidth

30.1.21.2.37 TListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.21.2.38 TListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
}
```

Delphi Examples:

```
{
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

procedure TForm1.AddClick(Sender: TObject);
begin
  ListBox1.Items.Add(Edit1.Text);
end;

procedure TForm1.SortClick(Sender: TObject);
begin
  ListBox1.Sorted := True;
end;
```

Items (see page 2429)

Style (see page 2436)

30.1.21.2.39 TListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

30.1.21.2.40 TListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.21.2.41 TListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.21.2.42 TListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

30.1.21.2.43 TListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);

30.1.21.3 TListBox Events

The events of the TListBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 2699)	Occurs when the user clicks the control.
	OnContextPopup (see page 2701)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2701)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2702)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2702)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2703)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2703)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2706)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2709)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2711)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2712)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2713)	Occurs when a control receives the input focus.
	OnExit (see page 2715)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2719)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2723)	Occurs when a key is pressed.
	OnKeyUp (see page 2724)	Occurs when the user releases a key that has been pressed.

	OnMeasureItem (see page 2725)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2727)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2728)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2730)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2731)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2731)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2733)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2735)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2736)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.21.3.1 TListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
```

```
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

30.1.21.3.2 TListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup

30.1.21.3.3 TListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataFind (see page 2439)

OnDataObject (see page 2439)

Style (see page 2436)

Count (see page 2427)

30.1.21.3.4 TListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 2438)

OnDataObject (see page 2439)

Style (see page 2436)

Count (see page 2427)

30.1.21.3.5 TListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

30.1.21.3.6 TListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

30.1.21.3.7 TListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
```

```
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type

30.1.21.3.8 TListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}
```

```
void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

30.1.21.3.9 TListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight property for fixed owner-draw list boxes or by the response to the OnMeasureItem event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
#include <memory>       //for STL auto_ptr class
```

```
Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = (dynamic_cast<TListBox *>(Control))->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
      pBitmap,
      Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
```

```
    ImageList1.GetBitmap(2, bitmap2);
    ListBox1.Items.AddObject('Butterfly', bitmap2);
  end;

  procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
  TOwnerDrawState);
  var
    Bitmap: TBitmap;      { temporary variable for the item's bitmap }
    Offset: Integer;      { text offset width }
  begin
    Bitmap := TBitmap.Create;
    with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
    begin
      FillRect(Rect);       { clear the rectangle }
      Offset := 2;          { provide default offset }
      Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
      if Bitmap <> nil then
      begin
        BrushCopy(
          Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
          Bitmap,
          Bounds(0, 0, Bitmap.Width, Bitmap.Height),
          clRed);  {render bitmap}
        Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
      end;
      TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
  text }
    end;
  end;

30.1.21.3.11 TListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

30.1.21.3.12 TListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
```

```
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)

30.1.21.3.13 TListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';
```

```
    { use the Courier font in the maskedit boxes }
    MaskEdit1.Font.Name := 'Courier';
    MaskEdit2.Font.Name := 'Courier';
    MaskEdit3.Font.Name := 'Courier';

    {
    initialize the mask of each maskedit box
    according to IP address coding conventions
    }
    MaskEdit1.EditMask := '!099.099.099.099;1; ';
    MaskEdit2.EditMask := '!099.099.099.099;1; ';
    MaskEdit3.EditMask := '!099.099.099.099;1; ';

    MaskEdit2.OnExit := MaskEdit2Exit;
  end;

  procedure TForm1.MaskEdit2Exit(Sender: TObject);
  var
    net1, net2, host1, host2,
    netmask1, netmask2, hostmask1, hostmask2,
    sub_net1, sub_net2, sub_host1, sub_host2: Integer;

    IP, mask: String;

  begin
    // extract the net and host address from the IP
    IP := MaskEdit1.Text;
    net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
    net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
    host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
    host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((net1 < 0) Or (net1 > 255) Or
        (net2 < 0) Or (net2 > 255) Or
        (host1 < 0) Or (host1 > 255) Or
        (host2 < 0) Or (host2 > 255)) then
      raise EArgumentException.Create('Not a valid IP address.');

    // extract the net and host mask from the subnet mask
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
```

```
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;
```

OnEnter

ActiveControl

30.1.21.3.14 TListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

KeyPreview

OnKeyPress

OnKeyUp

30.1.21.3.15 TListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
```

```
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

30.1.21.3.17 TListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
      int &Height)
{
  Graphics::TBitmap *bitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (bitmap && bitmap->Height > Height)
    Height = bitmap->Height;
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = dynamic_cast<Graphics::TBitmap *>((dynamic_cast<TListBox
*>(Control))->Items->Objects[Index]);
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
```

```
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, (dynamic_cast<TListBox
*>(Control))->Items->Strings[Index]);
}

#include <memory>       //for STL auto_ptr class

Graphics::TBitmap *bitmap0, *bitmap1, *bitmap2;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Making these static keeps them around until the project terminates.
  static std::auto_ptr<Graphics::TBitmap> _bitmap0Cleaner(bitmap0 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap1Cleaner(bitmap1 = new Graphics::TBitmap);
  static std::auto_ptr<Graphics::TBitmap> _bitmap2Cleaner(bitmap2 = new Graphics::TBitmap);
  bitmap0->LoadFromFile("../littleB_64.bmp");
//  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Butterfly", bitmap0);
  ImageList1->GetBitmap(3, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1); // no bitmap, see if it leaves this height at

30.1.21.3.18 TListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.21.3.19 TListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
```

```
*/

MouseCapture

30.1.21.3.20 TListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.21.3.21 TListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.21.3.22 TListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*

OnMouseUp

MouseCapture

30.1.21.3.23 TListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

30.1.21.3.24 TListBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnEndDock

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

30.1.21.3.25 TListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.22 TMemo Class

TMemo is a wrapper for a Windows multiline edit control.

Class Hierarchy

Pascal

```
TMemo = class(TCustomMemo);
```

C++

```
class TMemo : public TCustomMemo;
```

File

StdCtrls

Description

Use TMemo to put a standard Windows multiline edit control on a form. Multiline edit boxes allow the user to enter more than one line of text. They are appropriate for representing lengthy information.

TMemo implements the generic behavior introduced in TCustomMemo (see page 2443). TMemo publishes many of the properties inherited from TCustomMemo (see page 2443), but does not introduce any new behavior.

Note: Under Win 9x, there is a limit of 64k of text for this control.

30.1.22.1 TMemo Members

The following tables list the members exposed by TMemo.

Protected Methods

	Name	Description
	Change (see page 2348)	Generates an OnChange (see page 2381) event.
V	CreateParams (see page 2351)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateParams (see page 2447)	Initializes a window-creation parameter record passed in the Params parameter.
V	CreateWindowHandle (see page 2351)	Creates a Windows control to represent the control.
V	CreateWindowHandle (see page 2447)	Creates a window based on the window-creation parameter record.
V	CreateWnd (see page 2352)	Creates a Windows control corresponding to the edit control.

	DestroyWnd (see page 2354)	Destroys the Windows control that corresponds to the edit control.
	DoSetMaxLength (see page 2354)	Sets the MaxLength (see page 2368) property.
	DoSetTextHint (see page 2355)	Sets the value of TextHint (see page 2380).
	GetCaretPos (see page 2448)	Returns the value of the CaretPos (see page 2450) property.
	GetSelLength (see page 2356)	Returns the SelLength (see page 2371) property.
	GetSelStart (see page 2356)	Returns the SelStart (see page 2374) property.
	GetSelText (see page 2356)	Returns the SelText (see page 2377) property.
	KeyPress (see page 2448)	Ensures that return characters are not entered into the text when WantReturns (see page 2454) is false.
	Loaded (see page 2448)	Initializes the memo control when it is first loaded into memory.
	SetAlignment (see page 2361)	Sets the Alignment (see page 2365) property.
	SetAutoSize (see page 2361)	Sets the AutoSize (see page 2366) property.
	SetCaretPos (see page 2449)	Sets the CaretPos (see page 2450) property.
	SetLines (see page 2449)	Sets the Lines (see page 2451) property.
	SetScrollBars (see page 2449)	Sets the ScrollBars (see page 2452) property.
	SetSelLength (see page 2361)	Sets the SelLength (see page 2371) property.
	SetSelStart (see page 2362)	Sets the SelStart (see page 2374) property.
	SetWordWrap (see page 2450)	Sets the WordWrap (see page 2455) property.

Protected Properties

	Name	Description
	AutoSelect (see page 2365)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 2366)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	NumbersOnly (see page 2369)	Allows only numbers to be typed into the text edit.
	PasswordChar (see page 2370)	Indicates the character, if any, to display in place of the actual characters typed in the control.

Public Methods

	Name	Description
	Clear (see page 2348)	Deletes all text from the edit control.
	ClearSelection (see page 2349)	Removes the selected text from the edit control.
	ClearUndo (see page 2349)	Clears the undo buffer so that no changes to the text can be backed out.
	CopyToClipboard (see page 2349)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
	Create (see page 2347)	Creates an instance of TCustomEdit (see page 2345).
	Create (see page 2446)	Creates and initializes an instance of TCustomMemo (see page 2443).
	CutToClipboard (see page 2352)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
	DefaultHandler (see page 2354)	Provides message handling for all messages that the control does not fully process itself.
	Destroy (see page 2446)	Destroys an instance of TCustomMemo (see page 2443).
	GetControlsAlignment (see page 2355)	Indicates how text is aligned within the control.
	GetSelTextBuf (see page 2357)	Copies the selected text into a buffer and returns the number of characters copied.
	PasteFromClipboard (see page 2358)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	SelectAll (see page 2359)	Selects all text in the edit control.
	SetSelText (see page 2362)	Sets the SelText (see page 2377) property.
	SetSelTextBuf (see page 2363)	Replaces the selected text with a null-terminated string.
	Undo (see page 2364)	Backs out all changes in the undo buffer.

Public Properties

	Name	Description
	CanUndo (see page 2367)	Indicates whether the edit control contains changes that can be backed out.
	CaretPos (see page 2450)	Indicates the position of the caret in the client area of the memo.
	Modified (see page 2369)	Indicates whether the user edited the text of the edit control.

	SelLength (see page 2371)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 2374)	Specifies the position of the first selected character in the text.
	SelText (see page 2377)	Specifies the selected portion of the edit control's text.
	Text (see page 2379)	Contains a text string associated with the control.
	TextHint (see page 2380)	A hint or message to be displayed when the Text (see page 2379) property is empty.

Published Events

	Name	Description
	OnChange (see page 2777)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2778)	Occurs when the user clicks the control.
	OnContextPopup (see page 2780)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2780)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2781)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2784)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2787)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2787)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2788)	Occurs when a control receives the input focus.
	OnExit (see page 2791)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2795)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2798)	Occurs when a key is pressed.
	OnKeyUp (see page 2799)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2801)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2802)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2804)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2805)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2805)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2807)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2809)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2810)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2741)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2745)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2745)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 2746)	Specifies which edges of the control are beveled.
	BevelInner (see page 2746)	Specifies the cut of the inner bevel.
	BevelKind (see page 2747)	Specifies the control's bevel style.
	BevelOuter (see page 2747)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2747)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2748)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2748)	Determines the case of the text within the edit control.
	Color (see page 2749)	Specifies the background color of the control.
	Constraints (see page 2749)	Specifies the size constraints for the control.
	Ctl3D (see page 2750)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

	DoubleBuffered (see page 2750)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2752)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2753)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2753)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2755)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2755)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2756)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2757)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2757)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Lines (see page 2758)	Contains the individual lines of text in the memo control.
	MaxLength (see page 2759)	Specifies the maximum number of characters the user can enter into the edit control.
	OEMConvert (see page 2759)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2760)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2760)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2761)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2761)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2761)	Determines where a control looks for its font information.
	ParentShowHint (see page 2762)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2762)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2767)	Determines whether the user can change the text of the edit control.
	ScrollBars (see page 2768)	Determines whether the memo control has scroll bars.
	ShowHint (see page 2770)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2771)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2772)	Determines if the user can tab to a control.
	Visible (see page 2772)	Determines whether the component appears onscreen.
	WantReturns (see page 2774)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2774)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2775)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

30.1.22.2 TMemo Properties

The properties of the TMemo class are listed here.

Published Properties

	Name	Description
	Align (see page 2741)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2745)	Determines how the text is aligned within the text edit control.
	Anchors (see page 2745)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 2746)	Specifies which edges of the control are beveled.
	BevelInner (see page 2746)	Specifies the cut of the inner bevel.
	BevelKind (see page 2747)	Specifies the control's bevel style.
	BevelOuter (see page 2747)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2747)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2748)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 2748)	Determines the case of the text within the edit control.
	Color (see page 2749)	Specifies the background color of the control.

	Constraints (see page 2749)	Specifies the size constraints for the control.
	Ctl3D (see page 2750)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2750)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2752)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2753)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2753)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2755)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2755)	Controls the attributes of text written on or in the control.
	HideSelection (see page 2756)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 2757)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2757)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Lines (see page 2758)	Contains the individual lines of text in the memo control.
	MaxLength (see page 2759)	Specifies the maximum number of characters the user can enter into the edit control.
	OEMConvert (see page 2759)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 2760)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2760)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2761)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2761)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2761)	Determines where a control looks for its font information.
	ParentShowHint (see page 2762)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2762)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 2767)	Determines whether the user can change the text of the edit control.
	ScrollBars (see page 2768)	Determines whether the memo control has scroll bars.
	ShowHint (see page 2770)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2771)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2772)	Determines if the user can tab to a control.
	Visible (see page 2772)	Determines whether the component appears onscreen.
	WantReturns (see page 2774)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 2774)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 2775)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

30.1.22.2.1 TMemo.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The

value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
```

```
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

30.1.22.2.2 TMemo.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

Displaying and Editing Fields in an Edit Box

30.1.22.2.3 TMemo.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

30.1.22.2.4 TMemo.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

30.1.22.2.5 TMemo.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

30.1.22.2.6 TMemo.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

30.1.22.2.7 TMemo.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

30.1.22.2.8 TMemo.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.22.2.9 TMemo.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

30.1.22.2.10 TMemo.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

30.1.22.2.11 TMemo.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

30.1.22.2.12 TMemo.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.22.2.13 TMemo.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

30.1.22.2.14 TMemo.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
```

```
  This code requires a list box and three labels, each with a
  different font and color.  The DragMode property for each of
  the labels is dmAutomatic.  The user can select a label and
  drag it to a list box and drop it. When the label is dropped,
  the items in the list box assume the color and font of the
  dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

30.1.22.2.15 TMemo.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.22.2.16 TMemo.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.22.2.17 TMemo.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
```

```
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

Arranging the Order of Persistent Columns

30.1.22.2.18 TMemo.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.22.2.19 TMemo.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
```

```
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

30.1.22.2.20 TMemo.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

30.1.22.2.21 TMemo.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ResetImeComposition

SetIme

SetImeCompositionWindow

30.1.22.2.22 TMemo.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

30.1.22.2.23 TMemo.Lines Property

Contains the individual lines of text in the memo control.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Use Lines to manipulate text in an memo control on a line-by-line basis. Lines is a TStrings object, so the TStrings methods may be used for Lines to perform manipulations such as counting the lines of text, adding new lines, deleting lines, or replacing lines with new text.

To work with all the text at once, use the Text property. To manipulate individual lines of text, the Lines property works better.

Note: Although Lines is implemented as a TStrings descendant, it does not implement the support for associating objects with the strings in the list.

C++ Examples:

```
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.LoadFromFile('readme.txt');
  Caption:= Memo1.Lines[4];
end;
```

30.1.22.2.24 TMemo.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

30.1.22.2.25 TMemo.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

Text

30.1.22.2.26 TMemo.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.22.2.27 TMemo.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.22.2.28 TMemo.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.22.2.29 TMemo.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.22.2.30 TMemo.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

30.1.22.2.31 TMemo.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.22.2.32 TMemo.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
```

```
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then

```

```
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

  type
    TForm1 = class(TForm)

OnContextPopup

30.1.22.2.33 TMemo.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

30.1.22.2.34 TMemo.ScrollBars Property

Determines whether the memo control has scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give a multiline edit control horizontal or vertical scroll bars. ScrollBars can take one of the following values:

Value	Meaning
ssNone	The control has no scroll bars.
ssHorizontal	The control has a single scroll bar on the bottom edge.
ssVertical	The control has a single scroll bar on the right edge.
ssBoth	The control has a scroll bar on both the bottom and right edges.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

Displaying and Editing Text in a Memo Control

30.1.22.2.35 TMemo.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
```

```
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

ShowHint

Displaying Fly-over Help

30.1.22.2.36 TMemo.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the

control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.22.2.37 TMemo.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

30.1.22.2.38 TMemo.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
```

```
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

30.1.22.2.39 TMemo.WantReturns Property

Determines whether the user can insert return characters into the text.

Pascal

```
property WantReturns: Boolean;
```

C++

```
__property Boolean WantReturns;
```

Description

Set WantReturns to true to allow users to enter return characters into the text. Set WantReturns to false to allow the form to handle return characters instead.

For example, in a form with a default button (such as an OK button) and a memo control, if WantReturns is false, pressing Enter chooses the default button. If WantReturns is true, pressing Enter inserts a return character in the text.

Note: If WantReturns is false, users can still enter return characters into the text by pressing Ctrl+Enter.

See Also

Text

WantTabs (see page 2454)

30.1.22.2.40 TMemo.WantTabs Property

Determines whether the user can insert tab characters into the text.

Pascal

```
property WantTabs: Boolean;
```

C++

```
__property Boolean WantTabs;
```

Description

Set WantTabs to true to allow users to enter tab characters into the text. Set WantTabs to false if you want the tab character to select the next control on the form instead.

Note: If WantTabs is true, users can tab into the edit control, but they can't tab out.

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

30.1.22.2.41 TMemo.WordWrap Property

Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to make the edit control wrap text at the right margin so it fits in the client area. The wrapping is cosmetic only. The text does not include any return characters that were not explicitly entered. Set WordWrap to false to have the edit control show a separate line only where return characters were explicitly entered into the text.

Note: There should be no use for a horizontal scroll bar if WordWrap is true.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.

Displaying and Editing Text in a Memo Control

30.1.22.3 TMemo Events

The events of the TMemo class are listed here.

Published Events

	Name	Description
	OnChange (see page 2777)	Occurs when the text for the edit control may have changed.
	OnClick (see page 2778)	Occurs when the user clicks the control.
	OnContextPopup (see page 2780)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2780)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2781)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2784)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2787)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2787)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2788)	Occurs when a control receives the input focus.
	OnExit (see page 2791)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2795)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2798)	Occurs when a key is pressed.
	OnKeyUp (see page 2799)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2801)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2802)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2804)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2805)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2805)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2807)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2809)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2810)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.22.3.1 TMemo.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 2348)

Text

30.1.22.3.2 TMemo.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The

30.1.22.3.3 TMemo.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

30.1.22.3.5 TMemo.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

30.1.22.3.6 TMemo.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

DragKind

30.1.22.3.9 TMemo.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

30.1.22.3.10 TMemo.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // initialize the maskedit boxes to contain the empty string
  MaskEdit1->Text = "";
```

```
    MaskEdit2->Text = "";
    MaskEdit3->Text = "";

    // use the Courier font in the maskedit boxes
    MaskEdit1->Font->Name = "Courier";
    MaskEdit2->Font->Name = "Courier";
    MaskEdit3->Font->Name = "Courier";

    // initialize the mask of each maskedit box
    // according to IP address coding conventions
    MaskEdit1->EditMask = "!099.099.099.099;1; ";
    MaskEdit2->EditMask = "!099.099.099.099;1; ";
    MaskEdit3->EditMask = "!099.099.099.099;1; ";

    MaskEdit2->OnExit = MaskEdit2Exit;
}

void __fastcall TForm1::MaskEdit2Exit(TObject *Sender)

    String IP = MaskEdit1->Text;
    int net1 = IP.SubString(0, 3).TrimRight().ToInt();
    int net2 = IP.SubString(5, 3).TrimRight().ToInt();
    int host1 = IP.SubString(9, 3).TrimRight().ToInt();
    int host2 = IP.SubString(13, 3).TrimRight().ToInt();

    // a range test that you cannot validate through edit masks
    if (net1 < 0 || net1 > 255 ||
        net2 < 0 || net2 > 255 ||
        host1 < 0 || host1 > 255 ||
        host2 < 0 || host2 > 255)
      throw(Exception("Not a valid IP address."));

    // extract the net and host mask from the subnet mask
    String mask = MaskEdit2->Text;
    int netmask1 = mask.SubString(0, 3).TrimRight().ToInt();
    int netmask2 = mask.SubString(5, 3).TrimRight().ToInt();
    int hostmask1 = mask.SubString(9, 3).TrimRight().ToInt();
    int hostmask2 = mask.SubString(13, 3).TrimRight().ToInt();

    // a range test that you cannot validate through edit masks
    if (netmask1 < 0 || netmask1 > 255 ||
        netmask2 < 0 || netmask2 > 255 ||
        hostmask1 < 0 || hostmask1 > 255 ||
        hostmask2 < 0 || hostmask2 > 255)
      throw(Exception("Not a valid subnet mask."));

    // compute the subnet address using bit-wise AND
    int sub_net1 = net1 & netmask1;
    int sub_net2 = net2 & netmask2;
    int sub_host1 = host1 & hostmask1;
    int sub_host2 = host2 & hostmask2;

    // display the subnet address
    MaskEdit3->Text =
      String(sub_net1) + "." + String(sub_net2) + "." +
      String(sub_host1) + "." + String(sub_host2);
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);

ActiveControl

30.1.22.3.11 TMemo.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

KeyPreview

OnKeyPress

OnKeyUp

30.1.22.3.12 TMemo.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII

character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

OnKeyDown

OnKeyPress

30.1.22.3.14 TMemo.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

30.1.22.3.15 TMemo.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
```

```
*/

    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
```

```
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

30.1.22.3.16 TMemo.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.22.3.17 TMemo.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.22.3.18 TMemo.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseUp

MouseCapture

30.1.22.3.19 TMemo.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

30.1.22.3.20 TMemo.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.22.3.21 TMemo.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.23 TPushButtonActionLink Class

TPushButtonActionLink is an action link designed specifically for button control clients.

Class Hierarchy

Pascal

```
TPushButtonActionLink = class(TButtonActionLink);
```

C++

```
class TPushButtonActionLink : public TButtonActionLink;
```

File

StdCtrls

Description

TPushButtonActionLink is designed to specifically link actions to button control clients. TPushButtonActionLink inherits from its ancestors support for linking actions with the properties of components, generic controls, and windowed controls. TPushButtonActionLink overrides methods to set the client's property that corresponds to the action's ImageIndex property.

See Also

TButton (see page 2035)

TButtonActionLink (see page 2106)

TPushButtonActionLinkClass (see page 3013)

30.1.23.1 TPushButtonActionLink Members

The following tables list the members exposed by TPushButtonActionLink.

Protected Fields

	Name	Description
	FClient (see page 2107)	Specifies a client control.

Protected Methods

	Name	Description
	AssignClient (see page 2108)	Assigns a client button that is linked to the associated action.
	IsCheckedLinked (see page 2108)	Indicates whether the checked state for the action and the client are linked.
	IsImageIndexLinked (see page 2812)	Indicates whether the image index for the action and the client are linked.
	SetChecked (see page 2108)	Sets the checked state of a button control if the client is linked to the action for this property.
	SetImageIndex (see page 2812)	Introduces an interface for setting the image index for a client.

30.1.23.2 TPushButtonActionLink Methods

The methods of the TPushButtonActionLink class are listed here.

Protected Methods

	Name	Description
	IsImageIndexLinked (see page 2812)	Indicates whether the image index for the action and the client are linked.
	SetImageIndex (see page 2812)	Introduces an interface for setting the image index for a client.

30.1.23.2.1 TPushButtonActionLink.IsImageIndexLinked Method

Indicates whether the image index for the action and the client are linked.

Pascal

```
function IsImageIndexLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsImageIndexLinked();
```

Description

TActionLink descendants call IsImageIndexLinked to determine whether they need to propagate changes to the ImageIndex property of the action so that they are reflected by the client object. When IsImageIndexLinked returns true, the action controls the ImageIndex property: Changes to the ImageIndex property of the action are reflected by changes to the corresponding property of the client object. When IsImageIndexLinked returns false, the client object does not reflect the ImageIndex property of its action, either because it does not have a corresponding property, or, more commonly, because it manages the value of its corresponding property independently.

As implemented in TActionLink, IsImageIndexLinked merely checks that the Action property specifies a descendant of TCustomAction (that is, it is an action that has an ImageIndex property). Descendant classes override IsImageIndexLinked to determine whether the ImageIndex property is linked with the appropriate client property.

See Also

ImageIndex

ImageIndex

SetImageIndex

Action

30.1.23.2.2 TPushButtonActionLink.SetImageIndex Method

Introduces an interface for setting the image index for a client.

Pascal

```
procedure SetImageIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetImageIndex(int Value);
```

Description

The associated action calls SetImageIndex when its ImageIndex property changes so that the action link can propagate the new ImageIndex value to the client object.

Value specifies the new value of the ImageIndex property.

As implemented in TActionLink, SetImageIndex does nothing. Descendant classes override SetImageIndex to set the client property that corresponds to the action's ImageIndex property if the IsImageIndexLinked method returns true.

30.1.24 TRadioButton Class

TRadioButton is a wrapper for a system radio button.

Class Hierarchy

Pascal

```
TRadioButton = class(TButtonControl);
```

C++

```
class TRadioButton : public TButtonControl;
```

File

StdCtrls

Description

Use TRadioButton to add a radio button to a form. Radio buttons present a set of mutually exclusive options to the user- that is, only one radio button in a set can be selected at a time. When the user selects a radio button, the previously selected radio button becomes unselected. Radio buttons are frequently grouped in a radio group box (TGroupBox (see page 2535)). Add the group box to the form first, then get the radio buttons from the Component palette and put them into the group box. Or you can add a TRadioGroup, a group that already has radio buttons in it, so that you do not have to get the buttons from the Tool Palette.

By default, all radio buttons that are directly contained in the same windowed control container, such as a TRadioGroup or TPanel, are grouped. For example, two radio buttons on a form can be checked at the same time only if they are contained in separate containers, such as two different group boxes.

Radio Buttons

30.1.24.1 TRadioButton Members

The following tables list the members exposed by TRadioButton.

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2816)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2816)	Creates the underlying window.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2817)	Returns whether the button control is checked.
	SetChecked (see page 2817)	Sets the Checked property.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.

Public Methods

	Name	Description
	Create (see page 2815)	Creates an instance of TRadioButton (see page 2813).
	GetControlsAlignment (see page 2817)	Returns the alignment of any text in the control.

Published Events

	Name	Description
	OnClick (see page 2848)	Occurs when the user clicks the control.
	OnContextPopup (see page 2849)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2850)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2850)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2853)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2857)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2857)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2858)	Occurs when a control receives the input focus.
	OnExit (see page 2861)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2865)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2868)	Occurs when a key is pressed.
	OnKeyUp (see page 2869)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2871)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2872)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2874)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2874)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2875)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2877)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2879)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2880)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Action (see page 2818)	Designates the action associated with the control.
	Align (see page 2820)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2823)	Determines the position of the caption relative to the radio button.
	Anchors (see page 2823)	Specifies how the control is anchored to its parent.

	BiDiMode (see page 2824)	Specifies the bi-directional mode for the control.
	Caption (see page 2824)	Specifies a text string that identifies the control to the user.
	Checked (see page 2827)	Determines whether the option represented by the radio button is selected.
	Color (see page 2827)	Specifies the background color of the control.
	Constraints (see page 2828)	Specifies the size constraints for the control.
	Ctl3D (see page 2829)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2829)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2831)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2831)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2832)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2833)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2834)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2835)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2835)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2836)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2836)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2837)	Determines where a control looks for its font information.
	ParentShowHint (see page 2837)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2838)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2843)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2844)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2845)	Determines if the user can tab to a control.
	Visible (see page 2845)	Determines whether the component appears onscreen.
	WordWrap (see page 2847)	Specifies whether the button text wraps to fit the width of the control.

30.1.24.2 TRadioButton.Create Constructor

Creates an instance of TRadioButton (see page 2813).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRadioButton(TComponent * AOwner);
```

Description

Call Create to instantiate a radio button at runtime. Radio buttons added to forms at design time are created automatically.

AOwner is the component, typically a form, that becomes the value of the Owner property. The Owner is responsible for freeing the radio button object.

Owner

30.1.24.3 TRadioButton Methods

The methods of the TRadioButton class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 2816)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2816)	Creates the underlying window.
	GetChecked (see page 2817)	Returns whether the button control is checked.
	SetChecked (see page 2817)	Sets the Checked property.

Public Methods

	Name	Description
	GetControlsAlignment (see page 2817)	Returns the alignment of any text in the control.

30.1.24.3.1 TRadioButton.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

30.1.24.3.2 TRadioButton.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

30.1.24.3.3 TRadioButton.GetChecked Method

Returns whether the button control is checked.

Pascal

```
function GetChecked: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetChecked();
```

Description

GetChecked is the read implementation of the Checked property.

See Also

Checked (see page 2113)

30.1.24.3.4 TRadioButton.GetControlsAlignment Method

Returns the alignment of any text in the control.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the orientation of text in controls that do not have an Alignment (see page 2823) property.

GetControlsAlignment overrides the inherited method, returning taRightJustify if UseRightToLeftAlignment returns false. If UseRightToLeftAlignment returns true, GetControlsAlignment returns the opposite of the Alignment (see page 2823) property.

30.1.24.3.5 TRadioButton.SetChecked Method

Sets the Checked property.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked is the write implementer for the Checked property.

Checked (see page 2113)

30.1.24.4 TRadioButton Properties

The properties of the TRadioButton class are listed here.

Published Properties

	Name	Description
	Action (see page 2818)	Designates the action associated with the control.
	Align (see page 2820)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2823)	Determines the position of the caption relative to the radio button.
	Anchors (see page 2823)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2824)	Specifies the bi-directional mode for the control.
	Caption (see page 2824)	Specifies a text string that identifies the control to the user.
	Checked (see page 2827)	Determines whether the option represented by the radio button is selected.
	Color (see page 2827)	Specifies the background color of the control.
	Constraints (see page 2828)	Specifies the size constraints for the control.
	Ctl3D (see page 2829)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2829)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2831)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2831)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2832)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2833)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2834)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2835)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2835)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2836)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2836)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2837)	Determines where a control looks for its font information.
	ParentShowHint (see page 2837)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2838)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2843)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2844)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2845)	Determines if the user can tab to a control.
	Visible (see page 2845)	Determines whether the component appears onscreen.
	WordWrap (see page 2847)	Specifies whether the button text wraps to fit the width of the control.

30.1.24.4.1 TRadioButton.Action Property

Designates the action associated with the control.

Pascal

```
property Action;
```

C++

```
__property Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

C++ Examples:

```
/*
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
*/
void __fastcall TForm1::ChangeColor(TObject *Sender)
{
  // randomly change the color of the form
  Color = Random(0xFFFF);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // allocate memory for the Action property
  Action = new TBasicAction(this);

  // set the OnExecute event handler
  Action->OnExecute = ChangeColor;

  // initialize the random number generator
  Randomize();
}
```

Delphi Examples:

```
{
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
}
procedure TForm1.ChangeColor(Sender: TObject);
begin
  { randomly change the color of the form }
  Color := Random($FFFF);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { allocate memory for the Action property }
  Action := TBasicAction.Create(Self);

  { set the OnExecute event handler }
  Action.OnExecute := ChangeColor;

  { initialize the random number generator }
  Randomize;
end;
```

30.1.24.4.2 TRadioButton.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

Anchors

30.1.24.4.3 TRadioButton.Alignment Property

Determines the position of the caption relative to the radio button.

Pascal

```
property Alignment: TLeftRight;
```

C++

```
__property TLeftRight Alignment;
```

Description

Set Alignment to determine whether the caption of the radio button should appear to the left of the radio button (taLeftJustify) or to the right of the radio button (taRightJustify).

Note: Do not confuse the Alignment property with the alignment of the caption in the text area of the radio button. The caption always appears left aligned. Alignment only controls on which side of the button the text area appears.

See Also

Caption

30.1.24.4.4 TRadioButton.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.24.4.5 TRadioButton.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

30.1.24.4.6 TRadioButton.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
```

```
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
```

```
    for I := 0 to High(ButtonCaptions) do
      begin
        with TToolButton.Create(ToolBar) do
        begin
          Parent := ToolBar;
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
    ToolBar1.Free;
  end;
```

30.1.24.4.7 TRadioButton.Checked Property

Determines whether the option represented by the radio button is selected.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Read (see page 3634) Checked to determine whether the radio button is selected. Set Checked to true to select the radio button and deselect all other radio buttons in the same container. Set Checked to false to deselect the radio button, leaving no radio button in the group selected.

TRadioGroup

30.1.24.4.8 TRadioButton.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

30.1.24.4.9 TRadioButton.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.24.4.10 TRadioButton.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

30.1.24.4.11 TRadioButton.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
```

```
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

30.1.24.4.12 TRadioButton.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.24.4.13 TRadioButton.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.24.4.14 TRadioButton.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

30.1.24.4.15 TRadioButton.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.24.4.16 TRadioButton.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
```

```
  TMemo on a form.  During form creation, a list of font names
  is loaded into the combo box. When the combo box is clicked,
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i : Integer;
  begin
    for i := 0 to Screen.Fonts.Count - 1 do
     ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
  //  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
    RichEdit1.Lines.Text := 'How is it to be you?';
  end;

  procedure TForm1.ComboBox1Click(Sender: TObject);
  begin
    RichEdit1.Font.Name := ComboBox1.Text;
  end;
```

Displaying and Editing Text in a Memo Control

30.1.24.4.17 TRadioButton.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.24.4.18 TRadioButton.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.24.4.19 TRadioButton.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.24.4.20 TRadioButton.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.24.4.21 TRadioButton.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

30.1.24.4.22 TRadioButton.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.24.4.23 TRadioButton.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

30.1.24.4.24 TRadioButton.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.24.4.25 TRadioButton.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

30.1.24.4.26 TRadioButton.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.24.4.27 TRadioButton.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;

30.1.24.4.28 TRadioButton.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

30.1.24.5 TRadioButton Events

The events of the TRadioButton class are listed here.

Published Events

	Name	Description
	OnClick (see page 2848)	Occurs when the user clicks the control.
	OnContextPopup (see page 2849)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2850)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2850)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2853)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2857)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2857)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2858)	Occurs when a control receives the input focus.
	OnExit (see page 2861)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2865)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2868)	Occurs when a key is pressed.
	OnKeyUp (see page 2869)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2871)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2872)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2874)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2874)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2875)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2877)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2879)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2880)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.24.5.1 TRadioButton.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

30.1.24.5.2 TRadioButton.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

OnClick

Responding to User Actions at Runtime

30.1.24.5.4 TRadioButton.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");

TDragObject

30.1.24.5.5 TRadioButton.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
```

```
  }
}
```

Delphi Examples:

```
{

DragKind

30.1.24.5.8 TRadioButton.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/

30.1.24.5.9 TRadioButton.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/

OnEnter

ActiveControl

30.1.24.5.10 TRadioButton.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).

OnKeyPress

OnKeyUp

30.1.24.5.11 TRadioButton.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyUp

KeyPreview

30.1.24.5.12 TRadioButton.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

OnKeyDown

OnKeyPress

30.1.24.5.13 TRadioButton.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control.

However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

30.1.24.5.14 TRadioButton.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
```

```
}

// Use this code as the OnMouseUp event handler of the form:

30.1.24.5.15 TRadioButton.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.24.5.16 TRadioButton.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.24.5.17 TRadioButton.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;
```

```
procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;
```

30.1.24.5.19 TRadioButton.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.24.5.20 TRadioButton.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.25 TScrollBar Class

TScrollBar is a Windows scroll bar, which is used to scroll the contents of a window, form, or control.

Class Hierarchy

Pascal

```
TScrollBar = class(TWinControl);
```

C++

```
class TScrollBar : public TWinControl;
```

File

StdCtrls

Description

Use TScrollBar to add a free-standing scroll bar to a form. Many controls have properties that add scroll bars which are an integral part of the control (TControlScrollBar objects). TScrollBar allows controls that do not have integrated scroll bars or groupings of controls to be scrolled when the user manipulates the TScrollBar object.

When the bi-directional mode of a scroll bar is changed, its coordinate system is reversed. Position (see page 2912) zero in left-to-right mode is the left side, and position zero in right-to-left mode is the right side.

Specialized Input Controls

30.1.25.1 TScrollBar Members

The following tables list the members exposed by TScrollBar.

Protected Methods

	Name	Description
	Change (see page 2883)	Called when the Position (see page 2912) property changes.
V	CreateParams (see page 2884)	Initializes a window-creation parameter data structure.
V	CreateWnd (see page 2884)	Creates the underlying window.
	Scroll (see page 2885)	Triggers an `OnScroll` (see page 2942) event with the given `ScrollCode` parameter and updates the `ScrollPos` variable that is passed.

Public Methods

	Name	Description
V	Create (see page 2883)	Creates and initializes an instance of TScrollBar (see page 2881).
	SetParams (see page 2885)	Sets the Position (see page 2912), Max (see page 2900), and Min (see page 2901) property values all at once.

Published Events

	Name	Description
	OnChange (see page 2920)	Occurs immediately after the value of Position (see page 2912) changes.
	OnContextPopup (see page 2920)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2921)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2924)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2927)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2928)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2929)	Occurs when a control receives the input focus.
	OnExit (see page 2931)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2935)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2939)	Occurs when a key is pressed.
	OnKeyUp (see page 2940)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 2942)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2942)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 2942)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 2944)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2944)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2886)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2890)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2890)	Specifies the bi-directional mode for the control.
	Constraints (see page 2891)	Specifies the size constraints for the control.
	Ctl3D (see page 2892)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2892)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2894)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2894)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2895)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2896)	Controls whether the control responds to mouse, keyboard, and timer events.
	Kind (see page 2897)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 2898)	Determines how much Position (see page 2912) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Max (see page 2900)	Specifies the maximum position represented by the scroll bar.
	Min (see page 2901)	Specifies the minimum position represented by the scroll bar.
	PageSize (see page 2903)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 2905)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 2905)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2906)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 2906)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2907)	Identifies the pop-up menu associated with the control.
	Position (see page 2912)	Indicates the current position of the scroll bar.
	ShowHint (see page 2914)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 2915)	Determines how much Position (see page 2912) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 2917)	Indicates the position of the control in its parent's tab order.

	TabStop (see page 2918)	Determines if the user can tab to a control.
	Visible (see page 2918)	Determines whether the component appears onscreen.

30.1.25.2 TScrollBar.Create Constructor

Creates and initializes an instance of TScrollBar (see page 2881).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScrollBar(TComponent * AOwner);
```

Description

Call Create to create an instance of TScrollBar (see page 2881) at runtime. Scroll (see page 2885) bars placed on a form at design time are created automatically.

AOwner is the component that is responsible for freeing the scroll bar. This becomes the value of the Owner property.

Owner

30.1.25.3 TScrollBar Methods

The methods of the TScrollBar class are listed here.

Protected Methods

	Name	Description
	Change (see page 2883)	Called when the Position (see page 2912) property changes.
V	CreateParams (see page 2884)	Initializes a window-creation parameter data structure.
V	CreateWnd (see page 2884)	Creates the underlying window.
	Scroll (see page 2885)	Triggers an `OnScroll` (see page 2942) event with the given `ScrollCode` parameter and updates the `ScrollPos` variable that is passed.

Public Methods

	Name	Description
	SetParams (see page 2885)	Sets the Position (see page 2912), Max (see page 2900), and Min (see page 2901) property values all at once.

30.1.25.3.1 TScrollBar.Change Method

Called when the Position (see page 2912) property changes.

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

Override Change in a derived class to perform actions when the Position (see page 2912) of the scroll bar changes.

By default, Change calls the OnChange (see page 2920) event handler.

See Also

OnChange (see page 2920)

Position (see page 2912)

30.1.25.3.2 TScrollBar.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

30.1.25.3.3 TScrollBar.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

30.1.25.3.4 TScrollBar.Scroll Method

Triggers an `OnScroll` (see page 2942) event with the given `ScrollCode` parameter and updates the `ScrollPos` variable that is passed.

Pascal

```
procedure Scroll(ScrollCode: TScrollCode; var ScrollPos: Integer); dynamic;
```

C++

```
__fastcall Scroll(TScrollCode ScrollCode, int ScrollPos);
```

Description

Scroll is a protected routine in the TScrollBar (see page 2881) class that is used to trigger an `OnScroll` (see page 2942) event, with the given `ScrollCode` parameter.

Scroll also updates the value of the `ScrollPos` variable that is passed.

The following table gives the possible values for the `ScrollCode` parameter.

Value	Meaning
scLineUp	User clicked the top or left scroll arrow or pressed the Up or Left arrow key.
scLineDown	User clicked the bottom or right scroll arrow or pressed the Down or Right arrow key.
scPageUp	User clicked the area to the left of the thumb tab or pressed the PgUp key.
scPageDown	User clicked the area to the right of the thumb tab or pressed the PgDn key.
scPosition	User positioned the thumb tab and released it.
scTrack	User is moving the thumb tab.
scTop	User moved the thumb tab to the top or leftmost on the scroll bar.
scBottom	User moved the thumb tab to the bottom or rightmost on the scroll bar.
scEndScroll	User finished moving the thumb tab on the scroll bar.

See Also

OnScroll (see page 2942)

TScrollCode (see page 3004)

30.1.25.3.5 TScrollBar.SetParams Method

Sets the Position (see page 2912), Max (see page 2900), and Min (see page 2901) property values all at once.

Pascal

```
procedure SetParams(APosition: Integer; AMin: Integer; AMax: Integer);
```

C++

```
__fastcall SetParams(int APosition, int AMin, int AMax);
```

Description

Use the SetParams method to set the Position (see page 2912), Min (see page 2901), and Max (see page 2900) property values all at once, preventing repaints that would occur if each property value were set separately.

See Also

Max (see page 2900)

Min (see page 2901)

Position (see page 2912)

30.1.25.4 TScrollBar Properties

The properties of the TScrollBar class are listed here.

Published Properties

	Name	Description
	Align (see page 2886)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2890)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2890)	Specifies the bi-directional mode for the control.
	Constraints (see page 2891)	Specifies the size constraints for the control.
	Ctl3D (see page 2892)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2892)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2894)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2894)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2895)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2896)	Controls whether the control responds to mouse, keyboard, and timer events.
	Kind (see page 2897)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 2898)	Determines how much Position (see page 2912) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Max (see page 2900)	Specifies the maximum position represented by the scroll bar.
	Min (see page 2901)	Specifies the minimum position represented by the scroll bar.
	PageSize (see page 2903)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 2905)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 2905)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2906)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 2906)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2907)	Identifies the pop-up menu associated with the control.
	Position (see page 2912)	Indicates the current position of the scroll bar.
	ShowHint (see page 2914)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 2915)	Determines how much Position (see page 2912) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 2917)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2918)	Determines if the user can tab to a control.
	Visible (see page 2918)	Determines whether the component appears onscreen.

30.1.25.4.1 TScrollBar.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
```

```
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.

Parent

Anchors

30.1.25.4.2 TScrollBar.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.25.4.3 TScrollBar.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.25.4.4 TScrollBar.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.25.4.5 TScrollBar.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

30.1.25.4.6 TScrollBar.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
```

```
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

30.1.25.4.7 TScrollBar.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.25.4.8 TScrollBar.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.25.4.9 TScrollBar.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);

30.1.25.4.10 TScrollBar.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.25.4.11 TScrollBar.Kind Property

Specifies whether the scroll bar is horizontal or vertical.

Pascal

```
property Kind: TScrollBarKind;
```

C++

```
__property TScrollBarKind Kind;
```

Description

Set Kind to indicate the orientation of the scroll bar. These are the possible values:

Value	Meaning
sbHorizontal	Scroll (see page 2885) bar is horizontal
sbVertical	Scroll (see page 2885) bar is vertical

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
```

```
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

30.1.25.4.12 TScrollBar.LargeChange Property

Determines how much Position (see page 2912) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.

Pascal

```
property LargeChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc LargeChange;
```

Description

Set LargeChange to specify how much to change the value of Position (see page 2912) when the user clicks on the side of the thumb tab (that is, on the thumb tab track, but not on the thumb tab itself). The Max (see page 2900) and Min (see page 2901) properties define the total range over which Position (see page 2912) can vary.

For example, if Max (see page 2900) is 30000 and Min (see page 2901) is 0, the scroll box can assume 30,000 positions. If the LargeChange property setting is 10000 and the Position (see page 2912) property is 0, the user can click the scroll bar track three times after the thumb tab before it moves all the way to the end of the scroll bar (30000 / 10000 = 3).

LargeChange should correspond to the portion of this range that the user sees in one page or screen, expressed in the logical units used by the Max (see page 2900), Min (see page 2901), and Position (see page 2912) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

30.1.25.4.15 TScrollBar.PageSize Property

Specifies the size of the thumb tab.

Pascal

```
property PageSize: Integer;
```

C++

```
__property int PageSize;
```

Description

PageSize is the size of the thumb tab, measured in the same units as Position (see page 2912), Min (see page 2901), and Max (see page 2900) (not pixels).

C++ Examples:

```
/*
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
*/
void __fastcall SetThumbTab()
{
  // Get the minimum (default) size of the thumb tab
  int MinHeight = GetSystemMetrics(SM_CYVTHUMB);
  // Get the size of the scrollbar track
  int TrackHeight = Form1->ScrollBar1->ClientHeight - 2*GetSystemMetrics(SM_CYVSCROLL);
  // set PageSize to represent the visible portion of the scrolling range:
  Form1->ScrollBar1->PageSize = TrackHeight/(Form1->ScrollBar1->Max - Form1->ScrollBar1->Min +
1);
  // Don't let the thumb tab get too small
  if (Form1->ScrollBar1->PageSize < MinHeight)
  Form1->ScrollBar1->PageSize = MinHeight;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::ScrollBar1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1EndDrag(TObject *Sender, TObject *Target,
      int X, int Y)
{
 SetThumbTab();
}
```

Delphi Examples:

```
{
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
}
procedure SetThumbTab(wincontrol: TWinControl);
var
  TrackHeight: Integer; { the size of the scroll bar track }
  MinHeight: Integer; { the default size of the thumb tab }
begin
  MinHeight := GetSystemMetrics(SM_CYVTHUMB); { save default size }
  with Form1.ScrollBar1 do
  begin
    TrackHeight := wincontrol.ClientHeight - 2 * GetSystemMetrics(SM_CYVSCROLL);
```

```
      PageSize := TrackHeight div (Max - Min + 1);
      if PageSize < MinHeight then PageSize := MinHeight;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const
    Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    SetThumbTab(RichEdit1);
  end;
  procedure TForm1.RichEdit1Change(Sender: TObject);
  begin
    SetThumbTab(RichEdit1);
  end;
```

30.1.25.4.16 TScrollBar.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

BiDiMode

30.1.25.4.17 TScrollBar.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.25.4.18 TScrollBar.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.25.4.19 TScrollBar.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.25.4.20 TScrollBar.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
```

```
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.

30.1.25.4.21 TScrollBar.Position Property

Indicates the current position of the scroll bar.

Pascal

```
property Position: Integer;
```

C++

```
__property int Position;
```

Description

Read (see page 3634) Position to determine the current position of the thumb tab. This value can be used to determine how to scroll any components controlled by the scroll bar. When the user scrolls the scroll bar, the value of Position changes. Set Position to programmatically move the thumb tab of the scroll bar.

The number of possible positions on the scroll bar is determined by the difference between the Max (see page 2900) property and the Min (see page 2901) property. If Position has the same value as Min (see page 2901), the thumb tab appears at the far left of a horizontal scroll bar or the top of a vertical scroll bar. If Position has the same value as Max (see page 2900), the thumb tab appears at the far right of a horizontal scroll bar or the bottom of a vertical scroll bar.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];

30.1.25.4.22 TScrollBar.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.25.4.23 TScrollBar.SmallChange Property

Determines how much Position (see page 2912) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.

Pascal

```
property SmallChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc SmallChange;
```

Description

Set SmallChange to specify how much to change the value of Position (see page 2912) when the user clicks on the arrow buttons. The Max (see page 2900) and Min (see page 2901) properties define the total range over which Position (see page 2912) can vary.

For example, if Max (see page 2900) is 100 and Min (see page 2901) is 0, the scroll box can assume 100 positions. If the SmallChange property setting is 5 and the Position (see page 2912) property is 0, the user can click the down or right arrow button 20 times before the thumb tab is moved all the way to the end of the scroll bar.

SmallChange should correspond to the portion of this range that the user sees as one line or one item, expressed in the logical units used by the Max (see page 2900), Min (see page 2901), and Position (see page 2912) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
```

```
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];
  for (int i = 0; i < PageControl1->PageCount; i++)
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
  /* set up the scrollbar to reflect
     the structure of the page control */
  ScrollBar1->Max = PageControl1->PageCount - 1;
  ScrollBar1->Min = 0;
  ScrollBar1->SmallChange = 1;
  // set LargeChange to a single row of tabs
  ScrollBar1->LargeChange = PageControl1->ClientWidth / PageControl1->TabWidth;
}

30.1.25.4.24 TScrollBar.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

30.1.25.4.25 TScrollBar.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.25.4.26 TScrollBar.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)

30.1.25.5 TScrollBar Events

The events of the TScrollBar class are listed here.

Published Events

	Name	Description
	OnChange (see page 2920)	Occurs immediately after the value of Position (see page 2912) changes.
	OnContextPopup (see page 2920)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2921)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2924)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2927)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2928)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2929)	Occurs when a control receives the input focus.
	OnExit (see page 2931)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2935)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2939)	Occurs when a key is pressed.
	OnKeyUp (see page 2940)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 2942)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2942)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 2942)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 2944)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2944)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.25.5.1 TScrollBar.OnChange Event

Occurs immediately after the value of Position (see page 2912) changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write (see page 3707) an OnChange event handler to control another object or group of objects using TScrollBar (see page 2881). Adjust the objects controlled by the scroll bar to reflect the new value of Position (see page 2912).

OnChange occurs whether the value of Position (see page 2912) is changed by the user or programmatically. If the value of Position (see page 2912) is changed by the user, OnChange occurs immediately after the OnScroll (see page 2942) event.

See Also

OnScroll (see page 2942)

Position (see page 2912)

30.1.25.5.2 TScrollBar.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu

AutoPopup

30.1.25.5.3 TScrollBar.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)
```

```
{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*

TDragObject

30.1.25.5.4 TScrollBar.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

OnStartDock

30.1.25.5.6 TScrollBar.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

30.1.25.5.7 TScrollBar.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------

30.1.25.5.8 TScrollBar.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK

button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/

OnEnter

ActiveControl

30.1.25.5.9 TScrollBar.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

30.1.25.5.10 TScrollBar.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
```

```
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyUp

KeyPreview

30.1.25.5.11 TScrollBar.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
```

```
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin

OnKeyDown

OnKeyPress

30.1.25.5.12 TScrollBar.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.25.5.13 TScrollBar.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.25.5.14 TScrollBar.OnScroll Event

Occurs when the user scrolls the scroll bar with the mouse or keyboard.

Pascal

```
property OnScroll: TScrollEvent;
```

C++

```
__property TScrollEvent OnScroll;
```

Description

Write (see page 3707) an OnScroll to alter the way the scrollbar adjusts its position when the user scrolls the scroll bar.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;

30.1.25.5.15 TScrollBar.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.25.5.16 TScrollBar.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse

button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.26 TStaticText Class

TStaticText is a windowed control that displays text on a form.

Class Hierarchy

Pascal

```
TStaticText = class(TCustomStaticText);
```

C++

```
class TStaticText : public TCustomStaticText;
```

File

StdCtrls

Description

The TStaticText component functions like TLabel (see page 2607), except that it descends from TWinControl and therefore has a window handle. Use TStaticText instead of TLabel (see page 2607) when the component's accelerator key must belong

to a windowed control—for example, on an ActiveX property page.

Display Controls

30.1.26.1 TStaticText Members

The following tables list the members exposed by TStaticText.

Protected Methods

	Name	Description
	CreateParams (see page 2459)	Initializes a window-creation parameter data structure.
	Loaded (see page 2459)	Initializes the control after it is loaded from a stream.
	Notification (see page 2460)	Responds to notifications that components are being created or destroyed.
	SetAutoSize (see page 2460)	Sets the value of the AutoSize property.

Public Methods

	Name	Description
	Create (see page 2458)	Creates and initializes a TCustomStaticText (see page 2457) instance.

Published Events

	Name	Description
	OnClick (see page 2978)	Occurs when the user clicks the control.
	OnContextPopup (see page 2980)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2980)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2981)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2984)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2987)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2987)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2988)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2989)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2991)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2992)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2992)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2994)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2996)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2997)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2948)	Determines how the control aligns within its container (parent control).

	Alignment (see page 2951)	Determines how text is aligned within the component.
	Anchors (see page 2952)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2952)	Determines whether the component is automatically resized to accommodate its text.
	BevelEdges (see page 2953)	Specifies which edges of the control are beveled.
	BevelInner (see page 2953)	Specifies the cut of the inner bevel.
	BevelKind (see page 2954)	Specifies the control's bevel style.
	BevelOuter (see page 2954)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2954)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2955)	Determines the appearance of the control's border.
	Caption (see page 2955)	Specifies a text string that identifies the control to the user.
	Color (see page 2958)	Specifies the background color of the control.
	Constraints (see page 2959)	Specifies the size constraints for the control.
	DoubleBuffered (see page 2959)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2961)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2961)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2962)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2963)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2964)	Links the component with another windowed control.
	Font (see page 2964)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2965)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2966)	Determines where a control looks for its color information.
	ParentDoubleBuffered (see page 2966)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2966)	Determines where a control looks for its font information.
	ParentShowHint (see page 2967)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2968)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2973)	Enables accelerator characters.
	ShowHint (see page 2973)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2974)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2975)	Determines if the user can tab to a control.
	Transparent (see page 2975)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 2976)	Determines whether the component appears onscreen.

30.1.26.2 TStaticText Properties

The properties of the TStaticText class are listed here.

Published Properties

	Name	Description
	Align (see page 2948)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2951)	Determines how text is aligned within the component.
	Anchors (see page 2952)	Specifies how the control is anchored to its parent.
	AutoSize (see page 2952)	Determines whether the component is automatically resized to accommodate its text.
	BevelEdges (see page 2953)	Specifies which edges of the control are beveled.
	BevelInner (see page 2953)	Specifies the cut of the inner bevel.
	BevelKind (see page 2954)	Specifies the control's bevel style.
	BevelOuter (see page 2954)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2954)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2955)	Determines the appearance of the control's border.

	Caption (see page 2955)	Specifies a text string that identifies the control to the user.
	Color (see page 2958)	Specifies the background color of the control.
	Constraints (see page 2959)	Specifies the size constraints for the control.
	DoubleBuffered (see page 2959)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2961)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2961)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2962)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2963)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 2964)	Links the component with another windowed control.
	Font (see page 2964)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2965)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2966)	Determines where a control looks for its color information.
	ParentDoubleBuffered (see page 2966)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2966)	Determines where a control looks for its font information.
	ParentShowHint (see page 2967)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2968)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 2973)	Enables accelerator characters.
	ShowHint (see page 2973)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2974)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2975)	Determines if the user can tab to a control.
	Transparent (see page 2975)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 2976)	Determines whether the component appears onscreen.

30.1.26.2.1 TStaticText.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of

the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
```

```
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;

30.1.26.2.2 TStaticText.Alignment Property

Determines how text is aligned within the component.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

The possible values of Alignment are

Value	Meaning
taLeftJustify	Text is aligned at the left of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is aligned at the right of the control.

See Also

Font

Caption

30.1.26.2.3 TStaticText.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.26.2.4 TStaticText.AutoSize Property

Determines whether the component is automatically resized to accommodate its text.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

If AutoSize is true, the component is automatically resized— at runtime and design time— whenever the font size or Caption text changes.

Caption

Font

30.1.26.2.5 TStaticText.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

30.1.26.2.6 TStaticText.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

30.1.26.2.7 TStaticText.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

30.1.26.2.8 TStaticText.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

BevelWidth

30.1.26.2.9 TStaticText.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.26.2.10 TStaticText.BorderStyle Property

Determines the appearance of the control's border.

Pascal

```
property BorderStyle: TStaticBorderStyle;
```

C++

```
__property TStaticBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify the appearance of the border, if any, that appears around the text.

30.1.26.2.11 TStaticText.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is

used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());
```

```
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.26.2.12 TStaticText.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
```

```
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

30.1.26.2.13 TStaticText.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

30.1.26.2.14 TStaticText.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

30.1.26.2.15 TStaticText.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.26.2.16 TStaticText.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.26.2.17 TStaticText.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;

Arranging the Order of Persistent Columns

30.1.26.2.18 TStaticText.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled

controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.26.2.19 TStaticText.FocusControl Property

Links the component with another windowed control.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Use the FocusControl property to link the TCustomStaticText instance with another windowed control. If the text of Caption includes an accelerator key, the component specified by FocusControl receives focus when the accelerator is pressed.

30.1.26.2.20 TStaticText.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
```

```
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  */
  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    for (int i = 0; i < Screen->Fonts->Count; i++)
     ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
  //  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
  }

  void __fastcall TForm1::ComboBox1Change(TObject *Sender)
  {
    RichEdit1->Font->Name = ComboBox1->Text;
  }
```

Delphi Examples:

```
  {
  To use this example, place a TComboBox and TRichEdit or
  TMemo on a form.  During form creation, a list of font names
  is loaded into the combo box. When the combo box is clicked,
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i : Integer;
  begin
    for i := 0 to Screen.Fonts.Count - 1 do
     ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
  //  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
    RichEdit1.Lines.Text := 'How is it to be you?';
  end;

  procedure TForm1.ComboBox1Click(Sender: TObject);
  begin
    RichEdit1.Font.Name := ComboBox1.Text;
  end;
```

Displaying and Editing Text in a Memo Control

30.1.26.2.21 TStaticText.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

30.1.26.2.22 TStaticText.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

30.1.26.2.23 TStaticText.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.26.2.24 TStaticText.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

30.1.26.2.25 TStaticText.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.26.2.26 TStaticText.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)

    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

30.1.26.2.27 TStaticText.ShowAccelChar Property

Enables accelerator characters.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

If ShowAccelChar is true, an ampersand in the component's Caption text appears as an underline and makes the character after it into an accelerator key. If ShowAccelChar is false, ampersands appear as ampersands.

Caption

30.1.26.2.28 TStaticText.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
```

```
      strcpy(string, "Item");
      itoa(i, index, 10);
      strcat(string, index);
      ListBox1->Items->Add(string);
    }
    ListBox1->Hint = "Select an item";
    ListBox1->ShowHint = true;
    Application->ShowHint = true;
  }
  /*
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  */
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

30.1.26.2.29 TStaticText.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.26.2.30 TStaticText.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.26.2.31 TStaticText.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TCustomStaticText object to show through the background of the image. Set Transparent to false to make the background of the image opaque.

30.1.26.2.32 TStaticText.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/

30.1.26.3 TStaticText Events

The events of the TStaticText class are listed here.

Published Events

	Name	Description
	OnClick (see page 2978)	Occurs when the user clicks the control.
	OnContextPopup (see page 2980)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2980)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2981)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2984)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2987)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2987)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 2988)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2989)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2991)	Occurs when the user moves the mouse into a control.

	OnMouseLeave (see page 2992)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2992)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2994)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2996)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2997)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.26.3.1 TStaticText.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin

30.1.26.3.2 TStaticText.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

30.1.26.3.3 TStaticText.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

30.1.26.3.4 TStaticText.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{

30.1.26.3.5 TStaticText.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

30.1.26.3.8 TStaticText.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate.

At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.26.3.9 TStaticText.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
```

```
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.26.3.12 TStaticText.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}
```

```
// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

30.1.26.3.13 TStaticText.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
```

```
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

30.1.26.3.14 TStaticText.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.26.3.15 TStaticText.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCheckBoxState (see page 2999)	TCheckBoxState indicates the state of a check box control.
	TComboBoxStyle (see page 3000)	TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 2033) unit.
	TEditCharCase (see page 3000)	TEditCharCase indicates how a control forces the case of characters, if at all.
	TEllipsisPosition (see page 3001)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	TImageAlignment (see page 3002)	Alignment of image on TButton (see page 2035).
	TListBoxStyle (see page 3003)	TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.
	TScrollCode (see page 3004)	TScrollCode indicates what action the user performed on a scroll bar.
	TScrollStyle (see page 3005)	Identifies a set of scrollbars by their orientation.
	TStaticBorderStyle (see page 3006)	TStaticBorderStyle determines the appearance of the border on a static text control.
	TTextLayout (see page 3007)	TTextLayout indicates where text appears within the client area of a control.

Records

	Name	Description
	TSelection (see page 3006)	TSelection definese the start and position of a selection.

30.2.1 StdCtrls.TCheckBoxState Enumeration

TCheckBoxState indicates the state of a check box control.

Pascal

```
TCheckBoxState = (
  cbUnchecked,
  cbChecked,
  cbGrayed
);
```

C++

```
enum TCheckBoxState {
  cbUnchecked,
  cbChecked,
  cbGrayed
};
```

File

StdCtrls

Description

Following are the possible values of TCheckBoxState:

Value	Meaning
cbUnchecked	The check box has no check mark, indicating that the user has not selected the option.
cbChecked	The check box has a check mark in it, indicating that the user has selected the option.

cbGrayed	The check box has a check mark in it, but it is grayed.

30.2.2 StdCtrls.TComboBoxStyle Enumeration

TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 2033) unit.

Pascal

```
TComboBoxStyle = (
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
);
```

C++

```
enum TComboBoxStyle {
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
};
```

File

StdCtrls

Description

These are the values in the TComboBoxStyle type:

Value	Meaning
csDropDown	Creates a drop-down list with an edit box for manually entered text. All items are strings of the same height.
csSimple	Creates an edit box with a fixed list (list box) underneath. The length of the list is determined by the Height of the combo box.
csDropDownList	Creates a drop-down list with no edit box; the user cannot enter text manually. All items are strings of the same height.
csOwnerDrawFixed	Creates an owner-draw drop-down list with no edit box. Each item in the list is the height specified by the ItemHeight property.
csOwnerDrawVariable	Creates an owner-draw drop-down list with no edit box. List items can have varying heights.

30.2.3 StdCtrls.TEditCharCase Enumeration

TEditCharCase indicates how a control forces the case of characters, if at all.

Pascal

```
TEditCharCase = (
  ecNormal,
  ecUpperCase,
```

```
  ecLowerCase
);
```

C++

```
enum TEditCharCase {
  ecNormal,
  ecUpperCase,
  ecLowerCase
};
```

File

StdCtrls

Description

TEditCharCase specifies what case is given to text typed into a control. It can have one of the following values:

Value	Meaning
ecLowerCase	The text is converted to lowercase.
ecNormal	The text appears in mixed case. It is not forced into any case.
ecUpperCase	The text is converted to uppercase.

30.2.4 StdCtrls.TEllipsisPosition Enumeration

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
TEllipsisPosition = (
  epNone,
  epPathEllipsis,
  epEndEllipsis,
  epWordEllipsis
);
```

C++

```
enum TEllipsisPosition {
  epNone,
  epPathEllipsis,
  epEndEllipsis,
  epWordEllipsis
};
```

File

StdCtrls

Description

TEllipsisPosition specifies how an ellipsis is placed in text that does not fit in its allocated rectangle. The constants here correspond to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

The following table lists values for TEllipsisPosition:

Value	Meaning
epNone	An ellipsis is not inserted.

epPathEllipsis	Replaces text in the middle with an ellipsis so that the resulting text fits in the rectangle specified. If the text contains backslash (\) characters, treat the text as a path and attempt to preserve as much text as possible after the last backslash. Corresponds to a value of DT_PATH_ELLIPSIS in the **dwDTFormat** parameter.
epEndEllipsis	Replaces text at the end with an ellipsis so that the resulting text fits in the rectangle specified. Any word not fitting in the rectangle is truncated without adding an ellipsis. Corresponds to a value of DT_END_ELLIPSIS in the **dwDTFormat** parameter.
epWordEllipsis	Truncates any word that doesn't fit in the rectangle and adds ellipses. Corresponds to a value of DT_WORD_ELLIPSIS in the **dwDTFormat** parameter.

30.2.5 StdCtrls.TImageAlignment Enumeration

Alignment of image on TButton (see page 2035).

Pascal

```
TImageAlignment = (
  iaLeft,
  iaRight,
  iaTop,
  iaBottom,
  iaCenter
);
```

C++

```
enum TImageAlignment {
  iaLeft,
  iaRight,
  iaTop,
  iaBottom,
  iaCenter
};
```

File

StdCtrls

Description

TImageAlignment indicates the alignment of an image on a TButton (see page 2035), which is the value of its ImageAlignment property. Following are the possible values of TImageAlignment:

Value	Meaning
iaLeft	Left aligned.
iaRight	Right aligned.
iaTop	Top aligned.
iaBottom	Bottom aligned.
iaCenter	Center aligned.

See Also

TButton (see page 2035)

ImageAlignment (see page 2057)

30.2.6 StdCtrls.TListBoxStyle Enumeration

TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.

Pascal

```
TListBoxStyle = (
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
);
```

C++

```
enum TListBoxStyle {
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
};
```

File

StdCtrls

Description

The following table lists the values for the TListBoxStyle type:

Value	Meaning
lbStandard	All items are strings, with each item the same height.
lbOwnerDrawFixed	The list box is owner-drawn, but each item in the list box is the height specified by the ItemHeight property. Each time an item is displayed in an lbOwnerDrawFixed list box, the OnDrawItem event occurs. The event handler for OnDrawItem draws the specified item. The ItemHeight property determines the height of each of the items.
lbOwnerDrawVariable	The list box is owner-drawn, and items in the list box can be of varying heights. Each time an item is displayed in an lbOwnerDrawVariable list box, two events occur. The first is the OnMeasureItem event. The code for the OnMeasureItem handler can set the height of each item. Then the OnDrawItem event occurs. The code for the OnDrawItem handler draws each item in the list box using the size specified by the OnMeasureItem handler.
lbVirtual	The list box is virtual, but all items are strings with the same height. You must indicate the number of items in the list box by setting the Count property. You must supply the items in the list box using an OnData event handler. If the items have associated objects, you must supply them using an OnDataObject event handler. In addition, you must supply an OnDataFind event handler to provide the mapping from the strings in the list box to their indexes.
lbVirtualOwnerDraw	The list box is virtual and owner-drawn. All items are the same height. As with lbOwnerDrawFixed, the item height is specified by the ItemHeight property, and you must draw items using an OnDrawItem event handler. As with lbVirtual, you must set the Count property and supply OnData and OnDataFind event handlers to provide the mapping between items and indexes. If items are associated with objects, you must also supply an OnDataObject event handler.

30.2.7 StdCtrls.TScrollCode Enumeration

TScrollCode indicates what action the user performed on a scroll bar.

Pascal

```
TScrollCode = (
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
);
```

C++

```
enum TScrollCode {
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
};
```

File

StdCtrls

Description

TScrollCode describes the type of scrolling action requested. It can be any of the following values:

Value	Meaning
scLineUp	User clicked the top or left scroll arrow or pressed the Up or Left arrow key.
scLineDown	User clicked the bottom or right scroll arrow or pressed the Down or Right arrow key.
scPageUp	User clicked the area to the left of the thumb tab or pressed the PgUp key.
scPageDown	User clicked the area to the right of the thumb tab or pressed the PgDn key.
scPosition	User positioned the thumb tab and released it.
scTrack	User is moving the thumb tab.
scTop	User moved the thumb tab to the top or far left on the scroll bar.
scBottom	User moved the thumb tab to the bottom or far right on the scroll bar.
scEndScroll	User finished moving the thumb tab on the scroll bar.

30.2.8 StdCtrls.TScrollStyle Enumeration

Identifies a set of scrollbars by their orientation.

Pascal

```
TScrollStyle = (
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
);
```

C++

```
enum TScrollStyle {
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
};
```

File

StdCtrls

Description

TScrollStyle can have one of the following values:

Value	Meaning
ssNone	No scrollbars are indicated.
ssHorizontal	Only a horizontal scrollbar.
ssVertical	Only a vertical scrollbar.
ssBoth	Both a horizontal and a vertical scrollbar.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

30.2.9 StdCtrls.TSelection Record

TSelection definese the start and position of a selection.

Pascal

```
TSelection = record
  EndPos: Integer;
  StartPos: Integer;
end;
```

C++

```
struct TSelection {
  int EndPos;
  int StartPos;
};
```

File

StdCtrls

Description

TSelection is used internally in Delphi to hold the start and end position of a selection.

30.2.10 StdCtrls.TStaticBorderStyle Enumeration

TStaticBorderStyle determines the appearance of the border on a static text control.

Pascal

```
TStaticBorderStyle = (
  sbsNone,
  sbsSingle,
  sbsSunken
);
```

C++

```
enum TStaticBorderStyle {
  sbsNone,
  sbsSingle,
  sbsSunken
};
```

File

StdCtrls

Description

These are the values in the TStaticBorderStyle type:

Value	Meaning
sbsNone	No visible border.
sbsSingle	Single-line border.
sbsSunken	Raised border.

30.2.11 StdCtrls.TTextLayout Enumeration

TTextLayout indicates where text appears within the client area of a control.

Pascal

```
TTextLayout = (
  tlTop,
  tlCenter,
  tlBottom
);
```

C++

```
enum TTextLayout {
  tlTop,
  tlCenter,
  tlBottom
};
```

File

StdCtrls

Description

The following table describes the possible values:

Value	Meaning
tlTop	The text appears at the top of the its control.
tlCenter	The text is vertically centered in the control.
tlBottom	The text appears along the bottom of the control.

30.3 Types

The following table lists types in this documentation.

Types

Name	Description
TButtonActionLinkClass (see page 3008)	TButtonActionLinkClass defines the metaclass for TButtonActionLink (see page 2106).
TCustomComboBoxStringsClass (see page 3008)	TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 2339).
TDrawItemEvent (see page 3009)	TDrawItemEvent is the type of an OnDrawItem event handler.
TFNDrawText (see page 3010)	TFNDrawText represents the procedure type for the events that specify the details of the Text property of a control.
TLBFindDataEvent (see page 3010)	TLBFindDataEvent is the type of the list box OnDataFind event handler.
TLBGetDataEvent (see page 3011)	TLBGetDataEvent is the type of the list box OnData event handler.
TLBGetDataObjectEvent (see page 3011)	TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.
TMeasureItemEvent (see page 3012)	TMeasureItemEvent is the type for the OnMeasureItem event handler.
TOwnerDrawState (see page 3012)	Indicates state information that can influence how an item is drawn.
TPushButtonActionLinkClass (see page 3013)	TPushButtonActionLinkClass defines the metaclass for TPushButtonActionLink (see page 2811).
TScrollEvent (see page 3013)	TScrollEvent is the type of an OnScroll event handler.

30.3.1 StdCtrls.TButtonActionLinkClass Type

TButtonActionLinkClass defines the metaclass for TButtonActionLink (see page 2106).

Pascal

```
TButtonActionLinkClass = class of TButtonActionLink;
```

C++

```
TButtonActionLink TButtonActionLinkClass;
```

File

StdCtrls

Description

TButtonActionLinkClass is the metaclass for TButtonActionLink (see page 2106). Its value is the class reference for TButtonActionLink (see page 2106) or for one of its descendants.

See Also

TButtonActionLink (see page 2106)

Class References

30.3.2 StdCtrls.TCustomComboBoxStringsClass Type

TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 2339).

Pascal

```
TCustomComboBoxStringsClass = class of TCustomComboBoxStrings;
```

C++

```
TCustomComboBoxStrings TCustomComboBoxStringsClass;
```

File

StdCtrls

Description

TCustomComboBoxStringsClass is the type for a class reference of TCustomComboBoxStrings (see page 2339) or any of its descendants. It is a pointer to the runtime type information (RTTI) for the class type.

See Also

Class References

30.3.3 StdCtrls.TDrawItemEvent Type

TDrawItemEvent is the type of an OnDrawItem event handler.

Pascal

```
TDrawItemEvent = procedure (Control: TWinControl; Index: Integer; Rect: TRect; State:
TOwnerDrawState) of object;
```

C++

```
(Control: TWinControl; Index: Integer; Rect: TRect; State: TOwnerDrawState) (
TDrawItemEvent)();
```

File

StdCtrls

Description

TDrawItemEvent defines the type of method procedure that you must define in order to implement the OnDrawItem event of a visual component such as TListBox (see page 2657).

OnDrawItem is used to write a handler for drawing of the items in list boxes with the TListBoxStyle (see page 3003) Style values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

Control	is a reference to the component invoking the OnDrawEvent.
Index	is the index of the item in the list box.
Rect	defines the rectangle in which the user drawing must be made.
State	defines state of the item to be drawn.

OnDrawItem (see page 2709)

Style (see page 2695)

TListBoxStyle (see page 3003)

TOwnerDrawState

Procedural types

Creating events

30.3.4 StdCtrls.TFNDrawText Type

TFNDrawText represents the procedure type for the events that specify the details of the Text property of a control.

Pascal

```
TFNDrawText = procedure (DC: HDC; const Text: UnicodeString; var TextRect: TRect; TextFlags:
Cardinal) of object;
```

C++

```
(DC: HDC; const Text: UnicodeString; var TextRect: TRect; TextFlags: Cardinal) (
TFNDrawText)();
```

File

StdCtrls

Description

A variable of TFNDrawText type references an event that occurs when creating a control and specifies the details of the Text property.

See Also

Text

30.3.5 StdCtrls.TLBFindDataEvent Type

TLBFindDataEvent is the type of the list box OnDataFind event handler.

Pascal

```
TLBFindDataEvent = function (Control: TWinControl; FindString: string): Integer of object;
```

C++

```
(Control: TWinControl; FindString: string): Integer ( TLBFindDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item index is needed.

FindString is the text of the item whose index is needed.

The event handler returns the index of the item identified by FindString. This return value must be in the range from 0 to one less than the value of the Count property.

See Also

Procedural types

Creating events

30.3.6 StdCtrls.TLBGetDataEvent Type

TLBGetDataEvent is the type of the list box OnData event handler.

Pascal

```
TLBGetDataEvent = procedure (Control: TWinControl; Index: Integer; var Data: string) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var Data: string) ( TLBGetDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item is needed.

Index is the index of the desired item. Index must be less than the value of the Count property.

Data returns the string that is the value of the specified item.

See Also

Procedural types

Creating events

30.3.7 StdCtrls.TLBGetDataObjectEvent Type

TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.

Pascal

```
TLBGetDataObjectEvent = procedure (Control: TWinControl; Index: Integer; var DataObject:
TObject) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var DataObject: TObject) ( TLBGetDataObjectEvent)();
```

File

StdCtrls

Description

Control is the virtual list box that contains the item associated with the object.

Index is the index of the desired item. Index must be less than the value of the Count property.

DataObject returns the object associated with the specified item.

See Also

Procedural types

Creating events

30.3.8 StdCtrls.TMeasureItemEvent Type

TMeasureItemEvent is the type for the OnMeasureItem event handler.

Pascal

```
TMeasureItemEvent = procedure (Control: TWinControl; Index: Integer; var Height: Integer) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var Height: Integer) ( TMeasureItemEvent)();
```

File

StdCtrls

Description

TMeasureItemEvent is the type for event handlers on custom-drawn controls that allow different items in a list to have different heights.

Control is a reference to the control that contains the item.

Index is the index of the item in the Items property.

Height is the default height of the item, in pixels. The event handler can reset Height to the appropriate value.

See Also

Procedural types

Creating events

30.3.9 StdCtrls.TOwnerDrawState Type

Indicates state information that can influence how an item is drawn.

Pascal

```
TOwnerDrawState = Windows.TOwnerDrawState;
```

C++

```
Windows.TOwnerDrawState TOwnerDrawState;
```

File

StdCtrls

Description

TOwnerDrawState is used by event handlers in owner-draw controls to indicate the state of an item about to be drawn. It is a set that includes zero or more of the following:

Value	Meaning
odSelected	The item is selected.
odGrayed	The item should appear grayed.
odDisabled	The item is disabled.

odChecked	The item should appear checked. (This does not apply to all objects)
odFocused	Keyboard input is directed to the item.
odDefault	The item is the default item (This does not apply to all objects)
odHotLight	The item is hot-lighted because under the mouse (only if the operating system supports hot-lighting)
odInactive	The item and its associated menu are inactive
odNoAccel	Any underline of an accelerator character should be skipped when drawing the control
odNoFocusRect	Do not display visual cues that indicate focus
odReserved1	Not currently used.
odReserved2	Not currently used.
odComboBoxEdit	The drawing takes place in the edit box of a combo box control.

30.3.10 StdCtrls.TPushButtonActionLinkClass Type

TPushButtonActionLinkClass defines the metaclass for TPushButtonActionLink (see page 2811).

Pascal

```
TPushButtonActionLinkClass = class of TPushButtonActionLink;
```

C++

```
TPushButtonActionLink TPushButtonActionLinkClass;
```

File

StdCtrls

Description

TPushButtonActionLinkClass is the metaclass for TPushButtonActionLink (see page 2811). Its value is the class reference for TPushButtonActionLink (see page 2811) or for one of its descendants.

See Also

TPushButtonActionLink (see page 2811)

Class References

30.3.11 StdCtrls.TScrollEvent Type

TScrollEvent is the type of an OnScroll event handler.

Pascal

```
TScrollEvent = procedure (Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) of
object;
```

C++

```
(Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) ( TScrollEvent)();
```

File

StdCtrls

Description

TScrollEvent defines the type of method procedure that you must define in order to implement the OnScroll event of a visual component such as TScrollBar (see page 2881).

The OnScroll event occurs when the user scrolls a scroll bar with the mouse or keyboard.

Sender is a reference to the component invoking the OnScroll event.

ScrollCode defines the user scroll action that was performed.

ScrollPos provides the new scroll position.

See Also

OnScroll (see page 2942)

TScrollCode (see page 3004)

31 StdStyleActnCtrls Namespace

This is namespace StdStyleActnCtrls.

Topics

Name	Description
Classes (see page 3016)	The following table lists classes in this documentation.
Variables (see page 3019)	The following table lists variables in this documentation.

Classes

	Name	Description
	TStandardStyleActionBars (see page 3016)	This is class StdStyleActnCtrls.TStandardStyleActionBars.

Variables

Name	Description
StandardStyle (see page 3019)	This is variable StdStyleActnCtrls.StandardStyle.

31.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TStandardStyleActionBars (see page 3016)	This is class StdStyleActnCtrls.TStandardStyleActionBars.

31.1.1 TStandardStyleActionBars Class

Class Hierarchy

Pascal

```
TStandardStyleActionBars = class(TActionBarStyleEx);
```

C++

```
class TStandardStyleActionBars : public TActionBarStyleEx;
```

File

StdStyleActnCtrls

Description

This is class StdStyleActnCtrls.TStandardStyleActionBars.

31.1.1.1 TStandardStyleActionBars Members

The following tables list the members exposed by TStandardStyleActionBars.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 3017)	Returns the base class for ActionBand menus for customizing action bands.
	GetColorMapClass (see page 3017)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 3017)	Returns the control class type on an action bar item.
	GetPopupClass (see page 3018)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 3018)	This is GetScrollBtnClass, a member of class TStandardStyleActionBars.
	GetStyleName (see page 3018)	Returns the style associated with action manager.

31.1.1.2 TStandardStyleActionBars Methods

The methods of the TStandardStyleActionBars class are listed here.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 3017)	Returns the base class for ActionBand menus for customizing action bands.

	GetColorMapClass (see page 3017)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 3017)	Returns the control class type on an action bar item.
	GetPopupClass (see page 3018)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 3018)	This is GetScrollBtnClass, a member of class TStandardStyleActionBars.
	GetStyleName (see page 3018)	Returns the style associated with action manager.

31.1.1.2.1 TStandardStyleActionBars.GetAddRemoveItemClass Method

Returns the base class for ActionBand menus for customizing action bands.

Pascal

```
function GetAddRemoveItemClass(ActionBar: TCustomActionBar): TCustomAddRemoveItemClass;
override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass(TCustomActionBar ActionBar);
```

Description

Call GetAddRemoveItemClass to customize action bands.

See Also

TCustomAddRemoveItem

31.1.1.2.2 TStandardStyleActionBars.GetColorMapClass Method

Returns the class type of the colormap for an action bar.

Pascal

```
function GetColorMapClass(ActionBar: TCustomActionBar): TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetColorMapClass(TCustomActionBar ActionBar);
```

Description

Returns the class type TCustomActionBarColorMap, which is a colormap associated with an action bar. Override this method to customize the appearance of your applications.

31.1.1.2.3 TStandardStyleActionBars.GetControlClass Method

Returns the control class type on an action bar item.

Pascal

```
function GetControlClass(ActionBar: TCustomActionBar; AnItem: TActionClientItem):
TCustomActionControlClass; override;
```

C++

```
virtual __fastcall TCustomActionControlClass GetControlClass(TCustomActionBar ActionBar,
TActionClientItem AnItem);
```

Description

Returns the control class type on an item in the action bar, such as a button or menu item.

31.1.1.2.4 TStandardStyleActionBars.GetPopupClass Method

Returns the popup class added to a menu action band.

Pascal

```
function GetPopupClass(ActionBar: TCustomActionBar): TCustomPopupClass; override;
```

C++

```
virtual __fastcall TCustomPopupClass GetPopupClass(TCustomActionBar ActionBar);
```

Description

Call GetPopupClass to find the popup menu associated with a menu action band. Override GetPopupClass to change which popup class is associated with a menu action band depending on the state of the control.

See Also

TCustomActionPopupMenu

31.1.1.2.5 TStandardStyleActionBars.GetScrollBtnClass Method

Pascal

```
function GetScrollBtnClass: TCustomToolScrollBtnClass; override;
```

C++

```
virtual __fastcall TCustomToolScrollBtnClass GetScrollBtnClass();
```

Description

This is GetScrollBtnClass, a member of class TStandardStyleActionBars.

31.1.1.2.6 TStandardStyleActionBars.GetStyleName Method

Returns the style associated with action manager.

Pascal

```
function GetStyleName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetStyleName();
```

Description

Returns the value of the Style property.

31.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
StandardStyle (see page 3019)	This is variable StdStyleActnCtrls.StandardStyle.

31.2.1 StdStyleActnCtrls.StandardStyle Variable

Pascal

```
StandardStyle: TStandardStyleActionBars;
```

C++

```
TStandardStyleActionBars StandardStyle;
```

File

StdStyleActnCtrls

Description

This is variable StdStyleActnCtrls.StandardStyle.

32 StrUtils Namespace

This is namespace StrUtils.

Topics

Name	Description
Functions (see page 3024)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 3055)	The following table lists structs, records, enums in this documentation.
Types (see page 3056)	The following table lists types in this documentation.
Variables (see page 3058)	The following table lists variables in this documentation.
Constants (see page 3060)	The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 3060)	This is constant StrUtils.WordDelimiters.

Functions

	Name	Description
	AnsiContainsStr (see page 3025)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 3026)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 3026)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 3027)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 3028)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 3028)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 3029)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 3029)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 3030)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 3030)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 3031)	Replaces all occurrences of a substring within a string, using case-sensitive search.
	AnsiReplaceText (see page 3032)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 3032)	Indicates whether two strings are similar.
	AnsiReverseString (see page 3033)	Returns reversed string.
	AnsiRightStr (see page 3033)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 3034)	Indicates whether one string is a (case-sensitive) prefix of another.

	AnsiStartsText (see page 3034)	Indicates whether one string is a (case-insensitive) prefix of another.
	ContainsStr (see page 3035)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 3035)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 3036)	Converts an integer representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 3036)	Converts a Word representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.
	DupeString (see page 3037)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 3037)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 3038)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 3038)	Conditionally returns one of two specified values.
	IndexStr (see page 3039)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 3039)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 3040)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 3040)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 3040)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 3041)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MatchText (see page 3041)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MidBStr (see page 3042)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 3043)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 3043)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 3043)	Returns the index value of a substring.
	RandomFrom (see page 3044)	Returns a randomly selected element from an array.
	ReplaceStr (see page 3044)	Replaces all occurrences of a substring within a string, using case-sensitive search.
	ReplaceText (see page 3045)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 3046)	ResemblesText uses a Soundex (see page 3048) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 3048) method, and false otherwise.
	ReverseString (see page 3046)	Returns the reverse of a specified string.
	RightBStr (see page 3046)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 3047)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 3047)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 3048)	Locates a substring within a text buffer.
	SearchBuf (see page 3048)	Locates a substring within a text buffer.
	Soundex (see page 3048)	Converts a string into its Soundex representation.
	SoundexCompare (see page 3049)	Compares the Soundex (see page 3048) representations of two strings.
	SoundexInt (see page 3050)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 3050)	Indicates whether two strings are similar.
	SoundexSimilar (see page 3051)	Indicates whether two strings are similar.
	SoundexWord (see page 3052)	Converts a string into a Word that represents its phonetic value.

	StartsStr (see page 3052)	Determines whether the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StartsText (see page 3053)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 3053)	Inserts a substring into a specified position of a string, replacing the current characters.

Structs, Records, Enums

	Name	Description
	TStringSeachOption (see page 3055)	TStringSeachOption is an enumeration that describes the behavior of string searches.

Types

Name	Description
TCompareTextProc (see page 3056)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 3056)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 3050) function. The integer value can be from 1 to 8.
TSoundexLength (see page 3057)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 3057)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3055).

Variables

Name	Description
AnsiResemblesProc (see page 3058)	Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar.
ResemblesProc (see page 3058)	Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3058).

32.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiContainsStr (see page 3025)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 3026)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 3026)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 3027)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 3028)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 3028)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 3029)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 3029)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 3030)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 3030)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 3031)	Replaces all occurrences of a substring within a string, using case-sensitive search.
	AnsiReplaceText (see page 3032)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 3032)	Indicates whether two strings are similar.
	AnsiReverseString (see page 3033)	Returns reversed string.
	AnsiRightStr (see page 3033)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 3034)	Indicates whether one string is a (case-sensitive) prefix of another.
	AnsiStartsText (see page 3034)	Indicates whether one string is a (case-insensitive) prefix of another.
	ContainsStr (see page 3035)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 3035)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 3036)	Converts an integer representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 3036)	Converts a Word representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.
	DupeString (see page 3037)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 3037)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 3038)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 3038)	Conditionally returns one of two specified values.
	IndexStr (see page 3039)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 3039)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 3040)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 3040)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 3040)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 3041)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

	MatchText (see page 3041)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MidBStr (see page 3042)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 3043)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 3043)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 3043)	Returns the index value of a substring.
	RandomFrom (see page 3044)	Returns a randomly selected element from an array.
	ReplaceStr (see page 3044)	Replaces all occurrences of a substring within a string, using case-sensitive search.
	ReplaceText (see page 3045)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 3046)	ResemblesText uses a Soundex (see page 3048) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 3048) method, and false otherwise.
	ReverseString (see page 3046)	Returns the reverse of a specified string.
	RightBStr (see page 3046)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 3047)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 3047)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 3048)	Locates a substring within a text buffer.
	SearchBuf (see page 3048)	Locates a substring within a text buffer.
	Soundex (see page 3048)	Converts a string into its Soundex representation.
	SoundexCompare (see page 3049)	Compares the Soundex (see page 3048) representations of two strings.
	SoundexInt (see page 3050)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 3050)	Indicates whether two strings are similar.
	SoundexSimilar (see page 3051)	Indicates whether two strings are similar.
	SoundexWord (see page 3052)	Converts a string into a Word that represents its phonetic value.
	StartsStr (see page 3052)	Determines whether the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StartsText (see page 3053)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 3053)	Inserts a substring into a specified position of a string, replacing the current characters.

32.1.1 StrUtils.AnsiContainsStr Function

Indicates whether one string is a (case-sensitive) substring of another.

Pascal

```
function AnsiContainsStr(const AText: string; const ASubText: string): Boolean; overload;
```

C++

```
Boolean AnsiContainsStr(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

AnsiContainsStr returns true if the string specified by ASubText appears as a substring of the string specified by AText.

Comparison is performed case-sensitively.

See Also

AnsiResemblesText (see page 3032)

AnsiStartsStr (see page 3034)

AnsiEndsStr (see page 3026)

AnsiCompareStr (see page 4050)

Pos (see page 3627)

StringReplace (see page 4253)

AnsiContainsText (see page 3026)

32.1.2 StrUtils.AnsiContainsText Function

Indicates whether one string is a (case-insensitive) substring of another.

Pascal

```
function AnsiContainsText(const AText: string; const ASubText: string): Boolean; overload;
```

C++

```
Boolean AnsiContainsText(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

AnsiContainsText returns true if the string specified by ASubText appears as a substring of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiResemblesText (see page 3032)

AnsiStartsText (see page 3034)

AnsiEndsText (see page 3027)

AnsiCompareText (see page 4051)

Pos (see page 3627)

StringReplace (see page 4253)

AnsiContainsStr (see page 3025)

32.1.3 StrUtils.AnsiEndsStr Function

Indicates whether one string is a (case-sensitive) suffix of another.

Pascal

```
function AnsiEndsStr(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiEndsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiEndsStr returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiStartsStr (see page 3034)

AnsiContainsStr (see page 3025)

Pos (see page 3627)

RightStr (see page 3047)

AnsiEndsText (see page 3027)

32.1.4 StrUtils.AnsiEndsText Function

Indicates whether one string is a (case-insensitive) suffix of another.

Pascal

```
function AnsiEndsText(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiEndsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiEndsText returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiStartsText (see page 3034)

AnsiContainsText (see page 3026)

Pos (see page 3627)

RightStr (see page 3047)

32.1.5 StrUtils.AnsiIndexStr Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexStr(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int AnsiIndexStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexStr returns the 0-offset index of the first string it finds in AValues that matches AText case-sensitively. If the string specified by AText does not have an exact match in AValues, AnsiIndexStr returns –1.

See Also

AnsiMatchStr (see page 3029)

RandomFrom (see page 3044)

AnsiIndexText (see page 3028)

32.1.6 StrUtils.AnsiIndexText Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexText(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int AnsiIndexText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexText returns the 0-offset index of the first string it finds in AValues that matches AText case-insensitively. If the string specified by AText does not have a (possibly case-insensitive) match in AValues, AnsiIndexText returns –1. Comparisons are based on the current system locale.

See Also

AnsiMatchText (see page 3030)

RandomFrom (see page 3044)

AnsiIndexStr (see page 3028)

32.1.7 StrUtils.AnsiLeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function AnsiLeftStr(const AText: string; const ACount: Integer): string; overload;
```

C++

```
UnicodeString AnsiLeftStr(const UnicodeString AText, const int ACount);
```

File

StrUtils

Description

AnsiLeftStr returns the leading characters of AText up to a length of ACount characters.

See Also

Copy (see page 3547)

TrimLeft (see page 4301)

AnsiStartsText (see page 3034)

AnsiStartsStr (see page 3034)

LeftStr (see page 3040)

LeftBStr (see page 3040)

32.1.8 StrUtils.AnsiMatchStr Function

Indicates whether an array of strings contains an exact match to a specified string.

Pascal

```
function AnsiMatchStr(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean AnsiMatchStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchStr to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-sensitive.

See Also

AnsiIndexStr (see page 3028)

AnsiSameStr (see page 4055)

AnsiMatchText (see page 3030)

32.1.9 StrUtils.AnsiMatchText Function

Indicates whether an array of strings contains a case-insensitive match to a specified string.

Pascal

```
function AnsiMatchText(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean AnsiMatchText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchText to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-insensitive and use the current system locale.

AText is the string to locate.

AValues is the array of strings to search.

Note: AValues_Size is the index of the last element in AValues (one less than the number of elements).

AnsiMatchText returns true if AText (or a string that matches except for case) appears in AValues, false if it does not appear in the array.

See Also

AnsiIndexText (see page 3028)

AnsiSameText (see page 4055)

AnsiMatchStr (see page 3029)

32.1.10 StrUtils.AnsiMidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function AnsiMidStr(const AText: string; const AStart: Integer; const ACount: Integer):
string; overload;
```

C++

```
UnicodeString AnsiMidStr(const UnicodeString AText, const int AStart, const int ACount);
```

File

StrUtils

Description

AnsiMidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, AnsiMidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

See Also

Copy (see page 3547)

LeftStr (see page 3040)

RightStr (see page 3047)

MidStr (see page 3043)

MidBStr (see page 3042)

32.1.11 StrUtils.AnsiReplaceStr Function

Replaces all occurrences of a substring within a string, using case-sensitive search.

Pascal

```
function AnsiReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string; overload;
```

C++

```
UnicodeString AnsiReplaceStr(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

Use AnsiReplaceStr to replace all occurrences of the substring `AFromText` with the string `AToText`, within the string `AText`. AnsiReplaceStr returns the string obtained after replacement.

Use ReplaceText (see page 3045) to do a case-insensitive replacement.

Note: The `Ansi` prefix in the function name appears for backward compatibility reasons only. Both the parameters and the return value are of type `string`, which is an alias for `UnicodeString` (see page 3381). To do the replacement in an `AnsiString` context, use the ReplaceStr (see page 3044) function. Also, to do the replacement in a `WideString` (see page 3467) context, use the WideReplaceStr function.

Note: Recursive replacement of substrings is not supported. This means that if the substitution of `AToText` results in a new match for `AFromText`, that match is not replaced.

ReplaceStr (see page 3044) is the same function as AnsiReplaceStr. In writing your application, we recommend that you use ReplaceStr (see page 3044), to avoid any confusion caused by the `Ansi` prefix.

The StringReplace (see page 4253) function is a more general replacement routine, giving case-sensitivity options, as well as the option to decide whether to replace all occurrences or the first occurrence of the substring in the string.

See Also

ReplaceStr

WideReplaceStr (see page 6879)

StringReplace (see page 4253)

ReplaceText (see page 3045)

PosEx (see page 3043)

StuffString (see page 3053)

32.1.12 StrUtils.AnsiReplaceText Function

Replaces all case-insensitive matches of a substring with another string.

Pascal

```
function AnsiReplaceText(const AText: string; const AFromText: string; const AToText: string):
string; overload;
```

C++

```
UnicodeString AnsiReplaceText(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

Call AnsiReplaceText to scan the string specified by AText and replace all occurrences of the string specified by AFromText with the string specified by AToText. Occurrences of AFromText are identified by a case-insensitive comparison that uses the current system locale. The identification of substrings is not recursive: if the substitution of AToText results in a new match for AFromText, that match is not replaced.

See Also

AnsiContainsText (see page 3026)

AnsiReplaceStr (see page 3031)

StringReplace (see page 4253)

SearchBuf (see page 3048)

StuffString (see page 3053)

32.1.13 StrUtils.AnsiResemblesText Function

Indicates whether two strings are similar.

Pascal

```
function AnsiResemblesText(const AText: string; const AOther: string): Boolean; overload;
```

C++

```
Boolean AnsiResemblesText(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

Description

AnsiResemblesText returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

The algorithm that controls whether AnsiResemblesText considers two strings similar is specified by the AnsiResemblesProc (see page 3058) variable. By default, AnsiResemblesProc (see page 3058) is set to SoundexProc (see page 3050), which converts both strings to a phonetic representation using a Soundex (see page 3048) algorithm and compares up to 4 characters of the resulting phonetic representation. By changing the function assigned to AnsiResemblesProc (see page 3058), you can change the comparison made by AnsiResemblesText.

See Also

AnsiResemblesProc (see page 3058)

SoundexProc (see page 3050)

32.1.14 StrUtils.AnsiReverseString Function

Returns reversed string.

Pascal

```
function AnsiReverseString(const AText: string): string; overload;
```

C++

```
UnicodeString AnsiReverseString(const UnicodeString AText);
```

File

StrUtils

Description

AnsiReverseString returns AText with its characters reversed.

32.1.15 StrUtils.AnsiRightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function AnsiRightStr(const AText: string; const ACount: Integer): string; overload;
```

C++

```
UnicodeString AnsiRightStr(const UnicodeString AText, const int ACount);
```

File

StrUtils

Description

AnsiRightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, AnsiRightStr returns the string "grammer".

See Also

Copy (see page 3547)

TrimRight (see page 4302)

AnsiEndsText (see page 3027)

AnsiEndsStr (see page 3026)

RightStr (see page 3047)

RightBStr (see page 3046)

32.1.16 StrUtils.AnsiStartsStr Function

Indicates whether one string is a (case-sensitive) prefix of another.

Pascal

```
function AnsiStartsStr(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiStartsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiStartsStr returns true if the string specified by ASubText appears as the leading part of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiEndsStr (see page 3026)

AnsiContainsStr (see page 3025)

Pos (see page 3627)

LeftStr (see page 3040)

AnsiStartsText (see page 3034)

32.1.17 StrUtils.AnsiStartsText Function

Indicates whether one string is a (case-insensitive) prefix of another.

Pascal

```
function AnsiStartsText(const ASubText: string; const AText: string): Boolean; overload;
```

C++

```
Boolean AnsiStartsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

AnsiStartsText returns true if the string specified by ASubText appears as the leading part of the string specified by AText. Comparison is performed case-insensitively and uses the current system locale.

See Also

AnsiEndsText (see page 3027)

AnsiContainsText (see page 3026)

Pos (see page 3627)

LeftStr (see page 3040)

AnsiStartsStr (see page 3034)

32.1.18 StrUtils.ContainsStr Function

Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsStr(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsStr(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

For a case insensitive search, use the ContainsText (see page 3035) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsText (see page 3035)

32.1.19 StrUtils.ContainsText Function

Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsText(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsText(const UnicodeString AText, const UnicodeString ASubText);
```

File

StrUtils

Description

For a case sensitive search, use the ContainsStr (see page 3035) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsStr (see page 3035)

32.1.20 StrUtils.DecodeSoundexInt Function

Converts an integer representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexInt(AValue: Integer): string;
```

C++

```
UnicodeString DecodeSoundexInt(int AValue);
```

File

StrUtils

Description

Call DecodeSoundexInt to convert the integer representation of a string returned by the SoundexInt (see page 3050) function into the corresponding Soundex (see page 3048) string representation.

A Soundex (see page 3048) representation of a string is a phonetic encoding where each character of the Soundex (see page 3048) representation represents a family of similar phonemes.

See Also

SoundexInt (see page 3050)

DecodeSoundexWord (see page 3036)

Soundex (see page 3048)

32.1.21 StrUtils.DecodeSoundexWord Function

Converts a Word representation of a Soundex (see page 3048) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexWord(AValue: Word): string;
```

C++

```
UnicodeString DecodeSoundexWord(Word AValue);
```

File

StrUtils

Description

Call DecodeSoundexWord to convert the unsigned 16-bit representation of a string returned by the SoundexWord (see page 3052) function into the corresponding Soundex (see page 3048) string representation.

A Soundex (see page 3048) representation of a string is a phonetic encoding where each character of the Soundex (see page 3048) representation represents a family of similar phonemes.

See Also

SoundexWord (see page 3052)

DecodeSoundexInt (see page 3036)

Soundex (see page 3048)

32.1.22 StrUtils.DupeString Function

Returns the concatenation of a string with itself a specified number of repeats.

Pascal

```
function DupeString(const AText: string; ACount: Integer): string; overload;
```

C++

```
UnicodeString DupeString(const UnicodeString AText, int ACount);
```

File

StrUtils

Description

DupeString returns a string containing ACount repeats of the string specified by AText. For example,

S := DupeString('Ha', 5);

sets S to the string 'HaHaHaHaHa'.

See Also

StringOfChar (see page 3677)

StringReplace (see page 4253)

32.1.23 StrUtils.EndsStr Function

Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the EndsText (see page 3038) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsText (see page 3038)

32.1.24 StrUtils.EndsText Function

Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the EndsStr (see page 3037) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsStr (see page 3037)

32.1.25 StrUtils.IfThen Function

Conditionally returns one of two specified values.

Pascal

```
function IfThen(AValue: Boolean; const ATrue: string; AFalse: string = ''): string; overload;
```

C++

```
UnicodeString IfThen(Boolean AValue, const UnicodeString ATrue, UnicodeString AFalse = '');
```

File

StrUtils

Description

IfThen checks the expression passed as AValue and returns ATrue if it evaluates to true, or AFalse if it evaluates to false. In Delphi, if the AFalse parameter is omitted, IfThen returns 0 or an empty string when AValue evaluates to False.

32.1.26 StrUtils.IndexStr Function

IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexStr(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int IndexStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive comparison, use the IndexText (see page 3039) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexText (see page 3039)

32.1.27 StrUtils.IndexText Function

IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexText(const AText: string; const AValues: array of string): Integer; overload;
```

C++

```
int IndexText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the IndexStr (see page 3039) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexStr (see page 3039)

32.1.28 StrUtils.LeftBStr Function

Returns the substring of a specified number of bytes that appears at the start of a string.

Pascal

```
function LeftBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString LeftBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

LeftBStr returns the leading bytes of AText up to a length of AByteCount bytes.

Note: LeftBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use LeftStr (see page 3040).

See Also

Copy (see page 3547)

TrimLeft (see page 4301)

AnsiStartsText (see page 3034)

AnsiStartsStr (see page 3034)

AnsiLeftStr (see page 3029)

LeftStr (see page 3040)

32.1.29 StrUtils.LeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function LeftStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function LeftStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString LeftStr(const AnsiString AText, const int ACount);
BSTR LeftStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

LeftStr returns the leading characters of AText up to a length of ACount characters.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, LeftStr may return more than ACount bytes. To return a specific number of bytes, use LeftBStr (see page 3040).

See Also

Copy (see page 3547)

TrimLeft (see page 4301)

AnsiStartsText (see page 3034)

AnsiStartsStr (see page 3034)

AnsiLeftStr (see page 3029)

LeftBStr (see page 3040)

32.1.30 StrUtils.MatchStr Function

MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchStr(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean MatchStr(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive match, use the MatchText (see page 3041) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchText (see page 3041)

32.1.31 StrUtils.MatchText Function

MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchText(const AText: string; const AValues: array of string): Boolean; overload;
```

C++

```
Boolean MatchText(const UnicodeString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the MatchStr (see page 3041) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchStr (see page 3041)

32.1.32 StrUtils.MidBStr Function

Returns the substring of a specified number of bytes that appears at a specified position in a string.

Pascal

```
function MidBStr(const AText: AnsiString; const AByteStart: Integer; const AByteCount:
Integer): AnsiString;
```

C++

```
AnsiString MidBStr(const AnsiString AText, const int AByteStart, const int AByteCount);
```

File

StrUtils

Description

MidBStr returns a substring AByteCount bytes beginning at AByteStart bytes.

If AByteStart is larger than the length of AText in bytes, MidBStr returns an empty string.

If AByteCount specifies more bytes than are available, only the available bytes are returned.

Note: MidBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use MidStr (see page 3043).

See Also

Copy (see page 3547)

LeftStr (see page 3040)

RightStr (see page 3047)

AnsiMidStr (see page 3030)

MidStr (see page 3043)

32.1.33 StrUtils.MidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function MidStr(const AText: AnsiString; const AStart: Integer; const ACount: Integer):
AnsiString; overload;
function MidStr(const AText: WideString; const AStart: Integer; const ACount: Integer):
WideString; overload;
```

C++

```
AnsiString MidStr(const AnsiString AText, const int AStart, const int ACount);
BSTR MidStr(const BSTR AText, const int AStart, const int ACount);
```

File

StrUtils

Description

MidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, MidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, MidStr may return more than ACount bytes. To return a specific number of bytes, use MidBStr (see page 3042).

See Also

Copy (see page 3547)

LeftStr (see page 3040)

RightStr (see page 3047)

AnsiMidStr (see page 3030)

MidBStr (see page 3042)

32.1.34 StrUtils.PosEx Function

Returns the index value of a substring.

Pascal

```
function PosEx(const SubStr: string; const S: string; Offset: Integer = 1): Integer; overload;
```

C++

```
int PosEx(const UnicodeString SubStr, const UnicodeString S, int Offset = 1);
```

File

StrUtils

Description

PosEx returns the index of SubStr in S, beginning the search at Offset. If Offset is 1 (default), PosEx is equivalent to Pos (see

page 3627).

PosEx returns 0 if SubStr is not found, if Offset is greater than the length of S, or if Offset is less than 1.

See Also

Pos (see page 3627)

32.1.35 StrUtils.RandomFrom Function

Returns a randomly selected element from an array.

Pascal

```
function RandomFrom(const AValues: array of string): string; overload;
```

C++

```
UnicodeString RandomFrom(const array of string AValues);
```

File

StrUtils

Description

RandomFrom returns a randomly selected element from the array passed as the AValues argument. In C++, AValues_Size is the index of the last array element (one less than the number of elements.)

To initialize the random number generator, add a single call Randomize (see page 3633) or assign a value to the RandSeed (see page 3834) variable before making any calls to RandomFrom.

See Also

Randomize (see page 3633)

RandSeed (see page 3834)

32.1.36 StrUtils.ReplaceStr Function

Replaces all occurrences of a substring within a string, using case-sensitive search.

Pascal

```
function ReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
UnicodeString ReplaceStr(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

Use ReplaceStr to replace all occurrences of the substring `AFromText` with the string `AToText`, within the string `AText`. ReplaceStr returns the string obtained after replacement.

Use ReplaceText (see page 3045) to do a case-insensitive replacement.

Note: Both the parameters and the return value are of type `string`, which is an alias for `UnicodeString` (see page 3381). To do the replacement in an `AnsiString` context, use the ReplaceStr function. Also, to do the replacement in a `WideString` (see page 3467) context, use the WideReplaceStr function.

Note: Recursive replacement of substrings is not supported. This means that if the substitution of `AToText` results in a new match for `AFromText`, that match is not replaced.

ReplaceStr is the same function as AnsiReplaceStr (see page 3031).

The StringReplace (see page 4253) function is a more general replacement routine, giving case-sensitivity options, as well as the option to decide whether to replace all occurrences or the first occurrence of the substring in the string.

See Also

ReplaceStr

WideReplaceStr (see page 6879)

StringReplace (see page 4253)

ReplaceText (see page 3045)

PosEx (see page 3043)

StuffString (see page 3053)

32.1.37 StrUtils.ReplaceText Function

ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.

Pascal

```
function ReplaceText(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
UnicodeString ReplaceText(const UnicodeString AText, const UnicodeString AFromText, const
UnicodeString AToText);
```

File

StrUtils

Description

For a case sensitive replacement, use the ReplaceStr (see page 3044) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ReplaceStr (see page 3044)

32.1.38 StrUtils.ResemblesText Function

ResemblesText uses a Soundex (see page 3048) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 3048) method, and false otherwise.

Pascal

```
function ResemblesText(const AText: string; const AOther: string): Boolean; overload;
```

C++

```
Boolean ResemblesText(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

See Also

Commonly Used Long String Routines

String Types

String Constants

AnsiResemblesText (see page 3032)

32.1.39 StrUtils.ReverseString Function

Returns the reverse of a specified string.

Pascal

```
function ReverseString(const AText: string): string; overload;
```

C++

```
UnicodeString ReverseString(const UnicodeString AText);
```

File

StrUtils

Description

ReverseString returns the string specified by AText with the characters in reverse order.

See Also

DupeString (see page 3037)

32.1.40 StrUtils.RightBStr Function

Returns the substring of a specified number of bytes that appears at the end of a string.

Pascal

```
function RightBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString RightBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

RightBStr returns the trailing bytes of AText up to a length of AByteCount bytes.

Note: RightBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use RightStr (see page 3047).

See Also

Copy (see page 3547)

TrimRight (see page 4302)

AnsiEndsText (see page 3027)

AnsiEndsStr (see page 3026)

AnsiRightStr (see page 3033)

32.1.41 StrUtils.RightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function RightStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function RightStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString RightStr(const AnsiString AText, const int ACount);
BSTR RightStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

RightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, RightStr returns the string "grammer".

Note: If AText is an AnsiString and the current locale uses multi-byte characters, RightStr may return more than ACount bytes. To return a specific number of bytes, use RightBStr (see page 3046).

See Also

Copy (see page 3547)

TrimRight (see page 4302)

AnsiEndsText (see page 3027)

AnsiEndsStr (see page 3026)

AnsiRightStr (see page 3033)

32.1.42 StrUtils.SearchBuf Function

Locates a substring within a text buffer.

Pascal

```
function SearchBuf(Buf: PAnsiChar; BufLen: Integer; SelStart: Integer; SelLength: Integer;
SearchString: AnsiString; Options: TStringSearchOptions = [soDown]): PAnsiChar; overload;
function SearchBuf(Buf: PWideChar; BufLen: Integer; SelStart: Integer; SelLength: Integer;
SearchString: UnicodeString; Options: TStringSearchOptions = [soDown]): PWideChar; overload;
```

C++

```
PAnsiChar SearchBuf(PAnsiChar Buf, int BufLen, int SelStart, int SelLength, AnsiString
SearchString, TStringSearchOptions Options = [soDown]);
PWideChar SearchBuf(PWideChar Buf, int BufLen, int SelStart, int SelLength, UnicodeString
SearchString, TStringSearchOptions Options = [soDown]);
```

File

StrUtils

Description

Call SearchBuf to search for a specified search string within a text buffer.

Buf is the text buffer to search.

BufLen is the length, in bytes, of Buf.

SelStart is the first character of the search when Options indicates a backward search (does not include soDown). The first character in Buf has position 0.

SelLength is the number of characters after SelStart that the search begins when Options indicates a forward search (includes soDown).

SearchString is the string to find in Buf.

Options determines whether the search runs forward (soDown) or backward from SelStart or SelStart+SelLength, whether the search is case sensitive (soMatchCase), and whether the matching string must be a whole word (soWholeWord).

If SearchBuf finds a match, it returns a pointer to the first character of the matching string in Buf. If it does not find a match, SearchBuf returns nil (Delphi) or NULL (C++).

See Also

TFindDialog

32.1.43 StrUtils.Soundex Function

Converts a string into its Soundex representation.

Pascal

```
function Soundex(const AText: string; ALength: TSoundexLength = 4): string;
```

C++

```
UnicodeString Soundex(const UnicodeString AText, TSoundexLength ALength = 4);
```

File

StrUtils

Description

Soundex converts the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It returns up to the first ALength Soundex codes in the resulting string representation.

See Also

SoundexWord (see page 3052)

SoundexInt (see page 3050)

SoundexSimilar (see page 3051)

SoundexCompare (see page 3049)

SoundexProc (see page 3050)

32.1.44 StrUtils.SoundexCompare Function

Compares the Soundex (see page 3048) representations of two strings.

Pascal

```
function SoundexCompare(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Integer;
```

C++

```
int SoundexCompare(const UnicodeString AText, const UnicodeString AOther, TSoundexLength
ALength = 4);
```

File

StrUtils

Description

SoundexCompare uses a Soundex (see page 3048) algorithm to convert the strings specified by AText and AOther into phonetic representations where each character of the resulting string represents one of six families of similar phonemes. It then compares the first ALength characters of the resulting representations by calling AnsiCompareStr (see page 4050).

SoundexCompare returns 0 if the first ALength characters of the phonetic representations are identical, a value less then 0 if the representation of AText is less than the representation of AOther, and a value greater than 0 if the representation of AText is greater than the representation of AOther.

See Also

SoundexSimilar (see page 3051)

SoundexWord (see page 3052)

SoundexInt (see page 3050)

AnsiCompareStr (see page 4050)

Soundex (see page 3048)

SoundexProc (see page 3050)

32.1.45 StrUtils.SoundexInt Function

Converts a string into an integer that represents its phonetic value.

Pascal

```
function SoundexInt(const AText: string; ALength: TSoundexIntLength = 4): Integer;
```

C++

```
int SoundexInt(const UnicodeString AText, TSoundexIntLength ALength = 4);
```

File

StrUtils

Description

SoundexInt uses a Soundex (see page 3048) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an integer that uniquely represents the first ALength Soundex (see page 3048) codes in that string representation.

Note: The TSoundexIntLengthLength type represents an integer between 1 and 8. This is because the size of the integer return value limits the number of Soundex (see page 3048) codes that can be used in the final representation.

See Also

SoundexSimilar (see page 3051)

SoundexWord (see page 3052)

DecodeSoundexInt (see page 3036)

SoundexCompare (see page 3049)

Soundex (see page 3048)

SoundexProc (see page 3050)

32.1.46 StrUtils.SoundexProc Function

Indicates whether two strings are similar.

Pascal

```
function SoundexProc(const AText: string; const AOther: string): Boolean;
```

C++

```
Boolean SoundexProc(const UnicodeString AText, const UnicodeString AOther);
```

File

StrUtils

Description

SoundexProc returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar. SoundexProc is the default value of the AnsiResemblesProc (see page 3058) variable, which provides the underlying implementation of AnsiResemblesText (see page 3032).

SoundexProc uses a Soundex (see page 3048) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to 4 digits in the resulting representation, returning true if they are all the same and false if they are not.

Note: SoundexProc is the same as the SoundexSimilar (see page 3051) function using an ALength value of 4.

See Also

AnsiResemblesProc (see page 3058)

SoundexSimilar (see page 3051)

SoundexCompare (see page 3049)

SoundexWord (see page 3052)

SoundexInt (see page 3050)

Soundex (see page 3048)

AnsiResemblesText (see page 3032)

32.1.47 StrUtils.SoundexSimilar Function

Indicates whether two strings are similar.

Pascal

```
function SoundexSimilar(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Boolean;
```

C++

```
Boolean SoundexSimilar(const UnicodeString AText, const UnicodeString AOther, TSoundexLength
ALength = 4);
```

File

StrUtils

Description

SoundexSimilar returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

SoundexSimilar uses a Soundex (see page 3048) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to ALength digits in the resulting representation, returning true if they are all the same and false if they are not.

See Also

SoundexCompare (see page 3049)

SoundexWord (see page 3052)

SoundexInt (see page 3050)

Soundex (see page 3048)

SoundexProc (see page 3050)

32.1.48 StrUtils.SoundexWord Function

Converts a string into a Word that represents its phonetic value.

Pascal

```
function SoundexWord(const AText: string): Word;
```

C++

```
Word SoundexWord(const UnicodeString AText);
```

File

StrUtils

Description

SoundexWord uses a Soundex (see page 3048) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an unsigned 16-bit value that uniquely represents the first 4 Soundex (see page 3048) codes in that string representation.

See Also

SoundexSimilar (see page 3051)

SoundexInt (see page 3050)

DecodeSoundexWord (see page 3036)

SoundexCompare (see page 3049)

Soundex (see page 3048)

SoundexProc (see page 3050)

32.1.49 StrUtils.StartsStr Function

Determines whether the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.

Pascal

```
function StartsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsStr(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the StartsText (see page 3053) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsText (see page 3053)

32.1.50 StrUtils.StartsText Function

StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.

Pascal

```
function StartsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsText(const UnicodeString ASubText, const UnicodeString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the StartsStr (see page 3052) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsStr (see page 3052)

32.1.51 StrUtils.StuffString Function

Inserts a substring into a specified position of a string, replacing the current characters.

Pascal

```
function StuffString(const AText: string; AStart: Cardinal; ALength: Cardinal; const ASubText:
string): string; overload;
```

C++

```
UnicodeString StuffString(const UnicodeString AText, unsigned AStart, unsigned ALength, const
UnicodeString ASubText);
```

File

StrUtils

Description

StuffString returns a new string that is constructed by replacing the characters of AText specified by AStart and ALength with the string specified by ASubText.

AText is the string to which ASubText is added. It is not modified by StuffString.

AStart is the index of the first character in AText to be replaced, where 1 identifies the first character, 2 identifies the second character, and so on.

ALength is the number of characters in AText that are replaced by ASubText. If ALength is 0, ASubText is inserted into AText without removing any characters. If AText is negative, the characters preceding the insertion point are duplicated after the occurrence of ASubText in the result string.

ASubText is the substring to insert into AText, replacing the characters specified by AStart and ALength.

AnsiReplaceStr (see page 3031)

AnsiReplaceText (see page 3032)

StringReplace (see page 4253)

32.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TStringSeachOption (see page 3055)	TStringSeachOption is an enumeration that describes the behavior of string searches.

32.2.1 StrUtils.TStringSeachOption Enumeration

TStringSeachOption is an enumeration that describes the behavior of string searches.

Pascal

```
TStringSeachOption = (
  soDown,
  soMatchCase,
  soWholeWord
);
```

C++

```
enum TStringSeachOption {
  soDown,
  soMatchCase,
  soWholeWord
};
```

File

StrUtils

Description

Note the unusual spelling. TStringSeachOption can have one of the following values:

Value	Meaning
soDown	A forward search is performed through the target text from the specified start point to the end of the search buffer. If soDown is not specified a reverse search is performed from the start point to the begining of the search buffer.
soMatchCase	Performs a case sensitive search.
soWholeWord	Match whole words, not pieces of words. Whole words are determined using standard identifier parser rules.

See Also

Commonly Used Long String Routines

String Types

String Constants

TStringSearchOptions (see page 3057)

32.3 Types

The following table lists types in this documentation.

Types

Name	Description
TCompareTextProc (see page 3056)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 3056)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 3050) function. The integer value can be from 1 to 8.
TSoundexLength (see page 3057)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 3057)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3055).

32.3.1 StrUtils.TCompareTextProc Type

TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.

Pascal

```
TCompareTextProc = function (const AText, AOther: string): Boolean;
```

C++

```
(const AText, AOther: string): Boolean ( TCompareTextProc)();
```

File

StrUtils

See Also

TStringSeachOption (see page 3055)

32.3.2 StrUtils.TSoundexIntLength Type

TSoundexIntLength The maximum calculation length for the SoundexInt (see page 3050) function. The integer value can be from 1 to 8.

Pascal

```
TSoundexIntLength = 1..8;
```

C++

```
1..8 TSoundexIntLength;
```

File

StrUtils

Description

This value determines how many characters to use when generating the soundex string from the source string. There is a maximum of 8 characters due to the maximum capacity of the Integer type.

32.3.3 StrUtils.TSoundexLength Type

TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.

Pascal

```
TSoundexLength = 1..MaxInt;
```

C++

```
1..MaxInt TSoundexLength;
```

File

StrUtils

See Also

TSoundexIntLength (see page 3056)

32.3.4 StrUtils.TStringSearchOptions Type

TStringSearchOptions is set of the enumeration TStringSeachOption (see page 3055).

Pascal

```
TStringSearchOptions = set of TStringSeachOption;
```

C++

```
TStringSeachOption TStringSearchOptions;
```

File

StrUtils

Description

Note the unusual spelling of the enumeration.

See Also

TStringSeachOption (see page 3055)

32.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AnsiResemblesProc (see page 3058)	Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar.
ResemblesProc (see page 3058)	Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3058).

32.4.1 StrUtils.AnsiResemblesProc Variable

Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar.

Pascal

```
AnsiResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc AnsiResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 3032) function uses the function assigned to AnsiResemblesProc to determine when two strings should be considered similar. By default, AnsiResemblesProc is set to SoundexProc (see page 3050).

To make AnsiResemblesText (see page 3032) use a different algorithm, you can change AnsiResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundexSimilar (see page 3051) than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

See Also

AnsiResemblesText (see page 3032)

SoundexSimilar (see page 3051)

32.4.2 StrUtils.ResemblesProc Variable

Controls the algorithm used by AnsiResemblesText (see page 3032) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 3058).

Pascal

```
ResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc ResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 3032) function uses the function assigned to ResemblesProc to determine when two strings should be considered similar. By default, ResemblesProc is set to SoundexProc (see page 3050).

To make AnsiResemblesText (see page 3032) use a different algorithm, you can change ResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundexSimilar (see page 3051) than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

See Also

AnsiResemblesText (see page 3032)

AnsiResemblesProc (see page 3058)

SoundexSimilar (see page 3051)

32.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 3060)	This is constant StrUtils.WordDelimiters.

32.5.1 StrUtils.WordDelimiters Constant

Pascal

```
WordDelimiters: set of AnsiChar = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

C++

```
set of AnsiChar WordDelimiters = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

File

StrUtils

Description

This is constant StrUtils.WordDelimiters.

33 SvcMgr Namespace

This is namespace SvcMgr.

Topics

Name	Description

Structs, Records, Enums (see page 3102)	The following table lists structs, records, enums in this documentation.
Types (see page 3106)	The following table lists types in this documentation.
Variables (see page 3109)	The following table lists variables in this documentation.
Constants (see page 3110)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDependencies (see page 3063)	TDependencies is a container for TDependency (see page 3066) objects.
	TDependency (see page 3066)	TDependency object represents a dependent service or load ordering group used by TService (see page 3071) objects.
	TEventLogger (see page 3068)	This is class SvcMgr.TEventLogger.
	TService (see page 3071)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 3089)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 3095)	TServiceThread represents the thread associated with a specific service (TService (see page 3071) object).

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 3110)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

Structs, Records, Enums

	Name	Description
	TCurrentStatus (see page 3102)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 3103)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 3103)	TServiceType indicates the type of a service.
	TStartType (see page 3104)	TStartType indicates how a service starts up.

Types

Name	Description
TContinueEvent (see page 3106)	TContinueEvent is the type for event handlers that respond when the Service Control manager resumes a service.
TPauseEvent (see page 3106)	TPauseEvent is the type for event handlers that respond when the Service Control manager pauses a service.
TServiceController (see page 3107)	TServiceController is the type for a registered service's handler function.
TServiceEvent (see page 3107)	TServiceEvent is the procedure type used for service events that do not require parameters.
TStartEvent (see page 3108)	TStartEvent is the type for event handlers that respond when the Service Control manager starts a service.
TStopEvent (see page 3108)	TStopEvent is the type for event handlers that respond when the Service Control manager stops a service.

Variables

Name	Description
Application (see page 3109)	Represents a service Application for a service project.

33.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDependencies (see page 3063)	TDependencies is a container for TDependency (see page 3066) objects.
	TDependency (see page 3066)	TDependency object represents a dependent service or load ordering group used by TService (see page 3071) objects.
	TEventLogger (see page 3068)	This is class SvcMgr.TEventLogger.
	TService (see page 3071)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 3089)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 3095)	TServiceThread represents the thread associated with a specific service (TService (see page 3071) object).

33.1.1 TDependencies Class

TDependencies is a container for TDependency (see page 3066) objects.

Class Hierarchy

Pascal

```
TDependencies = class(TCollection);
```

C++

```
class TDependencies : public TCollection;
```

File

SvcMgr

Description

TDependencies is a collection of TDependency (see page 3066) objects, each of which represents a dependent service or load ordering group for a service (TService (see page 3071) instance). TDependencies objects are the implementation of the Dependencies property of TService (see page 3071).

See Also

TDependency (see page 3066)

TService (see page 3071)

33.1.1.1 TDependencies Members

The following tables list the members exposed by TDependencies.

Protected Methods

	Name	Description
	GetOwner (see page 3064)	Returns the owner of an object.

Public Methods

	Name	Description
	Create (see page 3064)	Creates an instance of a TDependencies (see page 3063) object.

Public Properties

	Name	Description
	Items (see page 3065)	Lists the dependency objects in the dependencies collection.

33.1.1.2 TDependencies.Create Constructor

Creates an instance of a TDependencies (see page 3063) object.

Pascal

```
constructor Create(Owner: TPersistent);
```

C++

```
__fastcall TDependencies(TPersistent * Owner);
```

Description

Applications should not need to call the constructor directly. Instances of TService (see page 3071) create the TDependencies (see page 3063) object from their own constructors. The Owner parameter is the TService (see page 3071) instance that uses the TDependencies (see page 3063) object to implement its Dependencies property.

Create sets the TDependency (see page 3066) owner to the Owner parameter and calls the inherited Create.

See Also

Create

TService (see page 3071)

33.1.1.3 TDependencies Methods

The methods of the TDependencies class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 3064)	Returns the owner of an object.

33.1.1.3.1 TDependencies.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

GetNamePath

TCollection

TComponent

Owner

33.1.1.4 TDependencies Properties

The properties of the TDependencies class are listed here.

Public Properties

	Name	Description
	Items (see page 3065)	Lists the dependency objects in the dependencies collection.

33.1.1.4.1 TDependencies.Items Property

Lists the dependency objects in the dependencies collection.

Pascal

```
property Items [Index: Integer]: TDependency;
```

C++

```
__property TDependency Items[int Index];
```

Description

The value of the Index parameter corresponds to the Index property of each TDependency (see page 3066) object in the collection. It represents the position of the dependency object in the dependencies collection.

Note: In Delphi, Items is the default property of TDependencies (see page 3063). This means that you can omit the property names. For example

Note: Service1.Dependencies.Items[i]

Note: can be written

Note: Service1.Dependencies[i]

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

Index

33.1.2 TDependency Class

TDependency object represents a dependent service or load ordering group used by TService (see page 3071) objects.

Class Hierarchy

Pascal

```
TDependency = class(TCollectionItem);
```

C++

```
class TDependency : public TCollectionItem;
```

File

SvcMgr

Description

A TDependency object represents a new service or load ordering group that must start before the service represented by a TService (see page 3071) object. Collections of dependency objects are TDependencies (see page 3063) objects. TService (see page 3071) has Dependencies and LoadGroup properties that use dependency collections. Each dependency has a Name (see page 3068) property that identifies the service or load ordering group, and a boolean IsGroup (see page 3067) property to indicate whether the dependency represents a load ordering group.

See Also

TDependencies (see page 3063)

TService (see page 3071)

Service Name Properties

33.1.2.1 TDependency Members

The following tables list the members exposed by TDependency.

Protected Methods

	Name	Description
	GetDisplayName (see page 3067)	Returns the name of the collection item as it appears in the collection editor.

Published Properties

	Name	Description
	IsGroup (see page 3067)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 3071) object).
	Name (see page 3068)	Identifies the dependent service or load ordering group used by a TService (see page 3071) object.

33.1.2.2 TDependency Methods

The methods of the TDependency class are listed here.

Protected Methods

	Name	Description
	GetDisplayName (see page 3067)	Returns the name of the collection item as it appears in the collection editor.

33.1.2.2.1 TDependency.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName

GetNamePath

33.1.2.3 TDependency Properties

The properties of the TDependency class are listed here.

Published Properties

	Name	Description
	IsGroup (see page 3067)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 3071) object).
	Name (see page 3068)	Identifies the dependent service or load ordering group used by a TService (see page 3071) object.

33.1.2.3.1 TDependency.IsGroup Property

Indicates whether the dependency represents a load ordering group for a service (TService (see page 3071) object).

Pascal

```
property IsGroup: Boolean;
```

C++

```
__property Boolean IsGroup;
```

Description

IsGroup indicates whether the dependency represents a load ordering group.

Note: : Because services and service groups share the same name space, group names must be prefixed by the SC_GROUP_IDENTIFIER character to distinguish them from service names. If IsGroup is set to true, SC_GROUP_IDENTIFIER will automatically be prefixed to the Dependency name (Name (see page 3068) property). DisplayName is not modified.

See Also

Name (see page 3068)

LoadGroup (see page 3080)

33.1.2.3.2 TDependency.Name Property

Identifies the dependent service or load ordering group used by a TService (see page 3071) object.

Pascal

```
property Name: String;
```

C++

```
__property UnicodeString Name;
```

Description

Name is the name identifying the service or load ordering group. If Name is the name of a service, Name reflects the actual ServiceStartName of a TService (see page 3071) instance.

The property editor for the Dependencies property of TService (see page 3071) technically uses the dependency's DisplayName to identify the dependency service in its collection list. However, Name and DisplayName are nearly always the same.

Dependency objects that are load ordering groups are prefixed by SC_GROUP_IDENTIFIER. Setting the IsGroup (see page 3067) property handles prefixing the Name automatically.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

DisplayName

LoadGroup (see page 3080)

TService (see page 3071)

33.1.3 TEventLogger Class

Class Hierarchy

Pascal

```
TEventLogger = class(TObject);
```

C++

```
class TEventLogger : public TObject;
```

File

SvcMgr

Description

This is class SvcMgr.TEventLogger.

33.1.3.1 TEventLogger Members

The following tables list the members exposed by TEventLogger.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3069)	This is Create, a member of class TEventLogger.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3070)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	LogMessage (see page 3070)	This is LogMessage, a member of class TEventLogger.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

33.1.3.2 TEventLogger.Create Constructor

Pascal

```
constructor Create(Name: String);
```

C++

```
__fastcall TEventLogger(UnicodeString Name);
```

Description

This is Create, a member of class TEventLogger.

33.1.3.3 TEventLogger.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEventLogger();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

33.1.3.4 TEventLogger Methods

The methods of the TEventLogger class are listed here.

Public Methods

	Name	Description
	LogMessage (see page 3070)	This is LogMessage, a member of class TEventLogger.

33.1.3.4.1 TEventLogger.LogMessage Method

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Word = 0; ID: DWord = 0);
```

C++

```
__fastcall LogMessage(UnicodeString Message, DWord EventType = 1, Word Category = 0, DWord ID
= 0);
```

Description

This is LogMessage, a member of class TEventLogger.

33.1.4 TService Class

TService encapsulates a Windows NT service.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TService = class(TDataModule);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TService : public TDataModule;
```

File

SvcMgr

Description

TService encapsulates a Windows NT service in an NT service application. A Win32 service is accessed via the Service Control Manager and can be started automatically at system boot, by a user through the Services control panel applet, or by a Win32-based application that uses the service functions. Services can execute even when no user is logged on to the system. Windows NT also supports a driver service that does not interact with the SCM.

See Also

TServiceApplication (see page 3089)

Service Applications

Service Name Properties

Service Threads

33.1.4.1 TService Members

The following tables list the members exposed by TService.

Protected Methods

	Name	Description
	Controller (see page 3074)	This is Controller, a member of class TService.
V	DoContinue (see page 3074)	This is DoContinue, a member of class TService.
V	DoCustomControl (see page 3074)	This is DoCustomControl, a member of class TService.
V	DoInterrogate (see page 3074)	This is DoInterrogate, a member of class TService.
V	DoPause (see page 3075)	This is DoPause, a member of class TService.
V	DoShutdown (see page 3075)	This is DoShutdown, a member of class TService.
V	DoStart (see page 3075)	This is DoStart, a member of class TService.
V	DoStop (see page 3075)	This is DoStop, a member of class TService.
	Main (see page 3077)	This is Main, a member of class TService.

Public Methods

	Name	Description
	CreateNew (see page 3073)	Instantiates and initializes a TService (see page 3071) object.
	Destroy (see page 3073)	Disposes of a TService (see page 3071) instance.
	GetServiceController (see page 3076)	Returns the service's registered handler function.
	LogMessage (see page 3076)	Sends an error message to the event log.
	ReportStatus (see page 3077)	Updates the Service Control Manager's status information for the calling service.

Public Properties

	Name	Description
	ErrCode (see page 3079)	Contains the service specific error code returned on starting or stopping the service.
	Param (see page 3081)	Lists the parameters to the service.
	ParamCount (see page 3081)	Indicates the number of startup parameters for the service.
	ServiceThread (see page 3082)	Identifies the dedicated thread for the service.
	Status (see page 3083)	Indicates the current state of the service.
	Terminated (see page 3084)	Indicates whether the service thread has terminated.
	Win32ErrCode (see page 3085)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Events

	Name	Description
	AfterInstall (see page 3085)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 3086)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 3086)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 3087)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 3087)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnExecute (see page 3088)	Occurs when the thread associated with the service starts up.
	OnPause (see page 3088)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 3088)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 3089)	OnStartup occurs when the service first starts up, before the OnExecute (see page 3088) event.
	OnStop (see page 3089)	Occurs when the Service Control manager stops the service.

Published Properties

	Name	Description
	AllowPause (see page 3078)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 3078)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 3078)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 3079)	Identifies the service in the Windows Service Control Manager.
	ErrorSeverity (see page 3080)	Indicates the severity of service startup failure.
	Interactive (see page 3080)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 3080)	Names of the load ordering group that includes the service.
	Password (see page 3081)	Specifies the password, optionally used depending upon the ServiceStartName (see page 3082), for accessing the service.
	ServiceStartName (see page 3082)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 3083)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 3083)	Indicates when or how the service starts.
	TagID (see page 3084)	Specifies a unique tag for the service within its LoadGroup (see page 3080).
	WaitHint (see page 3084)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

33.1.4.2 TService.CreateNew Constructor

Instantiates and initializes a TService (see page 3071) object.

Pascal

```
constructor CreateNew(AOwner: TComponent; Dummy: Integer = 0); override;
```

C++

```
virtual __fastcall TService(TComponent * AOwner, int Dummy = 0);
```

Description

Call CreateNew to instantiate a service object at runtime. Services added at design time are created automatically. The AOwner parameter specifies the TServiceApplication (see page 3089) object that is responsible for ultimately freeing the service. The Dummy parameter is not used. Use CreateNew rather than the Create constructor to instantiate a new service object at runtime. CreateNew does not attempt to stream in an associated DFM file that indicates any components added to the service at design time.

See Also

Owner

Create (see page 3064)

TServiceApplication (see page 3089)

33.1.4.3 TService.Destroy Destructor

Disposes of a TService (see page 3071) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TService();
```

Description

Destroy frees the memory associated with the objects for the Params and Dependencies (see page 3078) properties that were created in the constructor, and for the EventLogger object created in the LogMessage (see page 3076) method. Then it calls the inherited Destroy.

See Also

System::TObject::Free (see page 3372)

LogMessage (see page 3076)

33.1.4.4 TService Methods

The methods of the TService class are listed here.

Protected Methods

	Name	Description
	Controller (see page 3074)	This is Controller, a member of class TService.
	DoContinue (see page 3074)	This is DoContinue, a member of class TService.

	DoCustomControl (see page 3074)	This is DoCustomControl, a member of class TService.
	DoInterrogate (see page 3074)	This is DoInterrogate, a member of class TService.
	DoPause (see page 3075)	This is DoPause, a member of class TService.
	DoShutdown (see page 3075)	This is DoShutdown, a member of class TService.
	DoStart (see page 3075)	This is DoStart, a member of class TService.
	DoStop (see page 3075)	This is DoStop, a member of class TService.
	Main (see page 3077)	This is Main, a member of class TService.

Public Methods

	Name	Description
	GetServiceController (see page 3076)	Returns the service's registered handler function.
	LogMessage (see page 3076)	Sends an error message to the event log.
	ReportStatus (see page 3077)	Updates the Service Control Manager's status information for the calling service.

33.1.4.4.1 TService.Controller Method

Pascal

```
procedure Controller(CtrlCode: DWord);
```

C++

```
__fastcall Controller(DWord CtrlCode);
```

Description

This is Controller, a member of class TService.

33.1.4.4.2 TService.DoContinue Method

Pascal

```
function DoContinue: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoContinue();
```

Description

This is DoContinue, a member of class TService.

33.1.4.4.3 TService.DoCustomControl Method

Pascal

```
function DoCustomControl(CtrlCode: DWord): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoCustomControl(DWord CtrlCode);
```

Description

This is DoCustomControl, a member of class TService.

33.1.4.4.4 TService.DoInterrogate Method

Pascal

```
procedure DoInterrogate; virtual;
```

C++

```
virtual __fastcall DoInterrogate();
```

Description

This is DoInterrogate, a member of class TService.

33.1.4.4.5 TService.DoPause Method

Pascal

```
function DoPause: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoPause();
```

Description

This is DoPause, a member of class TService.

33.1.4.4.6 TService.DoShutdown Method

Pascal

```
procedure DoShutdown; virtual;
```

C++

```
virtual __fastcall DoShutdown();
```

Description

This is DoShutdown, a member of class TService.

33.1.4.4.7 TService.DoStart Method

Pascal

```
procedure DoStart; virtual;
```

C++

```
virtual __fastcall DoStart();
```

Description

This is DoStart, a member of class TService.

33.1.4.4.8 TService.DoStop Method

Pascal

```
function DoStop: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoStop();
```

Description

This is DoStop, a member of class TService.

33.1.4.4.9 TService.GetServiceController Method

Returns the service's registered handler function.

Pascal

```
function GetServiceController: TServiceController; virtual; abstract;
```

C++

```
virtual __fastcall TServiceController GetServiceController() = 0;
```

Description

GetServiceController returns the handler for the service. You do not need to call this function directly. The service object's main function calls it automatically.

Note: Each service in the service application has a main function for that service. When a request is made to start the service, the main thread of the service calls the RegisterServiceCtrlHandler function to register this control handler function. TService (see page 3071) automatically calls RegisterServiceCtrlHandler and returns this handler function. Because this function cannot be a class method (member function), the Service application wizard generates code that creates a non-member handler, (ServiceController) for your service object. This routine returns the service object's Handler (Controller (see page 3074)).

33.1.4.4.10 TService.LogMessage Method

Sends an error message to the event log.

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Integer = 0; ID: Integer
= 0);
```

C++

```
__fastcall LogMessage(UnicodeString Message, DWord EventType = 1, int Category = 0, int ID =
0);
```

Description

LogMessage sends an error message to the event log when an error or exception occurs. By default the EventType is EVENTLOG_ERROR_TYPE (usually indicating a loss of functionality or data) and the category and ID are zero. For example, if a service cannot be loaded as the system boots, it can log an error event, and the category and ID are zero.

The EventType specifies the type of event being logged. This parameter can be one of the following values.

Value	Meaning
EVENTLOG_WARNING_TYPE	Warning event
EVENTLOG_INFORMATION_TYPE	Information event
EVENTLOG_AUDIT_SUCCESS	Success Audit event
EVENTLOG_AUDIT_FAILURE	Failure Audit event
EVENTLOG_ERROR_TYPE	Error (see page 3560) event

The Category parameter specifies the event category, which is source-specific information and can have any value.

The ID parameter specifies the event identifier, which is the message that goes with this event as an entry in the message file associated with the event source.

33.1.4.4.11 TService.Main Method

Pascal

```
procedure Main(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall Main(DWord Argc, PLPSTR Argv);
```

Description

This is Main, a member of class TService.

33.1.4.4.12 TService.ReportStatus Method

Updates the Service Control Manager's status information for the calling service.

Pascal

```
procedure ReportStatus;
```

C++

```
__fastcall ReportStatus();
```

Description

ReportStatus sends current status information about the calling service to the Service Control Manager.

See Also

LogMessage (see page 3076)

Status (see page 3083)

WaitHint (see page 3084)

33.1.4.5 TService Properties

The properties of the TService class are listed here.

Public Properties

	Name	Description
	ErrCode (see page 3079)	Contains the service specific error code returned on starting or stopping the service.
R	Param (see page 3081)	Lists the parameters to the service.
R	ParamCount (see page 3081)	Indicates the number of startup parameters for the service.
R	ServiceThread (see page 3082)	Identifies the dedicated thread for the service.
	Status (see page 3083)	Indicates the current state of the service.
R	Terminated (see page 3084)	Indicates whether the service thread has terminated.
	Win32ErrCode (see page 3085)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Properties

	Name	Description
	AllowPause (see page 3078)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 3078)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 3078)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 3079)	Identifies the service in the Windows Service Control Manager.

	ErrorSeverity (see page 3080)	Indicates the severity of service startup failure.
	Interactive (see page 3080)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 3080)	Names of the load ordering group that includes the service.
	Password (see page 3081)	Specifies the password, optionally used depending upon the ServiceStartName (see page 3082), for accessing the service.
	ServiceStartName (see page 3082)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 3083)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 3083)	Indicates when or how the service starts.
	TagID (see page 3084)	Specifies a unique tag for the service within its LoadGroup (see page 3080).
	WaitHint (see page 3084)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

33.1.4.5.1 TService.AllowPause Property

Indicates whether clients are allowed to pause the service.

Pascal

```
property AllowPause: Boolean;
```

C++

```
__property Boolean AllowPause;
```

Description

AllowPause indicates whether clients of the service can pause and resume the service by calling the Windows API ControlService function. When AllowPause is true, an OnPause (see page 3088) event occurs before the service pauses, and an OnContinue (see page 3087) event occurs when the service resumes.

See Also

OnPause (see page 3088)

OnContinue (see page 3087)

33.1.4.5.2 TService.AllowStop Property

Indicates whether clients are allowed to stop the service.

Pascal

```
property AllowStop: Boolean;
```

C++

```
__property Boolean AllowStop;
```

Description

AllowStop indicates whether clients of the service can stop it by calling the Windows API ControlService function. When AllowStop is true, an OnStop (see page 3089) event occurs before the service stops.

See Also

OnStop (see page 3089)

33.1.4.5.3 TService.Dependencies Property

Lists the services or load ordering groups on which the service depends.

Pascal

```
property Dependencies: TDependencies;
```

C++

```
__property TDependencies Dependencies;
```

Description

Dependencies is a container for TDependency (see page 3066) objects, which are dependent services or load ordering groups that must start before this service. If the container is empty, the service has no dependencies.

Dependency on a service means that this service can only run if the service it depends on is running. Dependency on a group means that this service can run if at least one member of the group is running after an attempt to start all members of the group.

See Also

TDependency (see page 3066)

LoadGroup (see page 3080)

33.1.4.5.4 TService.DisplayName Property

Identifies the service in the Windows Service Control Manager.

Pascal

```
property DisplayName: String;
```

C++

```
__property UnicodeString DisplayName;
```

Description

DisplayName contains a string, with a maximum length of 256 characters, that is the name of the service as displayed in the Service Control Manager. User interface programs use DisplayName to identify the service. DisplayName is case-preserved in the Service Control Manager, however display name comparisons are always case-insensitive.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Name

ServiceStartName (see page 3082)

33.1.4.5.5 TService.ErrCode Property

Contains the service specific error code returned on starting or stopping the service.

Pascal

```
property ErrCode: DWord;
```

C++

```
__property DWord ErrCode;
```

Description

ErrCode specifies a service specific error code that the service returns when an error occurs while the service is starting or stopping. If ErrCode is not defined, the Win32ErrCode (see page 3085) property is used instead.

See Also

ReportStatus (see page 3077)

Win32ErrCode (see page 3085)

33.1.4.5.6 TService.ErrorSeverity Property

Indicates the severity of service startup failure.

Pascal

```
property ErrorSeverity: TErrorSeverity;
```

C++

```
__property TErrorSeverity ErrorSeverity;
```

Description

ErrorSeverity indicates the severity if this service fails to start during startup of the service application.

See Also

ErrCode (see page 3079)

ReportStatus (see page 3077)

Win32ErrCode (see page 3085)

33.1.4.5.7 TService.Interactive Property

Indicates whether the service is interactive with the Windows desktop.

Pascal

```
property Interactive: Boolean;
```

C++

```
__property Boolean Interactive;
```

Description

Interactive indicates whether the service can interact with the Windows desktop. Interactive only has an effect when ServiceType (see page 3083) is stWin32. For more information about creating interactive NT services, see the Microsoft Help.

See Also

ServiceType (see page 3083)

33.1.4.5.8 TService.LoadGroup Property

Names of the load ordering group that includes the service.

Pascal

```
property LoadGroup: String;
```

C++

```
__property UnicodeString LoadGroup;
```

Description

LoadGroup is the name of the load-ordering group that includes the service. This is used by other services that have

dependencies on the load ordering group (See Dependencies (see page 3078)). The registry lists load-ordering groups at HKEY_LOCAL_MACHINE\System (see page 3159)\CurrentControlSet\Control\ServiceGroupOrder. The order in which services are loaded depends on the order of the load groups in the Registry and the dependencies listed in service Dependencies (see page 3078) properties.

Because services and service groups share the same name space, the SC_GROUP_IDENTIFIER character must prefix group names to distinguish them from service names. This is automatically prefixed if the TDependency (see page 3066)'s IsGroup property is true.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Dependencies (see page 3078)

TagID (see page 3084)

33.1.4.5.9 TService.Param Property

Lists the parameters to the service.

Pascal

```
property Param [Index: Integer]: String;
```

C++

```
__property UnicodeString Param[int Index];
```

Description

Param is an indexed property that contains the parameters to the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

ParamCount (see page 3081)

33.1.4.5.10 TService.ParamCount Property

Indicates the number of startup parameters for the service.

Pascal

```
property ParamCount: Integer;
```

C++

```
__property int ParamCount;
```

Description

ParamCount is the number of parameters for the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

Param (see page 3081)

33.1.4.5.11 TService.Password Property

Specifies the password, optionally used depending upon the ServiceStartName (see page 3082), for accessing the service.

Pascal

```
property Password: String;
```

C++

```
__property UnicodeString Password;
```

Description

Password is the password for the account name specified by the ServiceStartName (see page 3082) property if the ServiceType (see page 3083) is stWin32.

If Password is nil (Delphi) or NULL (C++), or if it points to an empty string, the service has no password. If ServiceType (see page 3083) is stDevice or stFileSystem, this parameter is ignored.

See Also

ServiceStartName (see page 3082)

33.1.4.5.12 TService.ServiceStartName Property

ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.

Pascal

```
property ServiceStartName: String;
```

C++

```
__property UnicodeString ServiceStartName;
```

Description

ServiceStartName is the name used to start the service.

If ServiceType (see page 3083) is stWin32, ServiceStartName is the account name (in the form "DomainName\Username") which the service process is logged on as when it runs. If the account belongs to the built-in domain, ".\Username" can be specified. If the service application includes more than one service, leave ServiceStartName blank, and leave the Password (see page 3081) property blank.

If the service type is not stWin32, ServiceStartName is the driver object name (\FileSytems\Rdr or \Driver\Xns) which the input and output system uses to load the device driver. With device drivers or file systems drivers, you can leave ServiceStartName blank and the I/O system will create a default name based on the service name.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Password (see page 3081)

33.1.4.5.13 TService.ServiceThread Property

Identifies the dedicated thread for the service.

Pascal

```
property ServiceThread: TServiceThread;
```

C++

```
__property TServiceThread ServiceThread;
```

Description

ServiceThread is the instance of the TServiceThread (see page 3095) class that is the dedicated thread for the service. Each service in the service application has a dedicated thread that contains a loop in its Execute method for processing service requests. Often a service will spawn a new thread, derived from TThread, to free the service thread to continue processing service requests.

See Also

ProcessRequests (see page 3100)

TThread

33.1.4.5.14 TService.ServiceType Property

Identifies the type of the service as Win32, device driver, or file system driver.

Pascal

```
property ServiceType: TServiceType;
```

C++

```
__property TServiceType ServiceType;
```

Description

ServiceType indicates the type of service. ServiceType can be stWin32 (a Win32 service – the default), stDevice (a device driver), or stFileSystem (a file system driver).

See Also

Interactive (see page 3080)

33.1.4.5.15 TService.StartType Property

Indicates when or how the service starts.

Pascal

```
property StartType: TStartType;
```

C++

```
__property TStartType StartType;
```

Description

StartType specifies how and why the service starts

33.1.4.5.16 TService.Status Property

Indicates the current state of the service.

Pascal

```
property Status: TCurrentStatus;
```

C++

```
__property TCurrentStatus Status;
```

Description

Status indicates the current state of the service. The status information is displayed in the Service Control Manager.

See Also

ReportStatus (see page 3077)

33.1.4.5.17 TService.TagID Property

Specifies a unique tag for the service within its LoadGroup (see page 3080).

Pascal

```
property TagID: DWord;
```

C++

```
__property DWord TagID;
```

Description

TagID is the unique tag value for this service in its LoadGroup (see page 3080). If no tag is requested, this property is 0. Tags are only evaluated when the ServiceType (see page 3083) is not stWin32 and the StartType (see page 3083) is stBoot or stSystem.

See Also

Dependencies (see page 3078)

LoadGroup (see page 3080)

33.1.4.5.18 TService.Terminated Property

Indicates whether the service thread has terminated.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

Terminated indicates whether the dedicated thread that the service is running in has terminated.

See Also

Terminated

Terminate

33.1.4.5.19 TService.WaitHint Property

Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

Pascal

```
property WaitHint: Integer;
```

C++

```
__property int WaitHint;
```

Description

WaitHint specifies the amount of time, in milliseconds, that can elapse between a pending start, stop, pause, or continue

operation and the service setting its status with a call to the Windows API. Normally this is handled automatically. If the service performs a lengthy operation of more than WaitHint time in one of its event handlers, you should call ReportStatus (see page 3077) method to update to the Service Control Manager.

See Also

ReportStatus (see page 3077)

33.1.4.5.20 TService.Win32ErrCode Property

Indicates the Win32 error code reported by the service if a service specific code is not defined.

Pascal

```
property Win32ErrCode: DWord;
```

C++

```
__property DWord Win32ErrCode;
```

Description

Win32ErrCode specifies a Win32 error code that the service uses to report an error that occurs when it is starting or stopping. If an error code specific to the service is defined, this property is automatically set to ERROR_SERVICE_SPECIFIC_ERROR and the service specific error is reported instead.

See Also

ErrCode (see page 3079)

ReportStatus (see page 3077)

33.1.4.6 TService Events

The events of the TService class are listed here.

Published Events

	Name	Description
	AfterInstall (see page 3085)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 3086)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 3086)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 3087)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 3087)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnExecute (see page 3088)	Occurs when the thread associated with the service starts up.
	OnPause (see page 3088)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 3088)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 3089)	OnStartup occurs when the service first starts up, before the OnExecute (see page 3088) event.
	OnStop (see page 3089)	Occurs when the Service Control manager stops the service.

33.1.4.6.1 TService.AfterInstall Event

Occurs immediately after the service is registered with the Windows Service Control manager.

Pascal

```
property AfterInstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterInstall;
```

Description

Write (see page 3707) an AfterInstall event handler to take specific action immediately after the service is registered. Install services by running the service application with the INSTALL switch.

See Also

AfterUninstall (see page 3086)

OnStart (see page 3089)

OnExecute (see page 3088)

OnCreate

BeforeInstall (see page 3086)

33.1.4.6.2 TService.AfterUninstall Event

Occurs immediately after the service is removed from the Service Control manager's database.

Pascal

```
property AfterUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterUninstall;
```

Description

Write (see page 3707) an AfterUninstall event handler to take specific action immediately after the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterInstall (see page 3085)

OnStop (see page 3089)

BeforeUninstall (see page 3087)

Destroy

OnShutdown (see page 3088)

33.1.4.6.3 TService.BeforeInstall Event

Occurs before the service is first registered with the Windows Service Control manager.

Pascal

```
property BeforeInstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeInstall;
```

Description

Write (see page 3707) a BeforeInstall event handler to take specific action immediately before the service is first registered. Install services by running the service application with the INSTALL switch.

See Also

AfterInstall (see page 3085)

OnStart (see page 3089)

OnExecute (see page 3088)

OnCreate

BeforeUninstall (see page 3087)

33.1.4.6.4 TService.BeforeUninstall Event

Occurs immediately before the service is removed from the Service Control manager's database.

Pascal

```
property BeforeUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeUninstall;
```

Description

Write (see page 3707) a BeforeUninstall event handler to take specific action immediately before the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterUninstall (see page 3086)

OnStop (see page 3089)

BeforeInstall (see page 3086)

Destroy

OnShutdown (see page 3088)

33.1.4.6.5 TService.OnContinue Event

Occurs when the Service Control manager resumes the service after it has been paused.

Pascal

```
property OnContinue: TContinueEvent;
```

C++

```
__property TContinueEvent OnContinue;
```

Description

Write (see page 3707) an OnContinue event handler to take specific action when the Service Control manager resumes the service after it has been paused.

See Also

OnPause (see page 3088)

33.1.4.6.6 TService.OnExecute Event

Occurs when the thread associated with the service starts up.

Pascal

```
property OnExecute: TServiceEvent;
```

C++

```
__property TServiceEvent OnExecute;
```

Description

If you are not spawning a new thread to handle individual service requests in an OnStart (see page 3089) event handler, this is where you implement the service. When the OnExecute event handler finishes, the service thread terminates. Most OnExecute event handlers contain a loop that calls the service thread's ProcessRequests method so that other service requests are not locked out.

See Also

ProcessRequests (see page 3100)

OnStart (see page 3089)

33.1.4.6.7 TService.OnPause Event

Occurs when the Service Control manager pauses the service temporarily.

Pascal

```
property OnPause: TPauseEvent;
```

C++

```
__property TPauseEvent OnPause;
```

Description

Write (see page 3707) an OnPause event handler to take specific action when the service is temporarily paused.

See Also

OnContinue (see page 3087)

33.1.4.6.8 TService.OnShutdown Event

Occurs when the system running the service application is about to shut down.

Pascal

```
property OnShutdown: TServiceEvent;
```

C++

```
__property TServiceEvent OnShutdown;
```

Description

Write (see page 3707) an OnShutdown event handler to take specific action just before the service shuts down. The service application terminates immediately after OnShutdown.

See Also

OnStop (see page 3089)

OnStart (see page 3089)

OnPause (see page 3088)

33.1.4.6.9 TService.OnStart Event

OnStartup occurs when the service first starts up, before the OnExecute (see page 3088) event.

Pascal

```
property OnStart: TStartEvent;
```

C++

```
__property TStartEvent OnStart;
```

Description

This event should be used to initialize the service. For example, if each service request is handled in a separate thread (a good idea if handling the request takes much time) the thread for a request is spawned in an OnStart event handler.

See Also

OnStop (see page 3089)

OnContinue (see page 3087)

OnExecute (see page 3088)

33.1.4.6.10 TService.OnStop Event

Occurs when the Service Control manager stops the service.

Pascal

```
property OnStop: TStopEvent;
```

C++

```
__property TStopEvent OnStop;
```

Description

Write (see page 3707) an OnStop event handler to take specific action when the service stops.

See Also

OnShutdown (see page 3088)

OnStart (see page 3089)

OnPause (see page 3088)

33.1.5 TServiceApplication Class

TServiceApplication encapsulates a Windows NT service application.

Class Hierarchy

Pascal

```
[RootDesignerSerializerAttribute('', '', False)]
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TServiceApplication = class(TComponent);
```

C++

```
[RootDesignerSerializerAttribute('', '', False)]
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TServiceApplication : public TComponent;
```

File

SvcMgr

Description

TServiceApplication encapsulates a Windows NT application type known as a service. TServiceApplication provides the fundamental behavior of this type of application. Each Service project automatically declares an Application (see page 3109) variable of type TServiceApplication as the instance of the application. The Application (see page 3109) variable is added to a project by selecting File | New (see page 3619) from the menu of the IDE main window and selecting Service Application (see page 3109) in the New (see page 3619) Items dialog.

TServiceApplication contains TService (see page 3071) objects, each of which encapsulates a Windows NT service. The service application object provides methods to create service objects and to install, register, dispatch, and uninstall services.

When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

Note: Do not add the Forms or Httpapp units to the uses list of the project (Delphi) or includ the unit header for these units in the project source (C++). Those units declare conflicting Application (see page 3109) variables of types TApplication and TWebApplication, respectively.

See Also

Application (see page 3109)

TService (see page 3071)

Service Applications

Service Name\ Properties

33.1.5.1 TServiceApplication Members

The following tables list the members exposed by TServiceApplication.

Protected Methods

	Name	Description
	DispatchServiceMain (see page 3092)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 3092)	This is DoHandleException, a member of class TServiceApplication.
	Hook (see page 3093)	This is Hook, a member of class TServiceApplication.
	RegisterServices (see page 3093)	This is RegisterServices, a member of class TServiceApplication.

Public Methods

	Name	Description
	Create (see page 3091)	Instantiates a TServiceApplication (see page 3089) object.
	CreateForm (see page 3092)	Creates the service object or objects for the service application.

	Destroy (see page 3091)	Disposes of an instance of a TServiceApplication (see page 3089) object.
	Initialize (see page 3093)	Sets the initial state of the application and hides any associated MainForm.
	Installing (see page 3093)	This is Installing, a member of class TServiceApplication.
	Run (see page 3094)	Installs, registers, and adds services to its component list, and creates a thread for the service application.

Public Properties

	Name	Description
	DelayInitialize (see page 3094)	This is DelayInitialize, a member of class TServiceApplication.
	ServiceCount (see page 3094)	Indicates the number of services in the service application.
	Title (see page 3095)	Indicates the name of the title application.

33.1.5.2 TServiceApplication.Create Constructor

Instantiates a TServiceApplication (see page 3089) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TServiceApplication(TComponent * AOwner);
```

Description

Applications do not need to call the constructor directly. TServiceApplication (see page 3089) is instantiated by selecting File | New (see page 3619) from the menu of the IDE main window and selecting Service Application (see page 3109) in the New (see page 3619) Items dialog. An Application (see page 3109) variable of type TServiceApplication (see page 3089) is declared and initialized as the instance of the application.

33.1.5.3 TServiceApplication.Destroy Destructor

Disposes of an instance of a TServiceApplication (see page 3089) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TServiceApplication();
```

Description

You do not need to call the destructor directly. TServiceApplication (see page 3089) is destroyed when your application closes.

The destructor frees the memory associated with sub-objects.

See Also

System::TObject::Free (see page 3372)

33.1.5.4 TServiceApplication Methods

The methods of the TServiceApplication class are listed here.

Protected Methods

	Name	Description
	DispatchServiceMain (see page 3092)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 3092)	This is DoHandleException, a member of class TServiceApplication.
	Hook (see page 3093)	This is Hook, a member of class TServiceApplication.
	RegisterServices (see page 3093)	This is RegisterServices, a member of class TServiceApplication.

Public Methods

	Name	Description
	CreateForm (see page 3092)	Creates the service object or objects for the service application.
	Initialize (see page 3093)	Sets the initial state of the application and hides any associated MainForm.
	Installing (see page 3093)	This is Installing, a member of class TServiceApplication.
	Run (see page 3094)	Installs, registers, and adds services to its component list, and creates a thread for the service application.

33.1.5.4.1 TServiceApplication.CreateForm Method

Creates the service object or objects for the service application.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference); virtual;
```

C++

```
virtual __fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Do not call CreateForm in an application. The module manager calls CreateForm internally to register the service objects of the service application.

CreateForm instantiates a TService (see page 3071) object for each service contained in the service application. CreateForm is called automatically, for the first service, when the service application is first created. Subsequently, CreateForm is called for each new service added to the application. To add a new service, select File | New (see page 3619) from the menu of the IDE main window and choose Service in the New (see page 3619) Items dialog.

33.1.5.4.2 TServiceApplication.DispatchServiceMain Method

Pascal

```
procedure DispatchServiceMain(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall DispatchServiceMain(DWord Argc, PLPSTR Argv);
```

Description

This is DispatchServiceMain, a member of class TServiceApplication.

33.1.5.4.3 TServiceApplication.DoHandleException Method

Pascal

```
procedure DoHandleException(E: Exception); dynamic;
```

C++

```
__fastcall DoHandleException(Exception E);
```

Description

This is DoHandleException, a member of class TServiceApplication.

33.1.5.4.4 TServiceApplication.Hook Method

Pascal

```
function Hook(var Message: TMessage): Boolean;
```

C++

```
__fastcall Boolean Hook(TMessage Message);
```

Description

This is Hook, a member of class TServiceApplication.

33.1.5.4.5 TServiceApplication.Initialize Method

Sets the initial state of the application and hides any associated MainForm.

Pascal

```
procedure Initialize; virtual;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize sets the initial state of the application to hide any main form that may be associated with the application. Service applications are rarely interactive and do not typically have a form associated with them. If a form has been added to the application, Initialize hides it on start. Initialize then follows the standard (default) VCL application initialization process.

33.1.5.4.6 TServiceApplication.Installing Method

Pascal

```
function Installing: Boolean;
```

C++

```
__fastcall Boolean Installing();
```

Description

This is Installing, a member of class TServiceApplication.

33.1.5.4.7 TServiceApplication.RegisterServices Method

Pascal

```
procedure RegisterServices(Install: Boolean; Silent: Boolean);
```

C++

```
__fastcall RegisterServices(Boolean Install, Boolean Silent);
```

Description

This is RegisterServices, a member of class TServiceApplication.

33.1.5.4.8 TServiceApplication.Run Method

Installs, registers, and adds services to its component list, and creates a thread for the service application.

Pascal

```
procedure Run; virtual;
```

C++

```
virtual __fastcall Run();
```

Description

Run handles installing and uninstalling services, depending on the command line switches. When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

If not called with the /INSTALL or /UNINSTALL switch, Run creates a service application thread that responds to Windows messages from clients. Note that this thread is for the application and differs from the dedicated TServiceThread (see page 3095) instances associated with individual services in the application.

33.1.5.5 TServiceApplication Properties

The properties of the TServiceApplication class are listed here.

Public Properties

	Name	Description
	DelayInitialize (see page 3094)	This is DelayInitialize, a member of class TServiceApplication.
R	ServiceCount (see page 3094)	Indicates the number of services in the service application.
	Title (see page 3095)	Indicates the name of the title application.

33.1.5.5.1 TServiceApplication.DelayInitialize Property

Pascal

```
property DelayInitialize: Boolean;
```

C++

```
__property Boolean DelayInitialize;
```

Description

This is DelayInitialize, a member of class TServiceApplication.

33.1.5.5.2 TServiceApplication.ServiceCount Property

Indicates the number of services in the service application.

Pascal

```
property ServiceCount: Integer;
```

C++

```
__property int ServiceCount;
```

Description

ServiceCount is the number of services in the service application. Each service is encapsulated by a TService (see page 3071) instance and has its own dedicated service thread.

Note: If the Service application requires a user name and password, the application must implement only a single service.

See Also

TService (see page 3071)

33.1.5.5.3 TServiceApplication.Title Property

Indicates the name of the title application.

Pascal

```
property Title: string;
```

C++

```
__property UnicodeString Title;
```

Description

Title is the name of the service application. This text string appears below the icon of the application when it is minimized.

33.1.6 TServiceThread Class

TServiceThread represents the thread associated with a specific service (TService (see page 3071) object).

Class Hierarchy

Pascal

```
TServiceThread = class(TThread);
```

C++

```
class TServiceThread : public TThread;
```

File

SvcMgr

Description

TServiceThread is the thread associated with a service. Each service application has one or more service objects, each of which has its own dedicated thread. TServiceThread instances represent those threads.

Note: Service threads.

See Also

TService (see page 3071)

TServiceApplication (see page 3089)

Service Threads

33.1.6.1 TServiceThread Members

The following tables list the members exposed by TServiceThread.

Protected Methods

	Name	Description
	Execute (see page 3097)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
	Create (see page 3096)	Instantiates and initializes a TServiceThread (see page 3095) object.
	ProcessRequests (see page 3100)	Allows clients to invoke the service associated with the service thread.

33.1.6.2 TServiceThread.Create Constructor

Instantiates and initializes a TServiceThread (see page 3095) object.

Pascal

```
constructor Create(Service: TService);
```

C++

```
__fastcall TServiceThread(TService Service);
```

Description

Applications do not need to call the constructor directly. Instances of TService (see page 3071) create the TServiceThread (see page 3095) object on startup. The Service parameter is the TService (see page 3071) instance for which the TServiceThread (see page 3095) is the dedicated thread.

The constructor sets the FreeOnTerminate property to true and then calls the base class constructor so that the thread object is created with its Suspended property set to false.

See Also

FreeOnTerminate

Suspended

33.1.6.3 TServiceThread Methods

The methods of the TServiceThread class are listed here.

Protected Methods

	Name	Description
	Execute (see page 3097)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
	ProcessRequests (see page 3100)	Allows clients to invoke the service associated with the service thread.

33.1.6.3.1 TServiceThread.Execute Method

Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Pascal

```
procedure Execute; override;
```

C++

```
virtual __fastcall Execute();
```

Description

Override Execute and insert the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated property to determine if the thread needs to exit.

A thread executes when Create is called if CreateSuspended set to false, or when Resume is first called after the thread is created if CreateSuspended set to true.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize method.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

__fastcall TYouThread::TYouThread(bool suspended)
```

```
    : TThread(suspended)
{
}

void __fastcall TMyThread::Execute()
{
  Form1->Memo1->Lines->Add("Process has been running for this many seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo1->Lines->Add("Low priority process " + IntToStr(I));
    Sleep(1000);
  }
  mythreadRunning = FALSE;
}

void __fastcall TYouThread::Execute()
{
  Form1->Memo3->Lines->Add("Second low priority process has been running for this many
seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo3->Lines->Add("Second low priority process " + IntToStr(I));
    Sleep(1000);
  }
  youthreadRunning = FALSE;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMyThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (mythreadRunning == FALSE)
  {
    mythreadRunning = TRUE;
    SecondProcess = new TMyThread(True); // create suspended - secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form1->Memo2->Lines->Add("Do some work in the main process for 10 seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo2->Lines->Add("Main process " + IntToStr(I));
    Sleep(1000);
  }
}

void __fastcall TForm1::Button3Click(TObject *Sender)
{
  TYouThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (youthreadRunning == FALSE)
  {
    youthreadRunning = TRUE;
    SecondProcess = new TYouThread(True); // create suspended - secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
```

```
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  mythreadRunning = FALSE;
  youthreadRunning = FALSE;
}
```

Delphi Examples:

```
{
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes.  The
Execute procedure must be overridden in the extension class
of TThread or an "Abstract Error" will result. To create the
extension choose the File | New | Other | Thread Object menu.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (mythreadRunning = FALSE) then
  begin
    mythreadRunning:= TRUE;
    MyProcess := TMyThread.Create(True); { create suspended - secondprocess does not run yet }
    MyProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    MyProcess.Priority := tpLower;  // set the priority to lower than normal
    MyProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  if mythreadRunning then MyProcess.Terminate();
end;

procedure TMyThread.Execute;
var I: Integer;
begin
  Form1.Memo1.Lines.Add('Process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo1.Lines.Add('Low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
  mythreadRunning:= FALSE;
end;

procedure TYouThread.Execute;
var I: Integer;
begin
  Form1.Memo3.Lines.Add('Second low priority process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo3.Lines.Add('Second low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
    youthreadRunning:= FALSE;
end;

procedure TForm1.Button2Click(Sender: TObject);
```

```
var   I: Integer;
begin
  Form1.Memo2.Lines.Add('Do some work in the main process for 10 seconds:');
  for I := 0 to 10 do
  begin
    Form1.Memo2.Lines.Add('Main process ' + InttoStr(I));
    Sleep(1000);
  end;
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  if (youthreadRunning = FALSE) then
  begin
    youthreadRunning:= TRUE;
    YouProcess := TYouThread.Create(True); { create suspended – secondprocess does not run yet
}
    YouProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    YouProcess.Priority := tpLower;  // set the priority to lower than normal
    YouProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  if youthreadRunning then YouProcess.Terminate();
end;

procedure TForm1.FormCreate(Sender: TObject);
begin

33.1.6.3.2 TServiceThread.ProcessRequests Method

Allows clients to invoke the service associated with the service thread.

Pascal

```
procedure ProcessRequests(WaitForMessage: Boolean);
```

C++

```
__fastcall ProcessRequests(Boolean WaitForMessage);
```

Description

TServiceThread (see page 3095)'s ProcessRequests is called in the Execute (see page 3097) method after any associated service's OnExecute event handler has finished executing. For more information about optimizing service execution by spawning individual threads for each service request, see the Developer's Guide.

See Also

OnExecute (see page 3088)

33.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCurrentStatus (see page 3102)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 3103)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 3103)	TServiceType indicates the type of a service.
	TStartType (see page 3104)	TStartType indicates how a service starts up.

33.2.1 SvcMgr.TCurrentStatus Enumeration

TCurrentStatus indicates the state of a service.

Pascal

```
TCurrentStatus = (
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
);
```

C++

```
enum TCurrentStatus {
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
};
```

File

SvcMgr

Description

TCurrentStatus can have one of the following values:

Value	Meaning
csStopped	The service is not running.
csStartPending	The service is starting.
csStopPending	The service is stopping.
csRunning	The service is running.

csContinuePending	The service continue is pending.
csPausePending	The service pause is pending.
csPaused	The service is paused

33.2.2 SvcMgr.TErrorSeverity Enumeration

TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.

Pascal

```
TErrorSeverity = (
  esIgnore,
  esNormal,
  esSevere,
  esCritical
);
```

C++

```
enum TErrorSeverity {
  esIgnore,
  esNormal,
  esSevere,
  esCritical
};
```

File

SvcMgr

Description

TErrorSeverity can have one of the following values:

Value	What the startup program does
esIgnore	Logs the error and continues.
esNormal	Logs the error and displays a message, but continues.
esSevere	Logs the error but continues only if the last-known-good configuration is being started; otherwise the last-known-good configuration is started instead.
esCritical	Logs the error and starts up the last-known-good configuration instead. If this is the last-known-good configuration, the startup operation fails.

33.2.3 SvcMgr.TServiceType Enumeration

TServiceType indicates the type of a service.

Pascal

```
TServiceType = (
  stWin32,
  stDevice,
  stFileSystem
);
```

C++

```
enum TServiceType {
  stWin32,
  stDevice,
  stFileSystem
};
```

File

SvcMgr

Description

TServiceType can have one of the following values:

Value	Meaning
stWin32	a Win32 service.
stDevice	a device driver.
stFileSystem	a file system driver.

33.2.4 SvcMgr.TStartType Enumeration

TStartType indicates how a service starts up.

Pascal

```
TStartType = (
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
);
```

C++

```
enum TStartType {
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
};
```

File

SvcMgr

Description

The following table lists the possible values of TStartType:

StartType value	Service is started
stBoot(used only when ServiceType is not stWin32)	by the operating system loader
stSystem(used only when ServiceType is not stWin32)	after boot systems are initialized
stAuto	automatically during system startup

stManual	when a process calls the Windows StartService function
stDisabled	the service can't be started except by an administrator

33.3 Types

The following table lists types in this documentation.

Types

Name	Description
TContinueEvent (see page 3106)	TContinueEvent is the type for event handlers that respond when the Service Control manager resumes a service.
TPauseEvent (see page 3106)	TPauseEvent is the type for event handlers that respond when the Service Control manager pauses a service.
TServiceController (see page 3107)	TServiceController is the type for a registered service's handler function.
TServiceEvent (see page 3107)	TServiceEvent is the procedure type used for service events that do not require parameters.
TStartEvent (see page 3108)	TStartEvent is the type for event handlers that respond when the Service Control manager starts a service.
TStopEvent (see page 3108)	TStopEvent is the type for event handlers that respond when the Service Control manager stops a service.

33.3.1 SvcMgr.TContinueEvent Type

TContinueEvent is the type for event handlers that respond when the Service Control manager resumes a service.

Pascal

```
TContinueEvent = procedure (Sender: TService; var Continued: Boolean) of object;
```

C++

```
(Sender: TService; var Continued: Boolean) ( TContinueEvent)();
```

File

SvcMgr

Description

Sender is the service that the Service Control manager resumed.

Set Continued to true when the service resumes.

See Also

Procedural types

Creating events

33.3.2 SvcMgr.TPauseEvent Type

TPauseEvent is the type for event handlers that respond when the Service Control manager pauses a service.

Pascal

```
TPauseEvent = procedure (Sender: TService; var Paused: Boolean) of object;
```

C++

```
(Sender: TService; var Paused: Boolean) ( TPauseEvent)();
```

File

SvcMgr

Description

Sender is the service that the Service Control manager paused.

Set Paused to true if the event handler pauses the service.

See Also

Procedural types

Creating events

33.3.3 SvcMgr.TServiceController Type

TServiceController is the type for a registered service's handler function.

Pascal

```
TServiceController = procedure (CtrlCode: DWord);
```

C++

```
(CtrlCode: DWord) ( TServiceController)();
```

File

SvcMgr

Description

TServiceController is the type of the service handler function that the Service application wizard generates.

33.3.4 SvcMgr.TServiceEvent Type

TServiceEvent is the procedure type used for service events that do not require parameters.

Pascal

```
TServiceEvent = procedure (Sender: TService) of object;
```

C++

```
(Sender: TService) ( TServiceEvent)();
```

File

SvcMgr

Description

TServiceEvent specifies a method used for service events that have no event-specific parameters. TServiceEvent is used to execute a process that occurs typically during installation, uninstallation, or shutdown. It is also the event type for the main service execution. The Sender parameter is the service component receiving the event notification.

See Also

Procedural types

Creating events

33.3.5 SvcMgr.TStartEvent Type

TStartEvent is the type for event handlers that respond when the Service Control manager starts a service.

Pascal

```
TStartEvent = procedure (Sender: TService; var Started: Boolean) of object;
```

C++

```
(Sender: TService; var Started: Boolean) ( TStartEvent)();
```

File

SvcMgr

Description

Sender is the service that the Service Control manager started.

Set Started to true if the event handler starts the service..

See Also

Procedural types

Creating events

33.3.6 SvcMgr.TStopEvent Type

TStopEvent is the type for event handlers that respond when the Service Control manager stops a service.

Pascal

```
TStopEvent = procedure (Sender: TService; var Stopped: Boolean) of object;
```

C++

```
(Sender: TService; var Stopped: Boolean) ( TStopEvent)();
```

File

SvcMgr

Description

Sender is the service that the Service Control manager stopped.

Set Stopped to true if the event handler stops the service..

See Also

Procedural types

Creating events

33.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Application (see page 3109)	Represents a service Application for a service project.

33.4.1 SvcMgr.Application Variable

Represents a service Application for a service project.

Pascal

```
Application: TServiceApplication = nil;
```

C++

```
TServiceApplication Application = nil;
```

File

SvcMgr

Description

By default, when a new service Application project is created, the Forms designer constructs an Application object and assigns it to Application. If the project represents a service Application, Application is initialized to a TServiceApplication (see page 3089) object.

33.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 3110)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

33.5.1 SvcMgr.CM_SERVICE_CONTROL_CODE Constant

Pascal

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

C++

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

File

SvcMgr

Description

This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

34 SyncObjs Namespace

This is namespace SyncObjs.

Topics

Name	Description
Classes (see page 3112)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 3156)	The following table lists structs, records, enums in this documentation.
Types (see page 3157)	The following table lists types in this documentation.

Classes

	Name	Description
	TConditionVariableCS (see page 3112)	TConditionVariableCS allows the use of condition variables in combination with critical sections.
	TConditionVariableHelper (see page 3117)	TConditionVariableHelper is a class helper for the `TRTLConditionVariable` record.
	TConditionVariableMutex (see page 3120)	TConditionVariableMutex allows the use of condition variables in combination with mutexes.
	TCriticalSection (see page 3125)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TCriticalSectionHelper (see page 3130)	TCriticalSectionHelper is a record helper for the `TRTLCriticalSection` record.
	TEvent (see page 3133)	TEvent represents an external event.
	THandleObject (see page 3137)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 3143)	TMutex is a synchronization primitive used to guard a shared resource.
	TSemaphore (see page 3147)	TSemaphore is a synchronization primitive that manages the concurrent execution of threads, in the context of sharing a common resource.
	TSimpleEvent (see page 3152)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 3152)	TSynchroObject is the base class for all thread synchronization objects.

Structs, Records, Enums

	Name	Description
	TWaitResult (see page 3156)	TWaitResult indicates the reason an event object stopped waiting for its signal.

Types

Name	Description
THandleObjectArray (see page 3157)	THandleObjectArray represents an array of THandleObject (see page 3137).

34.1 Classes

The following table lists classes in this documentation.

Class Helpers

Name	Description
TConditionVariableHelper (see page 3117)	TConditionVariableHelper is a class helper for the `TRTLConditionVariable` record.
TCriticalSectionHelper (see page 3130)	TCriticalSectionHelper is a record helper for the `TRTLCriticalSection` record.

Classes

	Name	Description
	TConditionVariableCS (see page 3112)	TConditionVariableCS allows the use of condition variables in combination with critical sections.
	TConditionVariableMutex (see page 3120)	TConditionVariableMutex allows the use of condition variables in combination with mutexes.
	TCriticalSection (see page 3125)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TEvent (see page 3133)	TEvent represents an external event.
	THandleObject (see page 3137)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 3143)	TMutex is a synchronization primitive used to guard a shared resource.
	TSemaphore (see page 3147)	TSemaphore is a synchronization primitive that manages the concurrent execution of threads, in the context of sharing a common resource.
	TSimpleEvent (see page 3152)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 3152)	TSynchroObject is the base class for all thread synchronization objects.

34.1.1 TConditionVariableCS Class

TConditionVariableCS allows the use of condition variables in combination with critical sections.

Class Hierarchy

Pascal

```
TConditionVariableCS = class(TSynchroObject);
```

C++

```
class TConditionVariableCS : public TSynchroObject;
```

File

SyncObjs

Description

Use TConditionVariableCS in multi-threaded applications in which a thread is required to sleep, inside its critical section, until a specified condition becomes true. During this waiting period, other threads are able to run and are supposed to notify the sleeping thread when the condition becomes true.

When the condition variable is awakened, the critical section is automatically reacquired.

To create a condition variable, instantiate the TConditionVariableCS class. Then, in the executing code of each thread, use a

combination of WaitFor (see page 3116) and the Release (see page 3115) or ReleaseAll (see page 3116) methods in order to achieve the communication between threads.

See Also

Create (see page 3114)

34.1.1.1 TConditionVariableCS Members

The following tables list the members exposed by TConditionVariableCS.

Protected Fields

	Name	Description
	FConditionVariable (see page 3115)	This is FConditionVariable, a member of class TConditionVariableCS.

Public Methods

	Name	Description
	Acquire (see page 3115)	Raises an exception because a condition variable cannot be acquired.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3114)	Has no effect.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3115)	Wakes up a single thread sleeping on the condition variable.
	ReleaseAll (see page 3116)	Wakes up all threads sleeping on the condition variable.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	WaitFor (see page 3116)	This is the overview for the WaitFor method overload.

34.1.1.2 TConditionVariableCS.Create Constructor

Has no effect.

Pascal

```
constructor Create;
```

C++

```
__fastcall TConditionVariableCS();
```

Description

The Create method is empty and is only provided for code compatibility reasons.

See Also

Acquire (see page 3115)

Release (see page 3115)

ReleaseAll (see page 3116)

WaitFor (see page 3116)

34.1.1.3 TConditionVariableCS Fields

The fields of the TConditionVariableCS class are listed here.

Protected Fields

	Name	Description
	FConditionVariable (see page 3115)	This is FConditionVariable, a member of class TConditionVariableCS.

34.1.1.3.1 TConditionVariableCS.FConditionVariable Field

Pascal

```
FConditionVariable: TRTLConditionVariable;
```

C++

```
TRTLConditionVariable FConditionVariable;
```

Description

This is FConditionVariable, a member of class TConditionVariableCS.

34.1.1.4 TConditionVariableCS Methods

The methods of the TConditionVariableCS class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3115)	Raises an exception because a condition variable cannot be acquired.
	Release (see page 3115)	Wakes up a single thread sleeping on the condition variable.
	ReleaseAll (see page 3116)	Wakes up all threads sleeping on the condition variable.
	WaitFor (see page 3116)	This is the overview for the WaitFor method overload.

34.1.1.4.1 TConditionVariableCS.Acquire Method

Raises an exception because a condition variable cannot be acquired.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

The Acquire method raises an exception because condition variables cannot be acquired. Acquire is only provided for code compatibility reasons.

See Also

Create (see page 3114)

Release (see page 3115)

ReleaseAll (see page 3116)

WaitFor (see page 3116)

34.1.1.4.2 TConditionVariableCS.Release Method

Wakes up a single thread sleeping on the condition variable.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release to wake up a single thread sleeping on the condition variable.

Note: To reduce the number of context switches, make a call to Release after releasing the critical section.

See Also

ReleaseAll (see page 3116)

WaitFor (see page 3116)

34.1.1.4.3 TConditionVariableCS.ReleaseAll Method

Wakes up all threads sleeping on the condition variable.

Pascal

```
procedure ReleaseAll;
```

C++

```
__fastcall ReleaseAll();
```

Description

Call ReleaseAll to wake up all threads sleeping on the condition variable.

Note: To reduce the number of context switches, make a call to ReleaseAll after releasing the critical section.

See Also

Release (see page 3115)

WaitFor (see page 3116)

34.1.1.4.4 WaitFor Method

This is the overview for the WaitFor method overload.

Overload List

	Name	Description
	TConditionVariableCS.WaitFor (TCriticalSection, LongWord) (see page 3116)	Sleeps on the condition variable and releases the given critical section.
	TConditionVariableCS.WaitFor (TRTLCriticalSection, LongWord) (see page 3116)	Sleeps on the condition variable and releases the given critical section.

34.1.1.4.4.1 TConditionVariableCS.WaitFor Method (TCriticalSection, LongWord)

Sleeps on the condition variable and releases the given critical section.

Pascal

```
function WaitFor(CriticalSection: TCriticalSection; TimeOut: LongWord = INFINITE):
TWaitResult; overload;
function WaitFor(var CriticalSection: TRTLCriticalSection; TimeOut: LongWord = INFINITE):
TWaitResult; overload;
```

C++

```
__fastcall TWaitResult WaitFor(TCriticalSection CriticalSection, LongWord TimeOut = INFINITE);
__fastcall TWaitResult WaitFor(TRTLCriticalSection CriticalSection, LongWord TimeOut =
INFINITE);
```

Description

Call WaitFor to sleep on the condition variable and to release the critical section specified through the `CriticalSection` parameter.

The `TimeOut` parameter sets the time-out interval. When this interval elapses, the critical section is reacquired, even if the condition variable has not been awakened by other threads.

The result returned by the WaitFor function is of TWaitResult (see page 3156) type and can have one of the following values:

Value	Meaning
wrSignaled	The condition variable has been awakened.
wrTimeout	The time-out interval has elapsed without the condition variable being awakened.
wrAbandoned	The condition variable has been destroyed before the time-out interval has elapsed.
wrError	An error occured while waiting. Check the `LastError` property for an error code giving more information.

Condition variables might suddenly wake up, without making an explicit call to the Release (see page 3115) or ReleaseAll (see page 3116) methods. Also, other threads might manage to run before the thread that sleeps on the condition variable is awakened. Therefore, make the call to WaitFor inside a loop. To avoid the above mentioned errors, the loop should test that the desired condition becomes true even after the condition variable is awakened.

See Also

Release (see page 3115)

ReleaseAll (see page 3116)

34.1.2 TConditionVariableHelper Class Helper

TConditionVariableHelper is a class helper for the `TRTLConditionVariable` record.

Class Hierarchy

SyncObjs.TConditionVariableHelper

Pascal

```
TConditionVariableHelper = class helper for TRTLConditionVariable;
```

C++

```
class TConditionVariableHelper;
```

File

SyncObjs

Description

TConditionVariableHelper provides several operating-system-dependent helper routines for the `TRTLConditionVariable` record.

See Also

SleepCS (see page 3119)

Wake (see page 3120)

WakeAll (see page 3120)

TCriticalSection (see page 3125)

34.1.2.1 TConditionVariableHelper Members

The following tables list the members exposed by TConditionVariableHelper.

Public Methods

	Name	Description
	Create (see page 3118)	Initializes the condition variable.
	Free (see page 3119)	Has no effect.
	SleepCS (see page 3119)	Sleeps on the condition variable and releases the given critical section.
	Wake (see page 3120)	Wakes up a single thread sleeping on the condition variable.
	WakeAll (see page 3120)	Wakes up all threads sleeping on the condition variable.

34.1.2.2 TConditionVariableHelper Methods

The methods of the TConditionVariableHelper class are listed here.

Public Methods

	Name	Description
	Create (see page 3118)	Initializes the condition variable.
	Free (see page 3119)	Has no effect.
	SleepCS (see page 3119)	Sleeps on the condition variable and releases the given critical section.
	Wake (see page 3120)	Wakes up a single thread sleeping on the condition variable.
	WakeAll (see page 3120)	Wakes up all threads sleeping on the condition variable.

34.1.2.2.1 TConditionVariableHelper.Create Method

Initializes the condition variable.

Pascal

```
class function Create: TRTLConditionVariable; static;
```

C++

```
static __fastcall TRTLConditionVariable Create();
```

Description

Call Create to initialize the condition variable.

Note: Condition variables are shared by threads only inside the same process. They cannot be shared between processes.

See Also

Free (see page 3119)

SleepCS (see page 3119)

Wake (see page 3120)

WakeAll (see page 3120)

34.1.2.2.2 TConditionVariableHelper.Free Method

Has no effect.

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

The Free method is empty and is only provided for code compatibility reasons.

See Also

Create (see page 3118)

34.1.2.2.3 TConditionVariableHelper.SleepCS Method

Sleeps on the condition variable and releases the given critical section.

Pascal

```
function SleepCS(var CriticalSection: TRTLCriticalSection; dwMilliseconds: DWORD): Boolean;
```

C++

```
__fastcall Boolean SleepCS(TRTLCriticalSection CriticalSection, DWORD dwMilliseconds);
```

Description

Call SleepCS to sleep on the condition variable and to release the critical section specified through the `CriticalSection` parameter.

The `dwMilliseconds` parameter sets the time-out interval. When this interval elapses, the critical section is reacquired, even if the condition variable has not been awakened by other threads.

Condition variables might suddenly wake up without making an explicit call to the Wake (see page 3120) or to the WakeAll (see page 3120) method. Also, other threads might run before the thread that sleeps on the condition variable is awakened. Therefore, make the call to SleepCS inside a loop. To avoid the above mentioned errors, the loop should test that the desired condition becomes true even after the condition variable has awakened.

See Also

Wake (see page 3120)

WakeAll (see page 3120)

34.1.2.2.4 TConditionVariableHelper.Wake Method

Wakes up a single thread sleeping on the condition variable.

Pascal

```
procedure Wake;
```

C++

```
__fastcall Wake();
```

Description

Call Wake to wake up a single thread sleeping on the condition variable.

Note: To reduce the number of context switches, make a call to Wake after releasing the critical section.

See Also

SleepCS (see page 3119)

WakeAll (see page 3120)

34.1.2.2.5 TConditionVariableHelper.WakeAll Method

Wakes up all threads sleeping on the condition variable.

Pascal

```
procedure WakeAll;
```

C++

```
__fastcall WakeAll();
```

Description

Call Wake (see page 3120) to wake up all threads sleeping on the condition variable.

Note: To reduce the number of context switches, make a call to WakeAll after releasing the critical section.

See Also

SleepCS (see page 3119)

Wake (see page 3120)

34.1.3 TConditionVariableMutex Class

TConditionVariableMutex allows the use of condition variables in combination with mutexes.

Class Hierarchy

Pascal

```
TConditionVariableMutex = class(TSynchroObject);
```

C++

```
class TConditionVariableMutex : public TSynchroObject;
```

File

SyncObjs

Description

Use TConditionVariableMutex in multi-threaded applications in which a thread is required to release a mutex until a specified condition becomes true. During this waiting period, other threads are able to run and are supposed to notify the sleeping thread when the condition becomes true.

When the condition variable is awakened, the mutex is automatically reacquired.

To create a condition variable, simply instantiate the TConditionVariableMutex class. Then, in the executing code of each thread, use a combination of WaitFor (see page 3124) and the Release (see page 3124) or ReleaseAll (see page 3124) methods in order to achieve the communication between threads.

See Also

34.1.3.1 TConditionVariableMutex Members

The following tables list the members exposed by TConditionVariableMutex.

Public Methods

	Name	Description
	Acquire (see page 3123)	Raises an exception, since a condition variable cannot be acquired.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3122)	Initializes the mutex condition variable.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3123)	Destroys the mutex condition variable.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3124)	Wakes up a single thread sleeping on the mutex condition variable.
	ReleaseAll (see page 3124)	Wakes up all threads sleeping on the mutex condition variable.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	WaitFor (see page 3124)	Sleeps on the condition variable and releases the specified mutex.

34.1.3.2 TConditionVariableMutex.Create Constructor

Initializes the mutex condition variable.

Pascal

```
constructor Create;
```

C++

```
__fastcall TConditionVariableMutex();
```

Description

Call Create to initialize the mutex condition variable.

See Also

Acquire (see page 3123)

Destroy (see page 3123)

Release (see page 3124)

ReleaseAll (see page 3124)

WaitFor (see page 3124)

34.1.3.3 TConditionVariableMutex.Destroy Destructor

Destroys the mutex condition variable.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TConditionVariableMutex();
```

Description

Call Destroy to destroy the mutex condition variable.

See Also

Create (see page 3122)

Acquire (see page 3123)

Release (see page 3124)

ReleaseAll (see page 3124)

WaitFor (see page 3124)

34.1.3.4 TConditionVariableMutex Methods

The methods of the TConditionVariableMutex class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3123)	Raises an exception, since a condition variable cannot be acquired.
	Release (see page 3124)	Wakes up a single thread sleeping on the mutex condition variable.
	ReleaseAll (see page 3124)	Wakes up all threads sleeping on the mutex condition variable.
	WaitFor (see page 3124)	Sleeps on the condition variable and releases the specified mutex.

34.1.3.4.1 TConditionVariableMutex.Acquire Method

Raises an exception, since a condition variable cannot be acquired.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

The Acquire method raises an exception, since condition variables cannot be acquired. Acquire is only provided for code compatibility reasons.

See Also

Create (see page 3122)

Destroy (see page 3123)

Release (see page 3124)

ReleaseAll (see page 3124)

WaitFor (see page 3124)

34.1.3.4.2 TConditionVariableMutex.Release Method

Wakes up a single thread sleeping on the mutex condition variable.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release to wake up a single thread sleeping on the mutex condition variable.

Note: To reduce the number of context switches, make a call to Release after releasing the mutex.

See Also

ReleaseAll (see page 3124)

WaitFor (see page 3124)

34.1.3.4.3 TConditionVariableMutex.ReleaseAll Method

Wakes up all threads sleeping on the mutex condition variable.

Pascal

```
procedure ReleaseAll;
```

C++

```
__fastcall ReleaseAll();
```

Description

Call Release (see page 3124) to wake up all threads sleeping on the mutex condition variable.

Note: To reduce the number of context switches, make a call to ReleaseAll after releasing the mutex.

See Also

Release (see page 3124)

WaitFor (see page 3124)

34.1.3.4.4 TConditionVariableMutex.WaitFor Method

Sleeps on the condition variable and releases the specified mutex.

Pascal

```
function WaitFor(AExternalMutex: TMutex; TimeOut: LongWord = INFINITE): TWaitResult;
```

C++

```
__fastcall TWaitResult WaitFor(TMutex AExternalMutex, LongWord TimeOut = INFINITE);
```

Description

Call WaitFor to sleep on the condition variable and to release the mutex specified through the `AExternalMutex` parameter.

The `TimeOut` parameter sets the time-out interval. When this interval elapses, the mutex is reacquired, even if the condition variable has not been awakened by other threads.

The result returned by the WaitFor function is of TWaitResult (see page 3156) type and can have one of the following values:

Value	Meaning
wrSignaled	The condition variable has been awakened.
wrTimeout	The time-out interval has elapsed without the condition variable being awakened.
wrAbandoned	The condition variable had been destroyed before the time-out interval has elapsed.
wrError	An error occured while waiting. Check the `LastError` property for an error code giving more information.

Condition variables might suddenly wake up, without making an explicit call to the Release (see page 3124) or to the ReleaseAll (see page 3124) method. Also, other threads might run before the thread that sleeps on the condition variable is awakened. Therefore, make the call to WaitFor inside a loop. To avoid the above mentioned errors, the loop should test that the desired condition becomes true even after the condition variable has awakened.

See Also

Release (see page 3124)

ReleaseAll (see page 3124)

34.1.4 TCriticalSection Class

TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.

Class Hierarchy

Pascal

```
TCriticalSection = class(TSynchroObject);
```

C++

```
class TCriticalSection : public TSynchroObject;
```

File

SyncObjs

Description

Use TCriticalSection to safeguard operations that may be disrupted if another thread executes certain sections of code before the operation is completed. Critical sections work like gates that allow only a single thread to enter at a time. Because they block the execution of other threads, overusing critical sections can seriously interfere with performance.

Critical sections must be global in scope so that they are available to all threads. In every thread, any action that could interfere with the operations safeguarded by the critical section should only take place after calling the Acquire (see page 3128) or Enter (see page 3128) method. Threads that do not use the critical section for relevant operations can introduce bugs.

See Also

TThread

Using Critical Sections

34.1.4.1 TCriticalSection Members

The following tables list the members exposed by TCriticalSection.

Protected Fields

	Name	Description
	FSection (see page 3128)	This is FSection, a member of class TCriticalSection.

Public Methods

	Name	Description
	Acquire (see page 3128)	Binds the critical section to the calling thread.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3127)	Creates an instance of TCriticalSection (see page 3125).
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3127)	Destroys an instance of TCriticalSection (see page 3125).
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Enter (see page 3128)	Blocks other threads when the calling thread enters a thread-sensitive section.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	Leave (see page 3129)	Allows other threads to use the critical section.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3129)	Allows other threads to use the critical section.

	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	TryEnter (see page 3130)	Tries to enter a critical section.
	UnitName (see page 3380)	Returns a string containing the unit name.

34.1.4.2 TCriticalSection.Create Constructor

Creates an instance of TCriticalSection (see page 3125).

Pascal

```
constructor Create;
```

C++

```
__fastcall TCriticalSection();
```

Description

Call Create to create and initialize an instance of TCriticalSection (see page 3125). A TCriticalSection (see page 3125) object can be created for a single object that contains thread-sensitive code, or as a global object to be shared by several threads.

See Also

System::TObject::Create (see page 3355)

34.1.4.3 TCriticalSection.Destroy Destructor

Destroys an instance of TCriticalSection (see page 3125).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCriticalSection();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TCriticalSection (see page 3125) object is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

34.1.4.4 TCriticalSection Fields

The fields of the TCriticalSection class are listed here.

Protected Fields

	Name	Description
	FSection (see page 3128)	This is FSection, a member of class TCriticalSection.

34.1.4.4.1 TCriticalSection.FSection Field

Pascal

```
FSection: TRTLCriticalSection;
```

C++

```
TRTLCriticalSection FSection;
```

Description

This is FSection, a member of class TCriticalSection.

34.1.4.5 TCriticalSection Methods

The methods of the TCriticalSection class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3128)	Binds the critical section to the calling thread.
	Enter (see page 3128)	Blocks other threads when the calling thread enters a thread-sensitive section.
	Leave (see page 3129)	Allows other threads to use the critical section.
	Release (see page 3129)	Allows other threads to use the critical section.
	TryEnter (see page 3130)	Tries to enter a critical section.

34.1.4.5.1 TCriticalSection.Acquire Method

Binds the critical section to the calling thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire to block all other threads from acquiring this critical section until the Release (see page 3129) or Leave (see page 3129) method is called. Acquire does the same thing as the Enter (see page 3128) method.

See Also

Enter (see page 3128)

Leave (see page 3129)

Release (see page 3129)

Using Critical Sections

34.1.4.5.2 TCriticalSection.Enter Method

Blocks other threads when the calling thread enters a thread-sensitive section.

Pascal

```
procedure Enter;
```

C++

```
__fastcall Enter();
```

Description

Call Enter to block all other threads from entering code protected by this critical section until the Leave (see page 3129) or Release (see page 3129) method is called. Enter calls the Acquire (see page 3128) method to bind the critical section to the calling thread.

See Also

Acquire (see page 3128)

Leave (see page 3129)

Release (see page 3129)

34.1.4.5.3 TCriticalSection.Leave Method

Allows other threads to use the critical section.

Pascal

```
procedure Leave;
```

C++

```
__fastcall Leave();
```

Description

Call Leave at the end of a thread-sensitive section of code. Each call to Leave should be balanced by a call to Enter (see page 3128) or Acquire (see page 3128) at the beginning of the thread-sensitive section. Leave calls Release (see page 3129) to allow other threads to acquire the critical section.

See Also

Acquire (see page 3128)

Enter (see page 3128)

Release (see page 3129)

34.1.4.5.4 TCriticalSection.Release Method

Allows other threads to use the critical section.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release when the thread no longer needs to block other threads from executing code that is protected by this critical section. Each call to Release should be balance by an earlier call to Acquire (see page 3128) or Enter (see page 3128) that blocked other threads from executing. Release does the same thing as the Leave (see page 3129) method.

See Also

Acquire (see page 3128)

Enter (see page 3128)

Leave (see page 3129)

Using Critical Sections

34.1.4.5.5 TCriticalSection.TryEnter Method

Tries to enter a critical section.

Pascal

```
function TryEnter: Boolean;
```

C++

```
__fastcall Boolean TryEnter();
```

Description

Call TryEnter to block all the other threads from entering the code that is protected by this critical section until the Leave (see page 3129) or Release (see page 3129) methods are called.

TryEnter does not wait for other threads to leave the critical section. True is returned on success; False is returned if the section is acquired by another thread.

See Also

Acquire (see page 3128)

Leave (see page 3129)

Release (see page 3129)

34.1.5 TCriticalSectionHelper Class Helper

TCriticalSectionHelper is a record helper for the `TRTLCriticalSection` record.

Class Hierarchy

SyncObjs.TCriticalSectionHelper

Pascal

```
TCriticalSectionHelper = class helper for TRTLCriticalSection;
```

C++

```
class TCriticalSectionHelper;
```

File

SyncObjs

Description

TCriticalSectionHelper provides several operating-system-dependent helper routines for the `TRTLCriticalSection` record.

See Also

TCriticalSection (see page 3125)

TMutex (see page 3143)

TSemaphore (see page 3147)

TEvent (see page 3133)

TThread

THandleObject (see page 3137)

TConditionVariableCS (see page 3112)

TConditionVariableMutex (see page 3120)

TConditionVariableHelper (see page 3117)

34.1.5.1 TCriticalSectionHelper Members

The following tables list the members exposed by TCriticalSectionHelper.

Public Methods

	Name	Description
	Destroy (see page 3131)	Deletes the critical section from memory.
	Enter (see page 3132)	Waits until the critical section is free and then locks it.
	Free (see page 3132)	Deletes the critical section.
	Initialize (see page 3132)	Initializes the critical section.
	Leave (see page 3133)	Releases the lock on the critical section.
	TryEnter (see page 3133)	Attempts to acquire a lock on the critical section.

34.1.5.2 TCriticalSectionHelper Methods

The methods of the TCriticalSectionHelper class are listed here.

Public Methods

	Name	Description
	Destroy (see page 3131)	Deletes the critical section from memory.
	Enter (see page 3132)	Waits until the critical section is free and then locks it.
	Free (see page 3132)	Deletes the critical section.
	Initialize (see page 3132)	Initializes the critical section.
	Leave (see page 3133)	Releases the lock on the critical section.
	TryEnter (see page 3133)	Attempts to acquire a lock on the critical section.

34.1.5.2.1 TCriticalSectionHelper.Destroy Method

Deletes the critical section from memory.

Pascal

```
procedure Destroy;
```

C++

```
__fastcall Destroy();
```

Description

Call Destroy to delete the critical section from memory and to release all the resources used by the critical section.

See Also

Free (see page 3132)

Initialize (see page 3132)

34.1.5.2.2 TCriticalSectionHelper.Enter Method

Waits until the critical section is free and then locks it.

Pascal

```
procedure Enter;
```

C++

```
__fastcall Enter();
```

Description

Call Enter to grant ownership of the critical section to the calling thread.

If the critical section is not currently free, then the calling thread is added to the waiting queue of the critical section.

See Also

TryEnter (see page 3133)

Leave (see page 3133)

34.1.5.2.3 TCriticalSectionHelper.Free Method

Deletes the critical section.

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

Call Free to delete the critical section.

Free is an alias for the Destroy (see page 3131) method. You can use either of these methods, with the same effect.

See Also

Destroy (see page 3131)

Initialize (see page 3132)

34.1.5.2.4 TCriticalSectionHelper.Initialize Method

Initializes the critical section.

Pascal

```
procedure Initialize;
```

C++

```
__fastcall Initialize();
```

Description

Call Initialize to initialize the critical section.

See Also

Free (see page 3132)

Destroy (see page 3131)

34.1.5.2.5 TCriticalSectionHelper.Leave Method

Releases the lock on the critical section.

Pascal

```
procedure Leave;
```

C++

```
__fastcall Leave();
```

Description

Call Leave to release the lock on the critical section. This lock is acquired by using the Enter (see page 3132) method.

See Also

Enter (see page 3132)

34.1.5.2.6 TCriticalSectionHelper.TryEnter Method

Attempts to acquire a lock on the critical section.

Pascal

```
function TryEnter: Boolean;
```

C++

```
__fastcall Boolean TryEnter();
```

Description

Call TryEnter when attempting to lock the critical section.

If successful, the TryEnter method grants ownership of the critical section to the calling thread and returns True. Otherwise, it returns False and no ownership is granted.

See Also

Enter (see page 3132)

Leave (see page 3133)

34.1.6 TEvent Class

TEvent represents an external event.

Class Hierarchy

Pascal

```
TEvent = class(THandleObject);
```

C++

```
class TEvent : public THandleObject;
```

File

SyncObjs

Description

Use TEvent to signal that an event has occurred or a state has been reached.

In a multi-threaded application, use TEvent to allow one thread to signal to other threads that an event has occurred.

The handle of a TEvent object can also be used to communicate with other processes, so that an application can coordinate the timing of events with other applications. For example, use the handle of a TEvent object to wait until another process is ready to transfer information.

In a single-threaded application, use TEvent to coordinate between sections of code that respond to asynchronous events such as system events.

See Also

TThread

Waiting for a Task to Be Completed

34.1.6.1 TEvent Members

The following tables list the members exposed by TEvent.

Protected Fields

	Name	Description
	FHandle (see page 3140)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3140)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3140)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3154)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3135)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3139)	Destroys an instance of THandleObject (see page 3137).
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.

	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3154)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ResetEvent (see page 3136)	Turns off the signal of the event object.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	SetEvent (see page 3137)	Turns on the signal of the event object.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	WaitFor (see page 3141)	Waits until this THandleObject (see page 3137) object enters into the signaled state.
	WaitForMultiple (see page 3141)	Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

Public Properties

	Name	Description
	Handle (see page 3142)	Specifies the handle of the Windows object used by THandleObject (see page 3137).
	LastError (see page 3142)	Indicates the Windows error code obtained from Handle (see page 3142).

34.1.6.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TEvent.Create (Boolean) (see page 3135)	Instantiates a TEvent (see page 3133) object to represent an event object.
	TEvent.Create (PSecurityAttributes, Boolean, Boolean, string, Boolean) (see page 3135)	Instantiates a TEvent (see page 3133) object to represent an event object.

34.1.6.2.1 TEvent.Create Constructor (Boolean)

Instantiates a TEvent (see page 3133) object to represent an event object.

Pascal

```
constructor Create(EventAttributes: PSecurityAttributes; ManualReset: Boolean; InitialState:
Boolean; const Name: string; UseCOMWait: Boolean = False); overload;
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TEvent(PSecurityAttributes EventAttributes, Boolean ManualReset, Boolean
InitialState, const UnicodeString Name, Boolean UseCOMWait = False);
```

```
__fastcall TEvent(Boolean UseCOMWait = False);
```

Description

Call Create to create a TEvent (see page 3133) object. Create can generate a new event object or can provide access to an existing named event object.

Set `EventAttributes` parameter to specify the access rights and inheritance capabilities of the new event object. Calling Create with EventAttributes set to nil (Delphi) or NULL (C++) creates an event object with a default set of security attributes. If the TEvent (see page 3133) object is created to access an existing named event object, only the bInheritHandle field of EventAttributes is used, as the access rights were determined when the event object was created.

Set `ManualReset` to specify whether the signal of the TEvent (see page 3133) object can only be turned off by a call to the ResetEvent (see page 3136) method, or whether it is automatically reset when a single waiting thread is released. When ManualReset is true, the TEvent (see page 3133) signal stays set until the ResetEvent (see page 3136) method turns it off. When ManualReset is false, the signal is automatically turned off when only a single thread waits on the signal and that thread is released. If the TEvent (see page 3133) object is created to access an existing named event object, the ManualReset parameter is ignored.

Set `InitialState` to indicate whether the TEvent (see page 3133) object should be created with the signal set, or turned off. When InitialState is true, the TEvent (see page 3133) object is created with the signal set. If the TEvent (see page 3133) object is created to access an existing named event object, the InitialState parameter is ignored.

Set `Name` to provide a name for a new event object or to specify an existing named event object. If no other thread or process will need to access the event object to wait for its signal, Name can be left blank. Name can be a string of up to 260 characters, not including the backslash character (\). If Name is used to specify an existing event object, the value must match the name of the existing event in a case-sensitive comparison. If Name matches the name of an existing semaphore, mutex, or file-mapping object, the TEvent (see page 3133) object will be created with Handle (see page 3142) set to 0 and all method calls will fail.

Set `UseCOMWait` to **True** to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

See Also

Handle (see page 3142)

ResetEvent (see page 3136)

34.1.6.3 TEvent Methods

The methods of the TEvent class are listed here.

Public Methods

	Name	Description
	ResetEvent (see page 3136)	Turns off the signal of the event object.
	SetEvent (see page 3137)	Turns on the signal of the event object.

34.1.6.3.1 TEvent.ResetEvent Method

Turns off the signal of the event object.

Pascal

```
procedure ResetEvent;
```

C++

```
__fastcall ResetEvent();
```

Description

Call ResetEvent to signal that the event has not occurred or the desired state was not achieved. Other threads or processes that wait for the event will wait until the signal is turned on again by the SetEvent (see page 3137) method, the event object is destroyed, or the waiting process times out.

See Also

SetEvent (see page 3137)

WaitFor (see page 3141)

Waiting for a Task to Be Completed

34.1.6.3.2 TEvent.SetEvent Method

Turns on the signal of the event object.

Pascal

```
procedure SetEvent;
```

C++

```
__fastcall SetEvent();
```

Description

Call SetEvent to signal that the event has occurred or the desired state was achieved. Other threads or processes that wait for the event will resume execution with a return value indicating that the signal was set.

See Also

ResetEvent (see page 3136)

WaitFor (see page 3141)

Waiting for a Task to Be Completed

34.1.7 THandleObject Class

THandleObject is the base class for all thread synchronization objects that use a handle.

Class Hierarchy

Pascal

```
THandleObject = class(TSynchroObject);
```

C++

```
class THandleObject : public TSynchroObject;
```

File

SyncObjs

Description

Use THandleObject as a base class when defining an object that uses a handle when coordinating the execution of different threads in a multi-threaded application. Handled synchronization objects include event objects that allow threads to signal when

critical events have occurred.

Do not create instances of THandleObject. THandleObject is a base class that introduces properties for managing the handle of a synchronization object but does not provide a mechanism for acquiring that handle. Descendants of THandleObject must acquire the appropriate type of handle.

See Also

TThread

TEvent (see page 3133)

34.1.7.1 THandleObject Members

The following tables list the members exposed by THandleObject.

Protected Fields

	Name	Description
	FHandle (see page 3140)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3140)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3140)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 3154)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3139)	Instantiates a THandleObject (see page 3137) object.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3139)	Destroys an instance of THandleObject (see page 3137).
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.

	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3154)	Provides the interface for a method that releases the synchronization object for use by other threads.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	WaitFor (see page 3141)	Waits until this THandleObject (see page 3137) object enters into the signaled state.
	WaitForMultiple (see page 3141)	Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

Public Properties

	Name	Description
	Handle (see page 3142)	Specifies the handle of the Windows object used by THandleObject (see page 3137).
	LastError (see page 3142)	Indicates the Windows error code obtained from Handle (see page 3142).

34.1.7.2 THandleObject.Create Constructor

Instantiates a THandleObject (see page 3137) object.

Pascal

```
constructor Create(UseCOMWait: Boolean = False);
```

C++

```
__fastcall THandleObject(Boolean UseCOMWait = False);
```

Description

Call Create to create a THandleObject (see page 3137) object.

Set the `UseCOMWait` parameter to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

See Also

Handle (see page 3142)

34.1.7.3 THandleObject.Destroy Destructor

Destroys an instance of THandleObject (see page 3137).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THandleObject();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the THandleObject (see page 3137) reference is not nil and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

Handle (see page 3142)

34.1.7.4 THandleObject Fields

The fields of the THandleObject class are listed here.

Protected Fields

	Name	Description
	FHandle (see page 3140)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3140)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3140)	This is FUseCOMWait, a member of class THandleObject.

34.1.7.4.1 THandleObject.FHandle Field

Pascal

```
FHandle: THandle;
```

C++

```
THandle FHandle;
```

Description

This is FHandle, a member of class THandleObject.

34.1.7.4.2 THandleObject.FLastError Field

Pascal

```
FLastError: Integer;
```

C++

```
int FLastError;
```

Description

This is FLastError, a member of class THandleObject.

34.1.7.4.3 THandleObject.FUseCOMWait Field

Pascal

```
FUseCOMWait: Boolean;
```

C++

```
Boolean FUseCOMWait;
```

Description

This is FUseCOMWait, a member of class THandleObject.

34.1.7.5 THandleObject Methods

The methods of the THandleObject class are listed here.

Public Methods

	Name	Description
	WaitFor (see page 3141)	Waits until this THandleObject (see page 3137) object enters into the signaled state.
	WaitForMultiple (see page 3141)	Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

34.1.7.5.1 THandleObject.WaitFor Method

Waits until this THandleObject (see page 3137) object enters into the signaled state.

Pascal

```
function WaitFor(Timeout: LongWord): TWaitResult; virtual;
```

C++

```
virtual __fastcall TWaitResult WaitFor(LongWord Timeout);
```

Description

Call WaitFor to wait until a THandleObject (see page 3137) object enters into the signaled state. If the signaled state is not reached after `TimeOut` milliseconds, WaitFor returns anyway.

Use INFINITE (see page 3848) value for the `TimeOut` parameter to force WaitFor to wait an infinite amount of time.

The function returns a result of TWaitResult (see page 3156) type that can be used to detect how the operation finished.

See Also

WaitForMultiple (see page 3141)

LastError (see page 3142)

Waiting for a Task to Be Completed

34.1.7.5.2 THandleObject.WaitForMultiple Method

Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

Pascal

```
class function WaitForMultiple(const HandleObjs: THandleObjectArray; Timeout: LongWord; AAll:
Boolean; out SignaledObj: THandleObject; UseCOMWait: Boolean = False; Len: Integer = 0):
TWaitResult;
```

C++

```
__fastcall TWaitResult WaitForMultiple(const THandleObjectArray HandleObjs, LongWord Timeout,
Boolean AAll, THandleObject SignaledObj, Boolean UseCOMWait = False, int Len = 0);
```

Description

Call WaitForMultiple to wait until a list of THandleObject (see page 3137) objects enters into the signaled state. If the signaled state is not reached after `TimeOut` milliseconds, WaitForMultiple returns anyway.

The `HandleObjs` parameter contains the list of objects that are waited on.

If the `AAll` parameter is true, the call will finish only after all objects become signaled.

The first signaled object is passed into the `SignaledObj` parameter. This only happens if the function returns wrSignaled and `AAll` is False.

Set the `UseCOMWait` parameter to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

Len contains the number of objects that are monitored in the given list.

The function returns a result of TWaitResult (see page 3156) type, which can be used to detect how the operation finished.

See Also

WaitFor (see page 3141)

LastError (see page 3142)

Waiting for a Task to Be Completed

34.1.7.6 THandleObject Properties

The properties of the THandleObject class are listed here.

Public Properties

	Name	Description
	Handle (see page 3142)	Specifies the handle of the Windows object used by THandleObject (see page 3137).
	LastError (see page 3142)	Indicates the Windows error code obtained from Handle (see page 3142).

34.1.7.6.1 THandleObject.Handle Property

Specifies the handle of the Windows object used by THandleObject (see page 3137).

Pascal

```
property Handle: THandle;
```

C++

```
__property THandle Handle;
```

Description

Read (see page 3634) Handle to obtain the Windows handle for the synchronization object. Use Handle when making Windows API calls that require a handle to the synchronization object.

THandleObject (see page 3137) provides no mechanism for setting the Handle property. Descendants of THandleObject (see page 3137) set the Handle property to the handle for whatever Windows synchronization object they represent.

See Also

Destroy (see page 3139)

34.1.7.6.2 THandleObject.LastError Property

Indicates the Windows error code obtained from Handle (see page 3142).

Pascal

```
property LastError: Integer;
```

C++

```
__property int LastError;
```

Description

Read (see page 3634) LastError when an operation of the THandleObject (see page 3137) fails. LastError returns the Windows error code that represents the reason for the failure. If no operation failed, LastError is 0.

See Also

Handle (see page 3142)

34.1.8 TMutex Class

TMutex is a synchronization primitive used to guard a shared resource.

Class Hierarchy

Pascal

```
TMutex = class(THandleObject);
```

C++

```
class TMutex : public THandleObject;
```

File

SyncObjs

Description

Use TMutex to synchronize two or more threads and allow them to safely access a shared resource. A mutex creates a queue of threads that are waiting on a resource and allows only one thread to access that resource at any given moment.

A mutex is basically equivalent to a binary semaphore.

34.1.8.1 TMutex Members

The following tables list the members exposed by TMutex.

Protected Fields

	Name	Description
	FHandle (see page 3140)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3140)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3140)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
V	Acquire (see page 3146)	Attempts to acquire a lock on the mutex.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3145)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3139)	Destroys an instance of THandleObject (see page 3137).
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3146)	Releases the exclusive lock on the mutex.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
V	WaitFor (see page 3141)	Waits until this THandleObject (see page 3137) object enters into the signaled state.
	WaitForMultiple (see page 3141)	Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

Public Properties

	Name	Description
R	Handle (see page 3142)	Specifies the handle of the Windows object used by THandleObject (see page 3137).
R	LastError (see page 3142)	Indicates the Windows error code obtained from Handle (see page 3142).

34.1.8.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TMutex.Create (Boolean) (see page 3145)	Instantiates a TMutex (see page 3143) object.
	TMutex.Create (LongWord, Boolean, string, Boolean) (see page 3145)	Instantiates a TMutex (see page 3143) object.
	TMutex.Create (PSecurityAttributes, Boolean, string, Boolean) (see page 3145)	Instantiates a TMutex (see page 3143) object.

34.1.8.2.1 TMutex.Create Constructor (Boolean)

Instantiates a TMutex (see page 3143) object.

Pascal

```
constructor Create(UseCOMWait: Boolean = False); overload;
constructor Create(MutexAttributes: PSecurityAttributes; InitialOwner: Boolean; const Name:
string; UseCOMWait: Boolean = False); overload;
constructor Create(DesiredAccess: LongWord; InheritHandle: Boolean; const Name: string;
UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(Boolean UseCOMWait = False);
__fastcall TMutex(PSecurityAttributes MutexAttributes, Boolean InitialOwner, const
UnicodeString Name, Boolean UseCOMWait = False);
__fastcall TMutex(LongWord DesiredAccess, Boolean InheritHandle, const UnicodeString Name,
Boolean UseCOMWait = False);
```

Description

Call Create to create a TMutex (see page 3143) object.

The first version of the constructor creates an unnamed mutex with the default security descriptor, and it establishes that the thread that created the mutex is not its initial owner. Set the `UseCOMWait` parameter to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

The second version of the constructor allows opening an existing mutex, identified by its name. The parameters have the following meaning:

Parameter	Meaning
DesiredAccess	The type of access to the mutex. The constructor fails if the requested type of access is not permitted. It can be any combination of the following constants: **MUTEX_ALL_ACCESS**, **MUTEX_MODIFY_STATE**, **SYNCHRONIZE**, **_DELETE**, **READ_CONTROL**, **WRITE_DAC**, **WRITE_OWNER**. Any combination must include the **SYNCHRONIZE** access right, since this is specific to a mutex.
InheritHandle	Set this parameter for the child processes to inherit the mutex handle.
Name	The name of the mutex to open. Names are case-sensitive.
UseCOMWait	Set this parameter to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

The third version of the constructor creates a named mutex with several attributes, given through the following list of parameters:

Parameter	Meaning
MutexAttributes	The security attributes of the mutex. `MutexAttributes` is of a pointer type to a **_SECURITY_ATTRIBUTES** record, with the following fields: **nLength**, **lpSecurityDescriptor**, **InheritHandle**. The **nLength** field should always be equal to the size, in bytes, of the **_SECURITY_ATTRIBUTES** record. **lpSecurityDescriptor** is a pointer to the security descriptor of the mutex. Finally, **InheritHandle** is True if the handle to the mutex is to be inherited by child processes.
InitialOwner	Set this for the thread that created the mutex to be considered the initial owner of the mutex.
Name	The name of the mutex. Names are case-sensitive.
UseCOMWait	Set this parameter to ensure that when a thread is blocked and waiting for the object, any STA COM calls can be made back into this thread.

Acquire (see page 3146)

Release (see page 3146)

34.1.8.3 TMutex Methods

The methods of the TMutex class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3146)	Attempts to acquire a lock on the mutex.
	Release (see page 3146)	Releases the exclusive lock on the mutex.

34.1.8.3.1 TMutex.Acquire Method

Attempts to acquire a lock on the mutex.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use a shared resource.

The Acquire method waits until the mutex becomes free, and then acquires an exclusive lock. This blocks all other threads from acquiring the mutex. Later, calling the Release (see page 3146) method will make the mutex available for other threads to acquire.

See Also

Release (see page 3146)

Acquire (see page 3151)

34.1.8.3.2 TMutex.Release Method

Releases the exclusive lock on the mutex.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that has finished using a shared resource.

The Release method frees the exclusive lock and allows one of the blocked threads to acquire the mutex.

See Also

Acquire (see page 3146)

Release (see page 3151)

34.1.9 TSemaphore Class

TSemaphore is a synchronization primitive that manages the concurrent execution of threads, in the context of sharing a common resource.

Class Hierarchy

Pascal

```
TSemaphore = class(THandleObject);
```

C++

```
class TSemaphore : public THandleObject;
```

File

SyncObjs

Description

Use TSemaphore in multi-threaded applications that require safe access to a shared resource.

To each semaphore there is an associated counter variable. This variable gives the number of units of the shared resource that are currently free. The counter is decremented whenever a thread locks the semaphore and incremented when a thread releases the semaphore.

If a thread tries to lock the semaphore and the counter value is nil, then the thread adds to the semaphore waiting queue. The first thread in the semaphore queue locks the semaphore as soon as the counter value is nonzero.

When instantiating the TSemaphore class, the number of initial free units of the shared resource can be specified. This is actually the initial value of the semaphore counter variable.

Also, the number of available units of the shared resource can be specified through the `AMaximumCount` parameter of the TSemaphore class constructor.

Note: If the number of available units of the shared resource is one, then TSemaphore is called a binary semaphore and is basically equivalent to a TMutex (see page 3143).

34.1.9.1 TSemaphore Members

The following tables list the members exposed by TSemaphore.

Protected Fields

	Name	Description
	FHandle (see page 3140)	This is FHandle, a member of class THandleObject.
	FLastError (see page 3140)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 3140)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
V	Acquire (see page 3151)	Attempts to acquire a lock on the semaphore.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3149)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3139)	Destroys an instance of THandleObject (see page 3137).
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 3151)	This is the overview for the Release method overload.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
V	WaitFor (see page 3141)	Waits until this THandleObject (see page 3137) object enters into the signaled state.
	WaitForMultiple (see page 3141)	Waits until a list of THandleObject (see page 3137) objects enters into the signaled state.

Public Properties

	Name	Description
R	Handle (see page 3142)	Specifies the handle of the Windows object used by THandleObject (see page 3137).
R	LastError (see page 3142)	Indicates the Windows error code obtained from Handle (see page 3142).

34.1.9.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TSemaphore.Create (Boolean) (see page 3149)	Instantiates a TSemaphore (see page 3147) object.
	TSemaphore.Create (LongWord, Boolean, string, Boolean) (see page 3149)	Instantiates a TSemaphore (see page 3147) object.
	TSemaphore.Create (PSecurityAttributes, Integer, Integer, string, Boolean) (see page 3149)	Instantiates a TSemaphore (see page 3147) object.

34.1.9.2.1 TSemaphore.Create Constructor (Boolean)

Instantiates a TSemaphore (see page 3147) object.

Pascal

```
constructor Create(UseCOMWait: Boolean = False); overload;
constructor Create(SemaphoreAttributes: PSecurityAttributes; AInitialCount: Integer;
AMaximumCount: Integer; const Name: string; UseCOMWait: Boolean = False); overload;
constructor Create(DesiredAccess: LongWord; InheritHandle: Boolean; const Name: string;
UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TSemaphore(Boolean UseCOMWait = False);
__fastcall TSemaphore(PSecurityAttributes SemaphoreAttributes, int AInitialCount, int
AMaximumCount, const UnicodeString Name, Boolean UseCOMWait = False);
__fastcall TSemaphore(LongWord DesiredAccess, Boolean InheritHandle, const UnicodeString Name,
```

```
Boolean UseCOMWait = False);
```

Description

Call Create to create a TSemaphore (see page 3147) object.

The first version of the constructor creates an unnamed binary semaphore with an initial counter value of one. Also, the semaphore is created with the default security descriptor. This means that the child processes of the current process cannot inherit the handle to this semaphore. This is basically equivalent to creating an unnamed TMutex (see page 3143) object. Set the `UseCOMWait` parameter to ensure that when a thread is blocked and waiting for the object, any STA (single-threaded apartment) COM calls can still be made back into this thread.

The second version of the constructor allows opening an existing semaphore, identified by its name. The parameters have the following meaning:

Parameter	Meaning
DesiredAccess	The type of access to the semaphore. The constructor fails if the requested type of access is not permitted. It can be any combination of the following constants: **SEMAPHORE_ALL_ACCESS**, **SEMAPHORE_MODIFY_STATE**, **SYNCHRONIZE**, **_DELETE**, **READ_CONTROL**, **WRITE_DAC**, **WRITE_OWNER.**
InheritHandle	Set this paremeter for the child processes to inherit the handle.
Name	The name of the semaphore to open. Names are case-sensitive.
UseCOMWait	Set this parameter in order to ensure that when a thread is blocked and waiting for the object, any STA COM calls can still be made back into this thread.

The third version of the constructor creates a named semaphore with several attributes, given through the following list of parameters:

Parameter	Meaning
SemaphoreAttributes	The security attributes of the semaphore. `SemaphoreAttributes` is of a pointer type to a **_SECURITY_ATTRIBUTES** record, with the following fields: **nLength**, **lpSecurityDescriptor**, **InheritHandle**. The **nLength** field should always be equal to the size, in bytes, of the **_SECURITY_ATTRIBUTES** record. **lpSecurityDescriptor** is a pointer to the security descriptor of the semaphore. Finally, **InheritHandle** is True if the handle to the semaphore is to be inherited by child processes.
AInitialCount	The initial value of the semaphore counter variable, giving the initial number of free units of the shared resource.
AMaximumCount	The maximum value of the semaphore counter variable, giving the number of available units of the shared resource.
Name	The name of the semaphore. Names are case-sensitive.
UseCOMWait	Set this parameter in order to ensure that when a thread is blocked and waiting for the object, any STA COM calls can still be made back into this thread.

See Also

Acquire (see page 3151)

Release (see page 3151)

34.1.9.3 TSemaphore Methods

The methods of the TSemaphore class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3151)	Attempts to acquire a lock on the semaphore.
	Release (see page 3151)	This is the overview for the Release method overload.

34.1.9.3.1 TSemaphore.Acquire Method

Attempts to acquire a lock on the semaphore.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use some of a shared resource's units.

The Acquire method waits until the semaphore becomes free, that is, the number of free units of the resource is nonzero. Then the Acquire method acquires a lock on the semaphore.

If the semaphore is not free, then the calling thread is added to the semaphore waiting queue.

See Also

Release (see page 3151)

Acquire (see page 3146)

34.1.9.3.2 Release Method

This is the overview for the Release method overload.

Overload List

	Name	Description
	TSemaphore.Release () (see page 3151)	Releases one lock or several locks on the semaphore.
	TSemaphore.Release (Integer) (see page 3151)	Releases one lock or several locks on the semaphore.

34.1.9.3.2.1 TSemaphore.Release Method ()

Releases one lock or several locks on the semaphore.

Pascal

```
procedure Release; override; overload;
function Release(AReleaseCount: Integer): Integer; overload; reintroduce;
```

C++

```
virtual __fastcall Release();
__fastcall int Release(int AReleaseCount);
```

Description

Call Release from a thread that has finished using one or more units of a shared resource.

The Release method releases one or several locks on the semaphore. If several locks are to be freed, they are specified through

the `AReleaseCount` parameter.

If the number of free units of the shared resource plus the value of the `AReleaseCount` parameter exceeds the number of available units of the shared resource, specified through the `AMaximumCount` parameter of the constructor, then the semaphore counter variable is left unchanged and the Release function raises an error.

See Also

Acquire (see page 3151)

Release (see page 3146)

34.1.10 TSimpleEvent Class

TSimpleEvent represents an unnamed manual event object.

Class Hierarchy

Pascal

```
TSimpleEvent = class(TEvent);
```

C++

```
class TSimpleEvent : public TEvent;
```

File

SyncObjs

Description

Use TSimpleEvent to coordinate between threads that all have access to the same simple event object. TSimpleEvent can also be used in a single-threaded application to coordinate sections of code that respond to different asynchronous events such as system messages or user actions.

Because TSimpleEvent represents an unnamed event object, a single TSimpleEvent object must be within the scope of all code that uses it. To coordinate with code that is out of scope, or with other applications, use a named TEvent (see page 3133) object.

TThread

TEvent (see page 3133)

Waiting for a Task to Be Completed

Procedural types

Creating events

34.1.11 TSynchroObject Class

TSynchroObject is the base class for all thread synchronization objects.

Class Hierarchy

Pascal

```
TSynchroObject = class(TObject);
```

C++

```
class TSynchroObject : public TObject;
```

File

SyncObjs

Description

Use TSynchroObject as a base class when defining an object that coordinates the execution of different threads in a multi-threaded application. Synchronization objects include critical sections that temporarily block the execution of other threads which may interfere with the successful completion of a section of code, and event objects that allow threads to signal when critical events have occurred.

See Also

TCriticalSection (see page 3125)

TEvent (see page 3133)

TThread

34.1.11.1 TSynchroObject Members

The following tables list the members exposed by TSynchroObject.

Public Methods

	Name	Description
	Acquire (see page 3154)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.

	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 3154)	Provides the interface for a method that releases the synchronization object for use by other threads.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

34.1.11.2 TSynchroObject Methods

The methods of the TSynchroObject class are listed here.

Public Methods

	Name	Description
	Acquire (see page 3154)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 3154)	Provides the interface for a method that releases the synchronization object for use by other threads.

34.1.11.2.1 TSynchroObject.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; virtual;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject (see page 3152) does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 3154)

34.1.11.2.2 TSynchroObject.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; virtual;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject (see page 3152) does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 3154)

34.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TWaitResult (see page 3156)	TWaitResult indicates the reason an event object stopped waiting for its signal.

34.2.1 SyncObjs.TWaitResult Enumeration

TWaitResult indicates the reason an event object stopped waiting for its signal.

Pascal

```
TWaitResult = (
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError,
  wrIOCompletion
);
```

C++

```
enum TWaitResult {
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError,
  wrIOCompletion
};
```

File

SyncObjs

Description

TWaitResult includes the following values:

Value	Meaning
wrSignaled	The signal of the event object was set.
wrTimeOut	The time specified by the TimeOut parameter elapsed without the signal being set.
wrAbandoned	The event object was destroyed before the TimeOut period elapsed.
wrError	An error occurred while waiting. Check the LastError property for an error code giving more information.

34.3 Types

The following table lists types in this documentation.

Types

Name	Description
THandleObjectArray (see page 3157)	THandleObjectArray represents an array of THandleObject (see page 3137).

34.3.1 SyncObjs.THandleObjectArray Type

THandleObjectArray represents an array of THandleObject (see page 3137).

Pascal

```
THandleObjectArray = array of THandleObject;
```

C++

```
array of THandleObject THandleObjectArray;
```

File

SyncObjs

Description

THandleObjectArray is used by synchronization objects to store and manage objects of type THandleObject (see page 3137).

See Also

THandleObject (see page 3137)

35 System Namespace

This is namespace System.

Topics

Name	Description
Classes (see page 3174)	The following table lists classes in this documentation.
Interfaces (see page 3493)	The following table lists interfaces in this documentation.
Functions (see page 3506)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 3712)	The following table lists structs, records, enums in this documentation.
Types (see page 3750)	The following table lists types in this documentation.
Variables (see page 3806)	The following table lists variables in this documentation.
Constants (see page 3842)	The following table lists constants in this documentation.
Macros (see page 3892)	The following table lists macros in this documentation.

Classes

	Name	Description
	AnsiStringBase (see page 3174)	System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.
	AnsiStringT (see page 3207)	System::AnsiStringT is the C++ analog for the Delphi long string type.
	Currency (see page 3235)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 3255)	This is class System::CurrencyBase.
	DelphiInterface (see page 3256)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 3261)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	DynArrayException (see page 3271)	This is class System::DynArrayException.
	DynArrayNullData (see page 3272)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 3272)	This is class System::DynArrayOutOfRange.
	OleVariant (see page 3274)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	SmallString (see page 3307)	This is class System::SmallString.
	SmallStringBase (see page 3310)	This is class System::SmallStringBase.
	sPointer (see page 3311)	This is class System::sPointer.
	TAggregatedObject (see page 3313)	System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 3502) methods to delegate to the controlling IInterface (see page 3502).
	TClassHelperBase (see page 3318)	This is class System.TClassHelperBase.
	TContainedObject (see page 3320)	System::TContainedObject implements the IInterface (see page 3502) interface as an inner object in an aggregate.

	TDateTime (see page 3323)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.
	TDateTimeBase (see page 3341)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 3342)	System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 3502) implementation.
	TMetaClass (see page 3348)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TMonitor (see page 3349)	TMonitor provides methods for synchronizing the access of several threads to a single object.
	TObject (see page 3354)	System::TObject is the ultimate ancestor of all objects and components.
	UnicodeString (see page 3381)	System::UnicodeString is the C++ analog for the Delphi UnicodeString type.
	Variant (see page 3421)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	WideString (see page 3467)	System::WideString represents strings of 16-bit characters.

Constants

Name	Description
CompilerVersion (see page 3844)	Designates the version number of the Delphi compiler.
CPUi386 (see page 3844)	This is constant System.CPUi386.
CPUi486 (see page 3845)	This is constant System.CPUi486.
CPUPentium (see page 3845)	This is constant System.CPUPentium.
E_NOINTERFACE (see page 3845)	This is constant System.E_NOINTERFACE.
E_NOTIMPL (see page 3846)	This is constant System.E_NOTIMPL.
E_UNEXPECTED (see page 3846)	This is constant System.E_UNEXPECTED.
fmClosed (see page 3846)	This is constant System.fmClosed.
fmInOut (see page 3847)	This is constant System.fmInOut.
fmInput (see page 3847)	This is constant System.fmInput.
fmOutput (see page 3847)	This is constant System.fmOutput.
hfFieldSize (see page 3848)	This is constant System.hfFieldSize.
hfMonitorOffset (see page 3848)	This is constant System.hfMonitorOffset.
INFINITE (see page 3848)	This is constant System.INFINITE.
MaxInt (see page 3849)	The maximum value of the Integer data type.
MaxLongint (see page 3849)	The maximum value of the Longint data type.
NumSmallBlockTypes (see page 3849)	NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.
opAdd (see page 3850)	opAdd defines an addition operation.
opAnd (see page 3850)	opAnd defines a logical and operation.
opCmpEQ (see page 3851)	opCmpEQ defines an equality comparison operator.
opCmpGE (see page 3851)	opCmpGE defines a greater than or equal comparison operator.
opCmpGT (see page 3852)	opCmpGT defines a greater than comparison operator.
opCmpLE (see page 3852)	opCmpLE defines a less than or equal comparison operator.
opCmpLT (see page 3853)	opCmpLT defines a less than comparison operator.
opCmpNE (see page 3853)	opCmpNE defines an inequality comparison operator.
opCompare (see page 3854)	opCompare defines a comparison operation.
opDivide (see page 3854)	opDivide defines a divide operation.
opIntDivide (see page 3855)	opIntDivide defines an integer divide operation.
opModulus (see page 3855)	opModulus defines a modulus operation.
opMultiply (see page 3855)	opMultiply defines a multiply operation.
opNegate (see page 3856)	opNegate defines a negate operation.
opNot (see page 3856)	opNot defines a binary negation operation.
opOr (see page 3857)	opOr defines a logical or operation.
opShiftLeft (see page 3857)	opShiftLeft defines a bitwise shift left operation.
opShiftRight (see page 3858)	opShiftRight defines a bitwise shift right operation.
opSubtract (see page 3858)	opSubtract defines a subtraction operation.
opXor (see page 3859)	opXor defines a logical exclusive or operation.
RTLVersion (see page 3859)	Designates the version number of the Delphi runtime library.
S_FALSE (see page 3859)	This is constant System.S_FALSE.

S_OK (see page 3860)	This is constant System.S_OK.
sLineBreak (see page 3860)	Represents the character(s) used to generate a line feed.
tfCRLF (see page 3861)	This is constant System.tfCRLF.
varAny (see page 3861)	Represents a Variant (see page 3421) that can hold any value.
varArray (see page 3861)	Represents a Variant (see page 3421) that holds dynamic array data.
varBoolean (see page 3862)	Represents a Variant (see page 3421) that holds WordBool data.
varByRef (see page 3862)	Represents a Variant (see page 3421) that points to another variable.
varByte (see page 3863)	Represents a Variant (see page 3421) that holds byte data.
varCurrency (see page 3863)	Represents a Variant (see page 3421) that holds a monetary floating point value.
varDate (see page 3864)	Represents a Variant (see page 3421) that holds a TDateTime (see page 3323) value.
varDispatch (see page 3864)	Represents a Variant (see page 3421) that has been assigned an IDispatch (see page 3494) value.
varDouble (see page 3865)	Represents a Variant (see page 3421) that holds a floating point value.
varEmpty (see page 3865)	Represents a Variant (see page 3421) that has not yet been assigned a value.
varError (see page 3866)	Represents a Variant (see page 3421) that holds a 32 bit error code.
varInt64 (see page 3867)	Represents a Variant (see page 3421) that holds Int64 data.
varInteger (see page 3867)	Represents a Variant (see page 3421) that holds Integer data.
varLongWord (see page 3868)	Represents a Variant (see page 3421) that holds LongWord data.
varNull (see page 3868)	Represents a Variant (see page 3421) that holds a null value.
varOleStr (see page 3869)	Represents a Variant (see page 3421) that has been assigned a COM interface type string value.
varShortInt (see page 3869)	Represents a Variant (see page 3421) that holds ShortInt data.
varSingle (see page 3870)	Represents a Variant (see page 3421) that holds byte data.
varSmallint (see page 3870)	Represents a Variant (see page 3421) that holds Smallint data.
varStrArg (see page 3871)	Represents a Variant (see page 3421) that has holds a COM compatible string value.
varString (see page 3871)	Represents a Variant (see page 3421) that holds string data.
varTypeMask (see page 3872)	Defines a mask for filtering out the meta data part of a Variant (see page 3421) data type.
varUInt64 (see page 3872)	This is constant System.varUInt64.
varUnknown (see page 3873)	Represents a Variant (see page 3421) that holds an unknown value.
varUString (see page 3873)	This is constant System.varUString.
varVariant (see page 3873)	Represents a Variant (see page 3421) data type.
varWord (see page 3874)	Represents a Variant (see page 3421) that holds Word data.
vmtAddRef (see page 3874)	This is constant System.vmtAddRef.
vmtAfterConstruction (see page 3875)	This is constant System.vmtAfterConstruction.
vmtAutoTable (see page 3875)	This is constant System.vmtAutoTable.
vmtBeforeDestruction (see page 3875)	This is constant System.vmtBeforeDestruction.
vmtClassName (see page 3876)	This is constant System.vmtClassName.
vmtCreateObject (see page 3876)	This is constant System.vmtCreateObject.
vmtDefaultHandler (see page 3876)	This is constant System.vmtDefaultHandler.
vmtDestroy (see page 3877)	This is constant System.vmtDestroy.
vmtDispatch (see page 3877)	This is constant System.vmtDispatch.
vmtDynamicTable (see page 3877)	This is constant System.vmtDynamicTable.
vmtEquals (see page 3878)	This is constant System.vmtEquals.
vmtFieldTable (see page 3878)	This is constant System.vmtFieldTable.
vmtFreeInstance (see page 3878)	This is constant System.vmtFreeInstance.
vmtGetHashCode (see page 3879)	This is constant System.vmtGetHashCode.
vmtInitTable (see page 3879)	This is constant System.vmtInitTable.
vmtInstanceSize (see page 3879)	This is constant System.vmtInstanceSize.
vmtIntfTable (see page 3880)	This is constant System.vmtIntfTable.
vmtMethodTable (see page 3880)	This is constant System.vmtMethodTable.
vmtNewInstance (see page 3880)	This is constant System.vmtNewInstance.
vmtParent (see page 3881)	This is constant System.vmtParent.

vmtQueryInterface (see page 3881)	This is constant System.vmtQueryInterface.
vmtRelease (see page 3881)	This is constant System.vmtRelease.
vmtSafeCallException (see page 3882)	This is constant System.vmtSafeCallException.
vmtSelfPtr (see page 3882)	This is constant System.vmtSelfPtr.
vmtToString (see page 3882)	This is constant System.vmtToString.
vmtTypeInfo (see page 3883)	This is constant System.vmtTypeInfo.
vtAnsiString (see page 3883)	vtAnsiString defines an AnsiString TVarData (see page 3740) VType value.
vtBoolean (see page 3883)	vtBoolean defines a Boolean TVarData (see page 3740) VType value.
vtChar (see page 3884)	vtChar defines a Char TVarData (see page 3740) VType value.
vtClass (see page 3884)	vtClass defines a TClass (see page 3785) TVarData (see page 3740) VType value.
vtCurrency (see page 3885)	vtCurrency defines a Currency (see page 3235) TVarData (see page 3740) VType value.
vtExtended (see page 3885)	vtExtended defines an Extended TVarData (see page 3740) VType value.
vtInt64 (see page 3886)	vtInt64 defines an Int64 TVarData (see page 3740) VType value.
vtInteger (see page 3886)	vtInteger defines an Integer TVarData (see page 3740) VType value.
vtInterface (see page 3887)	vtInterface defines an Interface pointer TVarData (see page 3740) VType value.
vtObject (see page 3887)	vtObject defines a TObject (see page 3354) TVarData (see page 3740) VType value.
vtPChar (see page 3888)	vtPChar defines a PChar TVarData (see page 3740) VType value.
vtPointer (see page 3888)	vtPointer defines a Pointer TVarData (see page 3740) VType value.
vtPWideChar (see page 3889)	vtPWideChar defines a PWideChar TVarData (see page 3740) VType value.
vtString (see page 3889)	vtString defines a String TVarData (see page 3740) VType value.
vtUnicodeString (see page 3890)	This is constant System.vtUnicodeString.
vtVariant (see page 3890)	vtString (see page 3889) defines a Variant (see page 3421) TVarData (see page 3740) VType value.
vtWideChar (see page 3890)	vtWideChar defines a WideChar TVarData (see page 3740) VType value.
vtWideString (see page 3891)	vtWideString defines a WideString (see page 3467) TVarData (see page 3740) VType value.

Functions

	Name	Description
	Abs (see page 3511)	Returns an absolute value.
	AcquireExceptionObject (see page 3512)	Retains access to exception object.
	AddModuleUnloadProc (see page 3514)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	AddModuleUnloadProc (see page 3514)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	Addr (see page 3514)	Returns a pointer to a specified object.
	AllocMem (see page 3515)	AllocMem allocates a memory block and initializes each byte to zero.
	AnsiToUtf8 (see page 3517)	Converts a string encoded in Ansi to UTF-8.
	Append (see page 3520)	Prepares an existing file for adding text to the end.
	ArcTan (see page 3521)	Calculates the arctangent of a given number.
	Assert (see page 3522)	Tests whether a Boolean expression is true.
	Assert (see page 3522)	Tests whether a Boolean expression is true.
	Assigned (see page 3524)	Tests for a nil (unassigned) pointer or procedural variable.
	AssignFile (see page 3525)	Associates the name of an external file with a file variable.
	AttemptToUseSharedMemoryManager (see page 3527)	Attempts to use a shared memory manager.
	BeginThread (see page 3527)	Spawns a separate thread of execution.
	BlockRead (see page 3528)	Reads one or more records from an open file into a variable.
	BlockRead (see page 3528)	Reads one or more records from an open file into a variable.
	BlockWrite (see page 3530)	Writes one or more records from a variable to an open file.
	BlockWrite (see page 3530)	Writes one or more records from a variable to an open file.
	Break (see page 3531)	Causes the flow of control to exit a for, while, or repeat statement.
	ChDir (see page 3534)	Changes the current directory.
	ChDir (see page 3534)	Changes the current directory.

	CheckSafecallResult (see page 3536)	This is function System::CheckSafecallResult.
	Chr (see page 3536)	Returns the character for a specified ASCII value.
	Close (see page 3538)	Terminates the association between a file variable and an external file.
	CloseFile (see page 3539)	Terminates the association between file variable and an external disk file.
	CompToCurrency (see page 3542)	Converts a **Comp** value to a Currency (see page 3235) value.
	CompToDouble (see page 3543)	Converts a Comp value to a double value.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Continue (see page 3546)	Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.
	Copy (see page 3547)	Returns a substring of a string or a segment of a dynamic array.
	Cos (see page 3549)	Calculates the cosine of an angle.
	CurrencyToComp (see page 3550)	Converts a Currency (see page 3235) value to a Comp value.
	Dec (see page 3550)	Decrements a variable by 1 or N.
	Dec (see page 3550)	Decrements a variable by 1 or N.
	Delete (see page 3552)	Removes a substring from a string.
	Dispose (see page 3553)	Releases memory allocated for a dynamic variable.
	DoubleToComp (see page 3555)	Converts a double value to a Comp.
	DynArrayClear (see page 3555)	This is function System.DynArrayClear.
	DynArrayDim (see page 3555)	This is function System.DynArrayDim.
	DynArraySetLength (see page 3556)	This is function System.DynArraySetLength.
	EndThread (see page 3556)	Terminates the execution of a thread.
	EnumModules (see page 3556)	Executes a callback for all the modules in an application.
	EnumModules (see page 3556)	Executes a callback for all the modules in an application.
	EnumResourceModules (see page 3557)	Executes a callback for all resource modules in an application.
	EnumResourceModules (see page 3557)	Executes a callback for all resource modules in an application.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eoln (see page 3559)	Tests whether the file pointer is at the end of a line.
	Eoln (see page 3559)	Tests whether the file pointer is at the end of a line.
	Erase (see page 3560)	Deletes an external file.
	Error (see page 3560)	Error is used to generate a run-time exception.
	ExceptAddr (see page 3562)	Returns the address at which the current exception was raised.
	ExceptObject (see page 3562)	Returns current exception object.
	Exclude (see page 3564)	Removes an element from a Delphi set or removes an event handler in .NET applications.
	Exit (see page 3565)	Exits from the current procedure.
	Exp (see page 3567)	Returns the exponential of X.
	Exp (see page 3567)	Returns the exponential of X.
	FilePos (see page 3567)	Returns the current file position.
	FileSize (see page 3569)	Returns the number of records in a file.
	FillChar (see page 3570)	Fills contiguous bytes with a specified value.
	Finalize (see page 3572)	Uninitializes a dynamically allocated variable.
	Finalize (see page 3572)	Uninitializes a dynamically allocated variable.
	FindClassHInstance (see page 3573)	Returns the instance handle for the module in which a class type is defined.
	FindDynaInst (see page 3573)	This is function System::FindDynaInst.
	FindHInstance (see page 3574)	Returns the instance handle of the module that contains a specified address.
	FindResourceHInstance (see page 3574)	Returns the instance handle of the resource module associated with a specified `HInstance`.
	Flush (see page 3575)	Empties the buffer of a text file opened for output.
	FPower10 (see page 3576)	This is function System.FPower10.
	Frac (see page 3576)	Returns the fractional part of a real number.
	FreeMem (see page 3577)	FreeMem frees a memory block.

	FreeMem (see page 3577)	FreeMem frees a memory block.
	FreeMemory (see page 3579)	FreeMemory frees a memory block.
	Get8087CW (see page 3580)	Returns the value of the 8087 code word.
	GetDir (see page 3580)	Returns the current directory.
	GetHeapStatus (see page 3581)	Returns the current status of the memory manager.
	GetLastError (see page 3582)	Returns the last error reported by an operating system API call.
	GetMem (see page 3584)	GetMem allocates a memory block.
	GetMemory (see page 3585)	GetMemory allocates a memory block.
	GetMemoryManager (see page 3587)	Returns the entry points of the currently installed memory manager.
	GetMemoryManager (see page 3587)	Returns the entry points of the currently installed memory manager.
	GetMemoryManagerState (see page 3591)	Fetches state information for the Memory Manager.
	GetMemoryMap (see page 3592)	Fetches the memory map.
	GetMinimumBlockAlignment (see page 3592)	Gets the minimum memory block alignment.
	GetModuleFileName (see page 3593)	Returns the fully qualified name for a module, given its handle.
	GetVariantManager (see page 3594)	Returns the entry points of the routines that define variant behavior.
	Halt (see page 3594)	Initiates abnormal termination of a program.
	Halt (see page 3594)	Initiates abnormal termination of a program.
	Hi (see page 3595)	Returns the high-order byte of X as an unsigned value.
	High (see page 3596)	Returns the highest value in the range of an argument.
	Inc (see page 3597)	Increments an ordinal value by one or N.
	Inc (see page 3597)	Increments an ordinal value by one or N.
	Include (see page 3598)	Adds an element to a Delphi set or adds an event handler in .NET applications.
	Initialize (see page 3599)	Initializes a dynamically allocated variable.
	Initialize (see page 3599)	Initializes a dynamically allocated variable.
	Insert (see page 3601)	Inserts a substring into a string beginning at a specified point.
	Int (see page 3602)	Returns the integer part of a real number.
	IOResult (see page 3602)	Returns the status of the last I/O operation performed.
	IsMemoryManagerSet (see page 3604)	Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 3660) procedure.
	IsVariantManagerSet (see page 3606)	Indicates whether variant support is implemented in an application.
	Length (see page 3607)	Returns the number of characters in a string or elements in an array.
	Ln (see page 3608)	Returns the natural log of a real expression.
	Lo (see page 3609)	Returns the low order Byte of argument X.
	LoadResourceModule (see page 3609)	This is function System.LoadResourceModule.
	LoadResourceString (see page 3610)	This is function System::LoadResourceString.
	LoadResString (see page 3610)	This is function System.LoadResString.
	Low (see page 3610)	Returns the lowest value in a range.
	Mark (see page 3612)	This is function System.Mark.
	MemoryBarrier (see page 3612)	This is function System.MemoryBarrier.
	MkDir (see page 3612)	Creates a new subdirectory.
	MkDir (see page 3612)	Creates a new subdirectory.
	MonitorEnter (see page 3614)	Prohibits the access of all other threads but the calling one to the specified object.
	MonitorExit (see page 3614)	Releases a lock of the calling thread on the specified object.
	MonitorPulse (see page 3615)	Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases it.
	MonitorPulseAll (see page 3615)	Signals all threads in the waiting queue that either one of them will be able to lock the specified object as soon as the calling thread releases it.
	MonitorTryEnter (see page 3616)	Attempts to lock the specified object, so that only the calling thread is able to access it.
	MonitorWait (see page 3616)	Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.
	Move (see page 3617)	Copies bytes from a source to a destination.
	MoveChars (see page 3618)	Copies bytes from a source to a destination.
	New (see page 3619)	Creates a new dynamic variable and sets P to point to it.
	Odd (see page 3621)	Returns true if argument is an odd number.
	OleStrToString (see page 3622)	Copies data received from a COM interface to a string.

	OleStrToStrVar (see page 3622)	Copies a string from its COM representation to an existing Delphi string.
	OleStrToStrVar (see page 3622)	Copies a string from its COM representation to an existing Delphi string.
	Ord (see page 3623)	Returns the ordinal value of an ordinal-type expression.
	ParamCount (see page 3623)	Returns the number of parameters passed on the command line.
	ParamStr (see page 3625)	Returns a specified parameter from the command-line.
	Pi (see page 3626)	Returns 3.1415926535897932385.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pred (see page 3628)	Returns the predecessor of the argument.
	Ptr (see page 3630)	Converts a specified address to a pointer.
	PUCS4Chars (see page 3632)	Converts a UCS4 string to a null-terminated array of UCS4 characters.
	RaiseList (see page 3632)	This is function System.RaiseList.
	Random (see page 3632)	Generates random numbers within a specified range.
	Random (see page 3632)	Generates random numbers within a specified range.
	Randomize (see page 3633)	Initializes the random number generator with a random value.
	Read (see page 3634)	Read reads data from a file.
	Read (see page 3634)	Read reads data from a file.
	Read (see page 3634)	Read reads data from a file.
	Read (see page 3634)	Read reads data from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReallocMem (see page 3637)	ReallocMem reallocates a memory block.
	ReallocMemory (see page 3638)	ReallocMemory resizes a memory block.
	RegisterExpectedMemoryLeak (see page 3640)	Registers an expected memory leak.
	RegisterModule (see page 3640)	Registers the specified module.
	Release (see page 3641)	This is function System.Release.
	ReleaseExceptionObject (see page 3641)	Releases exception object acquired by AcquireExceptionObject (see page 3512).
	RemoveModuleUnloadProc (see page 3641)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	RemoveModuleUnloadProc (see page 3641)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	Rename (see page 3642)	Changes the name of an external file.
	Rename (see page 3642)	Changes the name of an external file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Rewrite (see page 3645)	Creates a new file and opens it.
	Rewrite (see page 3645)	Creates a new file and opens it.
	RmDir (see page 3647)	Deletes an empty subdirectory.
	RmDir (see page 3647)	Deletes an empty subdirectory.
	Round (see page 3648)	Returns the value of X rounded to the nearest whole number.
	RunError (see page 3649)	Stops execution and generates a runtime error.
	RunError (see page 3649)	Stops execution and generates a runtime error.
	Seek (see page 3650)	Moves the current position of a file to a specified component.
	SeekEof (see page 3651)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEof (see page 3651)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEoln (see page 3652)	Returns the end-of-line status of a file, ignoring whitespace.
	SeekEoln (see page 3652)	Returns the end-of-line status of a file, ignoring whitespace.

	Set8087CW (see page 3653)	Sets both the control word in the floating point unit and the variable NoErrMsg (see page 3832) declared in the system unit.
	SetCodePage (see page 3655)	This is function System.SetCodePage.
	SetInOutRes (see page 3655)	This is function System.SetInOutRes.
	SetLastError (see page 3656)	SetLastError sets the last API error code.
	SetLength (see page 3657)	Sets the length of a string or dynamic-array variable.
	SetLineBreakStyle (see page 3659)	Determines the end-of-line and end-of-file conventions for text file I/O.
	SetMemoryManager (see page 3660)	Sets entry points of the memory manager.
	SetMemoryManager (see page 3660)	Sets entry points of the memory manager.
	SetMinimumBlockAlignment (see page 3664)	Sets the minimum memory block alignment.
	SetMultiByteConversionCodePage (see page 3665)	Sets the code page used internally whenever multibyte characters are converted to/from WideChar.
	SetRaiseList (see page 3665)	This is function System.SetRaiseList.
	SetString (see page 3665)	Sets the contents and length of the given string.
	SetTextBuf (see page 3667)	Assigns an I/O buffer to a text file.
	SetTextBuf (see page 3667)	Assigns an I/O buffer to a text file.
	SetVariantManager (see page 3668)	Sets the entry points of routines that define variant behavior.
	ShareMemoryManager (see page 3668)	Shares the module's memory manager.
	Sin (see page 3669)	Returns the sine of the angle in radians.
	SizeOf (see page 3670)	Returns the number of bytes occupied by a variable or type.
	Slice (see page 3671)	Returns a sub-section of an array.
	Sqr (see page 3674)	Returns the square of a number.
	Sqr (see page 3674)	Returns the square of a number.
	Sqrt (see page 3675)	Returns the square root of X.
	Str (see page 3676)	Formats a string and returns it to a variable.
	Str (see page 3676)	Formats a string and returns it to a variable.
	StringCodePage (see page 3676)	Returns the code page associated with the string.
	StringCodePage (see page 3676)	Returns the code page associated with the string.
	StringElementSize (see page 3677)	Returns the number of bytes that represent a character in the string.
	StringElementSize (see page 3677)	Returns the number of bytes that represent a character in the string.
	StringOfChar (see page 3677)	Returns a string with a specified number of repeating characters.
	StringOfChar (see page 3677)	Returns a string with a specified number of repeating characters.
	StringRefCount (see page 3678)	Returns the reference count of a string.
	StringRefCount (see page 3678)	Returns the reference count of a string.
	StringToOleStr (see page 3678)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToOleStr (see page 3678)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToWideChar (see page 3679)	Returns a UNICODE string from an AnsiString.
	Succ (see page 3680)	Returns the successor of an argument.
	Swap (see page 3680)	Exchanges high order byte with the low order byte of an integer or word.
	SysAllocMem (see page 3681)	This is function System.SysAllocMem.
	SysFreeMem (see page 3681)	Frees the memory pointed to by a specified pointer.
	SysGetMem (see page 3682)	Allocates a specified number of bytes and returns a pointer to them.
	SysReallocMem (see page 3683)	Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.
	SysRegisterExpectedMemoryLeak (see page 3683)	This is function System.SysRegisterExpectedMemoryLeak.
	SysUnregisterExpectedMemoryLeak (see page 3684)	This is function System.SysUnregisterExpectedMemoryLeak.
	TextStart (see page 3684)	This is function System.TextStart.
	Trunc (see page 3684)	Truncates a real number to an integer.
	Truncate (see page 3685)	Deletes all the records after the current file position.
	UCS4StringToUnicodeString (see page 3686)	Converts an UCS-4 encoded string to an Unicode string.
	UCS4StringToWideString (see page 3687)	Converts a string of 4-byte Unicode characters into a WideString (see page 3467) value.
	UnicodeStringToUCS4String (see page 3689)	Converts an Unicode string to its UCS-4 encoded representation.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.

	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UnregisterExpectedMemoryLeak (see page 3694)	Unregisters an expected memory leak.
	UnregisterModule (see page 3694)	Unregisters the specified module.
	UpCase (see page 3695)	Converts a character to uppercase.
	UpCase (see page 3695)	Converts a character to uppercase.
	UTF8Decode (see page 3696)	Converts a UTF8 string to a Unicode string (WideString (see page 3467)).
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	Utf8ToAnsi (see page 3698)	Converts a UTF8 string to a string of Ansi characters.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	Utf8ToUnicode (see page 3699)	Converts a string of UTF-8 characters to a Unicode string.
	Utf8ToUnicode (see page 3699)	Converts a string of UTF-8 characters to a Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToWideString (see page 3700)	Converts an UTF-8 encoded string to a WideString (see page 3467).
	Val (see page 3701)	Converts a string to a numeric representation.
	VarArrayRedim (see page 3702)	Resizes a Variant (see page 3421) array.
	VarClear (see page 3704)	Empties a Variant (see page 3421), so that it is unassigned.
	WideCharLenToString (see page 3705)	Converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)**.
	WideCharLenToStrVar (see page 3706)	WideCharLenToStrVar converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)** or **AnsiString**.
	WideCharLenToStrVar (see page 3706)	WideCharLenToStrVar converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)** or **AnsiString**.
	WideCharToString (see page 3706)	Converts null-terminated **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.
	WideCharToStrVar (see page 3707)	Converts **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.
	WideStringToUCS4String (see page 3707)	Converts a WideString (see page 3467) value to a string of 4-byte Unicode characters.
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	YieldProcessor (see page 3711)	This is function System.YieldProcessor.

Interfaces

	Name	Description
	IComparable (see page 3493)	IComparable is the generic interface used to compare two objects.
	IDispatch (see page 3494)	IDispatch is the interface used to support Automation.
	IEnumerable (see page 3497)	IEnumerable is the generic interface for enumerable containers.

	IEnumerator (see page 3498)	IEnumerator is the generic interface for container enumerators.
	IEquatable (see page 3500)	IEquatable is the generic interface used to check the equality of two objects.
	IInterface (see page 3502)	IInterface is the base class for all interfaces defined in Delphi code.
	IInvokable (see page 3504)	IInvokable is the base class for invokable interfaces.

Macros

Name	Description
USE (see page 3892)	This is macro System::USE.
USEADDITIONALFILES (see page 3892)	This is macro System::USEADDITIONALFILES.
USEASM (see page 3893)	This is macro System::USEASM.
USEDATAMODULE (see page 3893)	This is macro System::USEDATAMODULE.
USEDATAMODULENS (see page 3893)	This is macro System::USEDATAMODULENS.
USEDEF (see page 3894)	This is macro System::USEDEF.
USEFILE (see page 3894)	This is macro System::USEFILE.
USEFORM (see page 3895)	This is macro System::USEFORM.
USEFORMNS (see page 3895)	This is macro System::USEFORMNS.
USEFORMRES (see page 3895)	This is macro System::USEFORMRES.
USEIDL (see page 3896)	This is macro System::USEIDL.
USELIB (see page 3896)	This is macro System::USELIB.
USEOBJ (see page 3896)	This is macro System::USEOBJ.
USEPACKAGE (see page 3897)	This is macro System::USEPACKAGE.
USERC (see page 3897)	This is macro System::USERC.
USERES (see page 3897)	This is macro System::USERES.
USETLB (see page 3898)	This is macro System::USETLB.
USEUNIT (see page 3898)	This is macro System::USEUNIT.

Structs, Records, Enums

	Name	Description
	PackageInfoTable (see page 3713)	A variable of type PackageInfoTable provides information on initializing or finalizing a series of package units.
	PackageUnitEntry (see page 3713)	A variable of type PackageUnitEntry provides information on initializing or finalizing a package unit.
	TCallDesc (see page 3714)	TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 3758) is a pointer to this descriptior.
	TChunkStatus (see page 3714)	TChunkStatus enumerates the possible states of a chunk of memory.
	TCVModInfo (see page 3715)	This is record System.TCVModInfo.
	TDispatchMessage (see page 3716)	This is record System.TDispatchMessage.
	TDispDesc (see page 3716)	This is record System.TDispDesc.
	TDynArrayTypeInfo (see page 3716)	This is record System.TDynArrayTypeInfo.
	TFileRec (see page 3717)	TFileRec is the internal format for typed and untyped files in the Delphi language.
	TGUID (see page 3718)	TGUID is a structured form of the value that uniquely identifies an interface.
	THeapBlock (see page 3720)	This is record System::THeapBlock.
	THeapStatus (see page 3720)	System::THeapStatus represents information about the global heap.
	TInitContext (see page 3721)	This is record System.TInitContext.
	TInterfaceEntry (see page 3722)	TInterfaceEntry encapsulates the information needed to dispatch interface calls.
	TInterfaceTable (see page 3723)	TInterfaceTable lists the interfaces that a class supports, and PInterfaceTable (see page 3766) points to this list.
	TLibModule (see page 3723)	System::TLibModule describes a module that is compiled with the application.
	TMemoryManager (see page 3724)	System::TMemoryManager defines the memory block entry points.
	TMemoryManagerEx (see page 3725)	System::TMemoryManagerEx defines extended memory block entry points.
	TMemoryManagerState (see page 3730)	System::TMemoryManagerState holds statistics about memory allocations.
	TMethod (see page 3731)	TMethod stores Code and Data fields to represent a method.
	TMinimumBlockAlignment (see page 3732)	TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.
	TModuleUnloadRec (see page 3732)	This is record System::TModuleUnloadRec.
	TMonitorSupport (see page 3733)	This is record System.TMonitorSupport.

	TResStringRec (see page 3733)	This is record System::TResStringRec.
	TRuntimeError (see page 3734)	TRuntimeError is an enumeration of internal runtime error codes.
	TSmallBlockTypeState (see page 3736)	System::TSmallBlockTypeState holds statistics about a small memory block.
	TTextLineBreakStyle (see page 3737)	TTextLineBreakStyle indicates the default set of characters used to divide lines in text.
	TTextRec (see page 3738)	TTextRec is the internal format for text files.
	TVarArray (see page 3739)	This is the descriptor type for safe arrays.
	TVarArrayBound (see page 3740)	Gives bound information for one dimension of a safe array.
	TVarData (see page 3740)	TVarData represents Variant (see page 3421) information.
	TVariantManager (see page 3745)	System::TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.
	TVarRec (see page 3747)	System::TVarRec is used inside a function with an untyped array parameter.
	TCallDesc (see page 3749)	This is type System::TCallDesc.
	TDispDesc (see page 3749)	This is type System::TDispDesc.

Types

Name	Description
CppLongInt (see page 3752)	This is type System.CppLongInt.
CppULongInt (see page 3753)	This is type System.CppULongInt.
GetPackageInfoTable (see page 3753)	This is type System.GetPackageInfoTable.
HGLOBAL (see page 3753)	This is type System.HGLOBAL.
HINST (see page 3754)	This is type System.HINST.
HMODULE (see page 3754)	This is type System.HMODULE.
HRESULT (see page 3754)	This is type System.HRESULT.
HRSRC (see page 3755)	This is type System.HRSRC.
Int16 (see page 3755)	Alias for `SmallInt`.
Int32 (see page 3755)	Alias for `Integer`.
Int8 (see page 3756)	Alias for `ShortInt`.
IntegerArray (see page 3756)	This is type System.IntegerArray.
IUnknown (see page 3756)	IUnknown is a special base interface.
PackageInfo (see page 3757)	PackageInfo is a pointer to a PackageInfoTable (see page 3713) variable.
PAnsiString (see page 3757)	PAnsiString is a pointer to an `AnsiString` variable.
PBoolean (see page 3758)	PBoolean is a pointer to a `Boolean` variable.
PByte (see page 3758)	PByte is a pointer to a `Byte` variable.
PCallDesc (see page 3758)	This is type System::PCallDesc.
PCardinal (see page 3759)	PCardinal is a pointer to a `Cardinal` variable.
PComp (see page 3759)	PComp is a pointer to a `Comp` variable.
PCurrency (see page 3759)	PCurrency is a pointer to a `Currency (see page 3235)` variable.
PCVModInfo (see page 3760)	This is type System.PCVModInfo.
PDate (see page 3760)	PDate is a pointer to a Date variable.
PDateTime (see page 3761)	PDateTime is a pointer to a TDateTime (see page 3323) variable.
PDispatch (see page 3761)	This is type System.PDispatch.
PDispDesc (see page 3761)	This is type System::PDispDesc.
PDouble (see page 3762)	PDouble is a pointer to a `Double` variable.
PDynArrayTypeInfo (see page 3762)	This is type System.PDynArrayTypeInfo.
PError (see page 3762)	This is type System.PError.
PExtended (see page 3763)	PExtended is a pointer to an `Extended` variable.
PGUID (see page 3763)	PGUID is a pointer to a TGUID (see page 3718) variable.
PInitContext (see page 3765)	This is type System.PInitContext.
PInt64 (see page 3765)	PInt64 is a pointer to an `Int64` variable.
PInteger (see page 3765)	PInteger is a pointer to an `Integer` variable.
PIntegerArray (see page 3766)	PIntegerArray is a pointer to an `IntegerArray (see page 3756)` variable.
PInterfaceEntry (see page 3766)	PInterfaceEntry is a pointer to a TInterfaceEntry (see page 3722) variable.
PInterfaceTable (see page 3766)	PInterfaceTable is a pointer to a TInterfaceTable (see page 3723) variable.

PLibModule (see page 3767)	PLibModule is a pointer to a System::TLibModule (see page 3723) variable.
PLongint (see page 3767)	PLongint is a pointer to a `LongInt` variable.
PLongWord (see page 3768)	PLongWord is a pointer to a `LongWord` variable.
PMemoryManager (see page 3768)	System::PMemoryManager is a pointer to a System::TMemoryManager (see page 3724) variable.
PMemoryManagerEx (see page 3768)	System::PMemoryManagerEx is a pointer to a System::TMemoryManagerEx (see page 3725) variable.
PModuleUnloadRec (see page 3769)	This is type System::PModuleUnloadRec.
PMonitor (see page 3769)	This is type System.PMonitor.
PMonitorSupport (see page 3769)	This is type System.PMonitorSupport.
PointerArray (see page 3770)	This is type System.PointerArray.
POleVariant (see page 3770)	POleVariant is a pointer to a System::OleVariant (see page 3274) variable.
PPAnsiChar (see page 3770)	This is type System.PPAnsiChar.
PPChar (see page 3771)	This is type System.PPChar.
PPCharArray (see page 3771)	This is type System.PPCharArray.
PPDispatch (see page 3771)	This is type System.PPDispatch.
PPMonitor (see page 3772)	This is type System.PPMonitor.
PPointer (see page 3772)	PPointer is a pointer to a `Pointer` variable.
PPointerArray (see page 3772)	PPointerArray is a pointer to a PointerArray (see page 3770) variable.
PPUnknown (see page 3773)	This is type System.PPUnknown.
PPWideChar (see page 3773)	This is type System.PPWideChar.
PRawByteString (see page 3773)	This is type System.PRawByteString.
PResStringRec (see page 3774)	This is type System::PResStringRec.
PShortInt (see page 3774)	PShortInt is a pointer to a `ShortInt` variable.
PShortString (see page 3774)	PShortString is a pointer to a `ShortString` variable.
PSingle (see page 3775)	PSingle is a pointer to a `Single` variable.
PSmallBlockTypeState (see page 3775)	This is type System::PSmallBlockTypeState.
PSmallInt (see page 3775)	PSmallInt is a pointer to a `SmallInt` variable.
PString (see page 3776)	PString is a pointer to a `String` variable.
PTextBuf (see page 3776)	This is type System.PTextBuf.
PUCS2Char (see page 3776)	This is type System.PUCS2Char.
PUCS4Char (see page 3777)	This is type System.PUCS4Char.
PUCS4CharArray (see page 3777)	This is type System.PUCS4CharArray.
PUInt64 (see page 3777)	This is type System.PUInt64.
PUnicodeString (see page 3778)	This is type System.PUnicodeString.
PUnitEntryTable (see page 3778)	PUnitEntryTable is a pointer to a UnitEntryTable (see page 3804) variable.
PUnknown (see page 3778)	PUnknown is a pointer to an IUnknown (see page 3756) variable.
PUTF8String (see page 3779)	This is type System.PUTF8String.
PVarArray (see page 3779)	Pointer type to a TVarArray (see page 3739).
PVarArrayBoundArray (see page 3779)	This is type System.PVarArrayBoundArray.
PVarArrayCoorArray (see page 3780)	Pointer type to a TVarArrayCoorArray (see page 3799).
PVarData (see page 3780)	This is type System.PVarData.
PVariant (see page 3780)	PVariant is a pointer to a System::Variant (see page 3421) variable.
PVariantManager (see page 3781)	This is type System::PVariantManager.
PVarRec (see page 3781)	System::PVarRec is a pointer to a System::TVarRec (see page 3747) variable.
PWideString (see page 3782)	PWideString is a pointer to a `WideString` (see page 3467) variable.
PWord (see page 3782)	PWord is a pointer to a `Word` variable.
PWordBool (see page 3782)	PWordBool is a pointer to a `WordBool` variable.
RawByteString (see page 3783)	RawByteString enables the passing of string data of any code page without doing any codepage conversions.
ResourceString (see page 3783)	This is type System::ResourceString.
TAssertErrorProc (see page 3783)	This is type System.TAssertErrorProc.
TBooleanDynArray (see page 3784)	This is type System::TBooleanDynArray.
TBoundArray (see page 3784)	This is type System.TBoundArray.
TByteDynArray (see page 3784)	This is type System::TByteDynArray.

TCardinalDynArray (see page 3785)	This is type System::TCardinalDynArray.
TClass (see page 3785)	TClass defines the metaclass for System::TObject (see page 3354).
TClassHelperBaseClass (see page 3786)	This is type System.TClassHelperBaseClass.
TDate (see page 3786)	TDate is used to represent a date.
TDateTime (see page 3787)	TDateTime represents a date-and-time value in the Delphi language.
TDLLProc (see page 3788)	This is type System.TDLLProc.
TDLLProcEx (see page 3788)	This is type System.TDLLProcEx.
TDoubleDynArray (see page 3788)	This is type System::TDoubleDynArray.
TEnumModuleFunc (see page 3789)	This is type System.TEnumModuleFunc.
TEnumModuleFuncLW (see page 3789)	This is type System.TEnumModuleFuncLW.
TFileIOFunc (see page 3789)	This is type System.TFileIOFunc.
THandle (see page 3790)	THandle is a general purpose data reference (handle).
TInt64DynArray (see page 3790)	This is type System::TInt64DynArray.
TIntegerDynArray (see page 3790)	This is type System::TIntegerDynArray.
TInterfacedClass (see page 3791)	TInterfacedClass defines the metaclass for System::TInterfacedObject (see page 3342).
TLongWordDynArray (see page 3791)	This is type System::TLongWordDynArray.
TMemoryMap (see page 3791)	TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 3714) values.
TModuleUnloadProc (see page 3792)	TModuleUnloadProc defines a procedure that can be called during package unload.
TModuleUnloadProcLW (see page 3793)	TModuleUnloadProcLW dehines a procedure that can be called during package unload.
TPCharArray (see page 3793)	This is type System.TPCharArray.
TResourceHandle (see page 3793)	This is type System.TResourceHandle.
TSafeCallErrorProc (see page 3794)	This is type System.TSafeCallErrorProc.
TShortIntDynArray (see page 3794)	This is type System::TShortIntDynArray.
TSingleDynArray (see page 3794)	This is type System::TSingleDynArray.
TSmallBlockTypeStates (see page 3795)	System::TSmallBlockTypeStates is an array of small memory block information records.
TSmallIntDynArray (see page 3795)	This is type System::TSmallIntDynArray.
TStringDynArray (see page 3796)	This is type System::TStringDynArray.
TSystemThreadEndProc (see page 3796)	This is type System.TSystemThreadEndProc.
TSystemThreadFuncProc (see page 3796)	This is type System.TSystemThreadFuncProc.
TTextBuf (see page 3797)	This is type System.TTextBuf.
TTextIOFunc (see page 3797)	This is type System.TTextIOFunc.
TThreadFunc (see page 3797)	System::TThreadFunc defines a new thread of execution.
TTime (see page 3798)	TTime is used to represent a time.
TUCS4CharArray (see page 3798)	This is type System.TUCS4CharArray.
TVarArrayBoundArray (see page 3798)	Gives bound information for all the dimensions of a safe array.
TVarArrayCoorArray (see page 3799)	Gives the position of an element in a safe array.
TVarOp (see page 3799)	TVarOp defines a Variant (see page 3421) operation.
TVarType (see page 3801)	This is type System.TVarType.
TWideStringDynArray (see page 3801)	This is type System::TWideStringDynArray.
TWordDynArray (see page 3801)	This is type System::TWordDynArray.
UCS2Char (see page 3802)	This is type System.UCS2Char.
UCS4Char (see page 3802)	UCS4Char is used for working with 4–byte Unicode characters.
UCS4String (see page 3802)	UCS4String is used for working with 4–byte Unicode characters.
UInt16 (see page 3803)	Alias for `Word`.
UInt32 (see page 3803)	Alias for `Cardinal`.
UInt8 (see page 3804)	Alias for `Byte`.
UnitEntryTable (see page 3804)	UnitEntryTable is an array type with entries of type PackageUnitEntry (see page 3713).
UTF8String (see page 3804)	UTF8String represents UTF-8 encoded Unicode strings.

Variables

Name	Description
AbstractErrorProc (see page 3807)	AbstractErrorProc defines a callback routine for abstract method call errors.
AllocMemCount (see page 3807)	Represents the total number of allocated memory blocks in a Delphi application.
AllocMemSize (see page 3809)	Represents the total size of allocated memory blocks.
AssertErrorProc (see page 3810)	Points to the assertion error-handler.
CmdLine (see page 3812)	Points to the command-line arguments specified when the application is invoked.
CmdShow (see page 3812)	Specifies the flags for displaying the application's main window.
CPUCount (see page 3813)	This is variable System.CPUCount.
DebugHook (see page 3813)	DebugHook is set if an application is running under the IDE debugger.
Default8087CW (see page 3813)	Specifies the Default 8087 control word.
DefaultSystemCodePage (see page 3815)	This is variable System.DefaultSystemCodePage.
DefaultTextLineBreakStyle (see page 3815)	Specifies the characters that are used by default to separate lines in text.
DefaultUnicodeCodePage (see page 3816)	This is variable System.DefaultUnicodeCodePage.
DispCallByIDProc (see page 3816)	This is variable System.DispCallByIDProc.
DLLProc (see page 3816)	Points to a procedure invoked by a DLL entry point.
envp (see page 3817)	This is variable System.envp.
ErrorAddr (see page 3817)	Contains the address of a statement causing a runtime error.
ErrorProc (see page 3818)	Points to the RTL runtime error handler.
ErrOutput (see page 3820)	ErrOutput specifies a write-only Text file associated with the process's error output file.
ExceptClsProc (see page 3820)	ExceptClsProc defines a pointer to a function called during exception handling.
ExceptionAcquired (see page 3821)	This is variable System.ExceptionAcquired.
ExceptionClass (see page 3821)	This is variable System.ExceptionClass.
ExceptObjProc (see page 3821)	ExceptObjProc defines a pointer to a function called during exception handling.
ExceptProc (see page 3822)	Points to the lowest-level exception handler.
ExitCode (see page 3823)	Contains the application's exit code.
ExitProc (see page 3823)	Points to a program's exit procedure (provided for backward compatibility).
ExitProcessProc (see page 3824)	Specifies the last procedure to execute before the application shuts down.
FileMode (see page 3824)	Indicates the access mode on typed and untyped files opened by the Reset (see page 3643) procedure.
HeapAllocFlags (see page 3825)	Indicates how the memory manager obtains memory from the operating system.
HPrevInst (see page 3826)	This is variable System.HPrevInst.
InitProc (see page 3826)	InitProc is the last installed initialization procedure.
Input (see page 3827)	Specifies a read-only Text file associated with the processes standard Input file.
IsConsole (see page 3828)	Indicates whether the module was compiled as a console application.
IsLibrary (see page 3828)	Indicates whether the module is a shared library.
IsMultiThread (see page 3829)	Indicates whether the application spawned additional threads using BeginThread (see page 3527) or TThread objects.
JITEnable (see page 3829)	Controls when the just-in-time debugger is called.
LibModuleList (see page 3830)	Lists module records for enumeration procedures.
MainInstance (see page 3830)	Indicates the instance handle for the main executable.
MainThreadID (see page 3831)	Indicates the instance handle for the current module's main thread of execution.
ModuleUnloadList (see page 3831)	This is variable System.ModuleUnloadList.
MonitorSupport (see page 3831)	This is variable System.MonitorSupport.
NeverSleepOnMMThreadContention (see page 3832)	Dictates memory manager behavior during a thread contention.
NoErrMsg (see page 3832)	Controls whether the application displays an error message when a runtime error occurs.
Output (see page 3833)	Specifies a write-only Text file associated with the process's standard output file.
RaiseExceptionProc (see page 3833)	Points to RaiseException Windows function.
RaiseExceptObjProc (see page 3834)	This is variable System.RaiseExceptObjProc.
RandSeed (see page 3834)	RandSeed stores the built-in random number generator's seed.
ReportMemoryLeaksOnShutdown (see page 3835)	Report memory leaks on shutdown.
RTLUnwindProc (see page 3835)	This is variable System.RTLUnwindProc.

SafeCallErrorProc (see page 3836)	SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.
SystemThreadEndProc (see page 3836)	This is variable System.SystemThreadEndProc.
SystemThreadFuncProc (see page 3837)	This is variable System.SystemThreadFuncProc.
Test8086 (see page 3837)	This is variable System.Test8086.
Test8087 (see page 3837)	This is variable System.Test8087.
TestFDIV (see page 3838)	This is variable System.TestFDIV.
UTF8CompareLocale (see page 3838)	This is variable System.UTF8CompareLocale.
VarAddRefProc (see page 3838)	The VarAddRefProc variable is used internally.
VarClearProc (see page 3839)	The VarClearProc variable is used internally.
VarCopyProc (see page 3839)	The VarCopyProc variable is used internally.
VarToLStrProc (see page 3840)	The VarToLStrProc variable is used internally.
VarToWStrProc (see page 3840)	The VarToWStrProc variable is used internally.

35.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	AnsiStringBase (see page 3174)	System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.
	Currency (see page 3235)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 3255)	This is class System::CurrencyBase.
	DynArrayException (see page 3271)	This is class System::DynArrayException.
	DynArrayNullData (see page 3272)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 3272)	This is class System::DynArrayOutOfRange.
	OleVariant (see page 3274)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	TAggregatedObject (see page 3313)	System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 3502) methods to delegate to the controlling IInterface (see page 3502).
	TClassHelperBase (see page 3318)	This is class System.TClassHelperBase.
	TContainedObject (see page 3320)	System::TContainedObject implements the IInterface (see page 3502) interface as an inner object in an aggregate.
	TDateTime (see page 3323)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.
	TDateTimeBase (see page 3341)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 3342)	System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 3502) implementation.
	TMetaClass (see page 3348)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TObject (see page 3354)	System::TObject is the ultimate ancestor of all objects and components.
	UnicodeString (see page 3381)	System::UnicodeString is the C++ analog for the Delphi UnicodeString type.
	Variant (see page 3421)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	WideString (see page 3467)	System::WideString represents strings of 16-bit characters.

Records

	Name	Description
	TMonitor (see page 3349)	TMonitor provides methods for synchronizing the access of several threads to a single object.

Templates

	Name	Description
	AnsiStringT (see page 3207)	System::AnsiStringT is the C++ analog for the Delphi long string type.
	DelphiInterface (see page 3256)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 3261)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	SmallString (see page 3307)	This is class System::SmallString.
	SmallStringBase (see page 3310)	This is class System::SmallStringBase.
	sPointer (see page 3311)	This is class System::sPointer.

35.1.1 AnsiStringBase Class

System::AnsiStringBase is the base class for the C++ analog of the Delphi long string type.

Class Hierarchy

Pascal

```
AnsiStringBase = class;
```

C++

```
class AnsiStringBase;
```

File

dstring.h

Description

System::AnsiStringBase exists to provide a place for methods/members that are common to all instantiations of the template class AnsiStringT (see page 3207)<CodePage (see page 3188)>. AnsiString itself is a typedef that is equivalent to AnsiStringT (see page 3207)<0>. You should never deal directly with System::AnsiStringBase.

System::AnsiStringT (see page 3207) is a template class that you use when handling a Delphi AnsiString that has a code page specified with it.

Delphi uses several string types. One important long string type is commonly known as System::AnsiString. Support for this type includes the following features:

- strings can be as large as available memory
- efficient use of memory is ensured through shared references
- routines and operators evaluate strings based on the current locale

Despite its name, System::AnsiStringBase is not restricted to the ANSI character set, and can use any character set supported by the current locale definition, including multi-byte and Unicode character sets.

System::AnsiStringBase variables that have not been assigned an initial value contain a zero-length string.

To use the C++ streaming operators (**<<** and **>>**) with System::AnsiStringBase, you must `iostream` before including `system.hpp` and use `AnsiStringT::c_str()` to return the internal string representation. The following example demonstrates the usage of AnsiString with stream operators:

```
#include <iostream>
#include <system.hpp>
int main() {
  AnsiString HelloStr = "hello";
  std::cout << HelloStr.c_str();
}
```

Note: Delphi also supports System::AnsiString, but implements it as a primitive type rather than a class.

UnicodeString (see page 3381) has become the default string type. By default, variables declared as type String are System::UnicodeString (see page 3381).

How to Handle Delphi AnsiString Code Page Specification in C++

System::WideString (see page 3467)

System::AnsiStringBase::[] (see page 3205)

System::AnsiStringBase::= (see page 3206)

System::AnsiStringBase::== (see page 3206)

System::AnsiStringBase::!= (see page 3204)

System::AnsiStringBase::> (see page 3207)

System::AnsiStringBase::>= (see page 3207)

System::AnsiStringBase::< (see page 3205)

System::AnsiStringBase::<= (see page 3206)

System::AnsiStringBase::+ (see page 3205)

System::AnsiStringT::+= (see page 3232)

35.1.1.1 AnsiStringBase Members

The following tables list the members exposed by AnsiStringBase.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3180)	System::AnsiStringBase::TStringFloatFormat is an enumerated list of formatting codes for float functions.
	TStringMbcsByteType (see page 3181)	Enumerated list of byte types in MCBS string.

Structures

	Name	Description
	StrRec (see page 3180)	This is record System::AnsiStringBase::StrRec.

Protected Data Members

	Name	Description
	Data (see page 3182)	This is Data, a member of class AnsiStringBase.

Protected Methods

	Name	Description
	_AnsiCat (see page 3184)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3184)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiCompare (see page 3185)	Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case-sensitively).
	AnsiCompareIC (see page 3185)	Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case insensitively).
	AnsiStringBase (see page 3178)	This is the overview for the AnsiStringBase constructor overload.
	GetRec (see page 3193)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3200)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Protected Operators

	Name	Description
	!= (see page 3204)	Compares two strings.
	< (see page 3205)	Compares two strings.
	<= (see page 3206)	Compares two strings.
	= (see page 3206)	Assigns the string rhs to this System::AnsiStringBase (see page 3174).
	== (see page 3206)	Compares the System::AnsiStringBase (see page 3174) with a specified string, returning true if they are the same.
	> (see page 3207)	Compares two strings.
	>= (see page 3207)	Compares two strings.

Public Methods

	Name	Description
	~AnsiStringBase (see page 3178)	Frees an instance of System::AnsiStringBase (see page 3174).

	AnsiLastChar (see page 3186)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiStringBase (see page 3174).
	AnsiPos (see page 3186)	Returns the index at which the specified substring begins.
	BytesOf (see page 3186)	Get string's data in bytes.
	ByteType (see page 3187)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase (see page 3174).
	cat_vprintf (see page 3187)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiStringBase (see page 3174).
	CodePage (see page 3188)	Gets code page of a System::AnsiStringBase (see page 3174).
	CurrToStr (see page 3188)	Converts a currency value to its string representation.
	CurrToStrF (see page 3188)	Converts a currency value to its string representation using the indicated float format convention.
	Delete (see page 3189)	Removes a specified number of characters from the string.
	ElementSize (see page 3189)	Gets element size of data in a System::AnsiStringBase (see page 3174).
	EnsureAnsi (see page 3189)	Ensure string's data is ANSI data.
	FloatToStrF (see page 3190)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3190)	Formats output using a resourced format string.
	Format (see page 3191)	System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase (see page 3174), format, and a series of array arguments, args.
	FormatFloat (see page 3191)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3193)	System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase (see page 3174).
	IntToHex (see page 3194)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3194)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3194)	Returns true if the System::AnsiStringBase (see page 3174) is empty.
	IsLeadByte (see page 3195)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3195)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3195)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3196)	Returns a pointer to the last character in a string.
	LastDelimiter (see page 3196)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3196)	Returns the length of the System::AnsiStringBase (see page 3174).
	LoadStr (see page 3196)	This is the overview for the LoadStr method overload.
	LoadString (see page 3197)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3198)	Returns a lower-case version of System::AnsiStringBase (see page 3174).
	Pos (see page 3198)	Returns the index at which a specified substring begins.
	RefCount (see page 3198)	Gets reference count of System::AnsiStringBase (see page 3174).
	SetLength (see page 3199)	Changes the length of the System::AnsiStringBase (see page 3174).
	StringOfChar (see page 3199)	Returns a string with the specified number of characters.
	SubString (see page 3199)	Returns a specified substring of the System::AnsiStringBase (see page 3174).
	swap (see page 3200)	Swap string pointers.
	ToDouble (see page 3200)	Converts the string to a floating-point value.
	ToInt (see page 3200)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3201)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3201)	Returns a new System::AnsiStringBase (see page 3174) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3201)	Returns a new System::AnsiStringBase (see page 3174) without leading spaces or control characters.
	TrimRight (see page 3202)	Returns a new System::AnsiStringBase (see page 3174) without trailing spaces or control characters.
	Unique (see page 3202)	Makes the System::AnsiStringBase (see page 3174) unique.
	UpperCase (see page 3202)	Returns an upper-case version of this System::AnsiStringBase (see page 3174).
	vprintf (see page 3202)	Sets the value of the System::AnsiStringBase (see page 3174) given a format string and its arguments.

	WideChar (see page 3203)	Converts the System::AnsiStringBase (see page 3174) to a wide-character array.
	WideCharBufSize (see page 3203)	Returns the size of the buffer required by the WideChar (see page 3203) function.

Public Operators

	Name	Description
	[] (see page 3204)	This is the overview for the [] operator overload.
	+ (see page 3205)	Concatenates two System::AnsiStringBase (see page 3174) values.

35.1.1.2 AnsiStringBase::~AnsiStringBase Destructor

Frees an instance of System::AnsiStringBase (see page 3174).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~AnsiStringBase();
```

Description

System::AnsiStringBase (see page 3174)::~AnsiStringBase (see page 3174) is the destructor for System::AnsiStringBase (see page 3174).

35.1.1.3 AnsiStringBase Constructor

This is the overview for the AnsiStringBase constructor overload.

Overload List

	Name	Description
	AnsiStringBase::AnsiStringBase () (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (AnsiStringBase&) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (char*, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (char*, int, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (char16_t*, int, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (char32_t*, int, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (double, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (UnicodeString &, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (wchar_t*, int, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).

	AnsiStringBase::AnsiStringBase (wchar_t, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).
	AnsiStringBase::AnsiStringBase (WideString &, int) (see page 3179)	Creates an instance of System::AnsiStringBase (see page 3174).

35.1.1.3.1 AnsiStringBase::AnsiStringBase Constructor ()

Creates an instance of System::AnsiStringBase (see page 3174).

Pascal

```
constructor Create;
constructor Create(const src: AnsiStringBase&);
constructor Create(const src: char*; codePage: Integer);
constructor Create(const src: char*; byteLen: Integer; codePage: Integer);
constructor Create(const src: wchar_t*; numwchar: Integer; codePage: Integer);
constructor Create(const src: char16_t*; numChar16: Integer; codePage: Integer);
constructor Create(const src: char32_t*; numChar32: Integer; codePage: Integer);
constructor Create(src: double; codePage: Integer);
constructor Create(src: wchar_t; codePage: Integer);
constructor Create(const src: WideString &; codePage: Integer);
constructor Create(const src: UnicodeString &; codePage: Integer);
```

C++

```
__fastcall AnsiStringBase();
__fastcall AnsiStringBase(const AnsiStringBase& src);
__fastcall AnsiStringBase(const char* src, int codePage);
__fastcall AnsiStringBase(const char* src, int byteLen, int codePage);
__fastcall AnsiStringBase(const wchar_t* src, int numwchar, int codePage);
__fastcall AnsiStringBase(const char16_t* src, int numChar16, int codePage);
__fastcall AnsiStringBase(const char32_t* src, int numChar32, int codePage);
__fastcall AnsiStringBase(double src, int codePage);
__fastcall AnsiStringBase(wchar_t src, int codePage);
__fastcall AnsiStringBase(const WideString & src, int codePage);
__fastcall AnsiStringBase(const UnicodeString & src, int codePage);
```

Description

System::AnsiStringBase::AnsiStringBase (see page 3174) is the constructor for System::AnsiStringBase (see page 3174).

If the constructor is given no arguments, the resulting System::AnsiStringBase (see page 3174) instance is an empty string. If the constructor is passed a single character, the resulting System::AnsiStringBase (see page 3174) instance has character length one, and contains that character. Other versions of the constructor copy the string passed as an argument, converting characters to `char` if necessary. When constructing a System::AnsiStringBase (see page 3174) instance from an array of `char` or `wchar_t`, the source string should be null terminated, unless an argument is given that indicates the number of characters in the array. For some overloads of the constructor, you can pass the code page you want for the string. In another overload, you can pass a floating point number to be converted to a string.

35.1.1.4 AnsiStringBase Structures

The structures of the AnsiStringBase class are listed here.

Structures

	Name	Description
	StrRec (see page 3180)	This is record System::AnsiStringBase::StrRec.

35.1.1.4.1 System::AnsiStringBase::StrRec Structure

Pascal

```
StrRec = record
  codePage: unsigned short;
  elemSize: unsigned short;
  refCnt: Integer;
  length: Integer;
end;
```

C++

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

File

dstring.h

Description

This is record System::AnsiStringBase::StrRec.

35.1.1.5 AnsiStringBase Enumerations

The enumerations of the AnsiStringBase class are listed here.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3180)	System::AnsiStringBase::TStringFloatFormat is an enumerated list of formatting codes for float functions.
	TStringMbcsByteType (see page 3181)	Enumerated list of byte types in MCBS string.

35.1.1.5.1 System::AnsiStringBase::TStringFloatFormat Enumeration

System::AnsiStringBase::TStringFloatFormat is an enumerated list of formatting codes for float functions.

Pascal

```
TStringFloatFormat = (
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
);
```

C++

```
enum TStringFloatFormat {
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
};
```

File

dstring.h

Description

System::AnsiStringBase::TStringFloatFormat defines an enumerated list of formatting codes for the float functions.

Format (see page 3191)	Defines
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3191) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

See Also

System::AnsiStringBase::FloatToStrF (see page 3190)

35.1.1.5.2 System::AnsiStringBase::TStringMbcsByteType Enumeration

Enumerated list of byte types in MCBS string.

Pascal

```
TStringMbcsByteType = (
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
);
```

C++

```
enum TStringMbcsByteType {
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
};
```

File

dstring.h

Description

System::AnsiStringBase::TStringMbcsByteType defines an enumerated list of byte types in multibyte character system (MBCS) string.

Constant	Meaning
mbSingleByte	Single byte character.
mbLeadByte	Lead byte of a multi-byte character.
mbTrailByte	Trailing byte of a multi-byte character.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.1.6 AnsiStringBase Data Members

The data members of the AnsiStringBase class are listed here.

Protected Data Members

	Name	Description
	Data (see page 3182)	This is Data, a member of class AnsiStringBase.

35.1.1.6.1 AnsiStringBase::Data Data Member

Pascal

```
Data: PChar;
```

C++

```
char * Data;
```

Description

This is Data, a member of class AnsiStringBase.

35.1.1.7 AnsiStringBase Methods

The methods of the AnsiStringBase class are listed here.

Protected Methods

	Name	Description
	_AnsiCat (see page 3184)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3184)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiCompare (see page 3185)	Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case-sensitively).
	AnsiCompareIC (see page 3185)	Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case insensitively).
	GetRec (see page 3193)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3200)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Public Methods

	Name	Description
	AnsiLastChar (see page 3186)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiStringBase (see page 3174).
	AnsiPos (see page 3186)	Returns the index at which the specified substring begins.
	BytesOf (see page 3186)	Get string's data in bytes.
	ByteType (see page 3187)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase (see page 3174).
	cat_vprintf (see page 3187)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiStringBase (see page 3174).
	CodePage (see page 3188)	Gets code page of a System::AnsiStringBase (see page 3174).
	CurrToStr (see page 3188)	Converts a currency value to its string representation.
	CurrToStrF (see page 3188)	Converts a currency value to its string representation using the indicated float format convention.
	Delete (see page 3189)	Removes a specified number of characters from the string.
	ElementSize (see page 3189)	Gets element size of data in a System::AnsiStringBase (see page 3174).
	EnsureAnsi (see page 3189)	Ensure string's data is ANSI data.
	FloatToStrF (see page 3190)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3190)	Formats output using a resourced format string.
	Format (see page 3191)	System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase (see page 3174), format, and a series of array arguments, args.
	FormatFloat (see page 3191)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3193)	System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase (see page 3174).
	IntToHex (see page 3194)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3194)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3194)	Returns true if the System::AnsiStringBase (see page 3174) is empty.
	IsLeadByte (see page 3195)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3195)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3195)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3196)	Returns a pointer to the last character in a string.
	LastDelimiter (see page 3196)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3196)	Returns the length of the System::AnsiStringBase (see page 3174).
	LoadStr (see page 3196)	This is the overview for the LoadStr method overload.
	LoadString (see page 3197)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3198)	Returns a lower-case version of System::AnsiStringBase (see page 3174).
	Pos (see page 3198)	Returns the index at which a specified substring begins.
	RefCount (see page 3198)	Gets reference count of System::AnsiStringBase (see page 3174).
	SetLength (see page 3199)	Changes the length of the System::AnsiStringBase (see page 3174).
	StringOfChar (see page 3199)	Returns a string with the specified number of characters.
	SubString (see page 3199)	Returns a specified substring of the System::AnsiStringBase (see page 3174).
	swap (see page 3200)	Swap string pointers.
	ToDouble (see page 3200)	Converts the string to a floating-point value.
	ToInt (see page 3200)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3201)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3201)	Returns a new System::AnsiStringBase (see page 3174) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3201)	Returns a new System::AnsiStringBase (see page 3174) without leading spaces or control characters.
	TrimRight (see page 3202)	Returns a new System::AnsiStringBase (see page 3174) without trailing spaces or control characters.
	Unique (see page 3202)	Makes the System::AnsiStringBase (see page 3174) unique.

	UpperCase (see page 3202)	Returns an upper-case version of this System::AnsiStringBase (see page 3174).
	vprintf (see page 3202)	Sets the value of the System::AnsiStringBase (see page 3174) given a format string and its arguments.
	WideChar (see page 3203)	Converts the System::AnsiStringBase (see page 3174) to a wide-character array.
	WideCharBufSize (see page 3203)	Returns the size of the buffer required by the WideChar (see page 3203) function.

35.1.1.7.1 _AnsiCat Method

This is the overview for the _AnsiCat method overload.

Overload List

	Name	Description
	AnsiStringBase::_AnsiCat (AnsiStringBase&, AnsiStringBase&) (see page 3184)	This is _AnsiCat, a member of class AnsiStringBase.
	AnsiStringBase::_AnsiCat (AnsiStringBase&, AnsiStringBase&, AnsiStringBase&) (see page 3184)	This is _AnsiCat, a member of class AnsiStringBase.

35.1.1.7.1.1 AnsiStringBase::_AnsiCat Method (AnsiStringBase&, AnsiStringBase&)

Pascal

```
procedure _AnsiCat(var dst: AnsiStringBase; const src: AnsiStringBase&); static;
```

C++

```
static __fastcall void _AnsiCat(AnsiStringBase& dst, const AnsiStringBase& src);
```

Description

This is _AnsiCat, a member of class AnsiStringBase.

35.1.1.7.1.2 AnsiStringBase::_AnsiCat Method (AnsiStringBase&, AnsiStringBase&, AnsiStringBase&)

Pascal

```
procedure _AnsiCat(var dst: AnsiStringBase; const src1: AnsiStringBase&; const src2:
AnsiStringBase&); static;
```

C++

```
static __fastcall void _AnsiCat(AnsiStringBase& dst, const AnsiStringBase& src1, const
AnsiStringBase& src2);
```

Description

This is _AnsiCat, a member of class AnsiStringBase.

35.1.1.7.2 AnsiStringBase::_AnsiFromPWChar Method

Pascal

```
procedure _AnsiFromPWChar(var dst: AnsiStringBase; const src: wchar_t*; len: Integer;
codePage: Integer); static;
```

C++

```
static __fastcall void _AnsiFromPWChar(AnsiStringBase& dst, const wchar_t* src, int len, int codePage);
```

Description

This is _AnsiFromPWChar, a member of class AnsiStringBase.

35.1.1.7.3 AnsiStringBase::AnsiCompare Method

Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case-sensitively).

Pascal

```
function AnsiCompare(const rhs: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiCompare(const AnsiStringBase& rhs) const;
```

Description

Compares this System::AnsiStringBase::AnsiStringBase (see page 3174) to rhs, with case sensitivity. The compare operation is controlled by the current Windows locale and is not necessarily the same as using the System::AnsiStringBase (see page 3174) comparison operators. System::AnsiStringBase::AnsiCompare is based on a locale-specific collating order. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

35.1.1.7.4 AnsiStringBase::AnsiCompareIC Method

Compares the System::AnsiStringBase::AnsiStringBase (see page 3174) to another specified string (case insensitively).

Pascal

```
function AnsiCompareIC(const rhs: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiCompareIC(const AnsiStringBase& rhs) const;
```

Description

System::AnsiStringBase::AnsiCompareIC compares this System::AnsiStringBase::AnsiStringBase (see page 3174) to rhs, without case sensitivity. The compare operation is controlled by the current Windows locale. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

35.1.1.7.5 AnsiStringBase::AnsiLastChar Method

Returns a pointer to the last full character in the System::AnsiStringBase::AnsiStringBase (see page 3174).

Pascal

```
function AnsiLastChar: char*;
```

C++

```
__fastcall char* AnsiLastChar() const;
```

Description

Returns a pointer to the last full character in the System::AnsiStringBase::AnsiStringBase (see page 3174). This function supports multibyte characters.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.1.7.6 AnsiStringBase::AnsiPos Method

Returns the index at which the specified substring begins.

Pascal

```
function AnsiPos(const subStr: AnsiStringBase&): Integer;
```

C++

```
__fastcall int AnsiPos(const AnsiStringBase& subStr) const;
```

Description

Returns the index in the System::AnsiStringBase::AnsiStringBase (see page 3174) at which the substring subStr begins, where 1 is the first character in the string, 2 is the second character, and so on. If the substring is not contained in the System::AnsiStringBase::AnsiStringBase (see page 3174), Pos (see page 3198) returns 0. This member function is the same as Pos (see page 3198) but supports multibyte character strings.

Note: See ByteType (see page 3187) for more information about multibyte characters.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.1.7.7 AnsiStringBase::BytesOf Method

Get string's data in bytes.

Pascal

```
function BytesOf: DynamicArray<System::Byte>;
```

C++

```
__fastcall DynamicArray<System::Byte> BytesOf() const;
```

Description

System::AnsiStringBase::BytesOf gets a byte array copy of a System::AnsiStringBase (see page 3174) string's data. The data is copied as is, with no encoding or decoding.

See Also

System::UnicodeString::BytesOf (see page 3391)

BytesOf (see page 4068)

35.1.1.7.8 AnsiStringBase::ByteType Method

Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase (see page 3174).

Pascal

```
function ByteType(index: Integer): TStringMbcsByteType;
```

C++

```
__fastcall TStringMbcsByteType ByteType(int index) const;
```

Description

System::AnsiStringBase::ByteType indicates what kind of byte exists at the byte indicated by index (counting from 1) in the System::AnsiStringBase (see page 3174). These are the possible return values.

Constant	Meaning
mbSingleByte	Single byte character.
mbLeadByte	Lead byte of a multi-byte character.
mbTrailByte	Trailing byte of a multi-byte character.

Some locales, including all Western locales, do not use multi-byte characters. Under those locales, System::AnsiStringBase::ByteType always returns mbSingleByte.

Note: No checking is done to ensure that Index is less than the length of S. It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

LeadBytes (see page 4354)

StrByteType (see page 4242)

35.1.1.7.9 AnsiStringBase::cat_vprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiStringBase::AnsiStringBase (see page 3174).

Pascal

```
function cat_vprintf(codePage: Integer; const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(int codePage, const char* format, va_list);
```

Description

Use cat_System::AnsiStringBase::cat_vprintf to append to the value of the System::AnsiStringBase::AnsiStringBase (see page 3174) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the number of bytes appended to the System::AnsiStringBase::AnsiStringBase (see page 3174).

See Also

System::AnsiStringBase::Format (see page 3191)

System::AnsiStringT::cat_printf (see page 3216)

System::AnsiStringT::cat_sprintf (see page 3216)

35.1.1.7.10 AnsiStringBase::CodePage Method

Gets code page of a System::AnsiStringBase (see page 3174).

Pascal

```
function CodePage: unsigned short;
```

C++

```
unsigned short CodePage() const;
```

Description

System::AnsiStringBase::CodePage gets the code page of a System::AnsiStringBase (see page 3174) instance. If the instance is empty, it returns the system default code page, System::DefaultSystemCodePage (see page 3815).

See Also

System::AnsiStringBase::GetRec (see page 3193)

35.1.1.7.11 AnsiStringBase::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase CurrToStr(Currency value, int codePage);
```

Description

System::AnsiStringBase::CurrToStr converts the currency value given by value to its string representation. The conversion using the sffGeneral floating-point conversion rules. For further details, see System::AnsiStringBase::CurrToStrF (see page 3188).

See Also

System::AnsiStringBase::CurrToStrF (see page 3188)

35.1.1.7.12 AnsiStringBase::CurrToStrF Method

Converts a currency value to its string representation using the indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase CurrToStrF(Currency value, TStringFloatFormat format, int
digits, int codePage);
```

Description

System::AnsiStringBase::CurrToStrF converts the currency value given by value to its string representation using the indicated float format convention. A call to System::AnsiStringBase::CurrToStrF corresponds to a call to FloatToStrF (see page 3190) with an implied precision of 19 digits.

35.1.1.7.13 AnsiStringBase::Delete Method

Removes a specified number of characters from the string.

Pascal

```
function Delete(index: Integer; count: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Delete(int index, int count);
```

Description

System::AnsiStringBase::Delete modifies the System::AnsiStringBase::AnsiStringBase (see page 3174) to remove count characters from the string beginning with the character at index, where 1 is the index of the first character. It returns the resulting modified string (*this).

If index is larger than the length of the System::AnsiStringBase::AnsiStringBase (see page 3174) or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, System::AnsiStringBase::Delete removes the rest of the string. If count is less than 0, no characters are deleted.

35.1.1.7.14 AnsiStringBase::ElementSize Method

Gets element size of data in a System::AnsiStringBase (see page 3174).

Pascal

```
function ElementSize: unsigned short;
```

C++

```
unsigned short ElementSize() const;
```

Description

System::AnsiStringBase::ElementSize gets the element size in bytes of the data in a System::AnsiStringBase (see page 3174) instance. If the instance is empty, this returns 1.

See Also

System::AnsiStringBase::Data (see page 3182)

System::AnsiStringBase::GetRec (see page 3193)

35.1.1.7.15 AnsiStringBase::EnsureAnsi Method

Ensure string's data is ANSI data.

Pascal

```
function EnsureAnsi: AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& EnsureAnsi();
```

Description

If the string's data is Unicode, i.e., its element length is 2, System::AnsiStringBase::EnsureAnsi converts the Unicode to ANSI using the current locale.

Note: In some cases, the conversion to an ANSI string may fail.

35.1.1.7.16 AnsiStringBase::FloatToStrF Method

Returns the string representation of a floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits, int codePage);
```

Description

The format parameter controls the format of the resulting string. The precision parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the digits parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3191) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator and ThousandSeparator global variables.

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

35.1.1.7.17 AnsiStringBase::FmtLoadStr Method

Formats output using a resourced format string.

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer; codePage: Integer):
AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FmtLoadStr(int ident, const TVarRec * args, int size, int
codePage);
```

Description

System::AnsiStringBase::FmtLoadStr loads a string from a program's resource string table and uses that string, plus the args array, as a parameter to Format (see page 3191). Ident is the string resource ID of the desired format string.

See Also

System::AnsiStringBase::LoadString (see page 3197)

System::AnsiStringBase::LoadStr (see page 3197)

35.1.1.7.18 AnsiStringBase::Format Method

System::AnsiStringBase::Formats a string assembled from an System::AnsiStringBase (see page 3174), format, and a series of array arguments, args.

Pascal

```
function Format(const format: AnsiStringBase&; const args: TVarRec *; size: Integer; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase Format(const AnsiStringBase& format, const TVarRec * args,
int size, int codePage);
```

Description

Use System::AnsiStringBase::Format to obtain an System::AnsiStringBase (see page 3174) whose value is the result of applying an array of arguments (args) to a given a format string (format). The last parameter (size) is the index of the last element in args (one less than the number of arguments).

Note that System::AnsiStringBase::Format is a static method. The returned value is a newly allocated System::AnsiStringBase (see page 3174), even if the method is called from an existing System::AnsiStringBase (see page 3174) instance.

For information on how System::AnsiStringBase::Format assembles a final string from its format string and arguments, see System::AnsiStringBase::Format Strings.

See Also

System::AnsiStringBase::printf

System::AnsiStringBase::sprintf

35.1.1.7.19 AnsiStringBase::FormatFloat Method

Formats the floating-point value given by value using the format string given by format.

Pascal

```
function FormatFloat(const format: AnsiStringBase&; const value: long double&; codePage:
Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase FormatFloat(const AnsiStringBase& format, const long double&
```

```
value, int codePage);
```

Description

The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the DecimalSeparator global variable, whose default value is specified in the Number Format (see page 3191) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the ThousandSeparator global variable, whose default value is specified in the Number Format (see page 3191) of the International section in the Windows Control Panel.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 3190) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 3191) string-1234-12340.50

Format (see page 3191) string-	1234	-1234	0.5	0
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	
#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

35.1.1.7.20 GetRec Method

This is the overview for the GetRec method overload.

Overload List

	Name	Description
	AnsiStringBase::GetRec () (see page 3193)	Gets a struct describing a System::AnsiStringBase (see page 3174).
	AnsiStringBase::GetRec () (see page 3193)	Gets a struct describing a System::AnsiStringBase (see page 3174).

35.1.1.7.20.1 AnsiStringBase::GetRec Method ()

Gets a struct describing a System::AnsiStringBase (see page 3174).

Pascal

```
function GetRec: const StrRec&;
function GetRec: StrRec&;
```

C++

```
const StrRec& GetRec() const;
StrRec& GetRec();
```

Description

System::AnsiStringBase::GetRec gets a struct that describes the contents of a System::AnsiStringBase (see page 3174) instance. The struct has this format:

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

35.1.1.7.21 AnsiStringBase::Insert Method

System::AnsiStringBase::Inserts a specified string into the System::AnsiStringBase (see page 3174).

Pascal

```
function Insert(const str: AnsiStringBase&; index: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Insert(const AnsiStringBase& str, int index);
```

Description

System::AnsiStringBase::Insert inserts the string str into this System::AnsiStringBase (see page 3174) beginning at the position index, where 1 is the first position in the string. It returns the resulting modified string (*this).

If index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to Length (see page 3196)(), turning the operation into an append.

If the str parameter is an empty string, System::AnsiStringBase::Insert does nothing.

System::AnsiStringBase::Insert throws an EOutOfMemory exception if the method is unable to allocate enough memory to accommodate the new, longer, string.

Note: The index parameter specifies the character, not the byte, when working with a multi-byte character system.

35.1.1.7.22 AnsiStringBase::IntToHex Method

Converts a number into a string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer; codePage: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase IntToHex(int value, int digits, int codePage);
```

Description

Value is the number to convert. Digits indicates the minimum number of hexadecimal digits.

35.1.1.7.23 AnsiStringBase::IsDelimiter Method

Returns true if the specified character matches any character in the delimiters string.

Pascal

```
function IsDelimiter(const delimiters: AnsiStringBase&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const AnsiStringBase& delimiters, int index) const;
```

Description

System::AnsiStringBase::IsDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character contained in delimiters. If the byte is part of a multi-byte character or not in delimiters, System::AnsiStringBase::IsDelimiter returns false.

35.1.1.7.24 AnsiStringBase::IsEmpty Method

Returns true if the System::AnsiStringBase (see page 3174) is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::AnsiStringBase::IsEmpty returns true if this System::AnsiStringBase (see page 3174) is empty, false otherwise.

35.1.1.7.25 AnsiStringBase::IsLeadByte Method

Returns true if the specified byte is a lead byte.

Pascal

```
function IsLeadByte(index: Integer): bool;
```

C++

```
__fastcall bool IsLeadByte(int index) const;
```

Description

System::AnsiStringBase::IsLeadByte returns true if the byte indicated by index (counting from 0) is the lead byte in a multi-byte character. If the byte is a trailing byte, or not part of a multi-byte character, System::AnsiStringBase::IsLeadByte returns false.

35.1.1.7.26 AnsiStringBase::IsPathDelimiter Method

Returns true if the specified character is '\'.

Pascal

```
function IsPathDelimiter(index: Integer): bool;
```

C++

```
__fastcall bool IsPathDelimiter(int index) const;
```

Description

System::AnsiStringBase::IsPathDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character containing the path delimiter ('\' on Windows, '/' on Linux).

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.1.7.27 AnsiStringBase::IsTrailByte Method

Returns true if the specified byte is of type mbTrailByte.

Pascal

```
function IsTrailByte(index: Integer): bool;
```

C++

```
__fastcall bool IsTrailByte(int index) const;
```

Description

System::AnsiStringBase::IsTrailByte returns true if the byte indicated by index (counting from 0) is the trailing byte in a multi-byte character. If the byte is a lead byte, or not part of a multi-byte character, System::AnsiStringBase::IsTrailByte returns false.

35.1.1.7.28 AnsiStringBase::LastChar Method

Returns a pointer to the last character in a string.

Pascal

```
function LastChar: char*;
```

C++

```
__fastcall char* LastChar() const;
```

Description

Call System::AnsiStringBase::LastChar to obtain a pointer to the last character in a string. This function supports multi-byte character sets (MBCS).

See Also

System::AnsiStringBase::AnsiLastChar (see page 3186)

35.1.1.7.29 AnsiStringBase::LastDelimiter Method

Returns the index of the rightmost character that matches any character in the delimiters string.

Pascal

```
function LastDelimiter(const delimiters: AnsiStringBase&): Integer;
```

C++

```
__fastcall int LastDelimiter(const AnsiStringBase& delimiters) const;
```

Description

System::AnsiStringBase::LastDelimiter returns the byte index in this System::AnsiStringBase (see page 3174) of the rightmost whole character that matches any character in delimiters except NULL The System::AnsiStringBase (see page 3174) may contain multibyte characters; delimiters must contain only single byte non-NULL characters.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.1.7.30 AnsiStringBase::Length Method

Returns the length of the System::AnsiStringBase (see page 3174).

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::AnsiStringBase::Length returns the number of bytes in this System::AnsiStringBase (see page 3174).

35.1.1.7.31 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	AnsiStringBase::LoadStr (HINSTANCE, int, int) (see page 3197)	Loads a string from the compiled resources of a specified module.
	AnsiStringBase::LoadStr (int, int) (see page 3197)	Loads a string from the compiled resources of a specified module.

35.1.1.7.31.1 AnsiStringBase::LoadStr Method (HINSTANCE, int, int)

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadStr(ident: Integer; codePage: Integer): AnsiStringBase; static;
function LoadStr(hInstance: HINSTANCE; ident: Integer; codePage: Integer): AnsiStringBase;
static;
```

C++

```
static __fastcall AnsiStringBase LoadStr(int ident, int codePage);
static __fastcall AnsiStringBase LoadStr(HINSTANCE hInstance, int ident, int codePage);
```

Description

System::AnsiStringBase::LoadStr loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource. If hInstance is not given, System::AnsiStringBase::LoadStr loads the string from the current module (executable or shared library)

If the string resource does not exist, System::AnsiStringBase::LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringBase::LoadString (see page 3197)

System::AnsiStringBase::FmtLoadStr (see page 3190)

35.1.1.7.32 AnsiStringBase::LoadString Method

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer; codePage: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& LoadString(HINSTANCE hInstance, int ident, int codePage);
```

Description

System::AnsiStringBase::LoadString loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource.

If the string resource does not exist, System::AnsiStringBase::LoadString returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringBase::LoadStr (see page 3197)

System::AnsiStringBase::FmtLoadStr (see page 3190)

35.1.1.7.33 AnsiStringBase::LowerCase Method

Returns a lower-case version of System::AnsiStringBase (see page 3174).

Pascal

```
function LowerCase(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase LowerCase(int codePage) const;
```

Description

System::AnsiStringBase::LowerCase returns a new System::AnsiStringBase (see page 3174) that contains all characters in this string, converted to lower case. The conversion uses the current locale . The original System::AnsiStringBase (see page 3174) remains unchanged.

35.1.1.7.34 AnsiStringBase::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: AnsiStringBase&): Integer;
```

C++

```
__fastcall int Pos(const AnsiStringBase& subStr) const;
```

Description

System::AnsiStringBase::Pos returns the index in the System::AnsiStringBase (see page 3174) at which the substring subStr begins, where 1 is the index of the first character, 2 is the index of the second character, and so on. If the substring is not contained in the System::AnsiStringBase (see page 3174), System::AnsiStringBase::Pos returns 0.

35.1.1.7.35 AnsiStringBase::RefCount Method

Gets reference count of System::AnsiStringBase (see page 3174).

Pascal

```
function RefCount: Integer;
```

C++

```
int RefCount() const;
```

Description

System::AnsiStringBase::RefCount gets the reference count of a System::AnsiStringBase (see page 3174) instance. If the instance is empty, it returns 0.

See Also

System::AnsiStringBase::GetRec (see page 3193)

35.1.1.7.36 AnsiStringBase::SetLength Method

Changes the length of the System::AnsiStringBase (see page 3174).

Pascal

```
function SetLength(newLength: Integer; codePage: Integer): AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& SetLength(int newLength, int codePage);
```

Description

System::AnsiStringBase::SetLength changes the string's length to newLength, truncating if necessary.

System::AnsiStringBase::SetLength reallocates the underlying array of characters that stores the value of the System::AnsiStringBase (see page 3174). Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate the System::AnsiStringBase (see page 3174), an EOutOfMemory exception is thrown. Following a call to System::AnsiStringBase::SetLength, the System::AnsiStringBase (see page 3174) is guaranteed not to be a shared reference.

System::AnsiStringBase::SetLength returns the modified System::AnsiStringBase (see page 3174) object (*this)

35.1.1.7.37 AnsiStringBase::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: char; count: Integer): AnsiStringBase; static;
```

C++

```
static __fastcall AnsiStringBase StringOfChar(char ch, int count);
```

Description

System::AnsiStringBase::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::AnsiStringBase (see page 3174) s = System::AnsiStringBase::System::AnsiStringBase::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

35.1.1.7.38 AnsiStringBase::SubString Method

Returns a specified substring of the System::AnsiStringBase (see page 3174).

Pascal

```
function SubString(index: Integer; count: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase SubString(int index, int count) const;
```

Description

System::AnsiStringBase::SubString returns a new System::AnsiStringBase (see page 3174) that is a substring of this System::AnsiStringBase (see page 3174). The substring contains count characters beginning at index.

35.1.1.7.39 AnsiStringBase::swap Method

Swap string pointers.

Pascal

```
function swap(var other: AnsiStringBase): AnsiStringBase&;
```

C++

```
AnsiStringBase& swap(AnsiStringBase& other);
```

Description

System::AnsiStringBase::swap swaps two System::AnsiStringBase (see page 3174) strings. Pointers to the data are swapped, and the data is not copied. This makes the swap operation efficient for sorting.

35.1.1.7.40 AnsiStringBase::ThrowIfOutOfRange Method

Pascal

```
procedure ThrowIfOutOfRange(idx: Integer); cdecl;
```

C++

```
__cdecl void ThrowIfOutOfRange(int idx) const;
```

Description

This is ThrowIfOutOfRange, a member of class AnsiStringBase.

35.1.1.7.41 AnsiStringBase::ToDouble Method

Converts the string to a floating-point value.

Pascal

```
function ToDouble: double;
```

C++

```
__fastcall double ToDouble() const;
```

Description

System::AnsiStringBase::ToDouble converts the string to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks in the string are ignored. The DecimalSeparator global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, an EConvertError exception is thrown.

35.1.1.7.42 AnsiStringBase::ToInt Method

Converts a string to an integer, throwing an exception if the string is invalid.

Pascal

```
function ToInt: Integer;
```

C++

```
__fastcall int ToInt() const;
```

Description

System::AnsiStringBase::ToInt converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, an EConvertError exception is thrown.

See Also

System::AnsiStringBase::ToIntDef (see page 3201)

35.1.1.7.43 AnsiStringBase::ToIntDef Method

Converts the string to an integer, returning a default value if the string is invalid.

Pascal

```
function ToIntDef(defaultValue: Integer): Integer;
```

C++

```
__fastcall int ToIntDef(int defaultValue) const;
```

Description

System::AnsiStringBase::ToIntDef converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, the value given by defaultValue is returned.

See Also

System::AnsiStringBase::ToInt (see page 3200)

35.1.1.7.44 AnsiStringBase::Trim Method

Returns a new System::AnsiStringBase (see page 3174) without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase Trim(int codePage) const;
```

Description

System::AnsiStringBase::Trim returns a new System::AnsiStringBase (see page 3174) removing leading and trailing spaces and control characters. Use System::AnsiStringBase::Trim to remove blank space before and after the first printing character.

35.1.1.7.45 AnsiStringBase::TrimLeft Method

Returns a new System::AnsiStringBase (see page 3174) without leading spaces or control characters.

Pascal

```
function TrimLeft(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase TrimLeft(int codePage) const;
```

Description

System::AnsiStringBase::TrimLeft returns a new System::AnsiStringBase (see page 3174) removing leading spaces and control characters. Use System::AnsiStringBase::TrimLeft to remove blank space before the first printing character.

35.1.1.7.46 AnsiStringBase::TrimRight Method

Returns a new System::AnsiStringBase (see page 3174) without trailing spaces or control characters.

Pascal

```
function TrimRight(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase TrimRight(int codePage) const;
```

Description

System::AnsiStringBase::TrimRight returns a new System::AnsiStringBase (see page 3174) removing trailing spaces and control characters. Use the System::AnsiStringBase::TrimRight function to remove blank space after the last printing character.

35.1.1.7.47 AnsiStringBase::Unique Method

Makes the System::AnsiStringBase (see page 3174) unique.

Pascal

```
function Unique: AnsiStringBase&;
```

C++

```
__fastcall AnsiStringBase& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::AnsiStringBase::Unique sets the reference count on the string for the System::AnsiStringBase (see page 3174) object to 1 so that it is the only object referencing that string.

35.1.1.7.48 AnsiStringBase::UpperCase Method

Returns an upper-case version of this System::AnsiStringBase (see page 3174).

Pascal

```
function UpperCase(codePage: Integer): AnsiStringBase;
```

C++

```
__fastcall AnsiStringBase UpperCase(int codePage) const;
```

Description

System::AnsiStringBase::UpperCase returns a new System::AnsiStringBase (see page 3174) that contains all characters in this string, converted to upper case. The conversion uses the current locale . The original System::AnsiStringBase (see page 3174) remains unchanged.

35.1.1.7.49 AnsiStringBase::vprintf Method

Sets the value of the System::AnsiStringBase (see page 3174) given a format string and its arguments.

Pascal

```
function vprintf(codePage: Integer; const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(int codePage, const char* format, va_list);
```

Description

Use System::AnsiStringBase::vprintf to set to the value of the System::AnsiStringBase (see page 3174) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the length of the final formatted string.

See Also

System::AnsiStringBase::Format (see page 3191)

System::AnsiStringBase::sprintf

System::AnsiStringBase::printf

System::AnsiStringBase::cat_vprintf (see page 3187)

35.1.1.7.50 AnsiStringBase::WideChar Method

Converts the System::AnsiStringBase (see page 3174) to a wide-character array.

Pascal

```
function WideChar(var dest: wchar_t; destSize: Integer; codePage: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* WideChar(wchar_t* dest, int destSize, int codePage) const;
```

Description

System::AnsiStringBase::WideChar converts the System::AnsiStringBase (see page 3174) to an array of wide characters, and returns the resulting wide-character array.

dest is a buffer the caller allocates to hold the return value. Use the System::AnsiStringBase::WideCharBufSize (see page 3203) method to determine the size needed to hold the entire string value.

destSize is the size, in bytes, of dest.

System::AnsiStringBase::WideChar returns a pointer to the wide-character array that is written to dest.

See Also

System::AnsiStringBase::WideCharBufSize (see page 3203)

35.1.1.7.51 AnsiStringBase::WideCharBufSize Method

Returns the size of the buffer required by the WideChar (see page 3203) function.

Pascal

```
function WideCharBufSize(codePage: Integer): Integer;
```

C++

```
__fastcall int WideCharBufSize(int codePage) const;
```

Description

System::AnsiStringBase::WideCharBufSize returns an integer value indicating the size of the buffer required by the WideChar (see page 3203) method in order to convert this string.

See Also

System::AnsiStringBase::WideChar (see page 3203)

35.1.1.8 AnsiStringBase Operators

The operators of the AnsiStringBase class are listed here.

Protected Operators

	Name	Description
	!= (see page 3204)	Compares two strings.
	< (see page 3205)	Compares two strings.
	<= (see page 3206)	Compares two strings.
	= (see page 3206)	Assigns the string rhs to this System::AnsiStringBase (see page 3174).
	== (see page 3206)	Compares the System::AnsiStringBase (see page 3174) with a specified string, returning true if they are the same.
	> (see page 3207)	Compares two strings.
	>= (see page 3207)	Compares two strings.

Public Operators

	Name	Description
	[] (see page 3204)	This is the overview for the [] operator overload.
	+ (see page 3205)	Concatenates two System::AnsiStringBase (see page 3174) values.

35.1.1.8.1 AnsiStringBase::!= Operator

Compares two strings.

Pascal

```
operator !=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator !=(const AnsiStringBase& rhs) const;
```

Description

Returns true if the strings are not the same, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::!= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.1.8.2 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	AnsiStringBase::[] (int) (see page 3205)	Returns the character at a specified index in the string.
	AnsiStringBase::[] (int) (see page 3205)	Returns the character at a specified index in the string.

35.1.1.8.2.1 AnsiStringBase::[] Operator (int)

Returns the character at a specified index in the string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall char operator [](const int idx) const;
__fastcall char& operator [](const int idx);
```

Description

This System::AnsiStringBase (see page 3174)::[] returns the byte in the string at index value idx. The System::AnsiStringBase (see page 3174)::[] assumes a base index of 1.

Note: If the string contains multi-byte characters, the System::AnsiStringBase (see page 3174)::[] may return a byte value that represents the wrong character and/or a partial character. For character-level access, use the SubString (see page 3199) method.

See Also

System::AnsiStringBase::SubString (see page 3199)

35.1.1.8.3 AnsiStringBase::+ Operator

Concatenates two System::AnsiStringBase (see page 3174) values.

Pascal

```
operator +(const rhs: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringBase operator +(const AnsiStringBase& rhs) const;
```

Description

The friend function returns an System::AnsiStringBase (see page 3174) that is the concatenation of strings lhs and rhs.

The method returns an System::AnsiStringBase (see page 3174) that is the concatenation of this System::AnsiStringBase (see page 3174) and rhs.

35.1.1.8.4 AnsiStringBase::< Operator

Compares two strings.

Pascal

```
operator <(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator <(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is less than rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::< performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.1.8.5 AnsiStringBase::<= Operator

Compares two strings.

Pascal

```
operator <=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator <=(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase::AnsiString is less than or equal to rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::<= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.1.8.6 AnsiStringBase::= Operator

Assigns the string rhs to this System::AnsiStringBase (see page 3174).

Pascal

```
operator =(const rhs: AnsiStringBase&);
```

C++

```
__fastcall AnsiStringBase& operator =(const AnsiStringBase& rhs);
```

Description

Use this System::AnsiStringBase (see page 3174)::= to assign the value of the System::AnsiStringBase (see page 3174) from another System::AnsiStringBase (see page 3174).

35.1.1.8.7 AnsiStringBase::== Operator

Compares the System::AnsiStringBase (see page 3174) with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator ==(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase (see page 3174) is the same as rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::== performs a simple byte-level numeric comparison. For locale

support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.1.8.8 AnsiStringBase::> Operator

Compares two strings.

Pascal

```
operator >(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator >(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase (see page 3174) is greater than rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::> performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.1.8.9 AnsiStringBase::>= Operator

Compares two strings.

Pascal

```
operator >=(const rhs: AnsiStringBase&);
```

C++

```
__fastcall bool operator >=(const AnsiStringBase& rhs) const;
```

Description

Returns true if this System::AnsiStringBase (see page 3174) is greater than or equal to rhs, false otherwise.

Note: This System::AnsiStringBase (see page 3174)::>= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3185) or AnsiCompareIC (see page 3185) methods.

See Also

System::AnsiStringBase::AnsiCompare (see page 3185)

System::AnsiStringBase::AnsiCompareIC (see page 3185)

35.1.2 AnsiStringT Template

System::AnsiStringT is the C++ analog for the Delphi long string type.

Class Hierarchy

Pascal

```
AnsiStringT<unsigned short CP> = class(AnsiStringBase);
```

C++

```
template <unsigned short CP>
class AnsiStringT : public AnsiStringBase;
```

File

dstring.h

Description

System::AnsiStringT exists to provide a place for methods/members that are common to all instantiations of the template class AnsiStringT<CodePage (see page 3217)>. AnsiString itself is a typedef that is equivalent to AnsiStringT<0>. You should never deal directly with System::AnsiStringT.

System::AnsiStringT is a template class that you use when handling a Delphi AnsiString that has a code page specified with it.

Delphi uses several string types. One important long string type is commonly known as System::AnsiString. Support for this type includes the following features:

- strings can be as large as available memory
- efficient use of memory is ensured through shared references
- routines and operators evaluate strings based on the current locale

System::AnsiStringT is a template class that holds code for each specific code page. Despite its name, System::AnsiStringT is not restricted to the ANSI character set, and can use any character set supported by the current locale definition, including multi-byte or Unicode character sets.

System::AnsiStringT variables that have not been assigned an initial value contain a zero-length string.

To use the C++ streaming operators (**<<** and **>>**) with System::AnsiStringT, you must `iostream` before including `system.hpp` and use `AnsiStringT::c_str (see page 3216)()` to return the internal string representation. The following example demonstrates the usage of AnsiString with stream operators:

```
#include <iostream>
#include <system.hpp>
int main() {
  AnsiString HelloStr = "hello";
  std::cout << HelloStr.c_str();
}
```

Note: Delphi also supports System::AnsiString, but implements it as a primitive type rather than a class. By default, variables declared as type String are System::UnicodeString (see page 3381).

How to Handle Delphi AnsiString Code Page Specification in C++

System::WideString (see page 3467)

System::AnsiStringT::[]

System::AnsiStringT::= (see page 3233)

System::AnsiStringT::== (see page 3234)

System::AnsiStringT::!= (see page 3232)

System::AnsiStringT::> (see page 3234)

System::AnsiStringT::>= (see page 3234)

System::AnsiStringT::< (see page 3233)

System::AnsiStringT::<= (see page 3233)

System::AnsiStringT::+ (see page 3232)

System::AnsiStringT::+= (see page 3232)

35.1.2.1 AnsiStringT Members

The following tables list the members exposed by AnsiStringT.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3180)	System::AnsiStringBase::TStringFloatFormat is an enumerated list of formatting codes for float functions.
	TStringMbcsByteType (see page 3181)	Enumerated list of byte types in MCBS string.

Structures

	Name	Description
	StrRec (see page 3180)	This is record System::AnsiStringBase::StrRec.

Protected Data Members

	Name	Description
	Data (see page 3182)	This is Data, a member of class AnsiStringBase.

Protected Methods

	Name	Description
	_AnsiCat (see page 3184)	This is the overview for the _AnsiCat method overload.
	_AnsiFromPWChar (see page 3184)	This is _AnsiFromPWChar, a member of class AnsiStringBase.
	AnsiStringBase (see page 3178)	This is the overview for the AnsiStringBase constructor overload.
	GetRec (see page 3193)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3200)	This is ThrowIfOutOfRange, a member of class AnsiStringBase.

Public Methods

	Name	Description
	~AnsiStringBase (see page 3178)	Frees an instance of System::AnsiStringBase (see page 3174).
	~AnsiStringT (see page 3211)	This is ~AnsiStringT, a member of class AnsiStringT.
	AnsiCompare (see page 3214)	Compares the System::AnsiStringT (see page 3207) to another specified string (case-sensitively).
	AnsiCompareIC (see page 3215)	Compares the System::AnsiStringT (see page 3207) to another specified string (case insensitively).
	AnsiLastChar (see page 3186)	Returns a pointer to the last full character in the System::AnsiStringBase::AnsiStringBase (see page 3174).
	AnsiPos (see page 3215)	Returns the index at which the specified substring begins.
	AnsiStringT (see page 3211)	This is the overview for the AnsiStringT constructor overload.
	BytesOf (see page 3186)	Get string's data in bytes.
	ByteType (see page 3187)	Indicates the kind of byte that occupies a specified position in the System::AnsiStringBase (see page 3174).
	c_str (see page 3216)	Returns the System::AnsiStringT (see page 3207) converted to a null-terminated character array.
	cat_printf (see page 3216)	Appends to the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.

	cat_sprintf (see page 3216)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).
	cat_vprintf (see page 3217)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).
	CodePage (see page 3217)	Gets code page of a System::AnsiStringT (see page 3207).
	CurrToStr (see page 3218)	Converts a currency value to its string representation.
	CurrToStrF (see page 3218)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 3218)	Returns a pointer to the underlying string System::AnsiStringT::data.
	Delete (see page 3219)	Removes a specified number of characters from the string.
	ElementSize (see page 3219)	Gets element size of data (see page 3218) in a System::AnsiStringT (see page 3207).
	EnsureAnsi (see page 3220)	Ensure string's data (see page 3218) is ANSI data (see page 3218).
	FloatToStrF (see page 3220)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3221)	Formats output using a resourced format string.
	Format (see page 3221)	System::AnsiStringT::Formats a string assembled from an System::AnsiStringT (see page 3207), format, and a series of array arguments, args.
	FormatFloat (see page 3222)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3223)	System::AnsiStringT::Inserts a specified string into the System::AnsiStringT (see page 3207).
	IntToHex (see page 3224)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3224)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3194)	Returns true if the System::AnsiStringBase (see page 3174) is empty.
	IsLeadByte (see page 3195)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 3195)	Returns true if the specified character is '\'.
	IsTrailByte (see page 3195)	Returns true if the specified byte is of type mbTrailByte.
	LastChar (see page 3196)	Returns a pointer to the last character in a string.
	LastDelimiter (see page 3224)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3196)	Returns the length of the System::AnsiStringBase (see page 3174).
	LoadStr (see page 3196)	This is the overview for the LoadStr method overload.
	LoadStr (see page 3224)	This is the overview for the LoadStr method overload.
	LoadString (see page 3225)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3226)	Returns a lower-case version of System::AnsiStringT (see page 3207).
	Pos (see page 3226)	Returns the index at which a specified substring begins.
	printf (see page 3226)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	RefCount (see page 3227)	Gets reference count of System::AnsiStringT (see page 3207).
	SetLength (see page 3227)	Changes the length of the System::AnsiStringT (see page 3207).
	sprintf (see page 3227)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	StringOfChar (see page 3228)	Returns a string with the specified number of characters.
	SubString (see page 3228)	Returns a specified substring of the System::AnsiStringT (see page 3207).
	swap (see page 3228)	Swap string pointers.
	ToDouble (see page 3200)	Converts the string to a floating-point value.
	ToInt (see page 3200)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3201)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without leading spaces or control characters.
	TrimRight (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without trailing spaces or control characters.
	Unique (see page 3229)	Makes the System::AnsiStringT (see page 3207) unique.
	UpperCase (see page 3230)	Returns an upper-case version of this System::AnsiStringT (see page 3207).

	vprintf (see page 3230)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	WideChar (see page 3230)	Converts the System::AnsiStringT (see page 3207) to a wide-character array.
	WideCharBufSize (see page 3231)	Returns the size of the buffer required by the WideChar (see page 3230) function.

Public Operators

	Name	Description
	!= (see page 3232)	Compares two strings.
	[] (see page 3204)	This is the overview for the [] operator overload.
	+ (see page 3232)	Concatenates two System::AnsiStringT (see page 3207) values.
	+= (see page 3232)	Append (see page 3520) an System::AnsiStringT (see page 3207).
	< (see page 3233)	Compares two strings.
	<= (see page 3233)	Compares two strings.
	= (see page 3233)	Assigns the string rhs to this System::AnsiStringT (see page 3207).
	== (see page 3234)	Compares the System::AnsiStringT (see page 3207) with a specified string, returning true if they are the same.
	> (see page 3234)	Compares two strings.
	>= (see page 3234)	Compares two strings.

35.1.2.2 AnsiStringT::~AnsiStringT Destructor

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~AnsiStringT();
```

Description

This is ~AnsiStringT, a member of class AnsiStringT.

35.1.2.3 AnsiStringT Constructor

This is the overview for the AnsiStringT constructor overload.

Overload List

	Name	Description
	AnsiStringT::AnsiStringT () (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (__int64) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (AnsiStringBase&) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (AnsiStringT&) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (AnsiStringT<OTHER_CP>&) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (char) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).

	AnsiStringT::AnsiStringT (char*) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (char*, int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (char16_t*, int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (char32_t*, int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (double) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (long) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (short) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (UnicodeString &) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (unsigned __int64) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (unsigned int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (unsigned long) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (unsigned short) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (wchar_t) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (wchar_t*, int) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).
	AnsiStringT::AnsiStringT (WideString &) (see page 3212)	Creates an instance of System::AnsiStringT (see page 3207).

35.1.2.3.1 AnsiStringT::AnsiStringT Constructor ()

Creates an instance of System::AnsiStringT (see page 3207).

Pascal

```
constructor Create;
constructor Create(const src: char*);
constructor Create(const src: AnsiStringT&);
constructor Create(const src: AnsiStringBase&);
constructor Create<unsigned short OTHER_CP>(const src: AnsiStringT<OTHER_CP>&);
constructor Create(const src: char*; byteLen: Integer);
constructor Create(const src: wchar_t*; numwchar: Integer = -1);
constructor Create(const src: char16_t*; numChar16: Integer = -1);
constructor Create(const src: char32_t*; numChar32: Integer = -1);
constructor Create(src: char);
constructor Create(src: wchar_t);
constructor Create(src: short);
```

```
constructor Create(src: unsigned short);
constructor Create(src: Integer);
constructor Create(src: unsigned int);
constructor Create(src: long);
constructor Create(src: unsigned long);
constructor Create(src: __int64);
constructor Create(src: unsigned __int64);
constructor Create(src: double);
constructor Create(const src: WideString &);
constructor Create(const src: UnicodeString &);
```

C++

```
__fastcall AnsiStringT();
__fastcall AnsiStringT(const char* src);
__fastcall AnsiStringT(const AnsiStringT& src);
__fastcall AnsiStringT(const AnsiStringBase& src);
template <unsigned short OTHER_CP> AnsiStringT<CP>(const AnsiStringT<OTHER_CP>& src);
__fastcall AnsiStringT(const char* src, int byteLen);
__fastcall AnsiStringT(const wchar_t* src, int numwchar = -1);
__fastcall AnsiStringT(const char16_t* src, int numChar16 = -1);
__fastcall AnsiStringT(const char32_t* src, int numChar32 = -1);
__fastcall AnsiStringT(char src);
__fastcall AnsiStringT(wchar_t src);
__fastcall AnsiStringT(short src);
__fastcall AnsiStringT(unsigned short src);
__fastcall AnsiStringT(int src);
__fastcall AnsiStringT(unsigned int src);
__fastcall AnsiStringT(long src);
__fastcall AnsiStringT(unsigned long src);
__fastcall AnsiStringT(__int64 src);
__fastcall AnsiStringT(unsigned __int64 src);
__fastcall AnsiStringT(double src);
__fastcall AnsiStringT(const WideString & src);
__fastcall AnsiStringT(const UnicodeString & src);
```

Description

System::AnsiStringT::AnsiStringT (see page 3207) is the constructor for System::AnsiStringT (see page 3207).

If the constructor is given no arguments, the resulting System::AnsiStringT (see page 3207) instance is an empty string. If the constructor is passed a single character, the resulting System::AnsiStringT (see page 3207) instance has character length one, and contains that character. Other versions of the constructor copy the string passed as an argument, converting characters to `char` if necessary. When constructing a System::AnsiStringT (see page 3207) instance from an array of `char` or `wchar_t`, the source string should be null terminated, unless an argument is given that indicates the number of characters in the array. For some overloads of the constructor, you can pass the code page you want for the string. In another overload, you can pass a floating point number to be converted to a string.

35.1.2.4 AnsiStringT Methods

The methods of the AnsiStringT class are listed here.

Public Methods

	Name	Description
	AnsiCompare (see page 3214)	Compares the System::AnsiStringT (see page 3207) to another specified string (case-sensitively).
	AnsiCompareIC (see page 3215)	Compares the System::AnsiStringT (see page 3207) to another specified string (case insensitively).
	AnsiPos (see page 3215)	Returns the index at which the specified substring begins.
	c_str (see page 3216)	Returns the System::AnsiStringT (see page 3207) converted to a null-terminated character array.

	cat_printf (see page 3216)	Appends to the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	cat_sprintf (see page 3216)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).
	cat_vprintf (see page 3217)	Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).
	CodePage (see page 3217)	Gets code page of a System::AnsiStringT (see page 3207).
	CurrToStr (see page 3218)	Converts a currency value to its string representation.
	CurrToStrF (see page 3218)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 3218)	Returns a pointer to the underlying string System::AnsiStringT::data.
	Delete (see page 3219)	Removes a specified number of characters from the string.
	ElementSize (see page 3219)	Gets element size of data (see page 3218) in a System::AnsiStringT (see page 3207).
	EnsureAnsi (see page 3220)	Ensure string's data (see page 3218) is ANSI data (see page 3218).
	FloatToStrF (see page 3220)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 3221)	Formats output using a resourced format string.
	Format (see page 3221)	System::AnsiStringT::Formats a string assembled from an System::AnsiStringT (see page 3207), format, and a series of array arguments, args.
	FormatFloat (see page 3222)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3223)	System::AnsiStringT::Inserts a specified string into the System::AnsiStringT (see page 3207).
	IntToHex (see page 3224)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3224)	Returns true if the specified character matches any character in the delimiters string.
	LastDelimiter (see page 3224)	Returns the index of the rightmost character that matches any character in the delimiters string.
	LoadStr (see page 3224)	This is the overview for the LoadStr method overload.
	LoadString (see page 3225)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 3226)	Returns a lower-case version of System::AnsiStringT (see page 3207).
	Pos (see page 3226)	Returns the index at which a specified substring begins.
	printf (see page 3226)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	RefCount (see page 3227)	Gets reference count of System::AnsiStringT (see page 3207).
	SetLength (see page 3227)	Changes the length of the System::AnsiStringT (see page 3207).
	sprintf (see page 3227)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	StringOfChar (see page 3228)	Returns a string with the specified number of characters.
	SubString (see page 3228)	Returns a specified substring of the System::AnsiStringT (see page 3207).
	swap (see page 3228)	Swap string pointers.
	Trim (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without leading spaces or control characters.
	TrimRight (see page 3229)	Returns a new System::AnsiStringT (see page 3207) without trailing spaces or control characters.
	Unique (see page 3229)	Makes the System::AnsiStringT (see page 3207) unique.
	UpperCase (see page 3230)	Returns an upper-case version of this System::AnsiStringT (see page 3207).
	vprintf (see page 3230)	Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.
	WideChar (see page 3230)	Converts the System::AnsiStringT (see page 3207) to a wide-character array.
	WideCharBufSize (see page 3231)	Returns the size of the buffer required by the WideChar (see page 3230) function.

35.1.2.4.1 AnsiStringT::AnsiCompare Method

Compares the System::AnsiStringT (see page 3207) to another specified string (case-sensitively).

Pascal

```
function AnsiCompare(const rhs: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiCompare(const AnsiStringT& rhs) const;
```

Description

Compares this System::AnsiStringT (see page 3207) to rhs, with case sensitivity. The compare operation is controlled by the current Windows locale and is not necessarily the same as using the System::AnsiStringT (see page 3207) comparison operators. System::AnsiStringT::AnsiCompare is based on a locale-specific collating order. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

35.1.2.4.2 AnsiStringT::AnsiCompareIC Method

Compares the System::AnsiStringT (see page 3207) to another specified string (case insensitively).

Pascal

```
function AnsiCompareIC(const rhs: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiCompareIC(const AnsiStringT& rhs) const;
```

Description

System::AnsiStringT::AnsiCompareIC compares this System::AnsiStringT (see page 3207) to rhs, without case sensitivity. The compare operation is controlled by the current Windows locale. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

35.1.2.4.3 AnsiStringT::AnsiPos Method

Returns the index at which the specified substring begins.

Pascal

```
function AnsiPos(const subStr: AnsiStringT&): Integer;
```

C++

```
__fastcall int AnsiPos(const AnsiStringT& subStr) const;
```

Description

Returns the index in the System::AnsiStringT (see page 3207) at which the substring subStr begins, where 1 is the first character in the string, 2 is the second character, and so on. If the substring is not contained in the System::AnsiStringT (see page 3207), Pos (see page 3226) returns 0. This member function is the same as Pos (see page 3226) but supports multibyte character strings.

Note: See ByteType (see page 3187) for more information about multibyte characters.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.2.4.4 AnsiStringT::c_str Method

Returns the System::AnsiStringT (see page 3207) converted to a null-terminated character array.

Pascal

```
function c_str: char*;
```

C++

```
__fastcall char* c_str() const;
```

Description

System::AnsiStringT::c_str returns a pointer to a null-terminated character array containing the same characters as the System::AnsiStringT (see page 3207). If the AnsiString is unassigned, c_str returns an empty string (“”).

Usually, the value returned by System::AnsiStringT::c_str points to the internal character array referenced by the data (see page 3218) property. This pointer is valid until the string is next modified (for example when the SetLength (see page 3227) method is called or the AnsiString goes out of scope). However, if the internal array is NULL, c_str() returns a pointer to a string literal.

The System::AnsiStringT::c_str method is intended primarily for reading the value of the AnsiString. To modify the string’s value, use the [] operator or System::AnsiStringT (see page 3207) methods such as Insert (see page 3223) and Delete (see page 3219).

35.1.2.4.5 AnsiStringT::cat_printf Method

Appends to the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.

Pascal

```
function cat_printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int cat_printf(const char* format, ...);
```

Description

Use cat_System::AnsiStringT::cat_printf to modify the value of the System::AnsiStringT (see page 3207) by appending the result of using a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the number of bytes appended to the System::AnsiStringT (see page 3207).

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::cat_sprintf (see page 3216)

System::AnsiStringT::cat_vprintf (see page 3217)

35.1.2.4.6 AnsiStringT::cat_sprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).

Pascal

```
function cat_sprintf(const format: char*; : ...): AnsiStringT&; cdecl;
```

C++

```
__cdecl AnsiStringT& cat_sprintf(const char* format, ...);
```

Description

Use cat_System::AnsiStringT::cat_sprintf to append to the value of the System::AnsiStringT (see page 3207) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

For example, the following code

```
AnsiString Salutation = "Mr."
AnsiString s = "";
s.cat_sprintf("Dear %s ", Salutation);
s.cat_sprintf("%s,", "Smith");
```

results in an System::AnsiStringT (see page 3207) with the value

```
Dear Mr. Smith,
```

This method returns a reference to the System::AnsiStringT (see page 3207) (*this) with the resulting value.

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::cat_printf (see page 3216)

System::AnsiStringT::cat_vprintf (see page 3217)

35.1.2.4.7 AnsiStringT::cat_vprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiStringT (see page 3207).

Pascal

```
function cat_vprintf(const format: char*; list: va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(const char* format, va_list list);
```

Description

Use cat_System::AnsiStringT::cat_vprintf to append to the value of the System::AnsiStringT (see page 3207) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the number of bytes appended to the System::AnsiStringT (see page 3207).

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::cat_printf (see page 3216)

System::AnsiStringT::cat_sprintf (see page 3216)

35.1.2.4.8 AnsiStringT::CodePage Method

Gets code page of a System::AnsiStringT (see page 3207).

Pascal

```
function CodePage: unsigned short;
```

C++

```
unsigned short CodePage() const;
```

Description

System::AnsiStringT::CodePage gets the code page of a System::AnsiStringT (see page 3207) instance. If the instance is empty, it returns the system default code page, System::DefaultSystemCodePage (see page 3815).

See Also

System::AnsiStringBase::GetRec (see page 3193)

35.1.2.4.9 AnsiStringT::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT CurrToStr(Currency value);
```

Description

System::AnsiStringT::CurrToStr converts the currency value given by value to its string representation. The conversion using the sffGeneral floating-point conversion rules. For further details, see System::AnsiStringT::CurrToStrF (see page 3218).

See Also

System::AnsiStringT::CurrToStrF (see page 3218)

35.1.2.4.10 AnsiStringT::CurrToStrF Method

Converts a currency value to its string representation using the indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer):
AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT CurrToStrF(Currency value, TStringFloatFormat format, int
digits);
```

Description

System::AnsiStringT::CurrToStrF converts the currency value given by value to its string representation using the indicated float format convention. A call to System::AnsiStringT::CurrToStrF corresponds to a call to FloatToStrF (see page 3220) with an implied precision of 19 digits.

35.1.2.4.11 AnsiStringT::data Method

Returns a pointer to the underlying string System::AnsiStringT::data.

Pascal

```
function data: const void*;
```

C++

```
__fastcall const void* data() const;
```

Description

System::AnsiStringT::data returns a pointer to a null-terminated character array that the System::AnsiStringT (see page 3207) uses to store its value. This is the same value as the one returned by the System::AnsiStringT::c_str (see page 3216) method, except that System::AnsiStringT::data returns a NULL pointer when the value is an empty string.

Note: Because System::AnsiStringT::data returns NULL instead of an empty string, it is useful for C++ functions that expect either a valid (non-empty) char* or NULL. The following example assumes that TCHAR mapping is not set to wchar_t:

```
AnsiString x;
    ShellExecute(0, static_cast<const char*>(x.data()), "File.txt", NULL, NULL, SW_SHOW);
```

If TCHAR mapping is set to wchar_t, ShellExecute becomes the wide version, ShellExecuteW. If you want to use the Ansi version of ShellExecute when TCHAR mapping is set to wchar_t, you should specify ShellExecuteA.

See Also

System::AnsiStringT::c_str (see page 3216)

TCHAR Mapping

35.1.2.4.12 AnsiStringT::Delete Method

Removes a specified number of characters from the string.

Pascal

```
function Delete(index: Integer; count: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Delete(int index, int count);
```

Description

System::AnsiStringT::Delete modifies the System::AnsiStringT (see page 3207) to remove count characters from the string beginning with the character at index, where 1 is the index of the first character. It returns the resulting modified string (*this).

If index is larger than the length of the System::AnsiStringT (see page 3207) or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, System::AnsiStringT::Delete removes the rest of the string. If count is less than 0, no characters are deleted.

35.1.2.4.13 AnsiStringT::ElementSize Method

Gets element size of data (see page 3218) in a System::AnsiStringT (see page 3207).

Pascal

```
function ElementSize: unsigned short;
```

C++

```
unsigned short ElementSize() const;
```

Description

System::AnsiStringT::ElementSize gets the element size in bytes of the data (see page 3218) in a System::AnsiStringT (see page 3207) instance. If the instance is empty, this returns 1.

See Also

System::AnsiStringT::data (see page 3218)

System::AnsiStringBase::GetRec (see page 3193)

35.1.2.4.14 AnsiStringT::EnsureAnsi Method

Ensure string's data (see page 3218) is ANSI data (see page 3218).

Pascal

```
function EnsureAnsi: AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& EnsureAnsi();
```

Description

If the string's data (see page 3218) is Unicode, i.e., its element length is 2, System::AnsiStringT::EnsureAnsi converts the Unicode to ANSI using the current locale.

Note: In some cases, the conversion to an ANSI string may fail.

35.1.2.4.15 AnsiStringT::FloatToStrF Method

Returns the string representation of a floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits);
```

Description

The format parameter controls the format of the resulting string. The precision parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the digits parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).

sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3221) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator and ThousandSeparator global variables.

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

35.1.2.4.16 AnsiStringT::FmtLoadStr Method

Formats output using a resourced format string.

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT FmtLoadStr(int ident, const TVarRec * args, int size);
```

Description

System::AnsiStringT::FmtLoadStr loads a string from a program's resource string table and uses that string, plus the args array, as a parameter to Format (see page 3221). Ident is the string resource ID of the desired format string.

See Also

System::AnsiStringT::LoadString (see page 3225)

System::AnsiStringT::LoadStr (see page 3225)

35.1.2.4.17 AnsiStringT::Format Method

System::AnsiStringT::Formats a string assembled from an System::AnsiStringT (see page 3207), format, and a series of array arguments, args.

Pascal

```
function Format(const format: AnsiStringT&; const args: TVarRec *; size: Integer):
AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT Format(const AnsiStringT& format, const TVarRec * args, int
size);
```

Description

Use System::AnsiStringT::Format to obtain an System::AnsiStringT (see page 3207) whose value is the result of applying an array of arguments (args) to a given a format string (format). The last parameter (size) is the index of the last element in args (one less than the number of arguments).

Note that System::AnsiStringT::Format is a static method. The returned value is a newly allocated System::AnsiStringT (see page 3207), even if the method is called from an existing System::AnsiStringT (see page 3207) instance.

For information on how System::AnsiStringT::Format assembles a final string from its format string and arguments, see System::AnsiStringT::Format Strings.

See Also

System::AnsiStringT::printf (see page 3226)

System::AnsiStringT::sprintf (see page 3227)

35.1.2.4.18 AnsiStringT::FormatFloat Method

Formats the floating-point value given by value using the format string given by format.

Pascal

```
function FormatFloat(const format: AnsiStringT&; const value: long double&): AnsiStringT;
static;
```

C++

```
static __fastcall AnsiStringT FormatFloat(const AnsiStringT& format, const long double& value);
```

Description

The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the DecimalSeparator global variable, whose default value is specified in the Number Format (see page 3221) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the ThousandSeparator global variable, whose default value is specified in the Number Format (see page 3221) of the International section in the Windows Control Panel.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 3220) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 3221) string-1234-12340.50

Format (see page 3221) string-	**1234**	**-1234**	**0.5**	**0**
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	
#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

35.1.2.4.19 AnsiStringT::Insert Method

System::AnsiStringT::Inserts a specified string into the System::AnsiStringT (see page 3207).

Pascal

```
function Insert(const str: AnsiStringT&; index: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Insert(const AnsiStringT& str, int index);
```

Description

System::AnsiStringT::Insert inserts the string str into this System::AnsiStringT (see page 3207) beginning at the position index, where 1 is the first position in the string. It returns the resulting modified string (*this).

If index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to Length (see page 3607)(), turning the operation into an append.

If the str parameter is an empty string, System::AnsiStringT::Insert does nothing.

System::AnsiStringT::Insert throws an EOutOfMemory exception if the method is unable to allocate enough memory to accommodate the new, longer, string.

Note: The index parameter specifies the character, not the byte, when working with a multi-byte character system.

35.1.2.4.20 AnsiStringT::IntToHex Method

Converts a number into a string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT IntToHex(int value, int digits);
```

Description

Value is the number to convert. Digits indicates the minimum number of hexadecimal digits.

35.1.2.4.21 AnsiStringT::IsDelimiter Method

Returns true if the specified character matches any character in the delimiters string.

Pascal

```
function IsDelimiter(const delimiters: AnsiStringT&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const AnsiStringT& delimiters, int index) const;
```

Description

System::AnsiStringT::IsDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character contained in delimiters. If the byte is part of a multi-byte character or not in delimiters, System::AnsiStringT::IsDelimiter returns false.

35.1.2.4.22 AnsiStringT::LastDelimiter Method

Returns the index of the rightmost character that matches any character in the delimiters string.

Pascal

```
function LastDelimiter(const delimiters: AnsiStringT&): Integer;
```

C++

```
__fastcall int LastDelimiter(const AnsiStringT& delimiters) const;
```

Description

System::AnsiStringT::LastDelimiter returns the byte index in this System::AnsiStringT (see page 3207) of the rightmost whole character that matches any character in delimiters except NULL The System::AnsiStringT (see page 3207) may contain multibyte characters; delimiters must contain only single byte non-NULL characters.

See Also

System::AnsiStringBase::ByteType (see page 3187)

35.1.2.4.23 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	AnsiStringT::LoadStr (HINSTANCE, int) (see page 3225)	Loads a string from the compiled resources of a specified module.
	AnsiStringT::LoadStr (int) (see page 3225)	Loads a string from the compiled resources of a specified module.

35.1.2.4.23.1 AnsiStringT::LoadStr Method (HINSTANCE, int)

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadStr(ident: Integer): AnsiStringT; static;
function LoadStr(hInstance: HINSTANCE; ident: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT LoadStr(int ident);
static __fastcall AnsiStringT LoadStr(HINSTANCE hInstance, int ident);
```

Description

System::AnsiStringT::LoadStr loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource. If hInstance is not given, System::AnsiStringT::LoadStr loads the string from the current module (executable or shared library)

If the string resource does not exist, System::AnsiStringT::LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringT::LoadString (see page 3225)

System::AnsiStringT::FmtLoadStr (see page 3221)

35.1.2.4.24 AnsiStringT::LoadString Method

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& LoadString(HINSTANCE hInstance, int ident);
```

Description

System::AnsiStringT::LoadString loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource.

If the string resource does not exist, System::AnsiStringT::LoadString returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiStringT::LoadStr (see page 3225)

System::AnsiStringT::FmtLoadStr (see page 3221)

35.1.2.4.25 AnsiStringT::LowerCase Method

Returns a lower-case version of System::AnsiStringT (see page 3207).

Pascal

```
function LowerCase: AnsiStringT;
```

C++

```
__fastcall AnsiStringT LowerCase() const;
```

Description

System::AnsiStringT::LowerCase returns a new System::AnsiStringT (see page 3207) that contains all characters in this string, converted to lower case. The conversion uses the current locale . The original System::AnsiStringT (see page 3207) remains unchanged.

35.1.2.4.26 AnsiStringT::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: AnsiStringT&): Integer;
```

C++

```
__fastcall int Pos(const AnsiStringT& subStr) const;
```

Description

System::AnsiStringT::Pos returns the index in the System::AnsiStringT (see page 3207) at which the substring subStr begins, where 1 is the index of the first character, 2 is the index of the second character, and so on. If the substring is not contained in the System::AnsiStringT (see page 3207), System::AnsiStringT::Pos returns 0.

35.1.2.4.27 AnsiStringT::printf Method

Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.

Pascal

```
function printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int printf(const char* format, ...);
```

Description

Use System::AnsiStringT::printf to set the value of the System::AnsiStringT (see page 3207) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the length of the final formatted string.

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::sprintf (see page 3227)

System::AnsiStringT::cat_printf (see page 3216)

System::AnsiStringT::vprintf (see page 3230)

35.1.2.4.28 AnsiStringT::RefCount Method

Gets reference count of System::AnsiStringT (see page 3207).

Pascal

```
function RefCount: Integer;
```

C++

```
int RefCount() const;
```

Description

System::AnsiStringT::RefCount gets the reference count of a System::AnsiStringT (see page 3207) instance. If the instance is empty, it returns 0.

See Also

System::AnsiStringBase::GetRec (see page 3193)

35.1.2.4.29 AnsiStringT::SetLength Method

Changes the length of the System::AnsiStringT (see page 3207).

Pascal

```
function SetLength(newLength: Integer): AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& SetLength(int newLength);
```

Description

System::AnsiStringT::SetLength changes the string's length to newLength, truncating if necessary.

System::AnsiStringT::SetLength reallocates the underlying array of characters that stores the value of the System::AnsiStringT (see page 3207). Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate the System::AnsiStringT (see page 3207), an EOutOfMemory exception is thrown. Following a call to System::AnsiStringT::SetLength, the System::AnsiStringT (see page 3207) is guaranteed not to be a shared reference.

System::AnsiStringT::SetLength returns the modified System::AnsiStringT (see page 3207) object (*this)

35.1.2.4.30 AnsiStringT::sprintf Method

Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.

Pascal

```
function sprintf(const format: char*; : ...): AnsiStringT&; cdecl;
```

C++

```
__cdecl AnsiStringT& sprintf(const char* format, ...);
```

Description

Use System::AnsiStringT::sprintf to set to the value of the System::AnsiStringT (see page 3207) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

This method returns a reference to the System::AnsiStringT (see page 3207) (*this) with the resulting value.

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::cat_sprintf (see page 3216)

System::AnsiStringT::printf (see page 3226)

System::AnsiStringT::vprintf (see page 3230)

35.1.2.4.31 AnsiStringT::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: char; count: Integer): AnsiStringT; static;
```

C++

```
static __fastcall AnsiStringT StringOfChar(char ch, int count);
```

Description

System::AnsiStringT::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::AnsiStringT (see page 3207) s = System::AnsiStringT::System::AnsiStringT::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

35.1.2.4.32 AnsiStringT::SubString Method

Returns a specified substring of the System::AnsiStringT (see page 3207).

Pascal

```
function SubString(index: Integer; count: Integer): AnsiStringT;
```

C++

```
__fastcall AnsiStringT SubString(int index, int count) const;
```

Description

System::AnsiStringT::SubString returns a new System::AnsiStringT (see page 3207) that is a substring of this System::AnsiStringT (see page 3207). The substring contains count characters beginning at index.

35.1.2.4.33 AnsiStringT::swap Method

Swap string pointers.

Pascal

```
function swap(var other: AnsiStringT): AnsiStringT&;
```

C++

```
AnsiStringT& swap(AnsiStringT& other);
```

Description

System::AnsiStringT::swap swaps two System::AnsiStringT (see page 3207) strings. Pointers to the data (see page 3218) are swapped, and the data (see page 3218) is not copied. This makes the swap operation efficient for sorting.

35.1.2.4.34 AnsiStringT::Trim Method

Returns a new System::AnsiStringT (see page 3207) without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim: AnsiStringT;
```

C++

```
__fastcall AnsiStringT Trim() const;
```

Description

System::AnsiStringT::Trim returns a new System::AnsiStringT (see page 3207) removing leading and trailing spaces and control characters. Use System::AnsiStringT::Trim to remove blank space before and after the first printing character.

35.1.2.4.35 AnsiStringT::TrimLeft Method

Returns a new System::AnsiStringT (see page 3207) without leading spaces or control characters.

Pascal

```
function TrimLeft: AnsiStringT;
```

C++

```
__fastcall AnsiStringT TrimLeft() const;
```

Description

System::AnsiStringT::TrimLeft returns a new System::AnsiStringT (see page 3207) removing leading spaces and control characters. Use System::AnsiStringT::TrimLeft to remove blank space before the first printing character.

35.1.2.4.36 AnsiStringT::TrimRight Method

Returns a new System::AnsiStringT (see page 3207) without trailing spaces or control characters.

Pascal

```
function TrimRight: AnsiStringT;
```

C++

```
__fastcall AnsiStringT TrimRight() const;
```

Description

System::AnsiStringT::TrimRight returns a new System::AnsiStringT (see page 3207) removing trailing spaces and control characters. Use the System::AnsiStringT::TrimRight function to remove blank space after the last printing character.

35.1.2.4.37 AnsiStringT::Unique Method

Makes the System::AnsiStringT (see page 3207) unique.

Pascal

```
function Unique: AnsiStringT&;
```

C++

```
__fastcall AnsiStringT& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::AnsiStringT::Unique sets the reference count on the string for the System::AnsiStringT (see page 3207) object to 1 so that it is the only object referencing that string.

35.1.2.4.38 AnsiStringT::UpperCase Method

Returns an upper-case version of this System::AnsiStringT (see page 3207).

Pascal

```
function UpperCase: AnsiStringT;
```

C++

```
__fastcall AnsiStringT UpperCase() const;
```

Description

System::AnsiStringT::UpperCase returns a new System::AnsiStringT (see page 3207) that contains all characters in this string, converted to upper case. The conversion uses the current locale . The original System::AnsiStringT (see page 3207) remains unchanged.

35.1.2.4.39 AnsiStringT::vprintf Method

Sets the value of the System::AnsiStringT (see page 3207) given a format string and its arguments.

Pascal

```
function vprintf(const format: char*; list: va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(const char* format, va_list list);
```

Description
