Use System::AnsiStringT::vprintf to set to the value of the System::AnsiStringT (see page 3207) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the length of the final formatted string.

See Also

System::AnsiStringT::Format (see page 3221)

System::AnsiStringT::sprintf (see page 3227)

System::AnsiStringT::printf (see page 3226)

System::AnsiStringT::cat_vprintf (see page 3217)

35.1.2.4.40 AnsiStringT::WideChar Method

Converts the System::AnsiStringT (see page 3207) to a wide-character array.

Pascal

```
function WideChar(var dest: wchar_t; destSize: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* WideChar(wchar_t* dest, int destSize) const;
```

Description

System::AnsiStringT::WideChar converts the System::AnsiStringT (see page 3207) to an array of wide characters, and returns the resulting wide-character array.

dest is a buffer the caller allocates to hold the return value. Use the System::AnsiStringT::WideCharBufSize (see page 3231) method to determine the size needed to hold the entire string value.

destSize is the size, in bytes, of dest.

System::AnsiStringT::WideChar returns a pointer to the wide-character array that is written to dest.

See Also

System::AnsiStringT::WideCharBufSize (see page 3231)

35.1.2.4.41 AnsiStringT::WideCharBufSize Method

Returns the size of the buffer required by the WideChar (see page 3230) function.

Pascal

```
function WideCharBufSize: Integer;
```

C++

```
__fastcall int WideCharBufSize() const;
```

Description

System::AnsiStringT::WideCharBufSize returns an integer value indicating the size of the buffer required by the WideChar (see page 3230) method in order to convert this string.

See Also

System::AnsiStringT::WideChar (see page 3230)

35.1.2.5 AnsiStringT Operators

The operators of the AnsiStringT class are listed here.

Public Operators

	Name	Description
	!= (see page 3232)	Compares two strings.
	+ (see page 3232)	Concatenates two System::AnsiStringT (see page 3207) values.
	+= (see page 3232)	Append (see page 3520) an System::AnsiStringT (see page 3207).
	< (see page 3233)	Compares two strings.
	<= (see page 3233)	Compares two strings.
	= (see page 3233)	Assigns the string rhs to this System::AnsiStringT (see page 3207).
	== (see page 3234)	Compares the System::AnsiStringT (see page 3207) with a specified string, returning true if they are the same.
	> (see page 3234)	Compares two strings.
	>= (see page 3234)	Compares two strings.

35.1.2.5.1 AnsiStringT::!= Operator

Compares two strings.

Pascal

```
operator !=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator !=(const AnsiStringT& rhs) const;
```

Description

Returns true if the strings are not the same, false otherwise.

Note: This System::AnsiStringT (see page 3207)::!= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.2.5.2 AnsiStringT::+ Operator

Concatenates two System::AnsiStringT (see page 3207) values.

Pascal

```
operator +(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT operator +(const AnsiStringT& rhs) const;
```

Description

The friend function returns an System::AnsiStringT (see page 3207) that is the concatenation of strings lhs and rhs.

The method returns an System::AnsiStringT (see page 3207) that is the concatenation of this System::AnsiStringT (see page 3207) and rhs.

35.1.2.5.3 AnsiStringT::+= Operator

Append (see page 3520) an System::AnsiStringT (see page 3207).

Pascal

```
operator +=(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT& operator +=(const AnsiStringT& rhs);
```

Description

The System::AnsiStringT (see page 3207)::+= concatenates this System::AnsiStringT (see page 3207) and rhs, assigning the result to this System::AnsiStringT (see page 3207).

The System::AnsiStringT (see page 3207)::+=() is not supported on a property with getter/setter functions.

35.1.2.5.4 AnsiStringT::< Operator

Compares two strings.

Pascal

```
operator <(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator <(const AnsiStringT& rhs) const;
```

Description

Returns true if this System::AnsiStringT::AnsiString is less than rhs, false otherwise.

Note: This System::AnsiStringT (see page 3207)::< performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.2.5.5 AnsiStringT::<= Operator

Compares two strings.

Pascal

```
operator <=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator <=(const AnsiStringT& rhs) const;
```

Description

Returns true if this System::AnsiStringT::AnsiString is less than or equal to rhs, false otherwise.

Note: This System::AnsiStringT (see page 3207)::<= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.2.5.6 AnsiStringT::= Operator

Assigns the string rhs to this System::AnsiStringT (see page 3207).

Pascal

```
operator =(const rhs: AnsiStringT&);
```

C++

```
__fastcall AnsiStringT& operator =(const AnsiStringT& rhs);
```

Description

Use this System::AnsiStringT (see page 3207)::= to assign the value of the System::AnsiStringT (see page 3207) from another System::AnsiStringT (see page 3207).

35.1.2.5.7 AnsiStringT::== Operator

Compares the System::AnsiStringT (see page 3207) with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator ==(const AnsiStringT& rhs) const;
```

Description

Returns true if this System::AnsiStringT (see page 3207) is the same as rhs, false otherwise.

Note: This System::AnsiStringT (see page 3207)::== performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.2.5.8 AnsiStringT::> Operator

Compares two strings.

Pascal

```
operator >(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator >(const AnsiStringT& rhs) const;
```

Description

Returns true if this System::AnsiStringT (see page 3207) is greater than rhs, false otherwise.

Note: This System::AnsiStringT (see page 3207)::> performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.2.5.9 AnsiStringT::>= Operator

Compares two strings.

Pascal

```
operator >=(const rhs: AnsiStringT&);
```

C++

```
__fastcall bool operator >=(const AnsiStringT& rhs) const;
```

Description

Returns true if this System::AnsiStringT (see page 3207) is greater than or equal to rhs, false otherwise.

Note: This System::AnsiStringT (see page 3207)::>= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 3214) or AnsiCompareIC (see page 3215) methods.

See Also

System::AnsiStringT::AnsiCompare (see page 3214)

System::AnsiStringT::AnsiCompareIC (see page 3215)

35.1.3 Currency Class

System::Currency is the C++ implementation of the Delphi System::Currency data type.

Class Hierarchy

Pascal

```
Currency = class(CurrencyBase);
```

C++

```
class Currency : public CurrencyBase;
```

File

syscurr.h

Description

System::Currency is a C++ class that implements a Delphi intrinsic type, also called System::Currency. Use System::Currency to hold monetary values.

Note: A System::Currency object is implemented as a 64-bit signed integer. Avoid operations that might cause integer overflow.

Note: Use only the operators defined by System::Currency. The compiler ignores any operators you overload yourself. Use the System::Currency constructors to create System::Currency objects from pointers to other System::Currency objects, and also from numeric and string values..

Note: To utilize the C++ streaming operators (<< and >>) with System::Currency, you must use #include <iostream> before #include <syscurr.h>. This occurs automatically if you include vcl.h, clx.h, or System.hpp. The following stream operators are defined:

```
ostream& operator << (ostream& os, const Currency& arg);
istream& operator >> (istream& is, Currency& arg);
```

See Also

System::CurrencyBase (see page 3255)

35.1.3.1 Currency Members

The following tables list the members exposed by Currency.

Public Data Members

	Name	Description
	Val (see page 3256)	This is Val, a member of class CurrencyBase.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 3253)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 3253)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 3255)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 3255)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

Public Methods

	Name	Description
	Currency (see page 3237)	This is the overview for the Currency constructor overload.

Public Operators

	Name	Description
	- (see page 3238)	This is the overview for the - operator overload.
	-- (see page 3239)	This is the overview for the -- operator overload.
	! (see page 3240)	Returns a new System::Currency::Currency (see page 3235) object that is the logical negation of this System::Currency::Currency (see page 3235) object.
	!= (see page 3240)	This is the overview for the != operator overload.
	% (see page 3241)	Returns a new System::Currency::Currency (see page 3235) object with the value that is the remainder of this System::Currency::Currency (see page 3235) object divided by a specified integer.
	%= (see page 3242)	Assigns this System::Currency::Currency (see page 3235) object the remainder of its initial value divided by integer rhs.
	* (see page 3242)	This is the overview for the * operator overload.
	*= (see page 3243)	Assigns this System::Currency::Currency (see page 3235) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3235) object rhs.
	/ (see page 3243)	This is the overview for the / operator overload.
	/= (see page 3244)	Assigns this System::Currency::Currency (see page 3235) object the result of its initial value divided by the value of System::Currency::Currency (see page 3235) object rhs.
	+ (see page 3244)	This is the overview for the + operator overload.
	++ (see page 3245)	This is the overview for the ++ operator overload.
	+= (see page 3246)	Increments the value of this System::Currency::Currency (see page 3235) object by the value of rhs.
	< (see page 3247)	This is the overview for the < operator overload.
	<= (see page 3247)	This is the overview for the <= operator overload.
	-= (see page 3249)	Decrements the value of this System::Currency::Currency (see page 3235) object by the value of rhs.
	= (see page 3248)	This is the overview for the = operator overload.
	== (see page 3249)	This is the overview for the == operator overload.
	> (see page 3250)	This is the overview for the > operator overload.
	>= (see page 3251)	This is the overview for the >= operator overload.
	double (see page 3252)	Converts the System::Currency::Currency (see page 3235) object to a double value.
	int (see page 3252)	Converts the System::Currency::Currency (see page 3235) object to an integer value

	System::String (see page 3252)	Converts the System::Currency::System::String object to a String that displays its value.

35.1.3.2 Currency Constructor

This is the overview for the Currency constructor overload.

Overload List

	Name	Description
	Currency::Currency () (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.
	Currency::Currency (Currency&) (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.
	Currency::Currency (CurrencyBase&) (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.
	Currency::Currency (double) (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.
	Currency::Currency (int) (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.
	Currency::Currency (System::String&) (see page 3237)	Creates and initializes a System::Currency::Currency (see page 3235) object.

35.1.3.2.1 Currency::Currency Constructor ()

Creates and initializes a System::Currency::Currency (see page 3235) object.

Pascal

```
constructor Create;
constructor Create(val: double);
constructor Create(val: Integer);
constructor Create(const src: CurrencyBase&);
constructor Create(const src: Currency&);
constructor Create(const src: System::String&);
```

C++

```
__fastcall Currency();
__fastcall Currency(double val);
__fastcall Currency(int val);
__fastcall Currency(const CurrencyBase& src);
__fastcall Currency(const Currency& src);
__fastcall Currency(const System::String& src);
```

Description

Use System::Currency::Currency (see page 3235) to instantiate a System::Currency::Currency (see page 3235) object.

When called with no parameters, the resulting object has a value of 0.

When called with a System::Currency::Currency (see page 3235) object as the src parameter, the resulting object is a copy of src (the copy constructor).

When called with a System::Currency::CurrencyBase (see page 3255) object as the src parameter, the resulting object has the same value as the src parameter. System::Currency::CurrencyBase (see page 3255) is the base class for the System::Currency::Currency (see page 3235) type. It has a single member, a public Val (see page 3701) field that

represents the value of the object.

When called with an AnsiString object as the src parameter, the value of the resulting object is the parsed value of the AnsiString. The AnsiString must represent a numeric value within the range valid for System::Currency::Currency (see page 3235) (-922337203685477.5808 to 922337203685477.5807).

When called with a double (see page 3252) or integer as the val parameter, the value of the resulting object is the value of the val parameter.

35.1.3.3 Currency Operators

The operators of the Currency class are listed here.

Public Operators

	Name	Description
	- (see page 3238)	This is the overview for the - operator overload.
	-- (see page 3239)	This is the overview for the -- operator overload.
	! (see page 3240)	Returns a new System::Currency::Currency (see page 3235) object that is the logical negation of this System::Currency::Currency (see page 3235) object.
	!= (see page 3240)	This is the overview for the != operator overload.
	% (see page 3241)	Returns a new System::Currency::Currency (see page 3235) object with the value that is the remainder of this System::Currency::Currency (see page 3235) object divided by a specified integer.
	%= (see page 3242)	Assigns this System::Currency::Currency (see page 3235) object the remainder of its initial value divided by integer rhs.
	* (see page 3242)	This is the overview for the * operator overload.
	*= (see page 3243)	Assigns this System::Currency::Currency (see page 3235) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3235) object rhs.
	/ (see page 3243)	This is the overview for the / operator overload.
	/= (see page 3244)	Assigns this System::Currency::Currency (see page 3235) object the result of its initial value divided by the value of System::Currency::Currency (see page 3235) object rhs.
	+ (see page 3244)	This is the overview for the + operator overload.
	++ (see page 3245)	This is the overview for the ++ operator overload.
	+= (see page 3246)	Increments the value of this System::Currency::Currency (see page 3235) object by the value of rhs.
	< (see page 3247)	This is the overview for the < operator overload.
	<= (see page 3247)	This is the overview for the <= operator overload.
	= (see page 3248)	This is the overview for the = operator overload.
	-= (see page 3249)	Decrements the value of this System::Currency::Currency (see page 3235) object by the value of rhs.
	== (see page 3249)	This is the overview for the == operator overload.
	> (see page 3250)	This is the overview for the > operator overload.
	>= (see page 3251)	This is the overview for the >= operator overload.
	double (see page 3252)	Converts the System::Currency::Currency (see page 3235) object to a double value.
	int (see page 3252)	Converts the System::Currency::Currency (see page 3235) object to an integer value
	System::String (see page 3252)	Converts the System::Currency::System::String object to a String that displays its value.

35.1.3.3.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	Currency::- () (see page 3239)	Returns a new System::Currency (see page 3235) object that is the negative value of this System::Currency (see page 3235) object.
	Currency::- (Currency&) (see page 3239)	Returns a new System::Currency (see page 3235) object that is the negative value of this System::Currency (see page 3235) object.
	Currency::- (double) (see page 3239)	Returns a new System::Currency (see page 3235) object that is the negative value of this System::Currency (see page 3235) object.
	Currency::- (int) (see page 3239)	Returns a new System::Currency (see page 3235) object that is the negative value of this System::Currency (see page 3235) object.

35.1.3.3.1.1 Currency::- Operator ()

Returns a new System::Currency (see page 3235) object that is the negative value of this System::Currency (see page 3235) object.

Pascal

```
operator -(const rhs: Currency&);
operator -(rhs: Integer);
operator -(rhs: double);
operator -;
```

C++

```
__fastcall Currency operator -(const Currency& rhs) const;
__fastcall Currency operator -(int rhs) const;
__fastcall Currency operator -(double rhs) const;
__fastcall Currency operator -() const;
```

Description

Use the unary – operator to change the sign of the System::Currency (see page 3235) object (effectively multiplying it by –1).

See Also

System::Currency::! (see page 3240)

35.1.3.3.2 -- Operator

This is the overview for the -- operator overload.

Overload List

	Name	Description
	Currency::-- () (see page 3240)	Decrements the value of the System::Currency::Currency (see page 3235) object by a specified integer value.
	Currency::-- (int) (see page 3240)	Decrements the value of the System::Currency::Currency (see page 3235) object by a specified integer value.

35.1.3.3.2.1 Currency::-- Operator ()

Decrements the value of the System::Currency::Currency (see page 3235) object by a specified integer value.

Pascal

```
operator --;
operator --(: Integer);
```

C++

```
Currency& operator --();
Currency operator --(int);
```

Description

Use the unary System::Currency (see page 3235)::-- to decrement the value of the System::Currency::Currency (see page 3235) object by 1.

Use the binary System::Currency (see page 3235)::-- to decrement the value by the integer specified as an operand.

See Also

System::Currency::++ (see page 3246)

System::Currency::-= (see page 3249)

System::Currency::- (see page 3239)

35.1.3.3.3 Currency::! Operator

Returns a new System::Currency::Currency (see page 3235) object that is the logical negation of this System::Currency::Currency (see page 3235) object.

Pascal

```
operator !;
```

C++

```
__fastcall Currency operator !() const;
```

Description

If the value of the System::Currency::Currency (see page 3235) object is nonzero, the System::Currency (see page 3235)::! returns 0. If the value of the System::Currency::Currency (see page 3235) object is 0, the System::Currency (see page 3235)::! returns 1.

See Also

System::Currency::!= (see page 3241)

System::Currency::- (see page 3239)

35.1.3.3.4 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	Currency::!= (Currency&) (see page 3241)	Tests for inequality between the System::Currency::Currency (see page 3235) object's value and a specified value.

	Currency::!= (double) (see page 3241)	Tests for inequality between the System::Currency::Currency (see page 3235) object's value and a specified value.
	Currency::!= (int) (see page 3241)	Tests for inequality between the System::Currency::Currency (see page 3235) object's value and a specified value.

35.1.3.3.4.1 Currency::!= Operator (Currency&)

Tests for inequality between the System::Currency::Currency (see page 3235) object's value and a specified value.

Pascal

```
operator !=(const rhs: Currency&);
operator !=(rhs: Integer);
operator !=(rhs: double);
```

C++

```
__fastcall bool operator !=(const Currency& rhs) const;
__fastcall bool operator !=(int rhs) const;
__fastcall bool operator !=(double rhs) const;
```

Description

The System::Currency (see page 3235)::!= compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. If the values differ, the System::Currency (see page 3235)::!= returns true. If the values are the same, the System::Currency (see page 3235)::!= returns false.

See Also

System::Currency::= (see page 3248)

System::Currency::> (see page 3250)

System::Currency::>= (see page 3251)

System::Currency::< (see page 3247)

System::Currency::<= (see page 3248)

35.1.3.3.5 Currency::% Operator

Returns a new System::Currency::Currency (see page 3235) object with the value that is the remainder of this System::Currency::Currency (see page 3235) object divided by a specified integer.

Pascal

```
operator %(rhs: Integer);
```

C++

```
__fastcall Currency operator %(int rhs) const;
```

Description

Use the System::Currency (see page 3235)::% to obtain the remainder from dividing the value of this System::Currency::Currency (see page 3235) object by the integer specified by the rhs operand.

See Also

System::Currency::%= (see page 3242)

System::Currency::/ (see page 3243)

35.1.3.3.6 Currency::%= Operator

Assigns this System::Currency::Currency (see page 3235) object the remainder of its initial value divided by integer rhs.

Pascal

```
operator %=(rhs: Integer);
```

C++

```
__fastcall Currency& operator %=(int rhs);
```

Description

Use the System::Currency (see page 3235)::%= to obtain the remainder from dividing this System::Currency::Currency (see page 3235) object's value by the Value of the System::Currency::Currency (see page 3235) object specified by rhs.

See Also

System::Currency::= (see page 3248)

System::Currency::/= (see page 3244)

System::Currency::% (see page 3241)

35.1.3.3.7 * Operator

This is the overview for the * operator overload.

Overload List

	Name	Description
	Currency::* (Currency&) (see page 3242)	Multiplies the value of the System::Currency::Currency (see page 3235) object by a specified value.
	Currency::* (double) (see page 3242)	Multiplies the value of the System::Currency::Currency (see page 3235) object by a specified value.
	Currency::* (int) (see page 3242)	Multiplies the value of the System::Currency::Currency (see page 3235) object by a specified value.

35.1.3.3.7.1 Currency::* Operator (Currency&)

Multiplies the value of the System::Currency::Currency (see page 3235) object by a specified value.

Pascal

```
operator *(const rhs: Currency&);
operator *(rhs: Integer);
operator *(rhs: double);
```

C++

```
__fastcall Currency operator *(const Currency& rhs) const;
__fastcall Currency operator *(int rhs) const;
__fastcall Currency operator *(double rhs) const;
```

Description

Use the System::Currency (see page 3235)::* to multiply the value of the System::Currency::Currency (see page 3235) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency (see page 3235)::*s:

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

multiples the values of integer lhs and System::Currency::Currency (see page 3235) object rhs and returns a new System::Currency::Currency (see page 3235) object with the resulting value.

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

multiples the values of double (see page 3252) lhs and System::Currency::Currency (see page 3235) object rhs and returns a new System::Currency::Currency (see page 3235) object with the resulting value.

See Also

System::Currency::*= (see page 3243)

System::Currency::/ (see page 3243)

35.1.3.3.8 Currency::*= Operator

Assigns this System::Currency::Currency (see page 3235) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 3235) object rhs.

Pascal

```
operator *=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator *=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3235)::*= to multiply this System::Currency::Currency (see page 3235) object's value by the Value of the System::Currency::Currency (see page 3235) object specified by rhs.

See Also

System::Currency::= (see page 3248)

System::Currency::/= (see page 3244)

System::Currency::* (see page 3242)

35.1.3.3.9 / Operator

This is the overview for the / operator overload.

Overload List

	Name	Description
	Currency::/ (Currency&) (see page 3243)	Divides the value of the System::Currency::Currency (see page 3235) object by a specified value.
	Currency::/ (double) (see page 3243)	Divides the value of the System::Currency::Currency (see page 3235) object by a specified value.
	Currency::/ (int) (see page 3243)	Divides the value of the System::Currency::Currency (see page 3235) object by a specified value.

35.1.3.3.9.1 Currency::/ Operator (Currency&)

Divides the value of the System::Currency::Currency (see page 3235) object by a specified value.

Pascal

```
operator /(const rhs: Currency&);
operator /(rhs: Integer);
operator /(rhs: double);
```

C++

```
__fastcall Currency operator /(const Currency& rhs) const;
__fastcall Currency operator /(int rhs) const;
__fastcall Currency operator /(double rhs) const;
```

Description

Use the System::Currency (see page 3235)::/ to divide the value of the System::Currency::Currency (see page 3235) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency (see page 3235)::/s:

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

divides the value of int (see page 3252) lhs by the value of System::Currency::Currency (see page 3235) object rhs and returns a new System::Currency::Currency (see page 3235) object with the resulting value.

```
friend Currency __fastcalloperator /(double lhs, const Currency& rhs);
```

divides the value of double (see page 3252) lhs by the value of System::Currency::Currency (see page 3235) object rhs and returns a System::Currency::Currency (see page 3235) object with the resulting value.

See Also

System::Currency::/= (see page 3244)

System::Currency::* (see page 3242)

System::Currency::% (see page 3241)

35.1.3.3.10 Currency::/= Operator

Assigns this System::Currency::Currency (see page 3235) object the result of its initial value divided by the value of System::Currency::Currency (see page 3235) object rhs.

Pascal

```
operator /=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator /=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3235)::/= to divide this System::Currency::Currency (see page 3235) object's value by the Value of the System::Currency::Currency (see page 3235) object specified by rhs.

See Also

System::Currency::= (see page 3248)

System::Currency::*= (see page 3243)

System::Currency::/ (see page 3243)

35.1.3.3.11 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	Currency::+ (Currency&) (see page 3245)	Adds a specified value to the System::Currency::Currency (see page 3235) object.
	Currency::+ (double) (see page 3245)	Adds a specified value to the System::Currency::Currency (see page 3235) object.
	Currency::+ (int) (see page 3245)	Adds a specified value to the System::Currency::Currency (see page 3235) object.

35.1.3.3.11.1 Currency::+ Operator (Currency&)

Adds a specified value to the System::Currency::Currency (see page 3235) object.

Pascal

```
operator +(const rhs: Currency&);
operator +(rhs: Integer);
operator +(rhs: double);
```

C++

```
__fastcall Currency operator +(const Currency& rhs) const;
__fastcall Currency operator +(int rhs) const;
__fastcall Currency operator +(double rhs) const;
```

Description

Use the System::Currency (see page 3235)::+ to add the value specified by the rhs operand to the System::Currency::Currency (see page 3235) object. If the rhs operand is another System::Currency::Currency (see page 3235) object, the System::Currency (see page 3235)::+ adds its value to the System::Currency::Currency (see page 3235) object. If it is an integer or double (see page 3252) value, the System::Currency (see page 3235)::+ adds that value to the value of the System::Currency::Currency (see page 3235) object.

Note that there are two related friend System::Currency (see page 3235)::+s:

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 3235) object that is the sum of int (see page 3252) lhs and System::Currency::Currency (see page 3235) object rhs.

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 3235) object that is the sum of double (see page 3252) lhs and System::Currency::Currency (see page 3235) object rhs.

See Also

System::Currency::+= (see page 3246)

System::Currency::++ (see page 3246)

System::Currency::- (see page 3239)

35.1.3.3.12 ++ Operator

This is the overview for the ++ operator overload.

Overload List

	Name	Description
	Currency::++ () (see page 3246)	Increments the value of the System::Currency::Currency (see page 3235) object by a specified integer value.
	Currency::++ (int) (see page 3246)	Increments the value of the System::Currency::Currency (see page 3235) object by a specified integer value.

35.1.3.3.12.1 Currency::++ Operator ()

Increments the value of the System::Currency::Currency (see page 3235) object by a specified integer value.

Pascal

```
operator ++;
operator ++(: Integer);
```

C++

```
Currency& operator ++();
Currency operator ++(int);
```

Description

Use the unary System::Currency (see page 3235)::++ to increment the value of the System::Currency::Currency (see page 3235) object by 1.

Use the binary System::Currency (see page 3235)::++ to increment the value by the integer specified as an operand.

See Also

System::Currency::-- (see page 3240)

System::Currency::+= (see page 3246)

System::Currency::+ (see page 3245)

35.1.3.3.13 Currency::+= Operator

Increments the value of this System::Currency::Currency (see page 3235) object by the value of rhs.

Pascal

```
operator +=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator +=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3235)::+= to add the value of another System::Currency::Currency (see page 3235) object to this one.

See Also

System::Currency::= (see page 3248)

System::Currency::-= (see page 3249)

System::Currency::+ (see page 3245)

System::Currency::++ (see page 3246)

35.1.3.3.14 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	Currency::< (Currency&) (see page 3247)	Tests whether this System::Currency::Currency (see page 3235) value is less than a specified value.
	Currency::< (double) (see page 3247)	Tests whether this System::Currency::Currency (see page 3235) value is less than a specified value.
	Currency::< (int) (see page 3247)	Tests whether this System::Currency::Currency (see page 3235) value is less than a specified value.

35.1.3.3.14.1 Currency::< Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3235) value is less than a specified value.

Pascal

```
operator <(const rhs: Currency&);
operator <(rhs: Integer);
operator <(rhs: double);
```

C++

```
__fastcall bool operator <(const Currency& rhs) const;
__fastcall bool operator <(int rhs) const;
__fastcall bool operator <(double rhs) const;
```

Description

The < System::Currency (see page 3235)::< compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3235) object has the lesser value, false otherwise.

See Also

System::Currency::!= (see page 3241)

System::Currency::> (see page 3250)

System::Currency::>= (see page 3251)

System::Currency::== (see page 3250)

System::Currency::<= (see page 3248)

35.1.3.3.15 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	Currency::<= (Currency&) (see page 3248)	Tests whether this System::Currency::Currency (see page 3235) value is less than or equal to a specified value.

	Currency::<= (double) (see page 3248)	Tests whether this System::Currency::Currency (see page 3235) value is less than or equal to a specified value.
	Currency::<= (int) (see page 3248)	Tests whether this System::Currency::Currency (see page 3235) value is less than or equal to a specified value.

35.1.3.3.15.1 Currency::<= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3235) value is less than or equal to a specified value.

Pascal

```
operator <=(const rhs: Currency&);
operator <=(rhs: Integer);
operator <=(rhs: double);
```

C++

```
__fastcall bool operator <=(const Currency& rhs) const;
__fastcall bool operator <=(int rhs) const;
__fastcall bool operator <=(double rhs) const;
```

Description

The <= System::Currency (see page 3235)::<= compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3235) object has a value less than or equal to that of rhs, false otherwise.

See Also

System::Currency::!= (see page 3241)

System::Currency::> (see page 3250)

System::Currency::>= (see page 3251)

System::Currency::< (see page 3247)

System::Currency::== (see page 3250)

35.1.3.3.16 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	Currency::= (Currency&) (see page 3248)	Assigns the value of the System::Currency::Currency (see page 3235) object.
	Currency::= (CurrencyBase&) (see page 3248)	Assigns the value of the System::Currency::Currency (see page 3235) object.
	Currency::= (double) (see page 3248)	Assigns the value of the System::Currency::Currency (see page 3235) object.
	Currency::= (int) (see page 3248)	Assigns the value of the System::Currency::Currency (see page 3235) object.

35.1.3.3.16.1 Currency::= Operator (Currency&)

Assigns the value of the System::Currency::Currency (see page 3235) object.

Pascal

```
operator =(rhs: double);
operator =(rhs: Integer);
operator =(const rhs: CurrencyBase&);
operator =(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator =(double rhs);
__fastcall Currency& operator =(int rhs);
__fastcall Currency& operator =(const CurrencyBase& rhs);
__fastcall Currency& operator =(const Currency& rhs);
```

Description

The assignment System::Currency (see page 3235)::= assigns the value of the rhs operand to the System::Currency::Currency (see page 3235) object. The assignment System::Currency (see page 3235)::= can take

a double (see page 3252) or integer value, which is assigned to the System::Currency::Currency (see page 3235) object.

a System::Currency::CurrencyBase (see page 3255) or System::Currency::Currency (see page 3235) object, whose value is assigned to the System::Currency::Currency (see page 3235) object.

35.1.3.3.17 Currency::-= Operator

Decrements the value of this System::Currency::Currency (see page 3235) object by the value of rhs.

Pascal

```
operator -=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator -=(const Currency& rhs);
```

Description

Use the System::Currency (see page 3235)::-= to subtract the value of another System::Currency::Currency (see page 3235) object from this one.

See Also

System::Currency::= (see page 3248)

System::Currency::+= (see page 3246)

System::Currency::- (see page 3239)

System::Currency::-- (see page 3240)

35.1.3.3.18 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	Currency::== (Currency&) (see page 3250)	Tests for equality between the System::Currency::Currency (see page 3235) object's value and a specified value.
	Currency::== (double) (see page 3250)	Tests for equality between the System::Currency::Currency (see page 3235) object's value and a specified value.

	Currency::== (int) (see page 3250)	Tests for equality between the System::Currency::Currency (see page 3235) object's value and a specified value.

35.1.3.3.18.1 Currency::== Operator (Currency&)

Tests for equality between the System::Currency::Currency (see page 3235) object's value and a specified value.

Pascal

```
operator ==(const rhs: Currency&);
operator ==(rhs: Integer);
operator ==(rhs: double);
```

C++

```
__fastcall bool operator ==(const Currency& rhs) const;
__fastcall bool operator ==(int rhs) const;
__fastcall bool operator ==(double rhs) const;
```

Description

The == System::Currency (see page 3235)::== compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. If the two values are the same, the System::Currency (see page 3235)::== returns true. If the values differ, the System::Currency (see page 3235)::== returns false.

See Also

System::Currency::!= (see page 3241)

System::Currency::> (see page 3250)

System::Currency::>= (see page 3251)

System::Currency::< (see page 3247)

System::Currency::<= (see page 3248)

35.1.3.3.19 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	Currency::> (Currency&) (see page 3250)	Tests whether this System::Currency::Currency (see page 3235) value is greater than a specified value.
	Currency::> (double) (see page 3250)	Tests whether this System::Currency::Currency (see page 3235) value is greater than a specified value.
	Currency::> (int) (see page 3250)	Tests whether this System::Currency::Currency (see page 3235) value is greater than a specified value.

35.1.3.3.19.1 Currency::> Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3235) value is greater than a specified value.

Pascal

```
operator >(const rhs: Currency&);
operator >(rhs: Integer);
operator >(rhs: double);
```

C++

```
__fastcall bool operator >(const Currency& rhs) const;
__fastcall bool operator >(int rhs) const;
__fastcall bool operator >(double rhs) const;
```

Description

The System::Currency (see page 3235)::> compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3235) object has a greater value than rhs, false otherwise.

See Also

System::Currency::!= (see page 3241)

System::Currency::== (see page 3250)

System::Currency::>= (see page 3251)

System::Currency::< (see page 3247)

System::Currency::<= (see page 3248)

35.1.3.3.20 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	Currency::>= (Currency&) (see page 3251)	Tests whether this System::Currency::Currency (see page 3235) value is greater than or equal to a specified value.
	Currency::>= (double) (see page 3251)	Tests whether this System::Currency::Currency (see page 3235) value is greater than or equal to a specified value.
	Currency::>= (int) (see page 3251)	Tests whether this System::Currency::Currency (see page 3235) value is greater than or equal to a specified value.

35.1.3.3.20.1 Currency::>= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 3235) value is greater than or equal to a specified value.

Pascal

```
operator >=(const rhs: Currency&);
operator >=(rhs: Integer);
operator >=(rhs: double);
```

C++

```
__fastcall bool operator >=(const Currency& rhs) const;
__fastcall bool operator >=(int rhs) const;
__fastcall bool operator >=(double rhs) const;
```

Description

The >= System::Currency (see page 3235)::>= compares the value of the System::Currency::Currency (see page 3235) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 3235) object's value is greater than or equal to the value of rhs, false otherwise.

See Also

System::Currency::!= (see page 3241)

System::Currency::> (see page 3250)

System::Currency::== (see page 3250)

System::Currency::< (see page 3247)

System::Currency::<= (see page 3248)

35.1.3.3.21 Currency::double Operator

Converts the System::Currency::Currency (see page 3235) object to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

double is a conversion System::Currency::double that converts a System::Currency::Currency (see page 3235) object to a double.

See Also

System::Currency::int (see page 3252)

System::Currency::System::String (see page 3252)

35.1.3.3.22 Currency::int Operator

Converts the System::Currency::Currency (see page 3235) object to an integer value

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

int is a conversion System::Currency::int that converts a System::Currency::Currency (see page 3235) object to an int.

See Also

System::Currency::double (see page 3252)

System::Currency::System::String (see page 3252)

35.1.3.3.23 Currency::System::String Operator

Converts the System::Currency::System::String object to a String that displays its value.

Pascal

```
operator System::String;
```

C++

```
__fastcall operator System::String() const;
```

Description

String is a conversion System::Currency::System::String that converts the currency value into its string representation. The conversion uses the ffGeneral floating point conversion rules. For further details, see the description of the CurrToStrF and FloatToStrF methods of the AnsiString class.

See Also

System::Currency::int (see page 3252)

System::Currency::double (see page 3252)

35.1.3.4 Currency Friends

The friends of the Currency class are listed here.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 3253)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 3253)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 3254)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 3255)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 3255)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

35.1.3.4.1 friend Currency __fastcall operator -(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).

35.1.3.4.2 friend Currency __fastcall operator -(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).

35.1.3.4.3 friend Currency __fastcall operator *(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).

35.1.3.4.4 friend Currency __fastcall operator *(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).

35.1.3.4.5 friend Currency __fastcall operator /(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).

35.1.3.4.6 friend Currency __fastcall operator /(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).

35.1.3.4.7 friend Currency __fastcall operator +(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).

35.1.3.4.8 friend Currency __fastcall operator +(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

35.1.4 CurrencyBase Class

Class Hierarchy

Pascal

```
CurrencyBase = class;
```

C++

```
class CurrencyBase;
```

File

syscurr.h

Description

This is class System::CurrencyBase.

35.1.4.1 CurrencyBase Members

The following tables list the members exposed by CurrencyBase.

Public Data Members

	Name	Description
	Val (see page 3256)	This is Val, a member of class CurrencyBase.

35.1.4.2 CurrencyBase Data Members

The data members of the CurrencyBase class are listed here.

Public Data Members

	Name	Description
	Val (see page 3256)	This is Val, a member of class CurrencyBase.

35.1.4.2.1 CurrencyBase::Val Data Member

Pascal

```
Val: __int64;
```

C++

```
__int64 Val;
```

Description

This is Val, a member of class CurrencyBase.

35.1.5 DelphiInterface Template

System::DelphiInterface is a C++ implementation of the Delphi interface.

Class Hierarchy

Pascal

```
DelphiInterface<class T> = class;
```

C++

```
template <class T>
class DelphiInterface;
```

File

systobj.h

Description

A Delphi interface is an abstract collection of properties, methods, and events with no implementation. It resembles a C++ class with only pure virtual methods. However a Delphi interface type supports built-in reference counting.

System::DelphiInterface is a C++ template that defines types compatible with Delphi interfaces, System::DelphiInterface defines reference counting logic in its initialization constructor, copy constructor, assignment operator, and destructor.

Note: Other operators that provide access to the underlying interface pointer do not handle reference counting. You may need to explicitly call AddRef or Release (see page 3258) to ensure proper reference counting.

System::DelphiInterface is a template:

```
template <class T> class RTL_DELPHIRETURN DelphiInterface;
```

where the T parameter is an underlying interface class or COM interface. In the object framework, the resulting System::DelphiInterface class is usually given a name such as _di_IUnknown, where IUnknown (see page 3756) is the name of the corresponding interface. Such interfaces are documented under the interface name (such as IFormDesigner).

See Also

System::Variant (see page 3421)

35.1.5.1 DelphiInterface Members

The following tables list the members exposed by DelphiInterface.

Public Methods

	Name	Description
	~DelphiInterface (see page 3257)	Frees an instance of System::DelphiInterface::DelphiInterface (see page 3256).
	DelphiInterface (see page 3257)	This is the overview for the DelphiInterface constructor overload.
	Release (see page 3258)	This is Release, a member of class DelphiInterface.

Public Operators

	Name	Description
	! (see page 3259)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 3256) object represents a NULL interface.
	& (see page 3259)	Returns a pointer to the underlying interface pointer.
	* (see page 3259)	Returns the underlying interface pointer.
	= (see page 3260)	This is the overview for the = operator overload.
	-> (see page 3260)	Provides access to the properties and methods on the underlying interface.
	T* (see page 3261)	This is T*, a member of class DelphiInterface.

35.1.5.2 DelphiInterface::~DelphiInterface Destructor

Frees an instance of System::DelphiInterface::DelphiInterface (see page 3256).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~DelphiInterface<T>();
```

Description

Before freeing the System::DelphiInterface::DelphiInterface (see page 3256) instance, System::DelphiInterface (see page 3256)::~DelphiInterface (see page 3256) calls the Release (see page 3258) method of the underlying interface.

35.1.5.3 DelphiInterface Constructor

This is the overview for the DelphiInterface constructor overload.

Overload List

	Name	Description
	DelphiInterface::DelphiInterface () (see page 3258)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3256).

	DelphiInterface::DelphiInterface (DelphiInterface<T> &) (see page 3258)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3256).
	DelphiInterface::DelphiInterface (T*) (see page 3258)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 3256).

35.1.5.3.1 DelphiInterface::DelphiInterface Constructor ()

Creates an instance of System::DelphiInterface::DelphiInterface (see page 3256).

Pascal

```
constructor Create;
constructor Create(const rhs: DelphiInterface<T> &);
constructor Create(var rhs: T);
```

C++

```
__fastcall DelphiInterface<T>();
__fastcall DelphiInterface<T>(const DelphiInterface<T> & rhs);
__fastcall DelphiInterface<T>(T* rhs);
```

Description

The System::DelphiInterface::DelphiInterface (see page 3256) constructor is overloaded to create a System::DelphiInterface::DelphiInterface (see page 3256) in one of three ways:

When used with no parameters, System::DelphiInterface::DelphiInterface (see page 3256) creates a NULL interface.

When used with another System::DelphiInterface::DelphiInterface (see page 3256) object (the copy constructor), System::DelphiInterface::DelphiInterface (see page 3256) creates a new copy of the interface specified by rhs, incrementing the reference count of the underlying interface.

When used with an interface pointer of the underlying type, System::DelphiInterface::DelphiInterface (see page 3256) wraps the underlying interface specified by rhs and increments its reference count.

35.1.5.4 DelphiInterface Methods

The methods of the DelphiInterface class are listed here.

Public Methods

	Name	Description
	Release (see page 3258)	This is Release, a member of class DelphiInterface.

35.1.5.4.1 DelphiInterface::Release Method

Pascal

```
function Release: Integer;
```

C++

```
int Release();
```

Description

This is Release, a member of class DelphiInterface.

35.1.5.5 DelphiInterface Operators

The operators of the DelphiInterface class are listed here.

Public Operators

	Name	Description
	! (see page 3259)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 3256) object represents a NULL interface.
	& (see page 3259)	Returns a pointer to the underlying interface pointer.
	* (see page 3259)	Returns the underlying interface pointer.
	= (see page 3260)	This is the overview for the = operator overload.
	-> (see page 3260)	Provides access to the properties and methods on the underlying interface.
	T* (see page 3261)	This is T*, a member of class DelphiInterface.

35.1.5.5.1 DelphiInterface::! Operator

Indicates whether the System::DelphiInterface::DelphiInterface (see page 3256) object represents a NULL interface.

Pascal

```
operator !;
```

C++

```
bool operator !() const;
```

Description

The ! System::DelphiInterface (see page 3256)::! returns true if the System::DelphiInterface::DelphiInterface (see page 3256) object represents a NULL interface, and false otherwise.

35.1.5.5.2 DelphiInterface::& Operator

Returns a pointer to the underlying interface pointer.

Pascal

```
operator &;
```

C++

```
__fastcall T** operator &();
```

Description

Use the & System::DelphiInterface (see page 3256)::& to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 3256)::&, because it provides no reference counting support. For example, when using this System::DelphiInterface (see page 3256)::& to programmatically replace the underlying interface, you must first call Release (see page 3258) to decrement the reference count of the current interface and, depending on whether you are using this as an additional interface reference, you may need to increment the reference count on the interface being added.

35.1.5.5.3 DelphiInterface::* Operator

Returns the underlying interface pointer.

Pascal

```
operator *;
```

C++

```
__fastcall T& operator *();
```

Description

Use the & System::DelphiInterface (see page 3256)::* to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 3256)::*, because it provides no reference counting support. For example, you may need to increment the reference count on the returned value.

35.1.5.5.4 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	DelphiInterface::= (DelphiInterface<T>&) (see page 3260)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3256).
	DelphiInterface::= (T *) (see page 3260)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3256).

35.1.5.5.4.1 DelphiInterface::= Operator (DelphiInterface<T>&)

Assigns a value to the System::DelphiInterface::DelphiInterface (see page 3256).

Pascal

```
operator =(var rhs: DelphiInterface<T>);
operator =(var rhs: T);
```

C++

```
__fastcall DelphiInterface<T>& operator =(DelphiInterface<T>& rhs);
__fastcall DelphiInterface<T>& operator =(T * rhs);
```

Description

The assignment System::DelphiInterface (see page 3256)::= assigns a value to the underlying interface from an interface pointer of the underlying type or from another System::DelphiInterface::DelphiInterface (see page 3256) object that wraps the same interface type.

This System::DelphiInterface (see page 3256)::= manages all reference counting issues. That is, it decrements the reference count on the current interface (if any) before making the assignment and increments the reference count on the newly assigned interface (if any).

35.1.5.5.5 DelphiInterface::-> Operator

Provides access to the properties and methods on the underlying interface.

Pascal

```
operator ->;
```

C++

```
__fastcall T* operator ->() const;
```

Description

Use the System::DelphiInterface (see page 3256)::-> to access the properties and methods of the underlying interface. If the

underlying interface is a dual interface, the System::DelphiInterface (see page 3256)::-> makes a vtable call.

35.1.5.5.6 DelphiInterface::T* Operator

Pascal

```
operator T*;
```

C++

```
__fastcall operator T*() const;
```

Description

This is T*, a member of class DelphiInterface.

35.1.6 DynamicArray Template

System::DynamicArray is the C++ analog for the Delphi dynamic array type.

Class Hierarchy

Pascal

```
DynamicArray<class T> = class;
```

C++

```
template <class T>
class DynamicArray;
```

File

sysdyn.h

Description

A Dynamic Array is a resizable collection implemented as an array. The System::DynamicArray template is a C++ implementation of Delphi Dynamic Array types. The System::DynamicArray template uses a binary layout compatible with the Delphi Dynamic Array implementation.

```
template <class T> class DELPHIRETURN DynamicArray;
```

You must specify one template parameter:

Parameter	Usage
type	the type of the elements

Length (see page 3270) of dynamic arrays

The size of a System::DynamicArray can be set or obtained from the Length (see page 3270) property:

//C++ example

```
DynamicArray<int> arrayOfInt;
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

To free a System::DynamicArray, assign it a Length (see page 3270) of zero.

Accessing data

Access elements of a Dynamic Array via the subscript [] operator:

//C++ example

```
void InitArray(DynamicArray<char> &c_array)
{
  c_array[0] = 'A';
  c_array[1] = 'B';
  cout << "Third char is: " << c_array[2];
}
```

Bounds of dynamic arrays

The Low (see page 3271) and High (see page 3270) properties of System::DynamicArrays return the low and high bounds of the array respectively.

//C++ example

```
int TotalArray(const DynamicArray<int>& arrayOfInt)
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

Note: The Low (see page 3271) property always returns 0. The High (see page 3270) property returns Length (see page 3270)-1. So you may also traverse a dynamic array via the following construct:

for (int i=0; i<arrayOfInt. Length (see page 3270); i++)

Assigning, comparing and copying dynamic arrays

Dynamic Arrays are reference counted. When a System::DynamicArray is assigned to another, only the reference is assigned (and the reference count adjusted), the content of the source is not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To copy the contents of a System::DynamicArray, you must use the Copy (see page 3265) (or CopyRange (see page 3266)) methods.

//C++ example

```
void foo(DynamicArray<int> &i_array)
{
  DynamicArray<int> temp = i_array;
  assert(temp == i_array); // temp and i_array point to same chunk
                           // of data..
  i_array[0] = 20;
  assert(temp[0] == 20); // Temp 'sees' changes to i_array..
  temp = i_array.Copy(); // Temp gets its own copy of data
  temp[0] = 10;
  assert(temp[0] != i_array[0]); // Above assignment did not
                                 // modify i_array.
}
```

Multidimensional dynamic arrays

Dynamic arrays can be multidimensional. Multidimensional dynamic arrays don't have to be rectangular. The Length (see page 3270) property can be used to set each dimension. The following example illustrates.

//C++ example

```
typedef DynamicArray< DynamicArray < AnsiString > > T2DStringArray;
void foo(T2DStringArray &s_array)
{
  SetLength(s_array, 10);
for (int i=0; i<s_array.Length; i++)
  { // Set lengths of second dimensions.(NOTE: non-rectangular)
    SetLength(s_array[i], i+1);
```

```
for (int j=0; j<s_array[i].Length; j++)
    /* */ s_array[i][j] = itoa(i*10+j);
  }
}
```

C++ & Delphi System::DynamicArrays

A dynamic array declared in C++ code can be used in Delphi code and vice versa. The following examples illustrate passing a one-dimensional and two-dimensional array between C++ and Delphi.

C++ System::DynamicArray Example

Delphi System::DynamicArray Example

35.1.6.1 DynamicArray Members

The following tables list the members exposed by DynamicArray.

Protected Methods

	Name	Description
	AllocData (see page 3265)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 3266)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 3267)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 3268)	This is IncRefCount, a member of class DynamicArray.
	SetData (see page 3268)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	~DynamicArray (see page 3263)	Frees a System::DynamicArray (see page 3261) object.
	Copy (see page 3265)	This is the overview for the Copy method overload.
	CopyRange (see page 3266)	This is the overview for the CopyRange method overload.
	DimCount (see page 3267)	This is DimCount, a member of class DynamicArray.
	DynamicArray (see page 3264)	This is the overview for the DynamicArray constructor overload.
	get_high (see page 3267)	This is get_high, a member of class DynamicArray.
	get_length (see page 3267)	This is get_length, a member of class DynamicArray.
	get_low (see page 3267)	This is get_low, a member of class DynamicArray.
	set_length (see page 3268)	This is set_length, a member of class DynamicArray.

Public Operators

	Name	Description
	[] (see page 3268)	This is the overview for the [] operator overload.
	= (see page 3269)	Assigns data from another Dynamic Array.
	== (see page 3269)	Compares two Dynamic Arrays for equality.

Public Properties

	Name	Description
R	High (see page 3270)	Indicates the high bounds of the array.
	Length (see page 3270)	Represents the number of elements in the System::DynamicArray (see page 3261).
R	Low (see page 3271)	Indicates the low bound of a dynamic array.

35.1.6.2 DynamicArray::~DynamicArray Destructor

Frees a System::DynamicArray (see page 3261) object.

Pascal

```
destructor Destroy;
```

C++

```
~DynamicArray();
```

Description

Do not call the dynamic array destructor. To free a dynamically allocated System::DynamicArray (see page 3261), assign it a Length (see page 3270) of zero. System::DynamicArray (see page 3261) instances on the stack are freed when they go out of scope.

35.1.6.3 DynamicArray Constructor

This is the overview for the DynamicArray constructor overload.

Overload List

	Name	Description
	DynamicArray::DynamicArray () (see page 3264)	Creates and initializes a System::DynamicArray::DynamicArray (see page 3261) object.
	DynamicArray::DynamicArray (DynamicArray<T>&) (see page 3264)	Creates and initializes a System::DynamicArray::DynamicArray (see page 3261) object.

35.1.6.3.1 DynamicArray::DynamicArray Constructor ()

Creates and initializes a System::DynamicArray::DynamicArray (see page 3261) object.

Pascal

```
constructor Create;
constructor Create(const src: DynamicArray<T>&);
```

C++

```
DynamicArray();
DynamicArray(const DynamicArray<T>& src);
```

Description

When called with no parameters, the constructor creates an empty dynamic array. Otherwise, it copies another System::DynamicArray::DynamicArray (see page 3261).

35.1.6.4 DynamicArray Methods

The methods of the DynamicArray class are listed here.

Protected Methods

	Name	Description
	AllocData (see page 3265)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 3266)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 3267)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 3268)	This is IncRefCount, a member of class DynamicArray.

	SetData (see page 3268)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	Copy (see page 3265)	This is the overview for the Copy method overload.
	CopyRange (see page 3266)	This is the overview for the CopyRange method overload.
	DimCount (see page 3267)	This is DimCount, a member of class DynamicArray.
	get_high (see page 3267)	This is get_high, a member of class DynamicArray.
	get_length (see page 3267)	This is get_length, a member of class DynamicArray.
	get_low (see page 3267)	This is get_low, a member of class DynamicArray.
	set_length (see page 3268)	This is set_length, a member of class DynamicArray.

35.1.6.4.1 DynamicArray::AllocData Method

Pascal

```
function AllocData(count: Integer): T*; static;
```

C++

```
static T* AllocData(int count);
```

Description

This is AllocData, a member of class DynamicArray.

35.1.6.4.2 Copy Method

This is the overview for the Copy method overload.

Overload List

	Name	Description
	DynamicArray::Copy () (see page 3265)	Copies the contents of a System::DynamicArray (see page 3261) to the specified System::DynamicArray (see page 3261).
	DynamicArray::Copy (DynamicArray<T> &) (see page 3265)	Copies the contents of a System::DynamicArray (see page 3261) to the specified System::DynamicArray (see page 3261).

35.1.6.4.2.1 DynamicArray::Copy Method ()

Copies the contents of a System::DynamicArray (see page 3261) to the specified System::DynamicArray (see page 3261).

Pascal

```
function Copy: DynamicArray<T>;
procedure Copy(var dst: DynamicArray<T>);
```

C++

```
DynamicArray<T> Copy() const;
void Copy(DynamicArray<T> & dst) const;
```

Description

Use System::DynamicArray::Copy to make a copy of a dynamic array. Dynamic arrays are reference counted. Therefore assigning one to another simply copies the reference, not the data. The System::DynamicArray::Copy method, on the other hand, makes a separate copy of the dynamic array. The original contents of the destination array are discarded.

The following code copies the contents of i_array into temp; temp and i_array must be of the same System::DynamicArray (see page 3261) type.

```
temp = i_array.Copy();
```

See Also

System::DynamicArray::CopyRange (see page 3266)

35.1.6.4.3 CopyRange Method

This is the overview for the CopyRange method overload.

Overload List

	Name	Description
	DynamicArray::CopyRange (DynamicArray<T> &, int, int) (see page 3266)	Copies a range of the contents of a System::DynamicArray (see page 3261) within a specified range.
	DynamicArray::CopyRange (int, int) (see page 3266)	Copies a range of the contents of a System::DynamicArray (see page 3261) within a specified range.

35.1.6.4.3.1 DynamicArray::CopyRange Method (DynamicArray<T> &, int, int)

Copies a range of the contents of a System::DynamicArray (see page 3261) within a specified range.

Pascal

```
function CopyRange(startIndex: Integer; count: Integer): DynamicArray<T>;
procedure CopyRange(var dst: DynamicArray<T>; startIndex: Integer; count: Integer);
```

C++

```
DynamicArray<T> CopyRange(int startIndex, int count) const;
void CopyRange(DynamicArray<T> & dst, int startIndex, int count) const;
```

Description

Use the System::DynamicArray::CopyRange method to copy a subrange of a dynamic array. The System::DynamicArray::CopyRange method is similar to the Copy (see page 3265) method except that you can specify the startIndex and the number of items to copy from the source object. The size of the destination array will be truncated or expanded to accommodate what has been copied.

newArray = array.System::DynamicArray::CopyRange(3, 5);

35.1.6.4.4 DynamicArray::DecRefCount Method

Pascal

```
procedure DecRefCount;
```

C++

```
void DecRefCount();
```

Description

This is DecRefCount, a member of class DynamicArray.

35.1.6.4.5 DynamicArray::DimCount Method

Pascal

```
function DimCount: Integer; static;
```

C++

```
static int DimCount();
```

Description

This is DimCount, a member of class DynamicArray.

35.1.6.4.6 DynamicArray::FreeData Method

Pascal

```
procedure FreeData;
```

C++

```
void FreeData();
```

Description

This is FreeData, a member of class DynamicArray.

35.1.6.4.7 DynamicArray::get_high Method

Pascal

```
function get_high: Integer;
```

C++

```
int get_high() const;
```

Description

This is get_high, a member of class DynamicArray.

35.1.6.4.8 DynamicArray::get_length Method

Pascal

```
function get_length: Integer;
```

C++

```
int get_length() const;
```

Description

This is get_length, a member of class DynamicArray.

35.1.6.4.9 DynamicArray::get_low Method

Pascal

```
function get_low: Integer;
```

C++

```
int get_low() const;
```

Description

This is get_low, a member of class DynamicArray.

35.1.6.4.10 DynamicArray::IncRefCount Method

Pascal

```
procedure IncRefCount;
```

C++

```
void IncRefCount();
```

Description

This is IncRefCount, a member of class DynamicArray.

35.1.6.4.11 DynamicArray::set_length Method

Pascal

```
procedure set_length(l: Integer);
```

C++

```
void set_length(int l);
```

Description

This is set_length, a member of class DynamicArray.

35.1.6.4.12 DynamicArray::SetData Method

Pascal

```
procedure SetData(var t: T);
```

C++

```
void SetData(T* t);
```

Description

This is SetData, a member of class DynamicArray.

35.1.6.5 DynamicArray Operators

The operators of the DynamicArray class are listed here.

Public Operators

	Name	Description
	[] (see page 3268)	This is the overview for the [] operator overload.
	= (see page 3269)	Assigns data from another Dynamic Array.
	== (see page 3269)	Compares two Dynamic Arrays for equality.

35.1.6.5.1 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	DynamicArray::[] (int) (see page 3269)	Provides access to the data held by the dynamic array.
	DynamicArray::[] (int) (see page 3269)	Provides access to the data held by the dynamic array.

35.1.6.5.1.1 DynamicArray::[] Operator (int)

Provides access to the data held by the dynamic array.

Pascal

```
operator [](index: Integer);
operator [](index: Integer);
```

C++

```
T& operator [](int index);
T operator [](int index) const;
```

Description

The const version of the System::DynamicArray (see page 3261)::[] returns a copy of the data at the specified subscript. The non-const version returns a reference to the data, allowing you to modify the data.

cout << i_array[0]=10;

35.1.6.5.2 DynamicArray::= Operator

Assigns data from another Dynamic Array.

Pascal

```
operator =(const src: DynamicArray<T>&);
```

C++

```
DynamicArray& operator =(const DynamicArray<T>& src);
```

Description

Dynamic Arrays are reference counted. When a System::DynamicArray (see page 3261) is assigned to another, only the reference is assigned (and the reference count adjusted), the contents of the source are not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To create a separate copy of the contents of a System::DynamicArray (see page 3261), use the Copy (see page 3265) (or CopyRange (see page 3266)) method.

See Also

System::DynamicArray::Copy (see page 3265)

35.1.6.5.3 DynamicArray::== Operator

Compares two Dynamic Arrays for equality.

Pascal

```
operator ==(const other: DynamicArray<T> &);
```

C++

```
bool operator ==(const DynamicArray<T> & other) const;
```

Description

The == System::DynamicArray (see page 3261)::== determines whether two dynamic arrays refer to the same memory. It does not compare the contents of the arrays.

35.1.6.6 DynamicArray Properties

The properties of the DynamicArray class are listed here.

Public Properties

	Name	Description
	High (see page 3270)	Indicates the high bounds of the array.
	Length (see page 3270)	Represents the number of elements in the System::DynamicArray (see page 3261).
	Low (see page 3271)	Indicates the low bound of a dynamic array.

35.1.6.6.1 DynamicArray::High Property

Indicates the high bounds of the array.

Pascal

```
property High: Integer;
```

C++

```
__property int High;
```

Description

Reading the System::DynamicArray::High property returns Length (see page 3270)-1.

The following function returns the sum of the contents of an integer type System::DynamicArray (see page 3261).

int TotalArray(const System::DynamicArray (see page 3261)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

See Also

System::DynamicArray::Length (see page 3270)

System::DynamicArray::Low (see page 3271)

35.1.6.6.2 DynamicArray::Length Property

Represents the number of elements in the System::DynamicArray (see page 3261).

Pascal

```
property Length: Integer;
```

C++

```
__property int Length;
```

Description

Use the System::DynamicArray::Length property to set or get the length of the dynamic array. The following code sets the length of a System::DynamicArray (see page 3261) to 10.

System::DynamicArray (see page 3261)<int> arrayOfInt;

```
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

SetSystem::DynamicArray::Length(arrayOfInt, 10);

To free a dynamic array, simply set its System::DynamicArray::Length to 0:

arrayOfInt.System::DynamicArray::Length = 0;

See Also

System::DynamicArray::High (see page 3270)

35.1.6.6.3 DynamicArray::Low Property

Indicates the low bound of a dynamic array.

Pascal

```
property Low: Integer;
```

C++

```
__property int Low;
```

Description

The System::DynamicArray::Low property always returns 0. The following function returns the sum of the contents of an integer type System::DynamicArray (see page 3261).

int TotalArray(const System::DynamicArray (see page 3261)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

See Also

System::DynamicArray::High (see page 3270)

35.1.7 DynArrayException Class

Class Hierarchy

Pascal

```
DynArrayException = class;
```

C++

```
class DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayException.

35.1.8 DynArrayNullData Class

Class Hierarchy

Pascal

```
DynArrayNullData = class(DynArrayException);
```

C++

```
class DynArrayNullData : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayNullData.

35.1.9 DynArrayOutOfRange Class

Class Hierarchy

Pascal

```
DynArrayOutOfRange = class(DynArrayException);
```

C++

```
class DynArrayOutOfRange : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayOutOfRange.

35.1.9.1 DynArrayOutOfRange Members

The following tables list the members exposed by DynArrayOutOfRange.

Public Data Members

	Name	Description
	m_Count (see page 3273)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 3273)	This is m_Index, a member of class DynArrayOutOfRange.

Public Methods

	Name	Description
	DynArrayOutOfRange (see page 3273)	This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

35.1.9.2 DynArrayOutOfRange::DynArrayOutOfRange Constructor

Pascal

```
constructor Create(index: Integer; count: Integer);
```

C++

```
DynArrayOutOfRange(int index, int count);
```

Description

This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

35.1.9.3 DynArrayOutOfRange Data Members

The data members of the DynArrayOutOfRange class are listed here.

Public Data Members

	Name	Description
	m_Count (see page 3273)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 3273)	This is m_Index, a member of class DynArrayOutOfRange.

35.1.9.3.1 DynArrayOutOfRange::m_Count Data Member

Pascal

```
m_Count: Integer;
```

C++

```
int m_Count;
```

Description

This is m_Count, a member of class DynArrayOutOfRange.

35.1.9.3.2 DynArrayOutOfRange::m_Index Data Member

Pascal

```
m_Index: Integer;
```

C++

```
int m_Index;
```

Description

This is m_Index, a member of class DynArrayOutOfRange.

35.1.10 OleVariant Class

System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.

Class Hierarchy

Pascal

```
OleVariant = class(Variant);
```

C++

```
class OleVariant : protected Variant;
```

File

sysvari.h

Description

System::OleVariant is a special descendant of the Variant (see page 3421) class that is used to represent COM interfaces or data that is passed over a COM interface. System::OleVariant inherits from Variant (see page 3421) as a protected class so that it can prevent operations on AnsiString (see page 3458) objects, which are not compatible with COM.

The syntax for using System::OleVariant is the same as that for using the Variant (see page 3421) class. Like the Variant (see page 3421) class, System::OleVariant has the following characteristics:

System::OleVariants can contain integer values, real values, string values, boolean values, date-and-time values, and Automation objects. In addition, System::OleVariants can contain arrays of varying size and dimension with elements of any of these types.

The special System::OleVariant value Unassigned is used to indicate that a System::OleVariant has not yet been assigned a value, and the special System::OleVariant value Null is used to indicate unknown or missing data.

A System::OleVariant can be combined with other System::OleVariants and it can be constructed from any of the following data types. The compiler automatically performs the necessary type conversions.

shortWordBool

intByte

floatVariant

doubleWideString

Currencywchar_t*

TDateTimeOle2::IDispatch (see page 3494)*

boolOle2::IUnknown (see page 3756)*

When an System::OleVariant contains an Automation object, the System::OleVariant can be used to get and set properties of the object, and to invoke methods on the object.

System::OleVariant variables are always initialized to be Unassigned when they are first created. This is true whether a System::OleVariant variable is global, local, or part of a structure such as an array.

Note that while System::OleVariants offer great flexibility, they also consume more memory than regular variables, and operations on System::OleVariants are substantially slower than operations on statically typed values.

Note: Use only the operators declared within System::OleVariant. The compiler will ignore any operators you overload yourself.

Note: For binary operators, if one operand is of type System::OleVariant, the other operand is automatically converted to type System::OleVariant.

See Also

System::Variant (see page 3421)

35.1.10.1 OleVariant Members

The following tables list the members exposed by OleVariant.

Public Data Members

	Name	Description
	TVarData::Reserved1 (see page 3284)	This is TVarData::Reserved1, a member of class OleVariant.
	TVarData::Reserved2 (see page 3284)	This is TVarData::Reserved2, a member of class OleVariant.
	TVarData::Reserved3 (see page 3284)	This is TVarData::Reserved3, a member of class OleVariant.
	TVarData::VArray (see page 3284)	This is TVarData::VArray, a member of class OleVariant.
	TVarData::VBoolean (see page 3285)	This is TVarData::VBoolean, a member of class OleVariant.
	TVarData::VByte (see page 3285)	This is TVarData::VByte, a member of class OleVariant.
	TVarData::VCurrency (see page 3285)	This is TVarData::VCurrency, a member of class OleVariant.
	TVarData::VDate (see page 3285)	This is TVarData::VDate, a member of class OleVariant.
	TVarData::VDispatch (see page 3285)	This is TVarData::VDispatch, a member of class OleVariant.
	TVarData::VDouble (see page 3286)	This is TVarData::VDouble, a member of class OleVariant.
	TVarData::VError (see page 3286)	This is TVarData::VError, a member of class OleVariant.
	TVarData::VInteger (see page 3286)	This is TVarData::VInteger, a member of class OleVariant.
	TVarData::VOleStr (see page 3286)	This is TVarData::VOleStr, a member of class OleVariant.
	TVarData::VPointer (see page 3287)	This is TVarData::VPointer, a member of class OleVariant.
	TVarData::VSingle (see page 3287)	This is TVarData::VSingle, a member of class OleVariant.
	TVarData::VSmallint (see page 3287)	This is TVarData::VSmallint, a member of class OleVariant.
	TVarData::VType (see page 3287)	This is TVarData::VType, a member of class OleVariant.
	TVarData::VUnknown (see page 3287)	This is TVarData::VUnknown, a member of class OleVariant.
	Variant::- (see page 3288)	This is Variant::-, a member of class OleVariant.
	Variant::! (see page 3288)	This is Variant::!, a member of class OleVariant.
	Variant::%= (see page 3288)	This is Variant::%=, a member of class OleVariant.
	Variant::&= (see page 3288)	This is Variant::&=, a member of class OleVariant.
	Variant::*= (see page 3289)	This is Variant::*=, a member of class OleVariant.
	Variant::/= (see page 3289)	This is Variant::/=, a member of class OleVariant.
	Variant::^= (see page 3289)	This is Variant::^=, a member of class OleVariant.
	Variant::__int64 (see page 3289)	This is Variant::__int64, a member of class OleVariant.
	Variant::|= (see page 3289)	This is Variant::|=, a member of class OleVariant.
	Variant::+= (see page 3290)	This is Variant::+=, a member of class OleVariant.
	Variant::<<= (see page 3290)	This is Variant::<<=, a member of class OleVariant.
	Variant::-= (see page 3290)	This is Variant::-=, a member of class OleVariant.
	Variant::>>= (see page 3290)	This is Variant::>>=, a member of class OleVariant.
	Variant::AnsiString (see page 3291)	This is Variant::AnsiString, a member of class OleVariant.
	Variant::ArrayDimCount (see page 3291)	This is Variant::ArrayDimCount, a member of class OleVariant.
	Variant::ArrayHighBound (see page 3291)	This is Variant::ArrayHighBound, a member of class OleVariant.
	Variant::ArrayLock (see page 3291)	This is Variant::ArrayLock, a member of class OleVariant.
	Variant::ArrayLowBound (see page 3291)	This is Variant::ArrayLowBound, a member of class OleVariant.
	Variant::ArrayRedim (see page 3292)	This is Variant::ArrayRedim, a member of class OleVariant.
	Variant::ArrayUnlock (see page 3292)	This is Variant::ArrayUnlock, a member of class OleVariant.

	Variant::AsType (see page 3292)	This is Variant::AsType, a member of class OleVariant.
	Variant::bool (see page 3292)	This is Variant::bool, a member of class OleVariant.
	Variant::Byte* (see page 3293)	This is Variant::Byte*, a member of class OleVariant.
	Variant::ChangeType (see page 3293)	This is Variant::ChangeType, a member of class OleVariant.
	Variant::char (see page 3293)	This is Variant::char, a member of class OleVariant.
	Variant::Clear (see page 3293)	This is Variant::Clear, a member of class OleVariant.
	Variant::Currency (see page 3293)	This is Variant::Currency, a member of class OleVariant.
	Variant::Currency* (see page 3294)	This is Variant::Currency*, a member of class OleVariant.
	Variant::double (see page 3294)	This is Variant::double, a member of class OleVariant.
	Variant::double* (see page 3294)	This is Variant::double*, a member of class OleVariant.
	Variant::float (see page 3294)	This is Variant::float, a member of class OleVariant.
	Variant::float* (see page 3295)	This is Variant::float*, a member of class OleVariant.
	Variant::GetElement (see page 3295)	This is Variant::GetElement, a member of class OleVariant.
	Variant::GetError (see page 3295)	This is Variant::GetError, a member of class OleVariant.
	Variant::IDispatch* (see page 3295)	This is Variant::IDispatch*, a member of class OleVariant.
	Variant::IInterface* (see page 3295)	This is Variant::IInterface*, a member of class OleVariant.
	Variant::int (see page 3296)	This is Variant::int, a member of class OleVariant.
	Variant::int* (see page 3296)	This is Variant::int*, a member of class OleVariant.
	Variant::IsArray (see page 3296)	This is Variant::IsArray, a member of class OleVariant.
	Variant::IsEmpty (see page 3296)	This is Variant::IsEmpty, a member of class OleVariant.
	Variant::IsNull (see page 3297)	This is Variant::IsNull, a member of class OleVariant.
	Variant::IUnknown* (see page 3297)	This is Variant::IUnknown*, a member of class OleVariant.
	Variant::long (see page 3297)	This is Variant::long, a member of class OleVariant.
	Variant::long* (see page 3297)	This is Variant::long*, a member of class OleVariant.
	Variant::PutElement (see page 3297)	This is Variant::PutElement, a member of class OleVariant.
	Variant::SetError (see page 3298)	This is Variant::SetError, a member of class OleVariant.
	Variant::short (see page 3298)	This is Variant::short, a member of class OleVariant.
	Variant::short* (see page 3298)	This is Variant::short*, a member of class OleVariant.
	Variant::signed char (see page 3298)	This is Variant::signed char, a member of class OleVariant.
	Variant::signed char* (see page 3299)	This is Variant::signed char*, a member of class OleVariant.
	Variant::TDateTime (see page 3299)	This is Variant::TDateTime, a member of class OleVariant.
	Variant::TDateTime* (see page 3299)	This is Variant::TDateTime*, a member of class OleVariant.
	Variant::Type (see page 3299)	This is Variant::Type, a member of class OleVariant.
	Variant::UnicodeString (see page 3299)	This is Variant::UnicodeString, a member of class OleVariant.
	Variant::unsigned char (see page 3300)	This is Variant::unsigned char, a member of class OleVariant.
	Variant::unsigned int (see page 3300)	This is Variant::unsigned int, a member of class OleVariant.
	Variant::unsigned int* (see page 3300)	This is Variant::unsigned int*, a member of class OleVariant.
	Variant::unsigned long (see page 3300)	This is Variant::unsigned long, a member of class OleVariant.
	Variant::unsigned short (see page 3301)	This is Variant::unsigned short, a member of class OleVariant.
	Variant::unsigned short* (see page 3301)	This is Variant::unsigned short*, a member of class OleVariant.
	Variant::WideString (see page 3301)	This is Variant::WideString, a member of class OleVariant.

Public Methods

	Name	Description
	~OleVariant (see page 3279)	Frees an instance of System::OleVariant (see page 3274).
	~Variant (see page 3424)	Frees a System::Variant::Variant (see page 3421) object.
	ArrayDimCount (see page 3429)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 3429)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 3429)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 3430)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 3430)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 3430)	Unlocks a variant array that was previously locked by ArrayLock (see page 3429).

	AsType (see page 3431)	Casts a System::Variant::Variant (see page 3421) object to the type specified by the argument VarType.
	ChangeType (see page 3431)	Changes the data type of a System::Variant::Variant (see page 3421) object once it has been instantiated.
	Clear (see page 3431)	System::Variant::Clears the value of the System::Variant::Variant (see page 3421).
	Empty (see page 3431)	This is Empty, a member of class Variant.
	GetBaseVariant (see page 3432)	Returns the System::Variant (see page 3421) that is assigned as the value of this System::Variant (see page 3421) when Type (see page 3436) is varSystem::Variant (see page 3421).
	GetElement (see page 3432)	This is the overview for the GetElement method overload.
	GetError (see page 3433)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and returns the integer value.
	IsArray (see page 3433)	Queries the VType of the base class TVarData (see page 3740) for the varArray (see page 3861) bit.
	IsEmpty (see page 3433)	Queries the VType of the base class TVarData (see page 3740).
	IsNull (see page 3434)	Queries the VType of the base class TVarData (see page 3740) for the varNull (see page 3868) bit.
	NoParam (see page 3434)	This is NoParam, a member of class Variant.
	OleVariant (see page 3279)	This is the overview for the OleVariant constructor overload.
	PutElement (see page 3434)	This is the overview for the PutElement method overload.
	Sanitized (see page 3435)	This is Sanitized, a member of class Variant.
	SetError (see page 3435)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and assigns the integer err as the value of the varError (see page 3866).
	Type (see page 3436)	Returns type code of a System::Variant (see page 3421) instance.
	Variant (see page 3424)	This is the overview for the Variant constructor overload.

Public Operators

	Name	Description
	- (see page 3439)	This is the overview for the - operator overload.
	! (see page 3439)	Returns a new System::Variant::Variant (see page 3421) that is the logical negation of this System::Variant::Variant (see page 3421).
	!= (see page 3301)	This is the overview for the != operator overload.
	!= (see page 3440)	This is the overview for the != operator overload.
	% (see page 3440)	This is the overview for the % operator overload.
	%= (see page 3441)	Returns this System::Variant::Variant (see page 3421) as the remainder from dividing its original value and the System::Variant::Variant (see page 3421) specified by rhs.
	& (see page 3442)	This is the overview for the & operator overload.
	&= (see page 3442)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise and operation.
	* (see page 3443)	This is the overview for the * operator overload.
	*= (see page 3443)	Multiplies this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) specified by rhs.
	/ (see page 3444)	This is the overview for the / operator overload.
	/= (see page 3444)	Divides this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) rhs.
	^ (see page 3445)	This is the overview for the ^ operator overload.
	^= (see page 3445)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise xor operation.
	__int64 (see page 3446)	This is __int64, a member of class Variant.
	| (see page 3446)	This is the overview for the | operator overload.
	|= (see page 3446)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise or operation.
	+ (see page 3447)	This is the overview for the + operator overload.
	+= (see page 3447)	Adds the System::Variant::Variant (see page 3421) specified by rhs to this System::Variant::Variant (see page 3421) object.
	< (see page 3302)	This is the overview for the < operator overload.
	< (see page 3448)	This is the overview for the < operator overload.

	<< (see page 3448)	This is the overview for the << operator overload.
	<<= (see page 3449)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 3421).
	<= (see page 3303)	This is the overview for the <= operator overload.
	<= (see page 3449)	This is the overview for the <= operator overload.
	-= (see page 3454)	Subtracts the System::Variant::Variant (see page 3421) specified by rhs from this System::Variant::Variant (see page 3421) object.
	= (see page 3303)	This is the overview for the = operator overload.
	= (see page 3450)	This is the overview for the = operator overload.
	== (see page 3305)	This is the overview for the == operator overload.
	== (see page 3455)	This is the overview for the == operator overload.
	> (see page 3306)	This is the overview for the > operator overload.
	> (see page 3456)	This is the overview for the > operator overload.
	>= (see page 3306)	This is the overview for the >= operator overload.
	>= (see page 3456)	This is the overview for the >= operator overload.
	>> (see page 3457)	This is the overview for the >> operator overload.
	>>= (see page 3458)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 3421).
	AnsiString (see page 3458)	Converts the System::Variant::Variant (see page 3421) to an AnsiString object.
	bool (see page 3458)	Converts the System::Variant::Variant (see page 3421) to a boolean value.
	char (see page 3459)	This is char, a member of class Variant.
	Currency (see page 3459)	Converts the System::Variant::Variant (see page 3421) to a Currency object.
	Currency* (see page 3459)	This is Currency*, a member of class Variant.
	double (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a double value.
	double* (see page 3460)	This is double*, a member of class Variant.
	float (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a float value.
	float* (see page 3460)	This is float*, a member of class Variant.
	IDispatch* (see page 3461)	Converts the System::Variant (see page 3421) to an System::Variant::IDispatch (see page 3494)* interface pointer.
	IInterface* (see page 3461)	This is IInterface*, a member of class Variant.
	int (see page 3461)	Converts the System::Variant::Variant (see page 3421) to an integer value.
	int* (see page 3461)	This is int*, a member of class Variant.
	IUnknown* (see page 3462)	Converts the System::Variant (see page 3421) to an System::Variant::IUnknown (see page 3756)* interface pointer.
	long (see page 3462)	This is long, a member of class Variant.
	long* (see page 3462)	This is long*, a member of class Variant.
	short (see page 3462)	Converts the System::Variant::Variant (see page 3421) to a short value.
	short* (see page 3463)	This is short*, a member of class Variant.
	signed char (see page 3463)	This is signed char, a member of class Variant.
	signed char* (see page 3463)	This is signed char*, a member of class Variant.
	TDateTime (see page 3463)	Converts the System::Variant::Variant (see page 3421) to a TDateTime object.
	TDateTime* (see page 3464)	This is TDateTime*, a member of class Variant.
	UnicodeString (see page 3464)	This is UnicodeString, a member of class Variant.
	unsigned char (see page 3464)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value.
	unsigned char* (see page 3465)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value. And returns a reference.
	unsigned int (see page 3465)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 3465)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 3465)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 3466)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value.
	unsigned short* (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value and returns a reference to the value.
	WideString (see page 3466)	This is WideString, a member of class Variant.

35.1.10.2 OleVariant::~OleVariant Destructor

Frees an instance of System::OleVariant (see page 3274).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~OleVariant();
```

Description

System::OleVariant (see page 3274)::~OleVariant (see page 3274) is the destructor for System::OleVariant (see page 3274) class.

35.1.10.3 OleVariant Constructor

This is the overview for the OleVariant constructor overload.

Overload List

	Name	Description
	OleVariant::OleVariant () (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (__int64) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (__int64*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (AnsiString&) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (bool) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (char) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (char*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (Currency) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (Currency*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (double) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (double*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (float) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (float*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.

	OleVariant::OleVariant (IDispatch* const) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (IInterface* const) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (int) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (int*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (int*, int, Word) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (IUnknown* const) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (long*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (OleVariant&) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (OleVariant*, int) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (short) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (short*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (signed char*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (TDateTime) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (TDateTime*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (UnicodeString&) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned char) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned char*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned int) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned int*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned long*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned short) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (unsigned short*) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (Variant&) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.

	OleVariant::OleVariant (wchar_t* const, bool) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.
	OleVariant::OleVariant (WideString&) (see page 3281)	Creates an instance of System::OleVariant (see page 3274) with a specified value.

35.1.10.3.1 OleVariant::OleVariant Constructor ()

Creates an instance of System::OleVariant (see page 3274) with a specified value.

Pascal

```
constructor Create;
constructor Create(const src: OleVariant&);
constructor Create(const src: Variant&);
constructor Create(const src: char);
constructor Create(const src: unsigned char);
constructor Create(const src: short);
constructor Create(const src: unsigned short);
constructor Create(const src: Integer);
constructor Create(const src: unsigned int);
constructor Create(const src: float);
constructor Create(const src: double);
constructor Create(const src: __int64);
constructor Create(const src: Currency);
constructor Create(const src: TDateTime);
constructor Create(const src: WideString&);
constructor Create(const src: UnicodeString&);
constructor Create(const src: bool);
constructor Create(const src: AnsiString&);
constructor Create(src: wchar_t* const; isBSTR: bool = true);
constructor Create(src: IDispatch* const);
constructor Create(src: IUnknown* const);
constructor Create(src: IInterface* const);
constructor Create(const src: char*);
constructor Create(var src: signed char);
constructor Create(var src: unsigned char);
constructor Create(var src: short);
constructor Create(var src: unsigned short);
constructor Create(var src: Integer);
constructor Create(var src: unsigned int);
constructor Create(var src: long);
constructor Create(var src: unsigned long);
constructor Create(var src: float);
constructor Create(var src: double);
constructor Create(var src: __int64);
constructor Create(var src: Currency);
constructor Create(var src: TDateTime);
constructor Create(const bounds: int*; const boundsSize: Integer; varType: Word);
constructor Create(const values: OleVariant*; const valuesSize: Integer);
```

C++

```
__fastcall OleVariant();
__fastcall OleVariant(const OleVariant& src);
__fastcall OleVariant(const Variant& src);
__fastcall OleVariant(const char src);
__fastcall OleVariant(const unsigned char src);
__fastcall OleVariant(const short src);
__fastcall OleVariant(const unsigned short src);
__fastcall OleVariant(const int src);
__fastcall OleVariant(const unsigned int src);
__fastcall OleVariant(const float src);
__fastcall OleVariant(const double src);
```

```
__fastcall OleVariant(const __int64 src);
__fastcall OleVariant(const Currency src);
__fastcall OleVariant(const TDateTime src);
__fastcall OleVariant(const WideString& src);
__fastcall OleVariant(const UnicodeString& src);
__fastcall OleVariant(const bool src);
__fastcall OleVariant(const AnsiString& src);
__fastcall OleVariant(wchar_t* const src, bool isBSTR = true);
__fastcall OleVariant(IDispatch* const src);
__fastcall OleVariant(IUnknown* const src);
__fastcall OleVariant(IInterface* const src);
__fastcall OleVariant(const char* src);
__fastcall OleVariant(signed char* src);
__fastcall OleVariant(unsigned char* src);
__fastcall OleVariant(short* src);
__fastcall OleVariant(unsigned short* src);
__fastcall OleVariant(int* src);
__fastcall OleVariant(unsigned int* src);
__fastcall OleVariant(long* src);
__fastcall OleVariant(unsigned long* src);
__fastcall OleVariant(float* src);
__fastcall OleVariant(double* src);
__fastcall OleVariant(__int64* src);
__fastcall OleVariant(Currency* src);
__fastcall OleVariant(TDateTime* src);
__fastcall OleVariant(const int* bounds, const int boundsSize, Word varType);
__fastcall OleVariant(const OleVariant* values, const int valuesSize);
```

Description

The System::OleVariant (see page 3274) constructor is overloaded to create an System::OleVariant (see page 3274), converting the src argument as appropriate. If no argument is given, System::OleVariant (see page 3274) creates an System::OleVariant (see page 3274) of type Unassigned.

35.1.10.4 OleVariant Data Members

The data members of the OleVariant class are listed here.

Public Data Members

	Name	Description
	TVarData::Reserved1 (see page 3284)	This is TVarData::Reserved1, a member of class OleVariant.
	TVarData::Reserved2 (see page 3284)	This is TVarData::Reserved2, a member of class OleVariant.
	TVarData::Reserved3 (see page 3284)	This is TVarData::Reserved3, a member of class OleVariant.
	TVarData::VArray (see page 3284)	This is TVarData::VArray, a member of class OleVariant.
	TVarData::VBoolean (see page 3285)	This is TVarData::VBoolean, a member of class OleVariant.
	TVarData::VByte (see page 3285)	This is TVarData::VByte, a member of class OleVariant.
	TVarData::VCurrency (see page 3285)	This is TVarData::VCurrency, a member of class OleVariant.
	TVarData::VDate (see page 3285)	This is TVarData::VDate, a member of class OleVariant.
	TVarData::VDispatch (see page 3285)	This is TVarData::VDispatch, a member of class OleVariant.
	TVarData::VDouble (see page 3286)	This is TVarData::VDouble, a member of class OleVariant.
	TVarData::VError (see page 3286)	This is TVarData::VError, a member of class OleVariant.
	TVarData::VInteger (see page 3286)	This is TVarData::VInteger, a member of class OleVariant.
	TVarData::VOleStr (see page 3286)	This is TVarData::VOleStr, a member of class OleVariant.
	TVarData::VPointer (see page 3287)	This is TVarData::VPointer, a member of class OleVariant.
	TVarData::VSingle (see page 3287)	This is TVarData::VSingle, a member of class OleVariant.
	TVarData::VSmallint (see page 3287)	This is TVarData::VSmallint, a member of class OleVariant.
	TVarData::VType (see page 3287)	This is TVarData::VType, a member of class OleVariant.
	TVarData::VUnknown (see page 3287)	This is TVarData::VUnknown, a member of class OleVariant.
	Variant::- (see page 3288)	This is Variant::-, a member of class OleVariant.

	Variant::! (see page 3288)	This is Variant::!, a member of class OleVariant.
	Variant::%= (see page 3288)	This is Variant::%=, a member of class OleVariant.
	Variant::&= (see page 3288)	This is Variant::&=, a member of class OleVariant.
	Variant::*= (see page 3289)	This is Variant::*=, a member of class OleVariant.
	Variant::/= (see page 3289)	This is Variant::/=, a member of class OleVariant.
	Variant::^= (see page 3289)	This is Variant::^=, a member of class OleVariant.
	Variant::__int64 (see page 3289)	This is Variant::__int64, a member of class OleVariant.
	Variant::|= (see page 3289)	This is Variant::|=, a member of class OleVariant.
	Variant::+= (see page 3290)	This is Variant::+=, a member of class OleVariant.
	Variant::<<= (see page 3290)	This is Variant::<<=, a member of class OleVariant.
	Variant::-= (see page 3290)	This is Variant::-=, a member of class OleVariant.
	Variant::>>= (see page 3290)	This is Variant::>>=, a member of class OleVariant.
	Variant::AnsiString (see page 3291)	This is Variant::AnsiString, a member of class OleVariant.
	Variant::ArrayDimCount (see page 3291)	This is Variant::ArrayDimCount, a member of class OleVariant.
	Variant::ArrayHighBound (see page 3291)	This is Variant::ArrayHighBound, a member of class OleVariant.
	Variant::ArrayLock (see page 3291)	This is Variant::ArrayLock, a member of class OleVariant.
	Variant::ArrayLowBound (see page 3291)	This is Variant::ArrayLowBound, a member of class OleVariant.
	Variant::ArrayRedim (see page 3292)	This is Variant::ArrayRedim, a member of class OleVariant.
	Variant::ArrayUnlock (see page 3292)	This is Variant::ArrayUnlock, a member of class OleVariant.
	Variant::AsType (see page 3292)	This is Variant::AsType, a member of class OleVariant.
	Variant::bool (see page 3292)	This is Variant::bool, a member of class OleVariant.
	Variant::Byte* (see page 3293)	This is Variant::Byte*, a member of class OleVariant.
	Variant::ChangeType (see page 3293)	This is Variant::ChangeType, a member of class OleVariant.
	Variant::char (see page 3293)	This is Variant::char, a member of class OleVariant.
	Variant::Clear (see page 3293)	This is Variant::Clear, a member of class OleVariant.
	Variant::Currency (see page 3293)	This is Variant::Currency, a member of class OleVariant.
	Variant::Currency* (see page 3294)	This is Variant::Currency*, a member of class OleVariant.
	Variant::double (see page 3294)	This is Variant::double, a member of class OleVariant.
	Variant::double* (see page 3294)	This is Variant::double*, a member of class OleVariant.
	Variant::float (see page 3294)	This is Variant::float, a member of class OleVariant.
	Variant::float* (see page 3295)	This is Variant::float*, a member of class OleVariant.
	Variant::GetElement (see page 3295)	This is Variant::GetElement, a member of class OleVariant.
	Variant::GetError (see page 3295)	This is Variant::GetError, a member of class OleVariant.
	Variant::IDispatch* (see page 3295)	This is Variant::IDispatch*, a member of class OleVariant.
	Variant::IInterface* (see page 3295)	This is Variant::IInterface*, a member of class OleVariant.
	Variant::int (see page 3296)	This is Variant::int, a member of class OleVariant.
	Variant::int* (see page 3296)	This is Variant::int*, a member of class OleVariant.
	Variant::IsArray (see page 3296)	This is Variant::IsArray, a member of class OleVariant.
	Variant::IsEmpty (see page 3296)	This is Variant::IsEmpty, a member of class OleVariant.
	Variant::IsNull (see page 3297)	This is Variant::IsNull, a member of class OleVariant.
	Variant::IUnknown* (see page 3297)	This is Variant::IUnknown*, a member of class OleVariant.
	Variant::long (see page 3297)	This is Variant::long, a member of class OleVariant.
	Variant::long* (see page 3297)	This is Variant::long*, a member of class OleVariant.
	Variant::PutElement (see page 3297)	This is Variant::PutElement, a member of class OleVariant.
	Variant::SetError (see page 3298)	This is Variant::SetError, a member of class OleVariant.
	Variant::short (see page 3298)	This is Variant::short, a member of class OleVariant.
	Variant::short* (see page 3298)	This is Variant::short*, a member of class OleVariant.
	Variant::signed char (see page 3298)	This is Variant::signed char, a member of class OleVariant.
	Variant::signed char* (see page 3299)	This is Variant::signed char*, a member of class OleVariant.
	Variant::TDateTime (see page 3299)	This is Variant::TDateTime, a member of class OleVariant.
	Variant::TDateTime* (see page 3299)	This is Variant::TDateTime*, a member of class OleVariant.
	Variant::Type (see page 3299)	This is Variant::Type, a member of class OleVariant.
	Variant::UnicodeString (see page 3299)	This is Variant::UnicodeString, a member of class OleVariant.
	Variant::unsigned char (see page 3300)	This is Variant::unsigned char, a member of class OleVariant.

	Variant::unsigned int (see page 3300)	This is Variant::unsigned int, a member of class OleVariant.
	Variant::unsigned int* (see page 3300)	This is Variant::unsigned int*, a member of class OleVariant.
	Variant::unsigned long (see page 3300)	This is Variant::unsigned long, a member of class OleVariant.
	Variant::unsigned short (see page 3301)	This is Variant::unsigned short, a member of class OleVariant.
	Variant::unsigned short* (see page 3301)	This is Variant::unsigned short*, a member of class OleVariant.
	Variant::WideString (see page 3301)	This is Variant::WideString, a member of class OleVariant.

35.1.10.4.1 OleVariant::TVarData::Reserved1 Data Member

Pascal

```
TVarData::Reserved1: __USING;
```

C++

```
__USING TVarData::Reserved1;
```

Description

This is TVarData::Reserved1, a member of class OleVariant.

35.1.10.4.2 OleVariant::TVarData::Reserved2 Data Member

Pascal

```
TVarData::Reserved2: __USING;
```

C++

```
__USING TVarData::Reserved2;
```

Description

This is TVarData::Reserved2, a member of class OleVariant.

35.1.10.4.3 OleVariant::TVarData::Reserved3 Data Member

Pascal

```
TVarData::Reserved3: __USING;
```

C++

```
__USING TVarData::Reserved3;
```

Description

This is TVarData::Reserved3, a member of class OleVariant.

35.1.10.4.4 OleVariant::TVarData::VArray Data Member

Pascal

```
TVarData::VArray: __USING;
```

C++

```
__USING TVarData::VArray;
```

Description

This is TVarData::VArray, a member of class OleVariant.

35.1.10.4.5 OleVariant::TVarData::VBoolean Data Member

Pascal

```
TVarData::VBoolean: __USING;
```

C++

```
__USING TVarData::VBoolean;
```

Description

This is TVarData::VBoolean, a member of class OleVariant.

35.1.10.4.6 OleVariant::TVarData::VByte Data Member

Pascal

```
TVarData::VByte: __USING;
```

C++

```
__USING TVarData::VByte;
```

Description

This is TVarData::VByte, a member of class OleVariant.

35.1.10.4.7 OleVariant::TVarData::VCurrency Data Member

Pascal

```
TVarData::VCurrency: __USING;
```

C++

```
__USING TVarData::VCurrency;
```

Description

This is TVarData::VCurrency, a member of class OleVariant.

35.1.10.4.8 OleVariant::TVarData::VDate Data Member

Pascal

```
TVarData::VDate: __USING;
```

C++

```
__USING TVarData::VDate;
```

Description

This is TVarData::VDate, a member of class OleVariant.

35.1.10.4.9 OleVariant::TVarData::VDispatch Data Member

Pascal

```
TVarData::VDispatch: __USING;
```

C++

```
__USING TVarData::VDispatch;
```

Description

This is TVarData::VDispatch, a member of class OleVariant.

35.1.10.4.10 OleVariant::TVarData::VDouble Data Member

Pascal

```
TVarData::VDouble: __USING;
```

C++

```
__USING TVarData::VDouble;
```

Description

This is TVarData::VDouble, a member of class OleVariant.

35.1.10.4.11 OleVariant::TVarData::VError Data Member

Pascal

```
TVarData::VError: __USING;
```

C++

```
__USING TVarData::VError;
```

Description

This is TVarData::VError, a member of class OleVariant.

35.1.10.4.12 OleVariant::TVarData::VInteger Data Member

Pascal

```
TVarData::VInteger: __USING;
```

C++

```
__USING TVarData::VInteger;
```

Description

This is TVarData::VInteger, a member of class OleVariant.

35.1.10.4.13 OleVariant::TVarData::VOleStr Data Member

Pascal

```
TVarData::VOleStr: __USING;
```

C++

```
__USING TVarData::VOleStr;
```

Description

This is TVarData::VOleStr, a member of class OleVariant.

35.1.10.4.14 OleVariant::TVarData::VPointer Data Member

Pascal

```
TVarData::VPointer: __USING;
```

C++

```
__USING TVarData::VPointer;
```

Description

This is TVarData::VPointer, a member of class OleVariant.

35.1.10.4.15 OleVariant::TVarData::VSingle Data Member

Pascal

```
TVarData::VSingle: __USING;
```

C++

```
__USING TVarData::VSingle;
```

Description

This is TVarData::VSingle, a member of class OleVariant.

35.1.10.4.16 OleVariant::TVarData::VSmallint Data Member

Pascal

```
TVarData::VSmallint: __USING;
```

C++

```
__USING TVarData::VSmallint;
```

Description

This is TVarData::VSmallint, a member of class OleVariant.

35.1.10.4.17 OleVariant::TVarData::VType Data Member

Pascal

```
TVarData::VType: __USING;
```

C++

```
__USING TVarData::VType;
```

Description

This is TVarData::VType, a member of class OleVariant.

35.1.10.4.18 OleVariant::TVarData::VUnknown Data Member

Pascal

```
TVarData::VUnknown: __USING;
```

C++

```
__USING TVarData::VUnknown;
```

Description

This is TVarData::VUnknown, a member of class OleVariant.

35.1.10.4.19 OleVariant::Variant::- Data Member

Pascal

```
Variant::-: __USING;
```

C++

```
__USING Variant::-;
```

Description

This is Variant::-, a member of class OleVariant.

35.1.10.4.20 OleVariant::Variant::! Data Member

Pascal

```
Variant::!: __USING;
```

C++

```
__USING Variant::!;
```

Description

This is Variant::!, a member of class OleVariant.

35.1.10.4.21 OleVariant::Variant::%= Data Member

Pascal

```
Variant::%=: __USING;
```

C++

```
__USING Variant::%=;
```

Description

This is Variant::%=, a member of class OleVariant.

35.1.10.4.22 OleVariant::Variant::&= Data Member

Pascal

```
Variant::&=: __USING;
```

C++

```
__USING Variant::&=;
```

Description

This is Variant::&=, a member of class OleVariant.

35.1.10.4.23 OleVariant::Variant::*= Data Member

Pascal

```
Variant::*=: __USING;
```

C++

```
__USING Variant::*=;
```

Description

This is Variant::*=, a member of class OleVariant.

35.1.10.4.24 OleVariant::Variant::/= Data Member

Pascal

```
Variant::/=: __USING;
```

C++

```
__USING Variant::/=;
```

Description

This is Variant::/=, a member of class OleVariant.

35.1.10.4.25 OleVariant::Variant::^= Data Member

Pascal

```
Variant::^=: __USING;
```

C++

```
__USING Variant::^=;
```

Description

This is Variant::^=, a member of class OleVariant.

35.1.10.4.26 OleVariant::Variant::__int64 Data Member

Pascal

```
Variant::__int64: __USING;
```

C++

```
__USING Variant::__int64;
```

Description

This is Variant::__int64, a member of class OleVariant.

35.1.10.4.27 OleVariant::Variant::|= Data Member

Pascal

```
Variant::|=: __USING;
```

C++

```
__USING Variant::|=;
```

Description

This is Variant::|=, a member of class OleVariant.

35.1.10.4.28 OleVariant::Variant::+= Data Member

Pascal

```
Variant::+=: __USING;
```

C++

```
__USING Variant::+=;
```

Description

This is Variant::+=, a member of class OleVariant.

35.1.10.4.29 OleVariant::Variant::<<= Data Member

Pascal

```
Variant::<<=: __USING;
```

C++

```
__USING Variant::<<=;
```

Description

This is Variant::<<=, a member of class OleVariant.

35.1.10.4.30 OleVariant::Variant::-= Data Member

Pascal

```
Variant::-=: __USING;
```

C++

```
__USING Variant::-=;
```

Description

This is Variant::-=, a member of class OleVariant.

35.1.10.4.31 OleVariant::Variant::>>= Data Member

Pascal

```
Variant::>>=: __USING;
```

C++

```
__USING Variant::>>=;
```

Description

This is Variant::>>=, a member of class OleVariant.

35.1.10.4.32 OleVariant::Variant::AnsiString Data Member

Pascal

```
Variant::AnsiString: __USING;
```

C++

```
__USING Variant::AnsiString;
```

Description

This is Variant::AnsiString, a member of class OleVariant.

35.1.10.4.33 OleVariant::Variant::ArrayDimCount Data Member

Pascal

```
Variant::ArrayDimCount: __USING;
```

C++

```
__USING Variant::ArrayDimCount;
```

Description

This is Variant::ArrayDimCount, a member of class OleVariant.

35.1.10.4.34 OleVariant::Variant::ArrayHighBound Data Member

Pascal

```
Variant::ArrayHighBound: __USING;
```

C++

```
__USING Variant::ArrayHighBound;
```

Description

This is Variant::ArrayHighBound, a member of class OleVariant.

35.1.10.4.35 OleVariant::Variant::ArrayLock Data Member

Pascal

```
Variant::ArrayLock: __USING;
```

C++

```
__USING Variant::ArrayLock;
```

Description

This is Variant::ArrayLock, a member of class OleVariant.

35.1.10.4.36 OleVariant::Variant::ArrayLowBound Data Member

Pascal

```
Variant::ArrayLowBound: __USING;
```

C++

```
__USING Variant::ArrayLowBound;
```

Description

This is Variant::ArrayLowBound, a member of class OleVariant.

35.1.10.4.37 OleVariant::Variant::ArrayRedim Data Member

Pascal

```
Variant::ArrayRedim: __USING;
```

C++

```
__USING Variant::ArrayRedim;
```

Description

This is Variant::ArrayRedim, a member of class OleVariant.

35.1.10.4.38 OleVariant::Variant::ArrayUnlock Data Member

Pascal

```
Variant::ArrayUnlock: __USING;
```

C++

```
__USING Variant::ArrayUnlock;
```

Description

This is Variant::ArrayUnlock, a member of class OleVariant.

35.1.10.4.39 OleVariant::Variant::AsType Data Member

Pascal

```
Variant::AsType: __USING;
```

C++

```
__USING Variant::AsType;
```

Description

This is Variant::AsType, a member of class OleVariant.

35.1.10.4.40 OleVariant::Variant::bool Data Member

Pascal

```
Variant::bool: __USING;
```

C++

```
__USING Variant::bool;
```

Description

This is Variant::bool, a member of class OleVariant.

35.1.10.4.41 OleVariant::Variant::Byte* Data Member

Pascal

```
Variant::Byte*: __USING;
```

C++

```
__USING Variant::Byte*;
```

Description

This is Variant::Byte*, a member of class OleVariant.

35.1.10.4.42 OleVariant::Variant::ChangeType Data Member

Pascal

```
Variant::ChangeType: __USING;
```

C++

```
__USING Variant::ChangeType;
```

Description

This is Variant::ChangeType, a member of class OleVariant.

35.1.10.4.43 OleVariant::Variant::char Data Member

Pascal

```
Variant::char: __USING;
```

C++

```
__USING Variant::char;
```

Description

This is Variant::char, a member of class OleVariant.

35.1.10.4.44 OleVariant::Variant::Clear Data Member

Pascal

```
Variant::Clear: __USING;
```

C++

```
__USING Variant::Clear;
```

Description

This is Variant::Clear, a member of class OleVariant.

35.1.10.4.45 OleVariant::Variant::Currency Data Member

Pascal

```
Variant::Currency: __USING;
```

C++

```
__USING Variant::Currency;
```

Description

This is Variant::Currency, a member of class OleVariant.

35.1.10.4.46 OleVariant::Variant::Currency* Data Member

Pascal

```
Variant::Currency*: __USING;
```

C++

```
__USING Variant::Currency*;
```

Description

This is Variant::Currency*, a member of class OleVariant.

35.1.10.4.47 OleVariant::Variant::double Data Member

Pascal

```
Variant::double: __USING;
```

C++

```
__USING Variant::double;
```

Description

This is Variant::double, a member of class OleVariant.

35.1.10.4.48 OleVariant::Variant::double* Data Member

Pascal

```
Variant::double*: __USING;
```

C++

```
__USING Variant::double*;
```

Description

This is Variant::double*, a member of class OleVariant.

35.1.10.4.49 OleVariant::Variant::float Data Member

Pascal

```
Variant::float: __USING;
```

C++

```
__USING Variant::float;
```

Description

This is Variant::float, a member of class OleVariant.

35.1.10.4.50 OleVariant::Variant::float* Data Member

Pascal

```
Variant::float*: __USING;
```

C++

```
__USING Variant::float*;
```

Description

This is Variant::float*, a member of class OleVariant.

35.1.10.4.51 OleVariant::Variant::GetElement Data Member

Pascal

```
Variant::GetElement: __USING;
```

C++

```
__USING Variant::GetElement;
```

Description

This is Variant::GetElement, a member of class OleVariant.

35.1.10.4.52 OleVariant::Variant::GetError Data Member

Pascal

```
Variant::GetError: __USING;
```

C++

```
__USING Variant::GetError;
```

Description

This is Variant::GetError, a member of class OleVariant.

35.1.10.4.53 OleVariant::Variant::IDispatch* Data Member

Pascal

```
Variant::IDispatch*: __USING;
```

C++

```
__USING Variant::IDispatch*;
```

Description

This is Variant::IDispatch*, a member of class OleVariant.

35.1.10.4.54 OleVariant::Variant::IInterface* Data Member

Pascal

```
Variant::IInterface*: __USING;
```

C++

```
__USING Variant::IInterface*;
```

Description

This is Variant::IInterface*, a member of class OleVariant.

35.1.10.4.55 OleVariant::Variant::int Data Member

Pascal

```
Variant::int: __USING;
```

C++

```
__USING Variant::int;
```

Description

This is Variant::int, a member of class OleVariant.

35.1.10.4.56 OleVariant::Variant::int* Data Member

Pascal

```
Variant::int*: __USING;
```

C++

```
__USING Variant::int*;
```

Description

This is Variant::int*, a member of class OleVariant.

35.1.10.4.57 OleVariant::Variant::IsArray Data Member

Pascal

```
Variant::IsArray: __USING;
```

C++

```
__USING Variant::IsArray;
```

Description

This is Variant::IsArray, a member of class OleVariant.

35.1.10.4.58 OleVariant::Variant::IsEmpty Data Member

Pascal

```
Variant::IsEmpty: __USING;
```

C++

```
__USING Variant::IsEmpty;
```

Description

This is Variant::IsEmpty, a member of class OleVariant.

35.1.10.4.59 OleVariant::Variant::IsNull Data Member

Pascal

```
Variant::IsNull: __USING;
```

C++

```
__USING Variant::IsNull;
```

Description

This is Variant::IsNull, a member of class OleVariant.

35.1.10.4.60 OleVariant::Variant::IUnknown* Data Member

Pascal

```
Variant::IUnknown*: __USING;
```

C++

```
__USING Variant::IUnknown*;
```

Description

This is Variant::IUnknown*, a member of class OleVariant.

35.1.10.4.61 OleVariant::Variant::long Data Member

Pascal

```
Variant::long: __USING;
```

C++

```
__USING Variant::long;
```

Description

This is Variant::long, a member of class OleVariant.

35.1.10.4.62 OleVariant::Variant::long* Data Member

Pascal

```
Variant::long*: __USING;
```

C++

```
__USING Variant::long*;
```

Description

This is Variant::long*, a member of class OleVariant.

35.1.10.4.63 OleVariant::Variant::PutElement Data Member

Pascal

```
Variant::PutElement: __USING;
```

C++

```
__USING Variant::PutElement;
```

Description

This is Variant::PutElement, a member of class OleVariant.

35.1.10.4.64 OleVariant::Variant::SetError Data Member

Pascal

```
Variant::SetError: __USING;
```

C++

```
__USING Variant::SetError;
```

Description

This is Variant::SetError, a member of class OleVariant.

35.1.10.4.65 OleVariant::Variant::short Data Member

Pascal

```
Variant::short: __USING;
```

C++

```
__USING Variant::short;
```

Description

This is Variant::short, a member of class OleVariant.

35.1.10.4.66 OleVariant::Variant::short* Data Member

Pascal

```
Variant::short*: __USING;
```

C++

```
__USING Variant::short*;
```

Description

This is Variant::short*, a member of class OleVariant.

35.1.10.4.67 OleVariant::Variant::signed char Data Member

Pascal

```
Variant::signed char: __USING;
```

C++

```
__USING Variant::signed char;
```

Description

This is Variant::signed char, a member of class OleVariant.

35.1.10.4.68 OleVariant::Variant::signed char* Data Member

Pascal

```
Variant::signed char*: __USING;
```

C++

```
__USING Variant::signed char*;
```

Description

This is Variant::signed char*, a member of class OleVariant.

35.1.10.4.69 OleVariant::Variant::TDateTime Data Member

Pascal

```
Variant::TDateTime: __USING;
```

C++

```
__USING Variant::TDateTime;
```

Description

This is Variant::TDateTime, a member of class OleVariant.

35.1.10.4.70 OleVariant::Variant::TDateTime* Data Member

Pascal

```
Variant::TDateTime*: __USING;
```

C++

```
__USING Variant::TDateTime*;
```

Description

This is Variant::TDateTime*, a member of class OleVariant.

35.1.10.4.71 OleVariant::Variant::Type Data Member

Pascal

```
Variant::Type: __USING;
```

C++

```
__USING Variant::Type;
```

Description

This is Variant::Type, a member of class OleVariant.

35.1.10.4.72 OleVariant::Variant::UnicodeString Data Member

Pascal

```
Variant::UnicodeString: __USING;
```

C++

```
__USING Variant::UnicodeString;
```

Description

This is Variant::UnicodeString, a member of class OleVariant.

35.1.10.4.73 OleVariant::Variant::unsigned char Data Member

Pascal

```
Variant::unsigned char: __USING;
```

C++

```
__USING Variant::unsigned char;
```

Description

This is Variant::unsigned char, a member of class OleVariant.

35.1.10.4.74 OleVariant::Variant::unsigned int Data Member

Pascal

```
Variant::unsigned int: __USING;
```

C++

```
__USING Variant::unsigned int;
```

Description

This is Variant::unsigned int, a member of class OleVariant.

35.1.10.4.75 OleVariant::Variant::unsigned int* Data Member

Pascal

```
Variant::unsigned int*: __USING;
```

C++

```
__USING Variant::unsigned int*;
```

Description

This is Variant::unsigned int*, a member of class OleVariant.

35.1.10.4.76 OleVariant::Variant::unsigned long Data Member

Pascal

```
Variant::unsigned long: __USING;
```

C++

```
__USING Variant::unsigned long;
```

Description

This is Variant::unsigned long, a member of class OleVariant.

35.1.10.4.77 OleVariant::Variant::unsigned short Data Member

Pascal

```
Variant::unsigned short: __USING;
```

C++

```
__USING Variant::unsigned short;
```

Description

This is Variant::unsigned short, a member of class OleVariant.

35.1.10.4.78 OleVariant::Variant::unsigned short* Data Member

Pascal

```
Variant::unsigned short*: __USING;
```

C++

```
__USING Variant::unsigned short*;
```

Description

This is Variant::unsigned short*, a member of class OleVariant.

35.1.10.4.79 OleVariant::Variant::WideString Data Member

Pascal

```
Variant::WideString: __USING;
```

C++

```
__USING Variant::WideString;
```

Description

This is Variant::WideString, a member of class OleVariant.

35.1.10.5 OleVariant Operators

The operators of the OleVariant class are listed here.

Public Operators

	Name	Description
	!= (see page 3301)	This is the overview for the != operator overload.
	< (see page 3302)	This is the overview for the < operator overload.
	<= (see page 3303)	This is the overview for the <= operator overload.
	= (see page 3303)	This is the overview for the = operator overload.
	== (see page 3305)	This is the overview for the == operator overload.
	> (see page 3306)	This is the overview for the > operator overload.
	>= (see page 3306)	This is the overview for the >= operator overload.

35.1.10.5.1 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	OleVariant::!= (char*) (see page 3302)	This is !=, a member of class OleVariant.
	OleVariant::!= (OleVariant&) (see page 3302)	This is !=, a member of class OleVariant.

35.1.10.5.1.1 OleVariant::!= Operator (OleVariant&)

Pascal

```
operator !=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator !=(const OleVariant& rhs) const;
```

Description

This is !=, a member of class OleVariant.

35.1.10.5.1.2 OleVariant::!= Operator (char*)

Pascal

```
operator !=(const rhs: char*);
```

C++

```
__fastcall bool operator !=(const char* rhs) const;
```

Description

This is !=, a member of class OleVariant.

35.1.10.5.2 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	OleVariant::< (char*) (see page 3303)	This is <, a member of class OleVariant.
	OleVariant::< (OleVariant&) (see page 3302)	This is <, a member of class OleVariant.

35.1.10.5.2.1 OleVariant::< Operator (OleVariant&)

Pascal

```
operator <(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator <(const OleVariant& rhs) const;
```

Description

This is <, a member of class OleVariant.

35.1.10.5.2.2 OleVariant::< Operator (char*)

Pascal

```
operator <(const rhs: char*);
```

C++

```
__fastcall bool operator <(const char* rhs) const;
```

Description

This is <, a member of class OleVariant.

35.1.10.5.3 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	OleVariant::<= (char*) (see page 3303)	This is <=, a member of class OleVariant.
	OleVariant::<= (OleVariant&) (see page 3303)	This is <=, a member of class OleVariant.

35.1.10.5.3.1 OleVariant::<= Operator (OleVariant&)

Pascal

```
operator <=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator <=(const OleVariant& rhs) const;
```

Description

This is <=, a member of class OleVariant.

35.1.10.5.3.2 OleVariant::<= Operator (char*)

Pascal

```
operator <=(const rhs: char*);
```

C++

```
__fastcall bool operator <=(const char* rhs) const;
```

Description

This is <=, a member of class OleVariant.

35.1.10.5.4 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	OleVariant::= (__int64) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (AnsiString&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).

	OleVariant::= (bool) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (char) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (char*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (Currency&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (Currency*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (double) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (double*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (float) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (IDispatch*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (int) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (IUnknown*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (long) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (OleVariant&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (short) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (signed char) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (TDateTime&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (TDateTime*) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (UnicodeString&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (unsigned char) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (unsigned int) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (unsigned long) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (unsigned short) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (Variant&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).
	OleVariant::= (WideString&) (see page 3304)	Copies a value into the System::OleVariant (see page 3274).

35.1.10.5.4.1 OleVariant::= Operator (AnsiString&)

Copies a value into the System::OleVariant (see page 3274).

Pascal

```
operator =(const rhs: OleVariant&);
operator =(const rhs: Variant&);
operator =(const rhs: AnsiString&);
operator =(const rhs: char*);
operator =(const rhs: WideString&);
operator =(const rhs: UnicodeString&);
operator =(const rhs: bool);
operator =(const rhs: char);
operator =(const rhs: signed char);
operator =(const rhs: unsigned char);
operator =(const rhs: short);
operator =(const rhs: unsigned short);
operator =(const rhs: Integer);
operator =(const rhs: unsigned int);
operator =(const rhs: long);
operator =(const rhs: unsigned long);
```

```
operator =(const rhs: float);
operator =(const rhs: double);
operator =(const rhs: __int64);
operator =(const rhs: TDateTime&);
operator =(const rhs: Currency&);
operator =(var rhs: double);
operator =(var rhs: TDateTime);
operator =(var rhs: Currency);
operator =(var rhs: IDispatch);
operator =(var rhs: IUnknown);
```

C++

```
__fastcall OleVariant& operator =(const OleVariant& rhs);
__fastcall OleVariant& operator =(const Variant& rhs);
__fastcall OleVariant& operator =(const AnsiString& rhs);
__fastcall OleVariant& operator =(const char* rhs);
__fastcall OleVariant& operator =(const WideString& rhs);
__fastcall OleVariant& operator =(const UnicodeString& rhs);
__fastcall OleVariant& operator =(const bool rhs);
__fastcall OleVariant& operator =(const char rhs);
__fastcall OleVariant& operator =(const signed char rhs);
__fastcall OleVariant& operator =(const unsigned char rhs);
__fastcall OleVariant& operator =(const short rhs);
__fastcall OleVariant& operator =(const unsigned short rhs);
__fastcall OleVariant& operator =(const int rhs);
__fastcall OleVariant& operator =(const unsigned int rhs);
__fastcall OleVariant& operator =(const long rhs);
__fastcall OleVariant& operator =(const unsigned long rhs);
__fastcall OleVariant& operator =(const float rhs);
__fastcall OleVariant& operator =(const double rhs);
__fastcall OleVariant& operator =(const __int64 rhs);
__fastcall OleVariant& operator =(const TDateTime& rhs);
__fastcall OleVariant& operator =(const Currency& rhs);
__fastcall OleVariant& operator =(double* rhs);
__fastcall OleVariant& operator =(TDateTime* rhs);
__fastcall OleVariant& operator =(Currency* rhs);
__fastcall OleVariant& operator =(IDispatch* rhs);
__fastcall OleVariant& operator =(IUnknown* rhs);
```

Description

The assignment operator converts the value of rhs, as appropriate, and assigns it to the System::OleVariant (see page 3274). If it is not possible to perform the conversion, an EVariantError exception is thrown.

35.1.10.5.5 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	OleVariant::== (char*) (see page 3306)	This is ==, a member of class OleVariant.
	OleVariant::== (OleVariant&) (see page 3305)	This is ==, a member of class OleVariant.

35.1.10.5.5.1 OleVariant::== Operator (OleVariant&)

Pascal

```
operator ==(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator ==(const OleVariant& rhs) const;
```

Description

This is ==, a member of class OleVariant.

35.1.10.5.5.2 OleVariant::== Operator (char*)

Pascal

```
operator ==(const rhs: char*);
```

C++

```
__fastcall bool operator ==(const char* rhs) const;
```

Description

This is ==, a member of class OleVariant.

35.1.10.5.6 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	OleVariant::> (char*) (see page 3306)	This is >, a member of class OleVariant.
	OleVariant::> (OleVariant&) (see page 3306)	This is >, a member of class OleVariant.

35.1.10.5.6.1 OleVariant::> Operator (OleVariant&)

Pascal

```
operator >(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator >(const OleVariant& rhs) const;
```

Description

This is >, a member of class OleVariant.

35.1.10.5.6.2 OleVariant::> Operator (char*)

Pascal

```
operator >(const rhs: char*);
```

C++

```
__fastcall bool operator >(const char* rhs) const;
```

Description

This is >, a member of class OleVariant.

35.1.10.5.7 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	OleVariant::>= (char*) (see page 3307)	This is >=, a member of class OleVariant.
	OleVariant::>= (OleVariant&) (see page 3307)	This is >=, a member of class OleVariant.

35.1.10.5.7.1 OleVariant::>= Operator (OleVariant&)

Pascal

```
operator >=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator >=(const OleVariant& rhs) const;
```

Description

This is >=, a member of class OleVariant.

35.1.10.5.7.2 OleVariant::>= Operator (char*)

Pascal

```
operator >=(const rhs: char*);
```

C++

```
__fastcall bool operator >=(const char* rhs) const;
```

Description

This is >=, a member of class OleVariant.

35.1.11 SmallString Template

Class Hierarchy

Pascal

```
SmallString<unsigned char sz> = class(SmallStringBase<sz>);
```

C++

```
template <unsigned char sz>
class SmallString : private SmallStringBase<sz>;
```

File

dstring.h

Description

This is class System::SmallString.

35.1.11.1 SmallString Members

The following tables list the members exposed by SmallString.

Public Methods

	Name	Description
	SmallString (see page 3308)	This is the overview for the SmallString constructor overload.

Public Operators

	Name	Description
	[] (see page 3309)	This is [], a member of class SmallString.
	= (see page 3309)	This is =, a member of class SmallString.
	AnsiString (see page 3310)	This is AnsiString, a member of class SmallString.

35.1.11.2 SmallString Constructor

This is the overview for the SmallString constructor overload.

Overload List

	Name	Description
	SmallString::SmallString () (see page 3308)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (AnsiString&) (see page 3308)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (char*) (see page 3309)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (SmallString&) (see page 3309)	This is SmallString, a member of class SmallString.

35.1.11.2.1 SmallString::SmallString Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall SmallString();
```

Description

This is SmallString, a member of class SmallString.

35.1.11.2.2 SmallString::SmallString Constructor (AnsiString&)

Pascal

```
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall SmallString(const AnsiString& src);
```

Description

This is SmallString, a member of class SmallString.

35.1.11.2.3 SmallString::SmallString Constructor (SmallString&)

Pascal

```
constructor Create(const src: SmallString&);
```

C++

```
__fastcall SmallString(const SmallString& src);
```

Description

This is SmallString, a member of class SmallString.

35.1.11.2.4 SmallString::SmallString Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall SmallString(const char* src);
```

Description

This is SmallString, a member of class SmallString.

35.1.11.3 SmallString Operators

The operators of the SmallString class are listed here.

Public Operators

	Name	Description
	[] (see page 3309)	This is [], a member of class SmallString.
	= (see page 3309)	This is =, a member of class SmallString.
	AnsiString (see page 3310)	This is AnsiString, a member of class SmallString.

35.1.11.3.1 SmallString::[] Operator

Pascal

```
operator [](const idx: unsigned char);
```

C++

```
__fastcall char& operator [](const unsigned char idx);
```

Description

This is [], a member of class SmallString.

35.1.11.3.2 SmallString::= Operator

Pascal

```
operator =(const rhs: SmallString&);
```

C++

```
__fastcall SmallString& operator =(const SmallString& rhs);
```

Description

This is =, a member of class SmallString.

35.1.11.3.3 SmallString::AnsiString Operator

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

This is AnsiString, a member of class SmallString.

35.1.12 SmallStringBase Template

Class Hierarchy

Pascal

```
SmallStringBase<unsigned char sz> = class;
```

C++

```
template <unsigned char sz>
class SmallStringBase;
```

File

dstring.h

Description

This is class System::SmallStringBase.

35.1.12.1 SmallStringBase Members

The following tables list the members exposed by SmallStringBase.

Protected Data Members

	Name	Description
	Data (see page 3311)	This is Data, a member of class SmallStringBase.
	Len (see page 3311)	This is Len, a member of class SmallStringBase.

35.1.12.2 SmallStringBase Data Members

The data members of the SmallStringBase class are listed here.

Protected Data Members

	Name	Description
	Data (see page 3311)	This is Data, a member of class SmallStringBase.
	Len (see page 3311)	This is Len, a member of class SmallStringBase.

35.1.12.2.1 SmallStringBase::Data Data Member

Pascal

```
[sz] Data: char;
```

C++

```
char Data[sz];
```

Description

This is Data, a member of class SmallStringBase.

35.1.12.2.2 SmallStringBase::Len Data Member

Pascal

```
Len: unsigned char;
```

C++

```
unsigned char Len;
```

Description

This is Len, a member of class SmallStringBase.

35.1.13 sPointer Template

Class Hierarchy

System::sPointer

Pascal

```
sPointer<typename T> = class;
```

C++

```
template <typename T>
class sPointer;
```

File

sysdyn.h

Description

This is class System::sPointer.

35.1.13.1 sPointer Members

The following tables list the members exposed by sPointer.

Public Methods

	Name	Description
	~sPointer (see page 3312)	This is ~sPointer, a member of class sPointer.
	sPointer (see page 3312)	This is the overview for the sPointer constructor overload.

Public Operators

	Name	Description
	& (see page 3313)	This is &, a member of class sPointer.
	-> (see page 3313)	This is ->, a member of class sPointer.

35.1.13.2 sPointer::~sPointer Destructor

Pascal

```
destructor Destroy;
```

C++

```
~sPointer();
```

Description

This is ~sPointer, a member of class sPointer.

35.1.13.3 sPointer Constructor

This is the overview for the sPointer constructor overload.

Overload List

	Name	Description
	sPointer::sPointer () (see page 3312)	This is sPointer, a member of class sPointer.
	sPointer::sPointer (T*) (see page 3312)	This is sPointer, a member of class sPointer.

35.1.13.3.1 sPointer::sPointer Constructor ()

Pascal

```
constructor Create;
```

C++

```
sPointer();
```

Description

This is sPointer, a member of class sPointer.

35.1.13.3.2 sPointer::sPointer Constructor (T*)

Pascal

```
constructor Create(var p: T);
```

C++

```
sPointer(T* p);
```

Description

This is sPointer, a member of class sPointer.

35.1.13.4 sPointer Operators

The operators of the sPointer class are listed here.

Public Operators

	Name	Description
	& (see page 3313)	This is &, a member of class sPointer.
	-> (see page 3313)	This is ->, a member of class sPointer.

35.1.13.4.1 sPointer::& Operator

Pascal

```
operator &;
```

C++

```
T* operator &();
```

Description

This is &, a member of class sPointer.

35.1.13.4.2 sPointer::-> Operator

Pascal

```
operator ->;
```

C++

```
T* operator ->();
```

Description

This is ->, a member of class sPointer.

35.1.14 TAggregatedObject Class

System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 3502) methods to delegate to the controlling IInterface (see page 3502).

Class Hierarchy

Pascal

```
TAggregatedObject = class(TObject);
```

C++

```
class TAggregatedObject : public TObject;
```

File

System.pas

Description

An aggregated object is an object composed of several interfaced objects. Each object implements its own behavior and interfaces, but all of the objects share the same reference count, which is that of the controller object. In the container pattern, the controller is the container object.

System::TAggregatedObject does not itself support any interfaces. However, as is typical of an aggregate, it does implement the methods of IInterface (see page 3502), which are used by the objects that descend from it. System::TAggregatedObject, therefore, serves as a base for classes that implement interfaces for creating objects that are part of an aggregate.

System::TAggregatedObject is used as a base for classes that create contained objects and connecting objects. Using System::TAggregatedObject ensures that calls to the IInterface (see page 3502) methods delegate to the controlling IInterface (see page 3502) of the aggregate.

The controlling IInterface (see page 3502) is specified in the constructor for System::TAggregatedObject and is indicated by the System::TAggregatedObject::Controller (see page 3317) property.

TConnectionPoints

35.1.14.1 TAggregatedObject Members

The following tables list the members exposed by TAggregatedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_AddRef method.
	_Release (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_Release method.
	QueryInterface (see page 3317)	Implements the IInterface (see page 3502) System::TAggregatedObject::QueryInterface method.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3315)	Instantiates an aggregated object.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	Controller (see page 3317)	Provides access to the controlling interface of the aggregate.

35.1.14.2 TAggregatedObject::Create Constructor

Instantiates an aggregated object.

Pascal

```
constructor Create(const Controller: IInterface);
```

C++

```
Create(const IInterface Controller);
```

Description

Call System::TAggregatedObject::Create to instantiate an aggregated object at runtime.

System::TAggregatedObject::Create allocates memory for an aggregated object and sets the System::TAggregatedObject::Controller (see page 3317) property to the System::TAggregatedObject::Controller (see page 3317) parameter passed to it. The System::TAggregatedObject::Controller (see page 3317) is the controlling interface of the aggregate. All other interfaces implemented in the aggregate delegate IInterface (see page 3502) method calls to this System::TAggregatedObject::Controller (see page 3317).

See Also

System::TAggregatedObject::Controller (see page 3317)

35.1.14.3 TAggregatedObject Methods

The methods of the TAggregatedObject class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_AddRef method.
	_Release (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_Release method.
	QueryInterface (see page 3317)	Implements the IInterface (see page 3502) System::TAggregatedObject::QueryInterface method.

35.1.14.3.1 TAggregatedObject::_AddRef Method

Implements the IInterface (see page 3502) System::TAggregatedObject::_AddRef method.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__stdcall Integer _AddRef();
```

Description

Do not call the protected System::TAggregatedObject::_AddRef method directly. System::TAggregatedObject::_AddRef is called through the interface to indicate that another object is using the interfaced object's interface pointer. When the other object is through with the interface, it calls System::TInterfacedObject::_Release (see page 3345) through the same interface. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TAggregatedObject::_Release (see page 3316)

System::TInterfacedObject::_Release (see page 3345)

35.1.14.3.2 TAggregatedObject::_Release Method

Implements the IInterface (see page 3502) System::TAggregatedObject::_Release method.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__stdcall Integer _Release();
```

Description

Do not call the protected _System::TAggregatedObject::_Release method directly. _System::TAggregatedObject::_Release is called through the IInterface (see page 3502) interface to indicate that another object is through with the interfaced object's interface pointer. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TInterfacedObject::_AddRef (see page 3345)

System::TAggregatedObject::_AddRef (see page 3316)

System::TInterfacedObject::BeforeDestruction (see page 3346)

System::TObject::BeforeDestruction (see page 3358)

35.1.14.3.3 TAggregatedObject::QueryInterface Method

Implements the IInterface (see page 3502) System::TAggregatedObject::QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

Do not call the protected System::TAggregatedObject::QueryInterface method directly. System::TAggregatedObject::QueryInterface is called through IInterface (see page 3502) to obtain an interface pointer for the interface identified by the IID parameter. If the object supports the requested interface, it is returned in the Obj parameter and System::TAggregatedObject::QueryInterface returns S_OK (see page 3860). If the object does not support the interface, System::TAggregatedObject::QueryInterface returns E_NOINTERFACE (see page 3845).

If System::TAggregatedObject::QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

See Also

System::TAggregatedObject::_AddRef (see page 3316)

System::TInterfacedObject::_AddRef (see page 3345)

35.1.14.4 TAggregatedObject Properties

The properties of the TAggregatedObject class are listed here.

Public Properties

	Name	Description
	Controller (see page 3317)	Provides access to the controlling interface of the aggregate.

35.1.14.4.1 TAggregatedObject::Controller Property

Provides access to the controlling interface of the aggregate.

Pascal

```
property Controller: IInterface;
```

C++

```
__property IInterface Controller;
```

Description

System::TAggregatedObject::Controller is the interface reference of the aggregate. System::TAggregatedObject (see page 3313) is used as part of an aggregate that has a single controlling IInterface (see page 3502). The IInterface (see page 3502) methods that are implemented in aggregated objects are delegated to the System::TAggregatedObject::Controller.

When the aggregated object is created, its constructor is passed a controlling IInterface (see page 3502). System::TAggregatedObject::Controller is initialized to this IInterface (see page 3502) in the constructor.

See Also

System::TAggregatedObject::Create (see page 3315)

35.1.15 TClassHelperBase Class

Class Hierarchy

Pascal

```
TClassHelperBase = class(TInterfacedObject, IInterface);
```

C++

```
class TClassHelperBase : public TInterfacedObject, public IInterface;
```

File

System

Description

This is class System.TClassHelperBase.

35.1.15.1 TClassHelperBase Members

The following tables list the members exposed by TClassHelperBase.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Fields

	Name	Description
	FInstance (see page 3320)	This is FInstance, a member of class TClassHelperBase.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Create (see page 3319)	This is _Create, a member of class TClassHelperBase.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

35.1.15.2 TClassHelperBase._Create Constructor

Pascal

```
constructor _Create(Instance: TObject);
```

C++

```
__fastcall TClassHelperBase(TObject * Instance);
```

Description

This is _Create, a member of class TClassHelperBase.

35.1.15.3 TClassHelperBase Fields

The fields of the TClassHelperBase class are listed here.

Protected Fields

	Name	Description
	FInstance (see page 3320)	This is FInstance, a member of class TClassHelperBase.

35.1.15.3.1 TClassHelperBase.FInstance Field

Pascal

```
FInstance: TObject;
```

C++

```
TObject * FInstance;
```

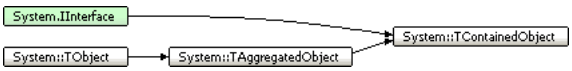
Description

This is FInstance, a member of class TClassHelperBase.

35.1.16 TContainedObject Class

System::TContainedObject implements the IInterface (see page 3502) interface as an inner object in an aggregate.

Class Hierarchy



Pascal

```
TContainedObject = class(TAggregatedObject, IInterface);
```

C++

```
class TContainedObject : public TAggregatedObject, public IInterface;
```

File

System.pas

Description

System::TContainedObject can be used as a base for classes that create inner, or contained, objects of an aggregate. In Delphi, use TComObject or its descendants to instantiate an outer object that supports aggregation.

- The following implementation rules apply to aggregatable (inner or contained) objects, and are supported by System::TContainedObject:
- When an object of its type is created, the creation succeeds only for a requested interface of type IInterface (see page 3502).
- The IInterface (see page 3502) methods _AddRef (see page 3316) and _Release (see page 3316) delegate to the controlling IInterface (see page 3502).
- QueryInterface (see page 3322) is implemented in System::TContainedObject only for interfaces implemented in the contained object.
- The reference count on the inner object is incremented in the containing object.

Note: In Delphi, System::TContainedObject is used as a base class for a connection point that must be an inner object in an aggregate.

Note: An aggregated object is an object that is composed of several interfaced objects. Each object implements its own behavior and interfaces, but all of the objects share the same reference count, which is that of the controller object. In the container pattern, the controller is the container object.

35.1.16.1 TContainedObject Members

The following tables list the members exposed by TContainedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_AddRef method.
	_Release (see page 3316)	Implements the IInterface (see page 3502) System::TAggregatedObject::_Release method.
V	QueryInterface (see page 3322)	Implements the IInterface (see page 3502) System::TContainedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3315)	Instantiates an aggregated object.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.

	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	Controller (see page 3317)	Provides access to the controlling interface of the aggregate.

35.1.16.2 TContainedObject Methods

The methods of the TContainedObject class are listed here.

Protected Methods

	Name	Description
V	QueryInterface (see page 3322)	Implements the IInterface (see page 3502) System::TContainedObject::QueryInterface method.

35.1.16.2.1 TContainedObject::QueryInterface Method

Implements the IInterface (see page 3502) System::TContainedObject::QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

Do not call the protected System::TContainedObject::QueryInterface method directly. System::TContainedObject::QueryInterface is called through IInterface (see page 3502) to obtain an interface pointer for the interface identified by the IID parameter. If the object supports the requested interface, it is returned in the Obj parameter and System::TInterfacedObject::QueryInterface (see page 3347) returns S_OK (see page 3860). If the object does not support the interface, System::TContainedObject::QueryInterface returns E_NOINTERFACE (see page 3845).

If System::TContainedObject::QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

QueryInterface (see page 3504)

35.1.17 TDateTime Class

System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.

Class Hierarchy

Pascal

```
TDateTime = class(TDateTimeBase);
```

C++

```
class TDateTime : public TDateTimeBase;
```

File

systdate.h

Description

System::TDateTime implements the Delphi System::TDateTime data type and the date/time runtime library routines that use the System::TDateTime data type.

The System::TDateTime class inherits a val data member declared as a double (see page 3340) that holds the date-time value. The integral part of a System::TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a System::TDateTime value is the time of day.

Following are some examples of System::TDateTime values and their corresponding dates and times:

0 12/30/1899 12:00 am

2.75 1/1/1900 6:00 pm

-1.25 12/29/1899 6:00 am

35065 1/1/1996 12:00 am

To find the fractional number of days between two dates, simply subtract the two values, unless one of the System::TDateTime values is negative. Similarly, to increment a date and time value by a certain fractional number of days, add the fractional number to the date and time value if the System::TDateTime value is positive.

When working with negative System::TDateTime values, computations must handle time portion separately. The fractional part reflects the fraction of a 24-hour day without regard to the sign of the System::TDateTime value. For example, 6:00 am on 12/29/1899 is –1.25, not –1 + 0.25, which would be –0.75. There are no System::TDateTime values between –1 and 0.

Note: Use only the operators declared by System::TDateTime. The compiler ignores any operators you overload yourself.

Warning: It is not possible to use System::TDateTime as a base class for inheriting. To add functionality to System::TDateTime, you must write a wrapper class.

Note: To utilize the C++ streaming operators (<< and >>) with Currency (see page 3235), you must use #include <iostream> before #include <systdate.h>. This occurs automatically if you include vcl.h, clx.h, or System.hpp. The following stream operators are defined:

ostream& operator << (ostream& os, const System::TDateTime& arg);

istream& operator >> (istream& is, System::TDateTime& arg);

35.1.17.1 TDateTime Members

The following tables list the members exposed by TDateTime.

Enumerations

	Name	Description
	TDateTimeFlag (see page 3327)	This is record System::TDateTime::TDateTimeFlag.

Public Data Members

	Name	Description
	Val (see page 3342)	This is Val, a member of class TDateTimeBase.

Public Methods

	Name	Description
	CurrentDate (see page 3328)	Returns the current date as a System::TDateTime::TDateTime (see page 3323) value.
	CurrentDateTime (see page 3328)	Returns the current date and time as a System::TDateTime::TDateTime (see page 3323) value.
	CurrentTime (see page 3328)	Returns the current time as a System::TDateTime::TDateTime (see page 3323) value.
	DateString (see page 3329)	Converts the date of the System::TDateTime::TDateTime (see page 3323) value to a string.
	DateTimeString (see page 3329)	Converts the System::TDateTime::TDateTime (see page 3323) value to a string.
	DayOfWeek (see page 3329)	Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 3323)
	DecodeDate (see page 3330)	Separates the System::TDateTime::TDateTime (see page 3323) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.
	DecodeTime (see page 3330)	Separates the System::TDateTime::TDateTime (see page 3323) value into hour, minute, second, and millisecond values and stores these values in the hour, min, sec, and msec parameters, respectively.
	FileDate (see page 3330)	Converts the date/time value to an OS date/time stamp.
	FileDateToDateTime (see page 3331)	Converts an OS timestamp value to System::TDateTime::TDateTime (see page 3323) value.
	FormatString (see page 3331)	Formats the System::TDateTime::TDateTime (see page 3323) object using the format given by format.
	TDateTime (see page 3325)	This is the overview for the TDateTime constructor overload.
	TimeString (see page 3333)	Converts the System::TDateTime::TDateTime (see page 3323) object to an AnsiString.

Public Operators

	Name	Description
	- (see page 3334)	This is the overview for the - operator overload.
	-- (see page 3334)	This is the overview for the -- operator overload.
	!= (see page 3335)	Compares two System::TDateTime::TDateTime (see page 3323) objects for inequality.
	+ (see page 3335)	This is the overview for the + operator overload.
	++ (see page 3336)	This is the overview for the ++ operator overload.
	+= (see page 3336)	This is the overview for the += operator overload.
	< (see page 3337)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than another specified System::TDateTime::TDateTime (see page 3323) value.
	<= (see page 3337)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.
	= (see page 3338)	This is the overview for the = operator overload.

	-= (see page 3338)	This is the overview for the -= operator overload.
	== (see page 3339)	Compares two System::TDateTime::TDateTime (see page 3323) objects for equality.
	> (see page 3339)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than another specified System::TDateTime::TDateTime (see page 3323) value.
	>= (see page 3340)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.
	double (see page 3340)	Converts the System::TDateTime::TDateTime (see page 3323) object to a double value.
	int (see page 3340)	Converts the System::TDateTime::TDateTime (see page 3323) object to an integer value.
	System::String (see page 3341)	Converts the System::TDateTime::TDateTime (see page 3323) object to a String.

35.1.17.2 TDateTime Constructor

This is the overview for the TDateTime constructor overload.

Overload List

	Name	Description
	TDateTime::TDateTime () (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (double) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (int) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (System::String&, TDateTimeFlag) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (TDateTime&) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (TDateTimeBase&) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short, unsigned short) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).
	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short, unsigned short, unsigned short, unsigned short, unsigned short) (see page 3325)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).

35.1.17.2.1 TDateTime::TDateTime Constructor ()

Creates and initializes an instance of System::TDateTime::TDateTime (see page 3323).

Pascal

```
constructor Create;
constructor Create(const src: TDateTimeBase&);
```

```
constructor Create(const src: TDateTime&);
constructor Create(const src: double);
constructor Create(const src: Integer);
constructor Create(const src: System::String&; flag: TDateTimeFlag = DateTime);
constructor Create(year: unsigned short; month: unsigned short; day: unsigned short);
constructor Create(hour: unsigned short; min: unsigned short; sec: unsigned short; msec:
unsigned short);
constructor Create(year: unsigned short; month: unsigned short; day: unsigned short; hour:
unsigned short; min: unsigned short; sec: unsigned short; msec: unsigned short);
```

C++

```
__fastcall TDateTime();
__fastcall TDateTime(const TDateTimeBase& src);
__fastcall TDateTime(const TDateTime& src);
__fastcall TDateTime(const double src);
__fastcall TDateTime(const int src);
__fastcall TDateTime(const System::String& src, TDateTimeFlag flag = DateTime);
__fastcall TDateTime(unsigned short year, unsigned short month, unsigned short day);
__fastcall TDateTime(unsigned short hour, unsigned short min, unsigned short sec, unsigned
short msec);
__fastcall TDateTime(unsigned short year, unsigned short month, unsigned short day, unsigned
short hour, unsigned short min, unsigned short sec, unsigned short msec);
```

Description

Use System::TDateTime::TDateTime (see page 3323) to instantiate a System::TDateTime::TDateTime (see page 3323) object.

When called with no arguments, the resulting System::TDateTime::TDateTime (see page 3323) object has a Val (see page 3701) data member of zero. This date and time corresponds to 12/30/1899 12:00 am.

When called with a System::TDateTime::TDateTime (see page 3323) object as the src parameter, the resulting object is a copy of src (the copy constructor).

When called with a System::TDateTime::TDateTimeBase (see page 3341) object as the src parameter, the resulting object has the same value as the src parameter. System::TDateTime::TDateTimeBase (see page 3341) is the base class for the System::TDateTime::TDateTime (see page 3323) type. It has a single member, a public Val (see page 3701) field that represents the value of the object.

When called with a double (see page 3340) or integer as the src parameter, the resulting object has the same value as the src parameter. The integral part of src is the number of days that have passed since 12/30/1899. The fractional part is the time of day, represented as a fraction of 24 hours.

When called with an AnsiString as the src parameter and a System::TDateTime::TDateTimeFlag (see page 3327) as the flag parameter, the resulting object's value is converted from the AnsiString. The flag parameter indicates whether the string contains a date, a time, or both. The default for the flag is DateTime.

When called with three unsigned shorts (as the year, month, and day parameters), the resulting object's value is assembled from the specified year, month, and day, with a time portion of 0 (midnight). The year must be between 1 and 9999. Valid month values are 1 through 12. Valid day values are 1 through 28, 29, 30, or 31, depending on the month value. For example, the possible day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the year value specifies a leap year.

When called with four unsigned shorts (as the hour, min, sec, and msec parameters), the resulting object's value represents a time based on the specified number of hours, minutes, seconds, and milliseconds past midnight. The date portion of the resulting value is 0 (12/30/1899). The hour must be between 0 and 23, the minute must be between 0 and 59, the second must be between 0 and 59, and the millisecond must be between 0 and 999.

Note: When the constructor calls for a conversion that can't be performed (an AnsiString that does not represent a date or time, or invalid year, month, day, hour, min, sec, or msec value), an EConvertError exception is thrown.

35.1.17.3 TDateTime Enumerations

The enumerations of the TDateTime class are listed here.

Enumerations

	Name	Description
	TDateTimeFlag (see page 3327)	This is record System::TDateTime::TDateTimeFlag.

35.1.17.3.1 System::TDateTime::TDateTimeFlag Enumeration

Pascal

```
TDateTimeFlag = (
  Date,
  Time,
  DateTime
);
```

C++

```
enum TDateTimeFlag {
  Date,
  Time,
  DateTime
};
```

File

systdate.h

Description

This is record System::TDateTime::TDateTimeFlag.

35.1.17.4 TDateTime Methods

The methods of the TDateTime class are listed here.

Public Methods

	Name	Description
	CurrentDate (see page 3328)	Returns the current date as a System::TDateTime::TDateTime (see page 3323) value.
	CurrentDateTime (see page 3328)	Returns the current date and time as a System::TDateTime::TDateTime (see page 3323) value.
	CurrentTime (see page 3328)	Returns the current time as a System::TDateTime::TDateTime (see page 3323) value.
	DateString (see page 3329)	Converts the date of the System::TDateTime::TDateTime (see page 3323) value to a string.
	DateTimeString (see page 3329)	Converts the System::TDateTime::TDateTime (see page 3323) value to a string.
	DayOfWeek (see page 3329)	Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 3323)
	DecodeDate (see page 3330)	Separates the System::TDateTime::TDateTime (see page 3323) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.
	DecodeTime (see page 3330)	Separates the System::TDateTime::TDateTime (see page 3323) value into hour, minute, second, and millisecond values and stores these values in the hour, min, sec, and msec parameters, respectively.
	FileDate (see page 3330)	Converts the date/time value to an OS date/time stamp.

	FileDateToDateTime (see page 3331)	Converts an OS timestamp value to System::TDateTime::TDateTime (see page 3323) value.
	FormatString (see page 3331)	Formats the System::TDateTime::TDateTime (see page 3323) object using the format given by format.
	TimeString (see page 3333)	Converts the System::TDateTime::TDateTime (see page 3323) object to an AnsiString.

35.1.17.4.1 TDateTime::CurrentDate Method

Returns the current date as a System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
function CurrentDate: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentDate();
```

Description

System::TDateTime::CurrentDate retrieves the current date and returns it as a new System::TDateTime::TDateTime (see page 3323) object with a 0 time value.

See Also

System::TDateTime::CurrentDateTime (see page 3328)

System::TDateTime::CurrentTime (see page 3328)

35.1.17.4.2 TDateTime::CurrentDateTime Method

Returns the current date and time as a System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
function CurrentDateTime: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentDateTime();
```

Description

System::TDateTime::CurrentDateTime retrieves the current date and time, and returns it as a new System::TDateTime::TDateTime (see page 3323) object.

See Also

System::TDateTime::CurrentTime (see page 3328)

System::TDateTime::CurrentDate (see page 3328)

35.1.17.4.3 TDateTime::CurrentTime Method

Returns the current time as a System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
function CurrentTime: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentTime();
```

Description

System::TDateTime::CurrentTime retrieves the current time and returns it as a new System::TDateTime::TDateTime (see page 3323) object with a 0 date value.

See Also

System::TDateTime::CurrentDateTime (see page 3328)

System::TDateTime::CurrentDate (see page 3328)

35.1.17.4.4 TDateTime::DateString Method

Converts the date of the System::TDateTime::TDateTime (see page 3323) value to a string.

Pascal

```
function DateString: System::String;
```

C++

```
__fastcall System::String DateString() const;
```

Description

System::TDateTime::DateString returns the value of the System::TDateTime::TDateTime (see page 3323) object as an AnsiString. The conversion uses the format specified by the ShortDateFormat global variable.

See Also

System::TDateTime::DateTimeString (see page 3329)

System::TDateTime::TimeString (see page 3333)

35.1.17.4.5 TDateTime::DateTimeString Method

Converts the System::TDateTime::TDateTime (see page 3323) value to a string.

Pascal

```
function DateTimeString: System::String;
```

C++

```
__fastcall System::String DateTimeString() const;
```

Description

System::TDateTime::DateTimeString returns an AnsiString object containing the date and time value (the Val (see page 3701) data member) of the System::TDateTime::TDateTime (see page 3323) object to a string. System::TDateTime::DateTimeString converts the System::TDateTime::TDateTime (see page 3323) value using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.

See Also

System::TDateTime::DateString (see page 3329)

System::TDateTime::TimeString (see page 3333)

35.1.17.4.6 TDateTime::DayOfWeek Method

Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 3323)

Pascal

```
function DayOfWeek: Integer;
```

C++

```
__fastcall int DayOfWeek() const;
```

Description

System::TDateTime::DayOfWeek returns an integer between 1 and 7. Sunday is treated as the first day of the week and Saturday as the seventh.

35.1.17.4.7 TDateTime::DecodeDate Method

Separates the System::TDateTime::TDateTime (see page 3323) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.

Pascal

```
procedure DecodeDate(var year: unsigned short; var month: unsigned short; var day: unsigned
short);
```

C++

```
__fastcall void DecodeDate(unsigned short* year, unsigned short* month, unsigned short* day)
const;
```

Description

Use System::TDateTime::DecodeDate() when you need to access the year, month, or day of a System::TDateTime::TDateTime (see page 3323) object's date portion.

35.1.17.4.8 TDateTime::DecodeTime Method

Separates the System::TDateTime::TDateTime (see page 3323) value into hour, minute, second, and millisecond values and stores these values in the hour, min, sec, and msec parameters, respectively.

Pascal

```
procedure DecodeTime(var hour: unsigned short; var min: unsigned short; var sec: unsigned
short; var msec: unsigned short);
```

C++

```
__fastcall void DecodeTime(unsigned short* hour, unsigned short* min, unsigned short* sec,
unsigned short* msec) const;
```

Description

Use System::TDateTime::DecodeTime() to access the hour, minute, second, or millisecond values of the System::TDateTime::TDateTime (see page 3323) object's time portion.

35.1.17.4.9 TDateTime::FileDate Method

Converts the date/time value to an OS date/time stamp.

Pascal

```
function FileDate: Integer;
```

C++

```
__fastcall int FileDate() const;
```

Description

Use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 3323) value to an OS date/time stamp. For example, use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 3323) value to a format that can be used as the Age parameter of FileSetDate. You may also need to use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 3323) so that it is compatible with the Time field of the TSearchRec structure used by the FindFirst and FindNext functions.

See Also

System::TDateTime::FileDateToDateTime (see page 3331)

FileSetDate (see page 4164)

TSearchRec (see page 4330)

35.1.17.4.10 TDateTime::FileDateToDateTime Method

Converts an OS timestamp value to System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
function FileDateToDateTime(fileDate: Integer): TDateTime; static;
```

C++

```
static __fastcall TDateTime FileDateToDateTime(int fileDate);
```

Description

A timestamp is a signed 32-bit integer, used by the OS to record information such as the date and time a file was modified. The precise format of a timestamp depends on the OS. Use System::TDateTime::FileDateToDateTime to convert a timestamp to a System::TDateTime::TDateTime (see page 3323) value.

For example, use System::TDateTime::FileDateToDateTime to convert the file timestamp returned by FileGetDate or FileAge. You may also need to use System::TDateTime::FileDateToDateTime to convert the Time field of the TSearchRec struct used by the FindFirst and FindNext functions.

See Also

FileGetDate (see page 4142)

FileAge (see page 4119)

TSearchRec (see page 4330)

35.1.17.4.11 TDateTime::FormatString Method

Formats the System::TDateTime::TDateTime (see page 3323) object using the format given by format.

Pascal

```
function FormatString(const format: System::String&): System::String;
```

C++

```
__fastcall System::String FormatString(const System::String& format) const;
```

Description

The following format specifiers are supported:

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames global variable.
ddddd	Displays the date using the format given by the ShortDateFormat global variable.
dddddd	Displays the date using the format given by the LongDateFormat global variable.
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec (see page 3550)) using the strings given by the ShortMonthNames global variable.
mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
t	Displays the time using the format given by the ShortTimeFormat global variable.
tt	Displays the time using the format given by the LongTimeFormat global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString global variable for any hour before noon, and the contents of the TimePMString global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator global variable.
:	Displays the time separator character given by the TimeSeparator global variable.
'xx'/"xx"	Characters enclosed in single or double (see page 3340) quotes are displayed as is, and do not affect formatting.

If the string given by the format parameter is empty, the System::TDateTime::TDateTime (see page 3323) value is formatted as if a c format specifier had been given.

35.1.17.4.12 TDateTime::TimeString Method

Converts the System::TDateTime::TDateTime (see page 3323) object to an AnsiString.

Pascal

```
function TimeString: System::String;
```

C++

```
__fastcall System::String TimeString() const;
```

Description

System::TDateTime::TimeString returns an AnsiString object containing the time value (the fractional portion of the Val (see page 3701) data member) of the System::TDateTime::TDateTime (see page 3323) object to a string. The conversion uses the format specified by the LongTimeFormat variable. Change the format of how the string is displayed by changing the value of one or more of the date/time formatting variables.

See Also

System::TDateTime::DateString (see page 3329)

System::TDateTime::DateTimeString (see page 3329)

35.1.17.5 TDateTime Operators

The operators of the TDateTime class are listed here.

Public Operators

	Name	Description
	- (see page 3334)	This is the overview for the - operator overload.
	-- (see page 3334)	This is the overview for the -- operator overload.
	!= (see page 3335)	Compares two System::TDateTime::TDateTime (see page 3323) objects for inequality.
	+ (see page 3335)	This is the overview for the + operator overload.
	++ (see page 3336)	This is the overview for the ++ operator overload.
	+= (see page 3336)	This is the overview for the += operator overload.
	< (see page 3337)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than another specified System::TDateTime::TDateTime (see page 3323) value.
	<= (see page 3337)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.
	= (see page 3338)	This is the overview for the = operator overload.
	-= (see page 3338)	This is the overview for the -= operator overload.
	== (see page 3339)	Compares two System::TDateTime::TDateTime (see page 3323) objects for equality.
	> (see page 3339)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than another specified System::TDateTime::TDateTime (see page 3323) value.
	>= (see page 3340)	Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.
	double (see page 3340)	Converts the System::TDateTime::TDateTime (see page 3323) object to a double value.
	int (see page 3340)	Converts the System::TDateTime::TDateTime (see page 3323) object to an integer value.
	System::String (see page 3341)	Converts the System::TDateTime::TDateTime (see page 3323) object to a String.

35.1.17.5.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	TDateTime::- (double) (see page 3334)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::- (int) (see page 3334)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::- (TDateTime&) (see page 3334)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::- (TDateTimeBase&) (see page 3334)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 3323) object.

35.1.17.5.1.1 TDateTime::- Operator (TDateTime&)

Subtracts a specified value from the System::TDateTime::TDateTime (see page 3323) object.

Pascal

```
operator -(const rhs: TDateTimeBase&);
operator -(const rhs: TDateTime&);
operator -(const rhs: double);
operator -(const rhs: Integer);
```

C++

```
__fastcall TDateTime operator -(const TDateTimeBase& rhs) const;
__fastcall TDateTime operator -(const TDateTime& rhs) const;
__fastcall TDateTime operator -(const double rhs) const;
__fastcall TDateTime operator -(const int rhs) const;
```

Description

Use the System::TDateTime (see page 3323)::- to subtract the value specified by the rhs operand from the System::TDateTime::TDateTime (see page 3323) object. The rhs operand represents the number of days (including fractional days) to subtract.

35.1.17.5.2 -- Operator

This is the overview for the -- operator overload.

Overload List

	Name	Description
	TDateTime::-- () (see page 3334)	Decrements the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.
	TDateTime::-- (int) (see page 3334)	Decrements the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.

35.1.17.5.2.1 TDateTime::-- Operator ()

Decrements the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.

Pascal

```
operator --;
operator --(: Integer);
```

C++

```
TDateTime& operator --();
TDateTime operator --(int);
```

Description

Use the unary System::TDateTime (see page 3323)::-- to decrement the value of the System::TDateTime::TDateTime (see page 3323) object by 1 day.

Use the binary System::TDateTime (see page 3323)::-- to decrement the value by the number of days specified by the integer operand.

35.1.17.5.3 TDateTime::!= Operator

Compares two System::TDateTime::TDateTime (see page 3323) objects for inequality.

Pascal

```
operator !=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator !=(const TDateTime& rhs) const;
```

Description

The != System::TDateTime (see page 3323)::!= returns true if the two objects do not have the same value, false otherwise.

35.1.17.5.4 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	TDateTime::+ (double) (see page 3335)	Adds a specified value to the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::+ (int) (see page 3335)	Adds a specified value to the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::+ (TDateTime&) (see page 3335)	Adds a specified value to the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::+ (TDateTimeBase&) (see page 3335)	Adds a specified value to the System::TDateTime::TDateTime (see page 3323) object.

35.1.17.5.4.1 TDateTime::+ Operator (TDateTime&)

Adds a specified value to the System::TDateTime::TDateTime (see page 3323) object.

Pascal

```
operator +(const rhs: TDateTimeBase&);
operator +(const rhs: TDateTime&);
operator +(const rhs: double);
operator +(const rhs: Integer);
```

C++

```
__fastcall TDateTime operator +(const TDateTimeBase& rhs) const;
__fastcall TDateTime operator +(const TDateTime& rhs) const;
__fastcall TDateTime operator +(const double rhs) const;
__fastcall TDateTime operator +(const int rhs) const;
```

Description

Use the + System::TDateTime (see page 3323)::+ to add the value specified by the rhs operand to the System::TDateTime::TDateTime (see page 3323) object. The rhs operand represents the number of days (including fractional days) to add.

35.1.17.5.5 ++ Operator

This is the overview for the ++ operator overload.

Overload List

	Name	Description
	TDateTime::++ () (see page 3336)	Increments the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.
	TDateTime::++ (int) (see page 3336)	Increments the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.

35.1.17.5.5.1 TDateTime::++ Operator ()

Increments the value of the System::TDateTime::TDateTime (see page 3323) object by a specified number of days.

Pascal

```
operator ++;
operator ++(: Integer);
```

C++

```
TDateTime& operator ++();
TDateTime operator ++(int);
```

Description

Use the unary ++ System::TDateTime (see page 3323)::++ to increment the value of the System::TDateTime::TDateTime (see page 3323) object by 1 day.

Use the binary ++ System::TDateTime (see page 3323)::++ to increment the value by the number of days specified by the integer operand.

35.1.17.5.6 += Operator

This is the overview for the += operator overload.

Overload List

	Name	Description
	TDateTime::+= (double) (see page 3337)	Increments the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.
	TDateTime::+= (int) (see page 3337)	Increments the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.

	TDateTime::+= (TDateTime&) (see page 3337)	Increments the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.
	TDateTime::+= (TDateTimeBase&) (see page 3337)	Increments the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.

35.1.17.5.6.1 TDateTime::+= Operator (TDateTime&)

Increments the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.

Pascal

```
operator +=(const rhs: TDateTimeBase&);
operator +=(const rhs: TDateTime&);
operator +=(const rhs: double);
operator +=(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator +=(const TDateTimeBase& rhs);
__fastcall TDateTime& operator +=(const TDateTime& rhs);
__fastcall TDateTime& operator +=(const double rhs);
__fastcall TDateTime& operator +=(const int rhs);
```

Description

Use the += System::TDateTime (see page 3323)::+= to add to the value specified by rhs to this System::TDateTime::TDateTime (see page 3323) value. The rhs operand represents the number of days (including fractional days) to add.

35.1.17.5.7 TDateTime::< Operator

Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than another specified System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
operator <(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator <(const TDateTime& rhs) const;
```

Description

The < System::TDateTime (see page 3323)::< returns true if this System::TDateTime::TDateTime (see page 3323) object has a value (Val (see page 3701) data member) less than that of the object specified by rhs, and false otherwise.

35.1.17.5.8 TDateTime::<= Operator

Tests whether this System::TDateTime::TDateTime (see page 3323) value is less than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
operator <=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator <=(const TDateTime& rhs) const;
```

Description

The <= System::TDateTime (see page 3323)::<= returns true if this System::TDateTime::TDateTime (see page 3323) object

has a value (Val (see page 3701) data member) less than or equal to that of the object specified by rhs, and false otherwise.

35.1.17.5.9 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	TDateTime::= (double) (see page 3338)	Assigns the value of the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::= (int) (see page 3338)	Assigns the value of the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::= (TDateTime&) (see page 3338)	Assigns the value of the System::TDateTime::TDateTime (see page 3323) object.
	TDateTime::= (TDateTimeBase&) (see page 3338)	Assigns the value of the System::TDateTime::TDateTime (see page 3323) object.

35.1.17.5.9.1 TDateTime::= Operator (TDateTime&)

Assigns the value of the System::TDateTime::TDateTime (see page 3323) object.

Pascal

```
operator =(const rhs: TDateTimeBase&);
operator =(const rhs: TDateTime&);
operator =(const rhs: double);
operator =(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator =(const TDateTimeBase& rhs);
__fastcall TDateTime& operator =(const TDateTime& rhs);
__fastcall TDateTime& operator =(const double rhs);
__fastcall TDateTime& operator =(const int rhs);
```

Description

The assignment System::TDateTime (see page 3323)::= assigns the value of the rhs operand to the System::TDateTime::TDateTime (see page 3323) object. The assignment System::TDateTime (see page 3323)::= can take

a double (see page 3340) or integer value, which is assigned to the System::TDateTime::TDateTime (see page 3323) object such that the integral part of rhs is the number of days that have passed since 12/30/1899 and the fractional part is the time of day, represented as a fraction of 24 hours.

a System::TDateTime::TDateTimeBase (see page 3341) or System::TDateTime::TDateTime (see page 3323) object, whose value is assigned to the System::TDateTime::TDateTime (see page 3323) object. (Note that System::TDateTime::TDateTimeBase (see page 3341) is the base class for the System::TDateTime::TDateTime (see page 3323) class. It has a single member, a public Val (see page 3701) field that represents the value of the object).

35.1.17.5.10 -= Operator

This is the overview for the -= operator overload.

Overload List

	Name	Description
	TDateTime::-= (double) (see page 3339)	Decrements the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.
	TDateTime::-= (int) (see page 3339)	Decrements the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.
	TDateTime::-= (TDateTime&) (see page 3339)	Decrements the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.
	TDateTime::-= (TDateTimeBase&) (see page 3339)	Decrements the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.

35.1.17.5.10.1 TDateTime::-= Operator (TDateTime&)

Decrements the value of this System::TDateTime::TDateTime (see page 3323) object by a specified value.

Pascal

```
operator -=(const rhs: TDateTimeBase&);
operator -=(const rhs: TDateTime&);
operator -=(const rhs: double);
operator -=(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator -=(const TDateTimeBase& rhs);
__fastcall TDateTime& operator -=(const TDateTime& rhs);
__fastcall TDateTime& operator -=(const double rhs);
__fastcall TDateTime& operator -=(const int rhs);
```

Description

Use the -= System::TDateTime (see page 3323)::-= to subtract the value specified by rhs from this System::TDateTime::TDateTime (see page 3323) value. The rhs operand represents the number of days (including fractional days) to subtract.

35.1.17.5.11 TDateTime::== Operator

Compares two System::TDateTime::TDateTime (see page 3323) objects for equality.

Pascal

```
operator ==(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator ==(const TDateTime& rhs) const;
```

Description

The == System::TDateTime (see page 3323)::== returns true if the two objects have the same value, false otherwise.

35.1.17.5.12 TDateTime::> Operator

Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than another specified System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
operator >(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator >(const TDateTime& rhs) const;
```

Description

The > System::TDateTime (see page 3323)::> returns true if this System::TDateTime::TDateTime (see page 3323) object has a value (Val (see page 3701) data member) greater than that of the object specified by rhs, and false otherwise.

35.1.17.5.13 TDateTime::>= Operator

Tests whether this System::TDateTime::TDateTime (see page 3323) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 3323) value.

Pascal

```
operator >=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator >=(const TDateTime& rhs) const;
```

Description

The >= System::TDateTime (see page 3323)::>= returns true if this System::TDateTime::TDateTime (see page 3323) object has a value (Val (see page 3701) data member) greater than or equal to that of the object specified by rhs, and false otherwise.

35.1.17.5.14 TDateTime::double Operator

Converts the System::TDateTime::TDateTime (see page 3323) object to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

The double conversion System::TDateTime::double returns a double that represents this System::TDateTime::TDateTime (see page 3323) object. The integral part of the double is the number of days that have passed since 12/30/1899. The fractional part is the time of day, represented as a fraction of 24 hours.

See Also

System::TDateTime::TDateTime (see page 3325)

35.1.17.5.15 TDateTime::int Operator

Converts the System::TDateTime::TDateTime (see page 3323) object to an integer value.

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

The int conversion System::TDateTime::int returns an int that is the integer conversion of the date portion of this System::TDateTime::TDateTime (see page 3323) object. The resulting integer is the number of days that have passed since

12/30/1899.

See Also

System::TDateTime::TDateTime (see page 3325)

35.1.17.5.16 TDateTime::System::String Operator

Converts the System::TDateTime::TDateTime (see page 3323) object to a String.

Pascal

```
operator System::String;
```

C++

```
__fastcall operator System::String() const;
```

Description

The String conversion System::TDateTime::System::String returns a String object that is the string conversion of this System::TDateTime (see page 3323) object. The conversion uses the format specified by the LongTimeFormat global variable of the System::TDateTime::TDateTime (see page 3323) formatting variables. Change the format of the string display by changing the values of some of the date and time variables.

See Also

System::TDateTime::DateTimeString (see page 3329)

35.1.18 TDateTimeBase Class

Class Hierarchy

Pascal

```
TDateTimeBase = class;
```

C++

```
class TDateTimeBase;
```

File

systdate.h

Description

This is class System::TDateTimeBase.

35.1.18.1 TDateTimeBase Members

The following tables list the members exposed by TDateTimeBase.

Public Data Members

	Name	Description
	Val (see page 3342)	This is Val, a member of class TDateTimeBase.

35.1.18.2 TDateTimeBase Data Members

The data members of the TDateTimeBase class are listed here.

Public Data Members

	Name	Description
	Val (see page 3342)	This is Val, a member of class TDateTimeBase.

35.1.18.2.1 TDateTimeBase::Val Data Member

Pascal

```
Val: double;
```

C++

```
double Val;
```

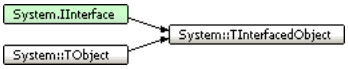
Description

This is Val, a member of class TDateTimeBase.

35.1.19 TInterfacedObject Class

System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 3502) implementation.

Class Hierarchy



Pascal

```
TInterfacedObject = class(TObject, IInterface);
```

C++

```
class TInterfacedObject : public TObject, public IInterface;
```

File

System.pas

Description

System::TInterfacedObject is a thread-safe base class for Delphi classes that support interfaces. System::TInterfacedObject provides basic reference-counting functionality that makes its descendant classes useful in both Delphi and C++ code.

Note: In Delphi, variables declared to be of type System::TInterfacedObject have dynamic-binding, meaning that an instance of a descendant class can be assigned to that variable at runtime. This is because System::TInterfacedObject implements System::TInterfacedObject::QueryInterface (see page 3347), which is called at runtime to query whether the instantiated object supports the requested interface. If it does, then the descendant object is successfully assigned to the variable. Without System::TInterfacedObject::QueryInterface (see page 3347) support, such an assignment would produce a compile-time error.

Note: In Delphi, a descendant of System::TInterfacedObject does not have a class factories or a CLSID. Thus it cannot be instantiated except by calling a constructor.

Note: System::TInterfacedObject does not implement the methods of the C++ version of IUnknown (see page 3756) or IInterface (see page 3502). This is not a problem when using C++ wrappers for System::TInterfacedObject descendants that are written in Delphi. However, if you are creating C++ descendants of System::TInterfacedObject, you must provide your own implementation of IUnknown (see page 3756). For information on how to do this, see Creating classes that support IUnknown (see page 3756) (supplied with C++ products only).

35.1.19.1 TInterfacedObject Members

The following tables list the members exposed by TInterfacedObject.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

35.1.19.2 TInterfacedObject Data Members

The data members of the TInterfacedObject class are listed here.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

35.1.19.2.1 TInterfacedObject::FRefCount Data Member

Pascal

```
FRefCount: Integer;
```

C++

```
Integer FRefCount;
```

Description

This is FRefCount, a member of class TInterfacedObject.

35.1.19.3 TInterfacedObject Methods

The methods of the TInterfacedObject class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.

35.1.19.3.1 TInterfacedObject::_AddRef Method

Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__stdcall Integer _AddRef();
```

Description

Do not call the protected System::TInterfacedObject::_AddRef method directly. System::TInterfacedObject::_AddRef is called through the interface to indicate that another object is using the interfaced object's interface pointer. When the other object is through with the interface, it calls System::TInterfacedObject::_Release (see page 3345) through the same interface. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

System::TInterfacedObject::_AddRef increments the System::TInterfacedObject::RefCount (see page 3347) property.

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TInterfacedObject::_Release (see page 3345)

35.1.19.3.2 TInterfacedObject::_Release Method

Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__stdcall Integer _Release();
```

Description

Do not call the protected _System::TInterfacedObject::_Release method directly. _System::TInterfacedObject::_Release is called through the IInterface (see page 3502) interface to indicate that another object is through with the interfaced object's interface pointer. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

_System::TInterfacedObject::_Release decrements the System::TInterfacedObject::RefCount (see page 3347) property.

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TInterfacedObject::_AddRef (see page 3345)

System::TInterfacedObject::BeforeDestruction (see page 3346)

35.1.19.3.3 TInterfacedObject::AfterConstruction Method

Responds after the last constructor executes.

Pascal

```
procedure AfterConstruction; virtual; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TInterfacedObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

When an instance of System::TInterfacedObject (see page 3342) is allocated, System::TInterfacedObject::RefCount (see page 3347) is incremented to prevent its destruction while processing the constructor. System::TInterfacedObject::AfterConstruction decrements that System::TInterfacedObject::RefCount (see page 3347) to re-establish the correct reference count after all constructors have executed.

See Also

System::TInterfacedObject::BeforeDestruction (see page 3346)

System::TInterfacedObject::NewInstance (see page 3346)

System::TInterfacedObject::RefCount (see page 3347)

35.1.19.3.4 TInterfacedObject::BeforeDestruction Method

Checks that the reference count is zero before allowing the interfaced object to be destroyed.

Pascal

```
procedure BeforeDestruction; virtual; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

System::TInterfacedObject::BeforeDestruction is called automatically immediately before the interfaced object's destructor. It checks that the reference count is zero, and, if it is not, raises an exception.

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TObject::Free (see page 3372)

35.1.19.3.5 TInterfacedObject::NewInstance Method

Allocates memory for each instance of an interfaced object.

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
TObject NewInstance();
```

Description

All constructors call System::TInterfacedObject::NewInstance automatically. System::TInterfacedObject::NewInstance calls System::TObject::InstanceSize (see page 3377) to determine how much memory to allocate from the heap to contain a particular instance. Do not call System::TInterfacedObject::NewInstance directly.

System::TInterfacedObject (see page 3342) overrides System::TInterfacedObject::NewInstance to increment the reference count when a new instance is created. This prevents any constructor from accidentally deleting the instance due to a

System::TInterfacedObject::RefCount (see page 3347) of zero. The System::TInterfacedObject::AfterConstruction (see page 3345) method decrements the value of System::TInterfacedObject::RefCount (see page 3347) after all constructors have executed.

See Also

System::TInterfacedObject::RefCount (see page 3347)

System::TObject::NewInstance (see page 3379)

System::TObject::InstanceSize (see page 3377)

System::TInterfacedObject::AfterConstruction (see page 3345)

35.1.19.3.6 TInterfacedObject::QueryInterface Method

Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

Do not call the protected System::TInterfacedObject::QueryInterface method directly. System::TInterfacedObject::QueryInterface is called through IInterface (see page 3502) to obtain an interface pointer for the interface identified by the IID parameter. If the object supports the requested interface, it is returned in the Obj parameter and System::TInterfacedObject::QueryInterface returns S_OK (see page 3860). If the object does not support the interface, System::TInterfacedObject::QueryInterface returns E_NOINTERFACE (see page 3845).

If System::TInterfacedObject::QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

See Also

System::TInterfacedObject::_AddRef (see page 3345)

35.1.19.4 TInterfacedObject Properties

The properties of the TInterfacedObject class are listed here.

Public Properties

	Name	Description
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

35.1.19.4.1 TInterfacedObject::RefCount Property

Indicates the number of interface pointers currently dependent upon the object.

Pascal

```
property RefCount: Integer;
```

C++

```
__property Integer RefCount;
```

Description

System::TInterfacedObject::RefCount defines the lifetime of the object. When System::TInterfacedObject::RefCount is zero, the object is destroyed.

System::TInterfacedObject::RefCount is incremented by calls to the _AddRef (see page 3345) method and decremented by the _Release (see page 3345) method.

Note: If the destructor is called on a System::TInterfacedObject (see page 3342) descendant that is not fully constructed (an exception was raised in the constructor), then System::TInterfacedObject::RefCount will have a value of 1. Otherwise, System::TInterfacedObject::RefCount will be zero.

35.1.20 TMetaClass Class

System::TMetaClass is the C++ representation of the Delphi class-reference type.

Class Hierarchy

Pascal

```
TMetaClass = class;
```

C++

```
class TMetaClass;
```

File

systobj.h

Description

System::TMetaClass allows operations to be performed directly on classes. This contrasts with class types, which can be instantiated as objects and which allow operations to be performed on those instances. The System::TMetaClass for a given class can be acquired by using the __classid keyword extension.

A variable of type System::TMetaClass can be NULL, which indicates that the variable does not currently reference a class.

Every class inherits a method function called ClassType, which returns a reference to the class of an object. The type of the value returned by ClassType is TClass (see page 3785) (System::TMetaClass*), which is a pointer to a System::TMetaClass.

The methods of System::TMetaClass correspond to the static methods of TObject (see page 3354). They have the same functionality but differ in parameters. Whereas the TObject (see page 3354) methods take a TClass (see page 3785) (System::TMetaClass*) as the first parameter, this parameter is implicit in the System::TMetaClass methods.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
#include <memory>       //for STL auto_ptr class

TMetaClass *MetaClass;
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<TClassFinder> myClassFinder(new TClassFinder(MetaClass, False));
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(Graphics::TBitmap); // bmp
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TMetafile); // emf
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TShape);  // nographic extension
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TImage); // nographic extension
  RegisterClasses(&MetaClass, 0);
}
```

System::TObject (see page 3354)

Class References

35.1.21 TMonitor Record

TMonitor provides methods for synchronizing the access of several threads to a single object.

Pascal

```
TMonitor = record
end;
```

C++

```
struct TMonitor {
public:
  struct TWaitingThread {
  };
};
```

File

System

Description

Use the class methods of TMonitor to synchronize the threads' access to resources in a multithreaded application.

See Also

Enter (see page 3350)

Exit (see page 3351)

Wait (see page 3353)

Pulse (see page 3352)

35.1.21.1 TMonitor Members

The following tables list the members exposed by TMonitor.

Public Methods

	Name	Description
	Enter (see page 3350)	This is the overview for the Enter method overload.
	Exit (see page 3351)	Releases a lock of the calling thread on the specified object.
	Pulse (see page 3352)	Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases the object.
	PulseAll (see page 3352)	Signals all threads in the waiting queue that one of them will be able to lock the specified object as soon as the calling thread releases the object.
	SetSpinCount (see page 3353)	SetSpinCount sets the number of times that Enter (see page 3350) attempts to lock the specified object.
	TryEnter (see page 3353)	Attempts to lock the specified object, so that only the calling thread is able to access the object.
	Wait (see page 3353)	Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.

35.1.21.2 TMonitor Methods

The methods of the TMonitor class are listed here.

Public Methods

	Name	Description
	Enter (see page 3350)	This is the overview for the Enter method overload.
	Exit (see page 3351)	Releases a lock of the calling thread on the specified object.
	Pulse (see page 3352)	Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases the object.
	PulseAll (see page 3352)	Signals all threads in the waiting queue that one of them will be able to lock the specified object as soon as the calling thread releases the object.
	SetSpinCount (see page 3353)	SetSpinCount sets the number of times that Enter (see page 3350) attempts to lock the specified object.
	TryEnter (see page 3353)	Attempts to lock the specified object, so that only the calling thread is able to access the object.
	Wait (see page 3353)	Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.

35.1.21.2.1 Enter Method

This is the overview for the Enter method overload.

Overload List

	Name	Description
	TMonitor.Enter (TObject) (see page 3350)	Prohibits the access of all other threads but the calling one to the specified object.
	TMonitor.Enter (TObject, Cardinal) (see page 3351)	Prohibits the access of all other threads but the calling one to the specified object.

35.1.21.2.1.1 TMonitor.Enter Method (TObject)

Prohibits the access of all other threads but the calling one to the specified object.

Pascal

```
class procedure Enter(AObject: TObject); overload; static;
```

C++

```
static __fastcall Enter(TObject * AObject);
```

Description

Use the Enter method to prohibit `AObject` from being accessed by threads, other than the calling one.

Before attempting to lock the specified object, Enter tests whether the thread that is currently locking the object, if any, has made an equal number of calls to Enter and to Exit (see page 3351). If not, the calling thread is blocked from accessing the object until the previous thread releases it.

The Enter function attempts to lock the specified object for the amount of time designated by the `Timeout` parameter. If the lock attempt is successful, Enter returns True, otherwise it returns False.

See Also

TryEnter (see page 3353)

Exit (see page 3351)

TMonitor (see page 3349)

35.1.21.2.1.2 TMonitor.Enter Method (TObject, Cardinal)

Prohibits the access of all other threads but the calling one to the specified object.

Pascal

```
class function Enter(AObject: TObject; Timeout: Cardinal): Boolean; overload; static;
```

C++

```
static __fastcall Boolean Enter(TObject * AObject, unsigned Timeout);
```

Description

Use the Enter method to prohibit `AObject` from being accessed by threads, other than the calling one.

Before attempting to lock the specified object, Enter tests whether the thread that is currently locking the object, if any, has made an equal number of calls to Enter and to Exit (see page 3351). If not, the calling thread is blocked from accessing the object until the previous thread releases it.

The Enter function attempts to lock the specified object for the amount of time designated by the `Timeout` parameter. If the lock attempt is successful, Enter returns True, otherwise it returns False.

See Also

TryEnter (see page 3353)

Exit (see page 3351)

TMonitor (see page 3349)

35.1.21.2.2 TMonitor.Exit Method

Releases a lock of the calling thread on the specified object.

Pascal

```
class procedure Exit(AObject: TObject); overload; static;
```

C++

```
static __fastcall Exit(TObject * AObject);
```

Description

Use the Exit method to release a lock of the calling thread on `AObject`, which is also owned by the thread. The object is released from all the locks of the calling thread as soon as the number of the thread's calls to Enter (see page 3350).

See Also

Enter (see page 3350)

TMonitor (see page 3349)

35.1.21.2.3 TMonitor.Pulse Method

Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases the object.

Pascal

```
class procedure Pulse(AObject: TObject); overload; static;
```

C++

```
static __fastcall Pulse(TObject * AObject);
```

Description

The Pulse method notifies the next thread in the waiting queue that it can move to the ready queue. Thus, as soon as the calling thread releases the lock on `AObject`, the next thread in the ready queue will lock `AObject`.

See Also

PulseAll (see page 3352)

TMonitor (see page 3349)

35.1.21.2.4 TMonitor.PulseAll Method

Signals all threads in the waiting queue that one of them will be able to lock the specified object as soon as the calling thread releases the object.

Pascal

```
class procedure PulseAll(AObject: TObject); overload; static;
```

C++

```
static __fastcall PulseAll(TObject * AObject);
```

Description

The PulseAll method notifies all threads in the waiting queue that one of them can move to the ready queue. As soon as the calling thread releases the lock on `AObject`, the first thread in the ready queue will lock `AObject`.

See Also

Pulse (see page 3352)

TMonitor (see page 3349)

35.1.21.2.5 TMonitor.SetSpinCount Method

SetSpinCount sets the number of times that Enter (see page 3350) attempts to lock the specified object.

Pascal

```
class procedure SetSpinCount(AObject: TObject; ASpinCount: Integer); static;
```

C++

```
static __fastcall SetSpinCount(TObject * AObject, int ASpinCount);
```

Description

Use SetSpinCount to set the number of attempts `ASpinCount` that Enter (see page 3350) makes trying to lock `AObject`.

See Also

Enter (see page 3350)

TMonitor (see page 3349)

35.1.21.2.6 TMonitor.TryEnter Method

Attempts to lock the specified object, so that only the calling thread is able to access the object.

Pascal

```
class function TryEnter(AObject: TObject): Boolean; overload; static;
```

C++

```
static __fastcall Boolean TryEnter(TObject * AObject);
```

Description

The TryEnter function attempts to lock the object given as parameter, so that only the calling thread can access the object.

TryEnter returns True if it manages to lock the object, or False otherwise.

As opposed to the Enter (see page 3350) method, TryEnter does not block the calling thread if the given object is currently owned by other threads.

See Also

Enter (see page 3350)

TMonitor (see page 3349)

35.1.21.2.7 TMonitor.Wait Method

Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.

Pascal

```
class function Wait(AObject: TObject; Timeout: Cardinal): Boolean; overload; static;
```

C++

```
static __fastcall Boolean Wait(TObject * AObject, unsigned Timeout);
```

Description

Use Wait to drop the lock on the specified object and also to put the calling thread in the waiting queue for the amount of time specified in the `Timeout` parameter. Hence, the calling thread is blocked until it is again able to lock `AObject`.

See Also

TMonitor (see page 3349)

35.1.22 TObject Class

System::TObject is the ultimate ancestor of all objects and components.

Class Hierarchy

Pascal

```
TObject = class;
```

C++

```
class TObject;
```

File

System.pas

Description

System::TObject encapsulates fundamental behavior common to objects by introducing methods that:

- Create (see page 3355), maintain and destroy instances of the object by allocating, initializing, and freeing required memory.
- Respond when object instances are created or destroyed. return class-type and instance information on an object and runtime type information (RTTI) about its published properties.
- Support message handling.
- Support interfaces that the object implements.

Use System::TObject as an immediate base class when declaring simple objects that do not need to persist (are not saved and reloaded) and that do not need to be assigned to other objects.

Much of the capability of objects is established by methods that System::TObject introduces. Many of these methods are used internally by IDEs and are not intended for users to call directly. Others are overridden in descendant objects that have more complex behavior.

Although System::TObject is the based object of a component framework, not all objects are components. All component classes are descended from TComponent.

Note: System::TObject is never directly instantiated. Although it does not use programming language features that prevent instantiation, System::TObject is an abstract class.

VCL Overview

35.1.22.1 TObject Members

The following tables list the members exposed by TObject.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

35.1.22.2 TObject::Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
Create();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject (see page 3354) allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3356)

System::TObject::Free (see page 3372)

35.1.22.3 TObject::Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; virtual;
```

C++

```
virtual Destroy();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free (see page 3372) instead. Free (see page 3372) verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject (see page 3354) deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free (see page 3372) on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free (see page 3372) provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

35.1.22.4 TObject Methods

The methods of the TObject class are listed here.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.

	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

35.1.22.4.1 TObject::AfterConstruction Method

Responds after the last constructor has executed.

Pascal

```
procedure AfterConstruction; virtual;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

The System::TObject::AfterConstruction method implemented in System::TObject (see page 3354) does nothing. Override this method when creating a class that takes some action after the object is created. For example, TCustomForm overrides System::TObject::AfterConstruction to generate an OnCreate event.

See Also

System::TObject::BeforeDestruction (see page 3358)

OnCreate

System::TObject::Create (see page 3355)

35.1.22.4.2 TObject::BeforeDestruction Method

Responds before the first destructor executes.

Pascal

```
procedure BeforeDestruction; virtual;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

System::TObject::BeforeDestruction is called automatically before the object's first destructor executes. Do not call it explicitly in your applications.

The System::TObject::BeforeDestruction method implemented in System::TObject (see page 3354) does nothing. Override this method when creating a class that takes some action before the object is destroyed. For example, TCustomForm overrides System::TObject::BeforeDestruction to generate an OnDestroy event.

Note: System::TObject::BeforeDestruction is not called when the object is destroyed before it is fully constructed. That is, if the object's constructor raises an exception, the destructor is called to dispose of the object, but System::TObject::BeforeDestruction is not called.

See Also

System::TObject::AfterConstruction (see page 3357)

OnDestroy

System::TObject::Destroy (see page 3356)

35.1.22.4.3 TObject::ClassInfo Method

Returns a pointer to the runtime type information (RTTI) table for the object type.

Pascal

```
class function ClassInfo: Pointer;
```

C++

```
Pointer ClassInfo();
```

Description

System::TObject::ClassInfo provides access to the RTTI table for a given object type.

Note: The format of the RTTI table is subject to change. Applications should use the other RTTI methods provided by System::TObject (see page 3354); these provide easy, consistent access to RTTI data.

Note: Some classes do not provide runtime type information. For these classes, System::TObject::ClassInfo returns nil (Delphi) or NULL (C++). All classes descended from TPersistent do provide runtime type information.

Note: The Delphi compiler does not provide RTTI by default. Most classes implemented in Delphi that need to provide RTTI are descended from TPersistent. If your Delphi class needs RTTI but not the full functionality of TPersistent, compile the code with the $M switch.

Note: The C++ compiler provides RTTI by default. This feature can be disabled as project option and selectively re-enabled using the __rtti keyword.

See Also

System::TObject::ClassType (see page 3364)

System::TObject::ClassName (see page 3359)

System::TObject::ClassParent (see page 3361)

System::TObject::FieldAddress (see page 3372)

System::TObject::MethodAddress (see page 3378)

System::TObject::InstanceSize (see page 3377)

System::TObject::MethodName (see page 3379)

System::TObject::InheritsFrom (see page 3376)

35.1.22.4.4 TObject::ClassName Method

Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

Pascal

```
class function ClassName: string;
```

C++

```
string ClassName();
```

Description

Use System::TObject::ClassName to obtain the class name from an object instance or class reference. This is useful for differentiating object instances that are assigned to a variable that has the type of an ancestor class.

Note: In C++ code, call System::TObject::ClassName as a method to obtain an object's class name. Use the global static function to obtain the class name from a metaclass object.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();
  while (ClassRef != NULL)
  {
    ListBox1->Items->Add(ClassRef->ClassName());
    ClassRef = ClassRef->ClassParent();
  };
}
/*
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
```

```
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
To run this example, add the example code to a new project.
The example code dynamically creates a TCoolbar and three
TCoolBand objects populated with a windowed control in each
TCoolBand.
*/
void AddBands(TCoolBar *CoolBar, TList *Objects)
{
  TControl *pCurrent;
  for (int i = 0; i < Objects->Count; i++)
  {
    pCurrent = reinterpret_cast<TControl *>(Objects->Items[i]);
    // only add windowed controls to the coolbar
    if (dynamic_cast<TWinControl *>(pCurrent) != NULL)
    {
      // Placing the control onto the CoolBar
      // causes the TCoolBar object to create a TCoolBand
      // and place the control within the band.
      pCurrent->Parent = CoolBar;   // This statement increments CoolBar->Bands->Count.
      // Get the reference of the TCoolBand just created and assign text.
      String S = pCurrent->ClassName();
      CoolBar->Bands->Items[CoolBar->Bands->Count - 1]->Text = S;
    }
  }
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TCoolBar *CoolBar = new TCoolBar(this); // The Ownder (Form1) will clean this up.
  CoolBar->Parent = this;
  CoolBar->Align = alTop;
  std::auto_ptr<TList> List(new TList);
  try
  {
    TControl *Control;
    Control = new TButton(CoolBar); // The Ownder (CoolBar) will clean this up.
    List->Add(Control);
    Control = new TCheckBox(CoolBar); // The Ownder (CoolBar) will clean this up.
    List->Add(Control);
    Control = new TEdit(CoolBar); // The Ownder (CoolBar) will clean this up.
    List->Add(Control);
    AddBands(CoolBar, List.get());
  }
  catch (...)
  {
    ShowMessage("Some objects could not be added to Coolband");
  }
}
```

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
    ClassRef := ClassRef.ClassParent;
  end;
end;
{
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
}
```

System::TObject::ClassType (see page 3364)

35.1.22.4.5 TObject::ClassNameIs Method

Determines whether an object is of a specific type.

Pascal

```
class function ClassNameIs(const Name: string): Boolean;
```

C++

```
Boolean ClassNameIs(const string Name);
```

Description

System::TObject::ClassNameIs determines whether an object instance or class reference has a class name that matches a specified string. This is useful to query objects across modules or shared libraries.

Note: In C++ code, call System::TObject::ClassNameIs as a method to compare an object's class name. Use the global static function to compare the class name from a metaclass object.

See Also

System::TObject::ClassName (see page 3359)

System::TObject::InheritsFrom (see page 3376)

35.1.22.4.6 TObject::ClassParent Method

Returns the type of the immediate ancestor of a class.

Pascal

```
class function ClassParent: TClass;
```

C++

```
TClass ClassParent();
```

Description

System::TObject::ClassParent returns the name of the parent class for an object instance or class reference. For System::TObject (see page 3354), System::TObject::ClassParent returns nil (Delphi) or NULL (C++).

Avoid using System::TObject::ClassParent in application code.

Note: In Delphi code, use the is or as operators instead of System::TObject::ClassParent.

Note: In C++ code, use a dynamic cast or the System::TObject::InheritsFrom (see page 3376) method instead of System::TObject::ClassParent.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();
  while (ClassRef != NULL)
  {
    ListBox1->Items->Add(ClassRef->ClassName());
    ClassRef = ClassRef->ClassParent();
  };
}
/*
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
    for (int i = 0; i < ComponentCount; i++)
      ListBox1->Items->InsertObject(0,
                                    Components[i]->Name,
                                    dynamic_cast<TObject *>(Components[i]));
  }

  void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
        TShiftState Shift, int X, int Y)
  {
    if (Button == mbRight)
    {
      TClass ClassRef;
      int Index = ListBox1->ItemAtPos(Point(X,Y), true);
      // only components that are controls have a position
      // make sure the component is a control
      for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
           ClassRef != NULL;
           ClassRef = ClassRef->ClassParent())
        if (String(ClassRef->ClassName()) == "TControl")
        {
          TControl *TheObject = dynamic_cast<TControl *>(ListBox1->Items->Objects[Index]);
          StatusBar1->SimpleText =
            TheObject->Name + " is at (" +
            IntToStr(TheObject->Left) + ", " +
            IntToStr(TheObject->Top) + ")";
          break;
        }
      if (ClassRef == NULL) // if it wasn't a control
        MessageBeep(0);
    }
  }
```

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
    ClassRef := ClassRef.ClassParent;
  end;
end;
{
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
}
```

35.1.22.4.7 TObject::ClassType Method

Returns the class reference for the object's class.

Pascal

```
function ClassType: TClass;
```

C++

```
__fastcall TClass ClassType();
```

Description

Note: System::TObject::ClassType dynamically determines the type of an object and returns its class reference, or metaclass.

Avoid using System::TObject::ClassType in application code.

Note: In Delphi code, use the is or as operators instead of System::TObject::ClassType.

Note: In C++ code, use a dynamic cast or the System::TObject::InheritsFrom (see page 3376) method instead of System::TObject::ClassType.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();
  while (ClassRef != NULL)
  {
    ListBox1->Items->Add(ClassRef->ClassName());
    ClassRef = ClassRef->ClassParent();
  };
}
/*
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
```

35.1.22.4.8 TObject::CleanupInstance Method

Performs finalization on long strings, variants, and interface variables within a class.

Pascal

```
procedure CleanupInstance;
```

C++

```
__fastcall CleanupInstance();
```

Description

Do not call System::TObject::CleanupInstance directly. System::TObject::CleanupInstance is called automatically when the object instance is destroyed.

System::TObject::CleanupInstance releases all long strings and variants. It sets long strings to empty and variants to Unassigned.

System::TObject::Destroy (see page 3356)

System::TObject::Free (see page 3372)

delete

35.1.22.4.9 TObject::DefaultHandler Method

Provides the interface for a method that processes message records.

Pascal

```
procedure DefaultHandler(var Message); virtual;
```

C++

```
virtual DefaultHandler(var  Message);
```

Description

System::TObject::DefaultHandler is called by System::TObject::Dispatch (see page 3369) when it cannot find a method for a particular message. System::TObject::DefaultHandler provides message handling for all messages for which an object does not have specific handlers. Descendant classes that process messages override System::TObject::DefaultHandler according to the types of messages they handle.

Note: In a Delphi message-handling method, calling inherited results in a call to the ancestor's System::TObject::DefaultHandler method only if that ancestor does not specify a message method for the particular message being handled. Otherwise, calling inherited results in a call to the specific handler for that type of message.

Delphi Examples:

```
{
This example demonstrates the use of message dispatching
on TObject and any descendants. Using the same techniques
a form of message based OOP can be acheived where an object
"implements" a certain interface based on messages.
}

{ Define the object interface messages }
const
  INTF_MESSAGE_LOWER_STR = 1;
```

```
    INTF_MESSAGE_UPPER_STR = 2;

  type
    { String container message that will be passed }
    TStrCntrMessage = packed record
      MessageId : Word;
      MsgText   : String;
    end;

    { String handler object that will serve requests }
    TStringHandler = class
    private
      procedure StrUpCase(var AMessage : TStrCntrMessage);
        message INTF_MESSAGE_UPPER_STR;

      procedure StrLowCase(var AMessage : TStrCntrMessage);
        message INTF_MESSAGE_LOWER_STR;

    public
      procedure DefaultHandler(var Message); override;

    end;

  { TStringHandler }

  procedure TStringHandler.DefaultHandler(var Message);
  var
    MessageId : Word absolute Message;
  begin
    { Display out message then pass control to default handler }
    MessageDlg('Unhandled message ' + IntToStr(MessageId) +
      ' received!', mtInformation, [mbOK], 0);

    inherited;
  end;

  procedure TStringHandler.StrLowCase(
    var AMessage: TStrCntrMessage);
  begin
    AMessage.MsgText := LowerCase(AMessage.MsgText);
  end;

  procedure TStringHandler.StrUpCase(
    var AMessage: TStrCntrMessage);
  begin
    AMessage.MsgText := UpperCase(AMessage.MsgText);
  end;

  { TForm2}

  procedure TForm2.FormCreate(Sender: TObject);
  var
    Hndlr: TStringHandler;
    Msg: TStrCntrMessage;
  begin
    { Create object instance, dispatch a message and free it }
    Hndlr := TStringHandler.Create();

    { Lower-case a string using messaging }
    Msg.MessageId := INTF_MESSAGE_LOWER_STR;
    Msg.MsgText := 'Hello World';

    Hndlr.Dispatch(Msg);

    MessageDlg('Lower-cased string: ' + Msg.MsgText,
      mtInformation, [mbOK], 0);
```

```
  { Upper-case a string using messaging }
  Msg.MessageId := INTF_MESSAGE_UPPER_STR;
  Msg.MsgText := 'Hello World';

  Hndlr.Dispatch(Msg);

  MessageDlg('Upper-cased string: ' + Msg.MsgText,
    mtInformation, [mbOK], 0);

  Hndlr.Free;
end;
```

See Also

System::TObject::Dispatch (see page 3369)

35.1.22.4.10 TObject::Dispatch Method

Calls message-handling methods for the object, based on the contents of the Message parameter.

Pascal

```
procedure Dispatch(var Message); virtual;
```

C++

```
virtual Dispatch(var  Message);
```

Description

Call System::TObject::Dispatch to automatically pass messages to the appropriate message handler.

System::TObject::Dispatch determines whether a message is in the list of message handlers declared for the object. If the object does not handle the message, System::TObject::Dispatch then examines the message-handler list of the ancestor class, and continues checking ancestors until it either finds a specific handler or runs out of ancestors, in which case it calls System::TObject::DefaultHandler (see page 3367).

The only assumption System::TObject::Dispatch makes about the data in Message is that the first two bytes contain a message ID—that is, an integer that determines which message handler System::TObject::Dispatch calls. Although any kind of data can be passed to System::TObject::Dispatch, most System::TObject (see page 3354) descendants expect a message record such as TMessage or a specific data structure type.

Delphi Examples:

```
{
This example demonstrates the use of message dispatching
on TObject and any descendants. Using the same techniques
a form of message based OOP can be acheived where an object
"implements" a certain interface based on messages.
}

{ Define the object interface messages }
const
  INTF_MESSAGE_LOWER_STR = 1;
  INTF_MESSAGE_UPPER_STR = 2;

type
  { String container message that will be passed }
  TStrCntrMessage = packed record
    MessageId : Word;
    MsgText   : String;
  end;

  { String handler object that will serve requests }
```

```
  TStringHandler = class
  private
    procedure StrUpCase(var AMessage : TStrCntrMessage);
      message INTF_MESSAGE_UPPER_STR;

    procedure StrLowCase(var AMessage : TStrCntrMessage);
      message INTF_MESSAGE_LOWER_STR;

  public
    procedure DefaultHandler(var Message); override;

  end;

{ TStringHandler }

procedure TStringHandler.DefaultHandler(var Message);
var
  MessageId : Word absolute Message;
begin
  { Display out message then pass control to default handler }
  MessageDlg('Unhandled message ' + IntToStr(MessageId) +
    ' received!', mtInformation, [mbOK], 0);

  inherited;
end;

procedure TStringHandler.StrLowCase(
  var AMessage: TStrCntrMessage);
begin
  AMessage.MsgText := LowerCase(AMessage.MsgText);
end;

procedure TStringHandler.StrUpCase(
  var AMessage: TStrCntrMessage);
begin
  AMessage.MsgText := UpperCase(AMessage.MsgText);
end;

{ TForm2}

procedure TForm2.FormCreate(Sender: TObject);
var
  Hndlr: TStringHandler;
  Msg: TStrCntrMessage;
begin
  { Create object instance, dispatch a message and free it }
  Hndlr := TStringHandler.Create();

  { Lower-case a string using messaging }
  Msg.MessageId := INTF_MESSAGE_LOWER_STR;
  Msg.MsgText := 'Hello World';

  Hndlr.Dispatch(Msg);

  MessageDlg('Lower-cased string: ' + Msg.MsgText,
    mtInformation, [mbOK], 0);

  { Upper-case a string using messaging }
  Msg.MessageId := INTF_MESSAGE_UPPER_STR;
  Msg.MsgText := 'Hello World';

  Hndlr.Dispatch(Msg);

  MessageDlg('Upper-cased string: ' + Msg.MsgText,
    mtInformation, [mbOK], 0);
```

```
  Hndlr.Free;
end;
```

TMessage

35.1.22.4.11 TObject::Equals Method

Checks if the current instance and the parameter are equal.

Pascal

```
function Equals(Obj: TObject): Boolean; virtual;
```

C++

```
virtual Boolean Equals(TObject Obj);
```

Description

The function has one parameter, **Obj** of type TObject (see page 3354).

By default, the System::TObject::Equals method shows if the addresses corresponding to the object and the parameter are identical. Returns a boolean value that represents the equality between the two addresses.

Note: System::TObject::Equals is supposed to be overridden in user derived classes, in order to provide consumer objects with an equality determining function.

System::TObject::InheritsFrom (see page 3376)

35.1.22.4.12 FieldAddress Method

This is the overview for the FieldAddress method overload.

Overload List

	Name	Description
	TObject::FieldAddress (ShortString) (see page 3372)	Returns the address of a published object field.
	TObject::FieldAddress (string) (see page 3372)	Returns the address of a published object field.

35.1.22.4.12.1 TObject::FieldAddress Method (ShortString)

Returns the address of a published object field.

Pascal

```
function FieldAddress(const Name: ShortString): Pointer; overload;
function FieldAddress(const Name: string): Pointer; overload;
```

C++

```
Pointer FieldAddress(const ShortString Name);
Pointer FieldAddress(const string Name);
```

Description

System::TObject::FieldAddress is used internally by the component streaming system to access a specified published field of an object. System::TObject::FieldAddress returns a pointer to the field if it exists. If the object has no published field by that name, System::TObject::FieldAddress returns nil (Delphi) or NULL (C++).

Programs should access and manipulate fields by using properties instead of System::TObject::FieldAddress.

35.1.22.4.13 TObject::Free Method

Destroys an object and frees its associated memory, if necessary.

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

Use System::TObject::Free to destroy an object. System::TObject::Free automatically calls the destructor if the object reference is not nil. Any object instantiated at runtime that does not have an owner should be destroyed by a call to System::TObject::Free so that it can be properly disposed of and its memory released. Unlike System::TObject::Destroy (see page 3356), System::TObject::Free is successful even if the object is nil; so if the object was never initialized, System::TObject::Free won't result in an error.

When you call System::TObject::Free for a component, it calls System::TObject::Free for all components that it owns—that is, all components in its component list. Since a form owns all the controls and other components that are created on it in design mode, those components are automatically freed when the form is freed. By default, all forms are owned by the Application object; when the application terminates, it frees the Application object, which frees all forms. For objects that are not components, or for components created with a nil owner, be sure to call System::TObject::Free after you are finished with them; otherwise the allocated memory will not be usable until after the application terminates.

Warning: Never explicitly free a component within one of its own event handlers or the event handler of a component it owns or contains. For example, don't free a button, or the form that owns the button, in its OnClick event handler.

To free a form, call its _Release method, which destroys the form and releases the memory allocated for it after all its event handlers and those of the components it contains are through executing.

Note: In C++ code, do not use System::TObject::Free to destroy an object. Use the delete keyword.

Delphi Examples:

```
{
This example demonstrates how to add and delete menu items
```

```
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type
  TForm1 = class(TForm)
    AddButton: TButton;
    EditButton: TButton;
    DestroyButton: TButton;
    PopupMenu1: TPopupMenu;
    procedure AddButtonClick(Sender: TObject);

35.1.22.4.14 TObject::FreeInstance Method

Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.

Pascal

```
procedure FreeInstance; virtual;
```

C++

```
virtual __fastcall FreeInstance();
```

Description

All destructors call System::TObject::FreeInstance automatically to deallocate memory that was allocated by overriding System::TObject::NewInstance (see page 3379).

Do not call System::TObject::FreeInstance directly. System::TObject::FreeInstance should be overridden if System::TObject::NewInstance (see page 3379) was overridden to change the way the object's instance data was allocated.

Like System::TObject::NewInstance (see page 3379), System::TObject::FreeInstance uses the value returned from System::TObject::InstanceSize (see page 3377) to deallocate the object's memory.

See Also

System::TObject::InstanceSize (see page 3377)

System::TObject::NewInstance (see page 3379)

35.1.22.4.15 TObject::GetHashCode Method

Returns an integer containing the hash code.

Pascal

```
function GetHashCode: Integer; virtual;
```

C++

```
virtual __fastcall Integer GetHashCode();
```

Description

By default, calling System::TObject::GetHashCode on an object, returns an integer representing the virtual address at which the object is stored.

Note: System::TObject::GetHashCode is supposed to be overridden in user derived classes, in order to provide consumer objects with an integer hash code representation.

See Also

System::TObject::MethodName (see page 3379)

System::TObject::InheritsFrom (see page 3376)

35.1.22.4.16 TObject::GetInterface Method

Retrieves a specified interface.

Pascal

```
function GetInterface(const IID: TGUID; out Obj): Boolean;
```

C++

```
Boolean GetInterface(const TGUID IID, out  Obj);
```

Description

System::TObject::GetInterface retrieves the interface designated by a GUID or type name. The basic implementation of System::TObject::GetInterface uses the GUID specified in the IID parameter. If the specified interface is supported by the class, it is returned in the Obj parameter, and System::TObject::GetInterface has a return value of true. Otherwise Obj contains nil (Delphi) or NULL (C++), and System::TObject::GetInterface returns false.

Note: In Delphi code, IID can be an interface name. The compiler automatically translates this name into the corresponding GUID.

Note: In C++ code, use the templated version of System::TObject::GetInterface to obtain an interface from a DelphiInterface (see page 3256) object.

System::TObject::GetInterface is equivalent to the as operator (Delphi) and dynamic casts (C++), except that System::TObject::GetInterface does not raise an exception if the interface is not supported.

See Also

System::TInterfacedObject::QueryInterface (see page 3347)

35.1.22.4.17 TObject::GetInterfaceEntry Method

Returns the entry for a specific interface implemented in a class.

Pascal

```
class function GetInterfaceEntry(const IID: TGUID): PInterfaceEntry;
```

C++

```
PInterfaceEntry GetInterfaceEntry(const TGUID IID);
```

Description

System::TObject::GetInterfaceEntry returns the class entry for the interface specified by the IID parameter.

Note: In Delphi Code, IID can be an interface name. The compiler replaces this name with the actual GUID.

Note: COM objects can use System::TObject::GetInterfaceEntry to automate dispatch calls to a dual-IDispatch (see page 3494) interface.

35.1.22.4.18 TObject::GetInterfaceTable Method

Returns a pointer to a structure containing all of the interfaces implemented by a given class.

Pascal

```
class function GetInterfaceTable: PInterfaceTable;
```

C++

```
PInterfaceTable GetInterfaceTable();
```

Description

System::TObject::GetInterfaceTable returns the interface entries for the class. This list contains only interfaces implemented by this class, not its ancestors. To find the ancestor list, iteratively call System::TObject::ClassParent (see page 3361) and then call System::TObject::GetInterfaceTable on the value it returns. To find the entry for a specific interface, use the System::TObject::GetInterfaceEntry (see page 3376) method instead.

See Also

System::TObject::GetInterfaceEntry (see page 3376)

System::TObject::ClassParent (see page 3361)

35.1.22.4.19 TObject::InheritsFrom Method

Determines the relationship of two object types.

Pascal

```
class function InheritsFrom(AClass: TClass): Boolean;
```

C++

```
Boolean InheritsFrom(TClass AClass);
```

Description

Use System::TObject::InheritsFrom to determine if a particular class type or object is an instance of a class or one of its descendants. System::TObject::InheritsFrom returns true if the object type specified in the aClass parameter is an ancestor of the object type or the type of the object itself. Otherwise, it returns false.

Note: System::TObject::InheritsFrom is similar to the Delphi is operator, but applies to class references.

Note: In C++ code, a non-static version of System::TObject::InheritsFrom is provided. This call is useful in determining whether a descendant class method or property can be used, given a variable of a base class. For example, use System::TObject::InheritsFrom to determine whether the Sender parameter in an event handler is of a particular class type or one of its descendants.

See Also

System::TObject::ClassParent (see page 3361)

System::TObject::ClassNameIs (see page 3361)

35.1.22.4.20 TObject::InitInstance Method

Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

Pascal

```
class function InitInstance(Instance: Pointer): TObject;
```

C++

```
TObject InitInstance(Pointer Instance);
```

Description

There should be no reason to call System::TObject::InitInstance directly. System::TObject::InitInstance is called by System::TObject::NewInstance (see page 3379) when an object is created. When overriding System::TObject::NewInstance (see page 3379), be sure to call System::TObject::InitInstance as the last statement.

System::TObject::InitInstance is not virtual, so you cannot override it: Instead, initialize any data for an object in the constructor.

See Also

System::TObject::Create (see page 3355)

System::TObject::NewInstance (see page 3379)

35.1.22.4.21 TObject::InstanceSize Method

Returns the size in bytes of each instance of the object type.

Pascal

```
class function InstanceSize: Longint;
```

C++

```
Longint InstanceSize();
```

Description

System::TObject::InstanceSize indicates how many bytes of memory are required for a class's instance data. System::TObject::InstanceSize is called from methods that allocate and deallocate memory. System::TObject::InstanceSize is not a virtual method, so it cannot be overridden. System::TObject::InstanceSize should be called only when implementing a custom version of System::TObject::NewInstance (see page 3379).

See Also

System::TObject::FreeInstance (see page 3374)

System::TObject::NewInstance (see page 3379)

35.1.22.4.22 MethodAddress Method

This is the overview for the MethodAddress method overload.

Overload List

	Name	Description
	TObject::MethodAddress (ShortString) (see page 3378)	Returns the address of a class method by name.
	TObject::MethodAddress (string) (see page 3378)	Returns the address of a class method by name.

35.1.22.4.22.1 TObject::MethodAddress Method (ShortString)

Returns the address of a class method by name.

Pascal

```
class function MethodAddress(const Name: ShortString): Pointer; overload;
class function MethodAddress(const Name: string): Pointer; overload;
```

C++

```
Pointer MethodAddress(const ShortString Name);
Pointer MethodAddress(const string Name);
```

Description

There are situations where it is useful to be able to invoke an object method without the need to hard code the method name in advance. Call System::TObject::MethodAddress to dynamically retrieve the address of such a method by specifying the method **Name** as a string.

An easy way to invoke the method is to define a procedure or function data type, such as :

type TProc = procedure of object;

Assign the object name, and the System::TObject::MethodAddress to a TMethod (see page 3731) variable, such as :

MethodVar.Data := Pointer(ObjectInstanceName);

MethodVar.Code := ObjectInstanceName.System::TObject::MethodAddress('MethodNameString');

And pass this in a call to a variable of the procedure or function type :

Proc := TProc(MethodVar);

Proc;

See Also

TMethod (see page 3731)

35.1.22.4.23 TObject::MethodName Method

Returns the name of a class method by address.

Pascal

```
class function MethodName(Address: Pointer): string;
```

C++

```
string MethodName(Pointer Address);
```

Description

There are situations where it is useful to be able to invoke an object method without the need to hard code the method name in advance. Call System::TObject::MethodAddress (see page 3378) to dynamically retrieve the address of such a method by specifying the method name as a string.

System::TObject::MethodName is the converse to this process - by supplying a method **Address**, the name of the method is returned as a string.

35.1.22.4.24 TObject::NewInstance Method

Allocates memory for an instance of an object type and returns a pointer to that new instance.

Pascal

```
class function NewInstance: TObject; virtual;
```

C++

```
virtual TObject NewInstance();
```

Description

All constructors call System::TObject::NewInstance automatically. System::TObject::NewInstance calls System::TObject::InstanceSize (see page 3377) to determine how much memory to allocate from the heap to contain a particular instance. Do not call System::TObject::NewInstance directly.

Override System::TObject::NewInstance only for special memory allocation requirements. For example, when allocating a large number of identical objects that all need to be in memory at the same time, you could allocate a single block of memory for the entire group, then override System::TObject::NewInstance to use part of that larger block for each instance.

If you override System::TObject::NewInstance to allocate memory, you may need to override System::TObject::FreeInstance (see page 3374) to deallocate the memory.

Note: By default System::TObject::NewInstance calls System::TObject::InitInstance (see page 3377).

See Also

System::TObject::FreeInstance (see page 3374)

System::TObject::InstanceSize (see page 3377)

System::TObject::InitInstance (see page 3377)

35.1.22.4.25 TObject::SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; virtual;
```

C++

```
virtual HResult SafeCallException(TObject ExceptObject, Pointer ExceptAddr);
```

Description

System::TObject::SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur.

As implemented in System::TObject (see page 3354), System::TObject::SafeCallException simply returns E_UNEXPECTED (see page 3846). This is the appropriate response for classes that do no support interfaces

35.1.22.4.26 TObject::ToString Method

Returns a string containing the class name.

Pascal

```
function ToString: string; virtual;
```

C++

```
virtual __fastcall string ToString();
```

Description

By default, the System::TObject::ToString returns a string containing the class name of the instance that is being called.

Example

Calling System::TObject::ToString on a TButton instance returns a string containing "TButton".

Note: System::TObject::ToString is intended to be overridden in user derived classes, in order to provide consumer objects with a string representation.

See Also

System::TObject::ClassType (see page 3364)

System::TObject::ClassName (see page 3359)

System::TObject::ClassParent (see page 3361)

System::TObject::FieldAddress (see page 3372)

System::TObject::MethodAddress (see page 3378)

System::TObject::InstanceSize (see page 3377)

System::TObject::MethodName (see page 3379)

System::TObject::InheritsFrom (see page 3376)

35.1.22.4.27 TObject::UnitName Method

Returns a string containing the unit name.

Pascal

```
class function UnitName: string;
```

C++

```
string UnitName();
```

Description

By default, calling System::TObject::UnitName on an object, returns a string representing the unit name where it is contained.

Example

Calling System::TObject::UnitName on a TButton instance returns a string containing "StdCtrls (see page 2033)".

System::TObject::MethodAddress (see page 3378)

System::TObject::InstanceSize (see page 3377)

System::TObject::MethodName (see page 3379)

System::TObject::InheritsFrom (see page 3376)

35.1.23 UnicodeString Class

System::UnicodeString is the C++ analog for the Delphi UnicodeString type.

Class Hierarchy

Pascal

```
UnicodeString = class;
```

C++

```
class UnicodeString;
```

File

ustring.h

Description

Delphi utilizes several string types. System::UnicodeString can contain both Unicode and ANSI strings. Support for this type includes the following features:

- strings as large as available memory;
- efficient use of memory through shared references;
- routines and operators that evaluate strings based on the current locale.

Despite its name, System::UnicodeString can represent both ANSI character set strings and Unicode strings.

System::UnicodeString variables that have not been assigned an initial value contain a zero-length string.

Note: Delphi also supports System::UnicodeString, but implements it as a primitive type rather than a class. By default, variables declared as type String are System::UnicodeString.

Note: To be compatible with Delphi, System::UnicodeString indexing is 1-based.

See Also

System::AnsiStringBase (see page 3174)

System::WideString (see page 3467)

System::UnicodeString::[] (see page 3414)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

System::UnicodeString::+= (see page 3416)

35.1.23.1 UnicodeString Members

The following tables list the members exposed by UnicodeString.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3388)	System::UnicodeString::TStringFloatFormat is an enumerated list of formatting codes for float functions.
	TStringLeadCharType (see page 3389)	Enumerated list of element types in a Unicode string.

Structures

	Name	Description
	StrRec (see page 3387)	Provides information about the Unicode string.

Protected Methods

	Name	Description
	GetRec (see page 3401)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3410)	Throws exception if index is out of range in System::UnicodeString (see page 3381).

Public Friends

Name	Description
UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs) (see page 3420)	This is friend UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs).
UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs) (see page 3420)	This is friend UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs).

Public Methods

	Name	Description
	~UnicodeString (see page 3384)	Frees an instance of System::UnicodeString (see page 3381).
	BytesOf (see page 3391)	Get string's data (see page 3396) in bytes.
	ByteType (see page 3391)	Indicates the kind of byte that occupies specified position in System::UnicodeString (see page 3381).
	c_str (see page 3392)	Returns a pointer to the underlying string System::UnicodeString::data (see page 3396) as const wchar_t*.
	cat_printf (see page 3392)	Appends to value of System::UnicodeString (see page 3381), given format string and its arguments.
	cat_sprintf (see page 3393)	Appends result of given format string and its arguments to end of System::UnicodeString (see page 3381).
	cat_vprintf (see page 3394)	Appends the result of given format string and its arguments to end of System::UnicodeString (see page 3381).
	CodePage (see page 3394)	Gets code page of a System::UnicodeString (see page 3381).
	Compare (see page 3394)	Compares the System::UnicodeString (see page 3381) to another specified string case-sensitively.
	CompareIC (see page 3395)	Compares System::UnicodeString (see page 3381) to another specified string case insensitively.
	CurrToStr (see page 3395)	Converts a currency value to its string representation.
	CurrToStrF (see page 3396)	Converts currency value to its string representation using indicated float format convention.
	data (see page 3396)	Returns a pointer to the underlying string System::UnicodeString::data.
	Delete (see page 3396)	Removes specified number of characters from string.
	ElementSize (see page 3397)	Gets element size of data (see page 3396) in a System::UnicodeString (see page 3381).
	EnsureUnicode (see page 3397)	Ensure that string contains Unicode data (see page 3396).
	FloatToStrF (see page 3397)	Returns string representation of floating-point value.
	FmtLoadStr (see page 3398)	Formats output using a resourced format string.
	Format (see page 3399)	Formats string assembled from System::UnicodeString (see page 3381), format, and array arguments.
	FormatFloat (see page 3399)	Formats floating-point value given by `value` using format string given by `format`.
	Insert (see page 3401)	Inserts specified string into System::UnicodeString (see page 3381).
	IntToHex (see page 3402)	Converts number into string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3402)	Returns true if the specified character matches any character in `delimiters` string.
	IsEmpty (see page 3402)	Indicates if System::UnicodeString (see page 3381) is empty.
	IsLeadSurrogate (see page 3403)	Tests if element is lead surrogate.
	IsPathDelimiter (see page 3403)	Indicates if specified character is a path delimiter.
	IsTrailSurrogate (see page 3403)	Tests if element is trail surrogate.
	LastChar (see page 3404)	Returns pointer to last character in System::UnicodeString (see page 3381).
	LastDelimiter (see page 3404)	Returns index of rightmost character that matches any character in `delimiters` string.
	Length (see page 3404)	Returns length in characters of System::UnicodeString (see page 3381).
	LoadStr (see page 3405)	This is the overview for the LoadStr method overload.
	LoadString (see page 3405)	Loads string from compiled resources of specified module.
	LowerCase (see page 3406)	Returns lower-case version of System::UnicodeString (see page 3381).
	Pos (see page 3406)	Returns character index at which specified substring begins.
	printf (see page 3406)	Sets value of System::UnicodeString (see page 3381) instance, given format string and its arguments.
	RefCount (see page 3407)	Gets reference count of System::UnicodeString (see page 3381).
	SetLength (see page 3407)	Changes character length of System::UnicodeString (see page 3381).
	sprintf (see page 3408)	Sets value of System::UnicodeString (see page 3381), given format string and its arguments.
	StringOfChar (see page 3408)	Returns string with specified number of characters.
	SubString (see page 3408)	Returns specified substring of System::UnicodeString (see page 3381).
	swap (see page 3409)	Swaps System::UnicodeString (see page 3381) with another string.

	t_str (see page 3409)	Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396) as const char*.
	ToDouble (see page 3410)	Converts string to floating-point value.
	ToInt (see page 3410)	Converts string to integer, throwing exception if string is invalid.
	ToIntDef (see page 3411)	Converts string to integer, returning default value if string is invalid.
	Trim (see page 3411)	Returns new System::UnicodeString (see page 3381) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3411)	Returns new System::UnicodeString (see page 3381) without leading spaces or control characters.
	TrimRight (see page 3412)	Returns new System::UnicodeString (see page 3381) without trailing spaces or control characters.
	UnicodeString (see page 3384)	This is the overview for the UnicodeString constructor overload.
	Unique (see page 3412)	Makes System::UnicodeString (see page 3381) instance unique.
	UpperCase (see page 3412)	Returns upper-case version of System::UnicodeString (see page 3381).
	vprintf (see page 3413)	Sets value of System::UnicodeString (see page 3381) given format string and its arguments.
	w_str (see page 3413)	Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396).

Public Operators

	Name	Description
	!= (see page 3414)	Compares two strings.
	[] (see page 3414)	This is the overview for the [] operator overload.
	+ (see page 3415)	Concatenates two System::UnicodeString (see page 3381) values.
	+= (see page 3416)	Append (see page 3520) System::UnicodeString (see page 3381).
	< (see page 3416)	Compares two strings.
	<= (see page 3417)	Compares two strings.
	= (see page 3418)	Assigns string `rhs` to System::UnicodeString (see page 3381).
	== (see page 3418)	Compares System::UnicodeString (see page 3381) with specified string.
	> (see page 3419)	Compares two strings.
	>= (see page 3419)	Compares two strings.

35.1.23.2 UnicodeString::~UnicodeString Destructor

Frees an instance of System::UnicodeString (see page 3381).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~UnicodeString();
```

Description

System::UnicodeString (see page 3381)::~UnicodeString (see page 3381) is the destructor for System::UnicodeString (see page 3381).

35.1.23.3 UnicodeString Constructor

This is the overview for the UnicodeString constructor overload.

Overload List

	Name	Description
	UnicodeString::UnicodeString () (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (__int64) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (AnsiStringT<codePage> &) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (char) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (char*) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (char*, int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (char16_t*, int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (char32_t*, int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (double) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (long) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (short) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (UnicodeString&) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (unsigned __int64) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (unsigned int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (unsigned long) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (unsigned short) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (wchar_t) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (wchar_t*) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (wchar_t*, int) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).
	UnicodeString::UnicodeString (WideString &) (see page 3386)	Creates instance of System::UnicodeString (see page 3381).

35.1.23.3.1 UnicodeString::UnicodeString Constructor ()

Creates instance of System::UnicodeString (see page 3381).

Pascal

```
constructor Create;
constructor Create(const src: char*);
constructor Create(const src: UnicodeString&);
constructor Create(const src: wchar_t*; len: Integer);
constructor Create(const src: char*; len: Integer);
constructor Create(const src: wchar_t*);
constructor Create(const src: char16_t*; numChar16: Integer = -1);
constructor Create(const src: char32_t*; numChar32: Integer = -1);
constructor Create(src: char);
constructor Create(src: wchar_t);
constructor Create(src: short);
constructor Create(src: unsigned short);
constructor Create(src: Integer);
constructor Create(src: unsigned int);
constructor Create(src: long);
constructor Create(src: unsigned long);
constructor Create(src: __int64);
constructor Create(src: unsigned __int64);
constructor Create(src: double);
constructor Create(const src: WideString &);
constructor Create<unsigned short codePage>(const src: AnsiStringT<codePage> &);
```

C++

```
__fastcall UnicodeString();
__fastcall UnicodeString(const char* src);
__fastcall UnicodeString(const UnicodeString& src);
__fastcall UnicodeString(const wchar_t* src, int len);
__fastcall UnicodeString(const char* src, int len);
__fastcall UnicodeString(const wchar_t* src);
__fastcall UnicodeString(const char16_t* src, int numChar16 = -1);
__fastcall UnicodeString(const char32_t* src, int numChar32 = -1);
__fastcall UnicodeString(char src);
__fastcall UnicodeString(wchar_t src);
__fastcall UnicodeString(short src);
__fastcall UnicodeString(unsigned short src);
__fastcall UnicodeString(int src);
__fastcall UnicodeString(unsigned int src);
__fastcall UnicodeString(long src);
__fastcall UnicodeString(unsigned long src);
__fastcall UnicodeString(__int64 src);
__fastcall UnicodeString(unsigned __int64 src);
__fastcall UnicodeString(double src);
__fastcall UnicodeString(const WideString & src);
template <unsigned short codePage> __fastcall UnicodeString(const AnsiStringT<codePage> & src);
```

Description

Call System::UnicodeString::UnicodeString (see page 3381) to create and initialize a System::UnicodeString (see page 3381) instance. If the constructor is given no arguments, the resulting System::UnicodeString (see page 3381) instance is an empty string. If the constructor is passed a single character, the resulting System::UnicodeString (see page 3381) instance has character length one, and contains that character. All other versions of the constructor copy the string passed as an argument, converting characters to `wchar_t` if necessary. When constructing a System::UnicodeString (see page 3381) instance from an array of `char` or `wchar_t`, the `src` string should be null terminated, unless a second argument is given that indicates the number of characters in the array.

35.1.23.4 UnicodeString Structures

The structures of the UnicodeString class are listed here.

Structures

	Name	Description
	StrRec (see page 3387)	Provides information about the Unicode string.

35.1.23.4.1 System::UnicodeString::StrRec Structure

Provides information about the Unicode string.

Pascal

```
StrRec = record
  codePage: unsigned short;
  elemSize: unsigned short;
  refCnt: Integer;
  length: Integer;
end;
```

C++

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

File

ustring.h

Description

s

Use System::UnicodeString::StrRec to retrieve information about the Unicode string. The fields of System::UnicodeString::StrRec and their meaning are given in the following table.

Field	Meaning
codePage	The code page of the Unicode string
elemSize	The number of bytes per character of the Unicode string
refCnt	The number of references to the Unicode string
length	The number of characters of the Unicode string

See Also

System::UnicodeString (see page 3381)

35.1.23.5 UnicodeString Enumerations

The enumerations of the UnicodeString class are listed here.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3388)	System::UnicodeString::TStringFloatFormat is an enumerated list of formatting codes for float functions.
	TStringLeadCharType (see page 3389)	Enumerated list of element types in a Unicode string.

35.1.23.5.1 System::UnicodeString::TStringFloatFormat Enumeration

System::UnicodeString::TStringFloatFormat is an enumerated list of formatting codes for float functions.

Pascal

```
TStringFloatFormat = (
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
);
```

C++

```
enum TStringFloatFormat {
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
};
```

File

ustring.h

Description

System::UnicodeString::TStringFloatFormat defines an enumerated list of formatting codes for the float functions.

Format (see page 3399)	Defines
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.

sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3399) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

See Also

System::UnicodeString::FloatToStrF (see page 3397)

35.1.23.5.2 System::UnicodeString::TStringLeadCharType Enumeration

Enumerated list of element types in a Unicode string.

Pascal

```
TStringLeadCharType = (
  ctNotLeadChar,
  ctbLeadSurrogate,
  ctTrailSurrogate
);
```

C++

```
enum TStringLeadCharType {
  ctNotLeadChar,
  ctbLeadSurrogate,
  ctTrailSurrogate
};
```

File

ustring.h

Description

System::UnicodeString::TStringLeadCharType defines an enumerated list of element types in a Unicode string.

Constant	Meaning
ctNotLeadChar	Not a lead element.
ctbLeadSurrogate	Lead surrogate pair element.
ctTrailSurrogate	Trailing surrogate pair element.

See Also

System::UnicodeString::ByteType (see page 3391)

35.1.23.6 UnicodeString Methods

The methods of the UnicodeString class are listed here.

Protected Methods

	Name	Description
	GetRec (see page 3401)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 3410)	Throws exception if index is out of range in System::UnicodeString (see page 3381).

Public Methods

	Name	Description
	BytesOf (see page 3391)	Get string's data (see page 3396) in bytes.
	ByteType (see page 3391)	Indicates the kind of byte that occupies specified position in System::UnicodeString (see page 3381).
	c_str (see page 3392)	Returns a pointer to the underlying string System::UnicodeString::data (see page 3396) as const wchar_t*.
	cat_printf (see page 3392)	Appends to value of System::UnicodeString (see page 3381), given format string and its arguments.
	cat_sprintf (see page 3393)	Appends result of given format string and its arguments to end of System::UnicodeString (see page 3381).
	cat_vprintf (see page 3394)	Appends the result of given format string and its arguments to end of System::UnicodeString (see page 3381).
	CodePage (see page 3394)	Gets code page of a System::UnicodeString (see page 3381).
	Compare (see page 3394)	Compares the System::UnicodeString (see page 3381) to another specified string case-sensitively.
	CompareIC (see page 3395)	Compares System::UnicodeString (see page 3381) to another specified string case insensitively.
	CurrToStr (see page 3395)	Converts a currency value to its string representation.
	CurrToStrF (see page 3396)	Converts currency value to its string representation using indicated float format convention.
	data (see page 3396)	Returns a pointer to the underlying string System::UnicodeString::data.
	Delete (see page 3396)	Removes specified number of characters from string.
	ElementSize (see page 3397)	Gets element size of data (see page 3396) in a System::UnicodeString (see page 3381).
	EnsureUnicode (see page 3397)	Ensure that string contains Unicode data (see page 3396).
	FloatToStrF (see page 3397)	Returns string representation of floating-point value.
	FmtLoadStr (see page 3398)	Formats output using a resourced format string.
	Format (see page 3399)	Formats string assembled from System::UnicodeString (see page 3381), format, and array arguments.
	FormatFloat (see page 3399)	Formats floating-point value given by `value` using format string given by `format`.
	Insert (see page 3401)	Inserts specified string into System::UnicodeString (see page 3381).
	IntToHex (see page 3402)	Converts number into string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3402)	Returns true if the specified character matches any character in `delimiters` string.
	IsEmpty (see page 3402)	Indicates if System::UnicodeString (see page 3381) is empty.
	IsLeadSurrogate (see page 3403)	Tests if element is lead surrogate.
	IsPathDelimiter (see page 3403)	Indicates if specified character is a path delimiter.
	IsTrailSurrogate (see page 3403)	Tests if element is trail surrogate.
	LastChar (see page 3404)	Returns pointer to last character in System::UnicodeString (see page 3381).
	LastDelimiter (see page 3404)	Returns index of rightmost character that matches any character in `delimiters` string.
	Length (see page 3404)	Returns length in characters of System::UnicodeString (see page 3381).
	LoadStr (see page 3405)	This is the overview for the LoadStr method overload.
	LoadString (see page 3405)	Loads string from compiled resources of specified module.
	LowerCase (see page 3406)	Returns lower-case version of System::UnicodeString (see page 3381).
	Pos (see page 3406)	Returns character index at which specified substring begins.
	printf (see page 3406)	Sets value of System::UnicodeString (see page 3381) instance, given format string and its arguments.
	RefCount (see page 3407)	Gets reference count of System::UnicodeString (see page 3381).
	SetLength (see page 3407)	Changes character length of System::UnicodeString (see page 3381).
	sprintf (see page 3408)	Sets value of System::UnicodeString (see page 3381), given format string and its arguments.
	StringOfChar (see page 3408)	Returns string with specified number of characters.
	SubString (see page 3408)	Returns specified substring of System::UnicodeString (see page 3381).
	swap (see page 3409)	Swaps System::UnicodeString (see page 3381) with another string.

	t_str (see page 3409)	Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396) as const char*.
	ToDouble (see page 3410)	Converts string to floating-point value.
	ToInt (see page 3410)	Converts string to integer, throwing exception if string is invalid.
	ToIntDef (see page 3411)	Converts string to integer, returning default value if string is invalid.
	Trim (see page 3411)	Returns new System::UnicodeString (see page 3381) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3411)	Returns new System::UnicodeString (see page 3381) without leading spaces or control characters.
	TrimRight (see page 3412)	Returns new System::UnicodeString (see page 3381) without trailing spaces or control characters.
	Unique (see page 3412)	Makes System::UnicodeString (see page 3381) instance unique.
	UpperCase (see page 3412)	Returns upper-case version of System::UnicodeString (see page 3381).
	vprintf (see page 3413)	Sets value of System::UnicodeString (see page 3381) given format string and its arguments.
	w_str (see page 3413)	Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396).

35.1.23.6.1 UnicodeString::BytesOf Method

Get string's data (see page 3396) in bytes.

Pascal

```
function BytesOf: DynamicArray<System::Byte>;
```

C++

```
__fastcall DynamicArray<System::Byte> BytesOf() const;
```

Description

System::UnicodeString::BytesOf gets a byte array copy of a System::UnicodeString (see page 3381)'s data (see page 3396). The data (see page 3396) is copied as is, with no encoding or decoding.

See Also

System::AnsiStringBase::BytesOf (see page 3186)

BytesOf (see page 4068)

35.1.23.6.2 UnicodeString::ByteType Method

Indicates the kind of byte that occupies specified position in System::UnicodeString (see page 3381).

Pascal

```
function ByteType(index: Integer): TStringLeadCharType;
```

C++

```
__fastcall TStringLeadCharType ByteType(int index) const;
```

Description

System::UnicodeString::ByteType indicates what kind of byte exists at the byte indicated by `index` (counting from 1) in the System::UnicodeString (see page 3381). Note that **index** is an element index into the string, not a character or byte index. These are the possible return values.

Constant	Meaning
ctNotLeadChar	Not a lead character.
ctbLeadSurrogate	Lead surrogate pair character.

ctTrailSurrogate	Trailing surrogate pair character.

Note: No checking is done to ensure that `index` is less than the length of the string. It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

LeadBytes (see page 4354)

StrByteType (see page 4242)

35.1.23.6.3 UnicodeString::c_str Method

Returns a pointer to the underlying string System::UnicodeString::data (see page 3396) as const wchar_t*.

Pascal

```
function c_str: wchar_t*;
```

C++

```
__fastcall wchar_t* c_str() const;
```

Description

System::UnicodeString::c_str returns a **wchar_t** pointer to the location in memory where the value of the System::UnicodeString (see page 3381) object is stored. If the System::UnicodeString (see page 3381) is unassigned, System::UnicodeString::c_str returns a **wchar_t** pointer to the empty string (“”).

Usually, the value returned by System::UnicodeString::c_str points to the internal character array referenced by the System::UnicodeString::data (see page 3396) function. This pointer is valid until the System::UnicodeString (see page 3381) is next modified (for example, when the System::UnicodeString::SetLength (see page 3407) method is called or the System::UnicodeString (see page 3381) goes out of scope). However, if the internal array is NULL, System::UnicodeString::c_str returns a **wchar_t** pointer to the empty string (“”).

The System::UnicodeString::c_str method is intended primarily for reading the value of the System::UnicodeString (see page 3381). To modify the System::UnicodeString (see page 3381)’s value, use the [] operator or System::UnicodeString (see page 3381) methods such as System::UnicodeString::Insert (see page 3401) and System::UnicodeString::Delete (see page 3396).

The System::UnicodeString::t_str (see page 3409) method returns **const char*** for backward compatiblity with the VCL and to preserve narrow data (see page 3396).

See Also

System::UnicodeString::data (see page 3396)

System::UnicodeString::Delete (see page 3396)

System::UnicodeString::Insert (see page 3401)

System::UnicodeString::SetLength (see page 3407)

System::UnicodeString::t_str (see page 3409)

35.1.23.6.4 UnicodeString::cat_printf Method

Appends to value of System::UnicodeString (see page 3381), given format string and its arguments.

Pascal

```
function cat_printf(const format: wchar_t*; : ...): Integer; cdecl;
```

C++

```
__cdecl int cat_printf(const wchar_t* format, ...);
```

Description

Use System::UnicodeString::cat_printf to modify the value of the System::UnicodeString (see page 3381) by appending the result of using a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the number of characters appended to the System::UnicodeString (see page 3381).

See Also

System::UnicodeString::cat_sprintf (see page 3393)

System::UnicodeString::cat_vprintf (see page 3394)

System::UnicodeString::Format (see page 3399)

System::UnicodeString::printf (see page 3406)

35.1.23.6.5 UnicodeString::cat_sprintf Method

Appends result of given format string and its arguments to end of System::UnicodeString (see page 3381).

Pascal

```
function cat_sprintf(const format: wchar_t*; : ...): UnicodeString&; cdecl;
```

C++

```
__cdecl UnicodeString& cat_sprintf(const wchar_t* format, ...);
```

Description

Use System::UnicodeString::cat_sprintf to append to the value of the System::UnicodeString (see page 3381) object, given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

For example, the following code

```
UnicodeString Salutation = "Mr."
UnicodeString s = "";
s.cat_sprintf("Dear %s ", Salutation);
s.cat_sprintf("%s,", "Smith");
```

results in an System::UnicodeString (see page 3381) object with the value

```
Dear Mr. Smith,
```

This method returns a reference to the System::UnicodeString (see page 3381) object (*this) with the resulting value.

See Also

System::UnicodeString::cat_printf (see page 3392)

System::UnicodeString::cat_vprintf (see page 3394)

System::UnicodeString::Format (see page 3399)

System::UnicodeString::sprintf (see page 3408)

35.1.23.6.6 UnicodeString::cat_vprintf Method

Appends the result of given format string and its arguments to end of System::UnicodeString (see page 3381).

Pascal

```
function cat_vprintf(const format: wchar_t*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(const wchar_t* format, va_list);
```

Description

Use System::UnicodeString::cat_vprintf to append to the value of the System::UnicodeString (see page 3381) object, given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using `va_start`.

This method returns the number of characters appended to the System::UnicodeString (see page 3381) object.

See Also

System::UnicodeString::Format (see page 3399)

System::UnicodeString::cat_printf (see page 3392)

System::UnicodeString::cat_sprintf (see page 3393)

System::UnicodeString::vprintf (see page 3413)

35.1.23.6.7 UnicodeString::CodePage Method

Gets code page of a System::UnicodeString (see page 3381).

Pascal

```
function CodePage: unsigned short;
```

C++

```
unsigned short CodePage() const;
```

Description

System::UnicodeString::CodePage gets the code page of a System::UnicodeString (see page 3381) instance. If the instance is empty, it returns the system default Unicode code page.

See Also

System::UnicodeString::GetRec (see page 3401)

35.1.23.6.8 UnicodeString::Compare Method

Compares the System::UnicodeString (see page 3381) to another specified string case-sensitively.

Pascal

```
function Compare(const rhs: UnicodeString&): Integer;
```

C++

```
__fastcall int Compare(const UnicodeString& rhs) const;
```

Description

Compares a System::UnicodeString (see page 3381) instance to `rhs`, with case sensitivity. Use

System::UnicodeString::CompareIC (see page 3395) to compare without case sensitivity. The compare operation should be the same as using the System::UnicodeString (see page 3381) comparison operators. System::UnicodeString::Compare is based on a locale-specific collating order. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

See Also

System::UnicodeString::CompareIC (see page 3395)

35.1.23.6.9 UnicodeString::CompareIC Method

Compares System::UnicodeString (see page 3381) to another specified string case insensitively.

Pascal

```
function CompareIC(const rhs: UnicodeString&): Integer;
```

C++

```
__fastcall int CompareIC(const UnicodeString& rhs) const;
```

Description

System::UnicodeString::CompareIC compares a System::UnicodeString (see page 3381) instance to `rhs`, without case sensitivity. Use System::UnicodeString::Compare (see page 3394) to compare with case sensitivity. The compare operation is controlled by the current Windows locale. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

See Also

System::UnicodeString::Compare (see page 3394)

35.1.23.6.10 UnicodeString::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency): String; static;
```

C++

```
static __fastcall UnicodeString CurrToStr(Currency value);
```

Description

System::UnicodeString::CurrToStr converts the currency value given by `value` to its string representation. The conversion uses the sffGeneral floating-point conversion rules (see System::UnicodeString::FloatToStrF (see page 3397)). For further details, see System::UnicodeString::CurrToStrF (see page 3396).

See Also

System::UnicodeString::CurrToStrF (see page 3396)

System::UnicodeString::FloatToStrF (see page 3397)

35.1.23.6.11 UnicodeString::CurrToStrF Method

Converts currency value to its string representation using indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer): String;
static;
```

C++

```
static __fastcall UnicodeString CurrToStrF(Currency value, TStringFloatFormat format, int
digits);
```

Description

System::UnicodeString::CurrToStrF converts the currency value given by `value` to its string representation using the indicated float format convention. A call to System::UnicodeString::CurrToStrF corresponds to a call to System::UnicodeString::FloatToStrF (see page 3397) with an implied precision of 19 digits.

See Also

System::UnicodeString::FloatToStrF (see page 3397)

35.1.23.6.12 UnicodeString::data Method

Returns a pointer to the underlying string System::UnicodeString::data.

Pascal

```
function data: const void*;
```

C++

```
__fastcall const void* data() const;
```

Description

System::UnicodeString::data returns a **wchar_t** pointer to the System::UnicodeString (see page 3381) object that it uses to store its value. This is the same value as the one returned by the System::UnicodeString::c_str (see page 3392) method, except that System::UnicodeString::c_str (see page 3392) returns a pointer to an empty string when the string is unassigned.

See Also

System::UnicodeString::c_str (see page 3392)

35.1.23.6.13 UnicodeString::Delete Method

Removes specified number of characters from string.

Pascal

```
function Delete(index: Integer; count: Integer): UnicodeString&;
```

C++

```
__fastcall UnicodeString& Delete(int index, int count);
```

Description

System::UnicodeString::Delete modifies the System::UnicodeString (see page 3381) object to remove `count` characters from the string beginning with the character at `index`, where 1 is the index of the first character. It returns the resulting modified string (*this).

If `index` is larger than the character length of the System::UnicodeString (see page 3381) object or less than 1, no characters are deleted.

If `count` specifies more characters than remain starting at the `index`, System::UnicodeString::Delete removes the rest of the string. If `count` is less than 0, no characters are deleted.

35.1.23.6.14 UnicodeString::ElementSize Method

Gets element size of data (see page 3396) in a System::UnicodeString (see page 3381).

Pascal

```
function ElementSize: unsigned short;
```

C++

```
unsigned short ElementSize() const;
```

Description

System::UnicodeString::ElementSize gets the element size in bytes of the data (see page 3396) in a System::UnicodeString (see page 3381) instance. If the instance is empty, this returns 2.

See Also

System::UnicodeString::data (see page 3396)

System::UnicodeString::GetRec (see page 3401)

35.1.23.6.15 UnicodeString::EnsureUnicode Method

Ensure that string contains Unicode data (see page 3396).

Pascal

```
function EnsureUnicode: UnicodeString&;
```

C++

```
__fastcall UnicodeString& EnsureUnicode();
```

Description

If the string data (see page 3396) in the System::UnicodeString (see page 3381) instance is not Unicode, System::UnicodeString::EnsureUnicode converts it to Unicode.

35.1.23.6.16 UnicodeString::FloatToStrF Method

Returns string representation of floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer): String; static;
```

C++

```
static __fastcall UnicodeString FloatToStrF(long double value, TStringFloatFormat format, int
```

```
precision, int digits);
```

Description

The `format` parameter controls the format of the resulting string. The `precision` parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the `digits` parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the `digits` parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the `CurrencyString`, `CurrencyFormat`, `NegCurrFormat`, `ThousandSeparator`, and `DecimalSeparator` global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3399) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the `Digits` parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the `DecimalSeparator` and `ThousandSeparator` global variables.

If the given value is NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

35.1.23.6.17 UnicodeString::FmtLoadStr Method

Formats output using a resourced format string.

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer): String; static;
```

C++

```
static __fastcall UnicodeString FmtLoadStr(int ident, const TVarRec * args, int size);
```

Description

System::UnicodeString::FmtLoadStr loads a string from a program's resource string table and uses that string, plus the `args` array, as a parameter to the System::UnicodeString::Format (see page 3399) function. `Ident` is the string resource ID of the desired format string.

See Also

System::UnicodeString::Format (see page 3399)

System::UnicodeString::LoadStr (see page 3405)

System::UnicodeString::LoadString (see page 3405)

35.1.23.6.18 UnicodeString::Format Method

Formats string assembled from System::UnicodeString (see page 3381), format, and array arguments.

Pascal

```
function Format(const format: UnicodeString&; const args: TVarRec *; size: Integer): String;
static;
```

C++

```
static __fastcall UnicodeString Format(const UnicodeString& format, const TVarRec * args, int
size);
```

Description

Use System::UnicodeString::Format to obtain a System::UnicodeString (see page 3381) object whose value is the result of applying an array of arguments (`args`) to a given standard C++ format specifier string (`format`). The last parameter (`size`) is the 1-based index of the last element in `args` (one less than the number of arguments).

Note that System::UnicodeString::Format is a static method. The returned value is a newly allocated System::UnicodeString (see page 3381), even if the method is called with an existing System::UnicodeString (see page 3381) instance.

See Also

System::UnicodeString::printf (see page 3406)

System::UnicodeString::sprintf (see page 3408)

35.1.23.6.19 UnicodeString::FormatFloat Method

Formats floating-point value given by `value` using format string given by `format`.

Pascal

```
function FormatFloat(const format: UnicodeString&; const value: long double&): String; static;
```

C++

```
static __fastcall UnicodeString FormatFloat(const UnicodeString& format, const long double&
value);
```

Description

The following format specifiers are supported in the `format` string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.

.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the `DecimalSeparator` global variable, whose default value is specified in the Number Format (see page 3399) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output has thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the `ThousandSeparator` global variable, whose default value is specified in the Number Format (see page 3399) of the International section in the Windows Control Panel.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to System::UnicodeString::FloatToStrF (see page 3397) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 3399) string-1234-12340.50

Format (see page 3399) string-	**1234**	**-1234**	**0.5**	**0**
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	

#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

See Also

System::UnicodeString::FloatToStrF (see page 3397)

35.1.23.6.20 GetRec Method

This is the overview for the GetRec method overload.

Overload List

	Name	Description
	UnicodeString::GetRec () (see page 3401)	Gets a struct describing a System::UnicodeString (see page 3381).
	UnicodeString::GetRec () (see page 3401)	Gets a struct describing a System::UnicodeString (see page 3381).

35.1.23.6.20.1 UnicodeString::GetRec Method ()

Gets a struct describing a System::UnicodeString (see page 3381).

Pascal

```
function GetRec: const StrRec&;
function GetRec: StrRec&;
```

C++

```
const StrRec& GetRec() const;
StrRec& GetRec();
```

Description

System::UnicodeString::GetRec gets a struct that describes the contents of a System::UnicodeString (see page 3381) instance. The struct has this format:

```
struct StrRec {
  unsigned short codePage;
  unsigned short elemSize;
  int refCnt;
  int length;
};
```

35.1.23.6.21 UnicodeString::Insert Method

Inserts specified string into System::UnicodeString (see page 3381).

Pascal

```
function Insert(const str: UnicodeString&; index: Integer): UnicodeString&;
```

C++

```
__fastcall UnicodeString& Insert(const UnicodeString& str, int index);
```

Description

System::UnicodeString::Insert inserts the string `str` into this System::UnicodeString (see page 3381) object beginning at the position `index`, where 1 is the first position in the string. It returns the resulting modified string (*this).

If `index` is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to System::UnicodeString::Length (see page 3404), turning the operation into an append.

If the `str` parameter is an empty string, System::UnicodeString::Insert does nothing.

System::UnicodeString::Insert throws an EOutOfMemory exception if the method is unable to allocate enough memory to accommodate the new, longer string.

Note: The `index` parameter always specifies the character, not the byte, index.

See Also

System::UnicodeString::Length (see page 3404)

35.1.23.6.22 UnicodeString::IntToHex Method

Converts number into string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer): String; static;
```

C++

```
static __fastcall UnicodeString IntToHex(int value, int digits);
```

Description

`Value` is the number to convert. `Digits` indicates the minimum number of hexadecimal digits.

35.1.23.6.23 UnicodeString::IsDelimiter Method

Returns true if the specified character matches any character in `delimiters` string.

Pascal

```
function IsDelimiter(const delimiters: UnicodeString&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const UnicodeString& delimiters, int index) const;
```

Description

System::UnicodeString::IsDelimiter returns true if the character indicated by `index` (counting from 1) is a character contained in `delimiters`. If the character is not in `delimiters`, System::UnicodeString::IsDelimiter returns false.

See Also

System::UnicodeString::LastDelimiter (see page 3404)

35.1.23.6.24 UnicodeString::IsEmpty Method

Indicates if System::UnicodeString (see page 3381) is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::UnicodeString::IsEmpty returns true if a System::UnicodeString (see page 3381) object is empty, false otherwise.

35.1.23.6.25 UnicodeString::IsLeadSurrogate Method

Tests if element is lead surrogate.

Pascal

```
function IsLeadSurrogate(index: Integer): bool;
```

C++

```
__fastcall bool IsLeadSurrogate(int index) const;
```

Description

System::UnicodeString::IsLeadSurrogate returns true if the indexed element is a lead surrogate and false otherwise. Note that **index** is an element index into the string, not a character or byte index.

See Also

System::UnicodeString::ByteType (see page 3391)

System::UnicodeString::IsTrailSurrogate (see page 3403)

35.1.23.6.26 UnicodeString::IsPathDelimiter Method

Indicates if specified character is a path delimiter.

Pascal

```
function IsPathDelimiter(index: Integer): bool;
```

C++

```
__fastcall bool IsPathDelimiter(int index) const;
```

Description

System::UnicodeString::IsPathDelimiter returns true if the character indicated by `index` (counting from 1) is the path delimiter ('\' on Windows, '/' on Linux).

35.1.23.6.27 UnicodeString::IsTrailSurrogate Method

Tests if element is trail surrogate.

Pascal

```
function IsTrailSurrogate(index: Integer): bool;
```

C++

```
__fastcall bool IsTrailSurrogate(int index) const;
```

Description

System::UnicodeString::IsTrailSurrogate returns true if the indexed element is a trail surrogate and false otherwise. Note that **index** is an element index into the string, not a character or byte index.

See Also

System::UnicodeString::ByteType (see page 3391)

System::UnicodeString::IsLeadSurrogate (see page 3403)

35.1.23.6.28 UnicodeString::LastChar Method

Returns pointer to last character in System::UnicodeString (see page 3381).

Pascal

```
function LastChar: wchar_t*;
```

C++

```
__fastcall wchar_t* LastChar() const;
```

Description

Returns a pointer to the last character in a System::UnicodeString (see page 3381) instance. This function supports multibyte characters, returning a multibyte character when appropriate.

35.1.23.6.29 UnicodeString::LastDelimiter Method

Returns index of rightmost character that matches any character in `delimiters` string.

Pascal

```
function LastDelimiter(const delimiters: UnicodeString&): Integer;
```

C++

```
__fastcall int LastDelimiter(const UnicodeString& delimiters) const;
```

Description

System::UnicodeString::LastDelimiter returns the 1-based character index in the System::UnicodeString (see page 3381) object of the rightmost character that matches any character in `delimiters` except NULL The System::UnicodeString (see page 3381) object may contain multibyte characters; `delimiters` must contain non-NULL characters.

See Also

System::UnicodeString::IsDelimiter (see page 3402)

35.1.23.6.30 UnicodeString::Length Method

Returns length in characters of System::UnicodeString (see page 3381).

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::UnicodeString::Length returns the number of characters (not necessarily bytes) in a System::UnicodeString (see page 3381) object.

35.1.23.6.31 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	UnicodeString::LoadStr (HINSTANCE, int) (see page 3405)	Loads string from compiled resources of specified module.
	UnicodeString::LoadStr (int) (see page 3405)	Loads string from compiled resources of specified module.

35.1.23.6.31.1 UnicodeString::LoadStr Method (HINSTANCE, int)

Loads string from compiled resources of specified module.

Pascal

```
function LoadStr(ident: Integer): String; static;
function LoadStr(hInstance: HINSTANCE; ident: Integer): String; static;
```

C++

```
static __fastcall UnicodeString LoadStr(int ident);
static __fastcall UnicodeString LoadStr(HINSTANCE hInstance, int ident);
```

Description

System::UnicodeString::LoadStr loads a specified string resource.

`ident` is the resource identifier of the string.

`hInstance` is the instance handle of the module that contains the string resource. If `hInstance` is not given, System::UnicodeString::LoadStr loads the string from the current module (executable or shared library)

If the string resource does not exist, System::UnicodeString::LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::UnicodeString::LoadString (see page 3405)

System::UnicodeString::FmtLoadStr (see page 3398)

35.1.23.6.32 UnicodeString::LoadString Method

Loads string from compiled resources of specified module.

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer): UnicodeString&;
```

C++

```
__fastcall UnicodeString& LoadString(HINSTANCE hInstance, int ident);
```

Description

System::UnicodeString::LoadString loads a specified string resource.

`ident` is the resource identifier of the string.

`hInstance` is the instance handle of the module that contains the string resource.

If the string resource does not exist, System::UnicodeString::LoadString returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::UnicodeString::LoadStr (see page 3405)

System::UnicodeString::FmtLoadStr (see page 3398)

35.1.23.6.33 UnicodeString::LowerCase Method

Returns lower-case version of System::UnicodeString (see page 3381).

Pascal

```
function LowerCase: String;
```

C++

```
__fastcall UnicodeString LowerCase() const;
```

Description

System::UnicodeString::LowerCase returns a new System::UnicodeString (see page 3381) instance that contains all characters in this string, converted to lower case. The conversion uses the current locale when appropriate. The original System::UnicodeString (see page 3381) instance remains unchanged.

See Also

System::UnicodeString::UpperCase (see page 3412)

35.1.23.6.34 UnicodeString::Pos Method

Returns character index at which specified substring begins.

Pascal

```
function Pos(const subStr: UnicodeString&): Integer;
```

C++

```
__fastcall int Pos(const UnicodeString& subStr) const;
```

Description

System::UnicodeString::Pos returns the character index in the System::UnicodeString (see page 3381) instance at which the substring `subStr` begins, where 1 is the index of the first character, 2 is the index of the second character, and so on. If the substring is not contained in the System::UnicodeString (see page 3381), System::UnicodeString::Pos returns 0.

See Also

System::UnicodeString::SubString (see page 3408)

35.1.23.6.35 UnicodeString::printf Method

Sets value of System::UnicodeString (see page 3381) instance, given format string and its arguments.

Pascal

```
function printf(const format: wchar_t*; : ...): Integer; cdecl;
```

C++

```
__cdecl int printf(const wchar_t* format, ...);
```

Description

Use System::UnicodeString::printf to set the value of a System::UnicodeString (see page 3381) instance, given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the length in characters of the final formatted string.

See Also

System::UnicodeString::cat_printf (see page 3392)

System::UnicodeString::Format (see page 3399)

System::UnicodeString::sprintf (see page 3408)

System::UnicodeString::vprintf (see page 3413)

35.1.23.6.36 UnicodeString::RefCount Method

Gets reference count of System::UnicodeString (see page 3381).

Pascal

```
function RefCount: Integer;
```

C++

```
int RefCount() const;
```

Description

System::UnicodeString::RefCount gets the reference count of a System::UnicodeString (see page 3381) instance. If the instance is empty, it returns 0.

See Also

System::UnicodeString::GetRec (see page 3401)

35.1.23.6.37 UnicodeString::SetLength Method

Changes character length of System::UnicodeString (see page 3381).

Pascal

```
function SetLength(newLength: Integer): UnicodeString&;
```

C++

```
__fastcall UnicodeString& SetLength(int newLength);
```

Description

System::UnicodeString::SetLength changes the string's character length to `newLength`, truncating if necessary.

System::UnicodeString::SetLength reallocates the underlying array of characters that stores the value of the System::UnicodeString (see page 3381) instance. Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate the System::UnicodeString (see page 3381) instance, an EOutOfMemory exception is thrown. Following a call to System::UnicodeString::SetLength, the System::UnicodeString (see page 3381) instance is guaranteed not to be a shared reference.

System::UnicodeString::SetLength returns the modified System::UnicodeString (see page 3381) object (*this)

35.1.23.6.38 UnicodeString::sprintf Method

Sets value of System::UnicodeString (see page 3381), given format string and its arguments.

Pascal

```
function sprintf(const format: wchar_t*; : ...): UnicodeString&; cdecl;
```

C++

```
__cdecl UnicodeString& sprintf(const wchar_t* format, ...);
```

Description

Use System::UnicodeString::sprintf to set to the value of the System::UnicodeString (see page 3381) instance, given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

This method returns a reference to the System::UnicodeString (see page 3381) instance (*this) with the resulting value.

See Also

System::UnicodeString::Format (see page 3399)

System::UnicodeString::cat_sprintf (see page 3393)

System::UnicodeString::printf (see page 3406)

System::UnicodeString::vprintf (see page 3413)

35.1.23.6.39 UnicodeString::StringOfChar Method

Returns string with specified number of characters.

Pascal

```
function StringOfChar(ch: wchar_t; count: Integer): String; static;
```

C++

```
static __fastcall UnicodeString StringOfChar(wchar_t ch, int count);
```

Description

System::UnicodeString::StringOfChar returns a string containing `count` characters with the character value given by `ch`. For example,

```
UnicodeString (see page 3381) s = System::UnicodeString::UnicodeString (see page 3381)().StringOfChar('A', 4);
```

sets `s` to the string "AAAA".

35.1.23.6.40 UnicodeString::SubString Method

Returns specified substring of System::UnicodeString (see page 3381).

Pascal

```
function SubString(index: Integer; count: Integer): String;
```

C++

```
__fastcall UnicodeString SubString(int index, int count) const;
```

Description

System::UnicodeString::SubString returns a new System::UnicodeString (see page 3381) instance that is a substring of this System::UnicodeString (see page 3381) instance. The substring contains `count` characters beginning at `index`, which is a character index.

See Also

System::UnicodeString::Pos (see page 3406)

35.1.23.6.41 UnicodeString::swap Method

Swaps System::UnicodeString (see page 3381) with another string.

Pascal

```
function swap(var other: String): UnicodeString&;
```

C++

```
UnicodeString& swap(UnicodeString& other);
```

Description

System::UnicodeString::swap swaps a System::UnicodeString (see page 3381) with a given string. Swapping is not done by copying, but by swapping references. This is a very efficient operation, well suited to sorting strings, for example.

35.1.23.6.42 UnicodeString::t_str Method

Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396) as const char*.

Pascal

```
function t_str: char*;
```

C++

```
__fastcall char* t_str();
```

Description

The default VCL string type is now UnicodeString (see page 3381) instead of AnsiString. For backward compatibility, the method System::UnicodeString::t_str returns **const char*** (instead of **const wchar_t***), by narrowing the wide data (see page 3396) of the UnicodeString (see page 3381) instance. This behavior can be unexpected, because code might not expect a call to t_str() to corrupt the underlying data (see page 3396). You can observe this behavior in code that displays the underlying data (see page 3396) in the UI, such as a TListItem.

For example, in the following case the TCHAR mapping option is set by default to char, and the data (see page 3396) displays by the ListView are corrupted after the call to t_str() on the last line of the method:

```
void ProcessSelectedItem(const char* item);
void __fastcall TForm6::ListView1DblClick(TObject *Sender)
{
  int index = ListView1->Selected->Index;
  TListItem *ClassItem = ListView1->Items->Item[index];
  ProcessSelectedItem(ClassItem->Caption.t_str());
}
```

Whenever the TCHAR mapping option is set to **char** (the default setting), you should not use System::UnicodeString::t_str on fields or properties that do not expect the underlying data (see page 3396) to be narrowed. Instead, you can change the behavior of System::UnicodeString::t_str by setting the TCHAR_mapping option to **wchar_t**. You can make this project setting on the **Project ▸ Options ▸ Directories and Conditionals** dialog box, and it will ensure that t_str() returns the UnicodeString (see page 3381)'s wide data (see page 3396) without modifying it.

See Also

System::UnicodeString::c_str (see page 3392)

35.1.23.6.43 UnicodeString::ThrowIfOutOfRange Method

Throws exception if index is out of range in System::UnicodeString (see page 3381).

Pascal

```
procedure ThrowIfOutOfRange(idx: Integer); cdecl;
```

C++

```
__cdecl void ThrowIfOutOfRange(int idx) const;
```

Description

System::UnicodeString::ThrowIfOutOfRange throws an `ERangeError` exception if the given 1-based character index is out of range for a System::UnicodeString (see page 3381) instance. Specifically, it throws an exception if the index is less than 1 or greater than the character length of the string.

35.1.23.6.44 UnicodeString::ToDouble Method

Converts string to floating-point value.

Pascal

```
function ToDouble: double;
```

C++

```
__fastcall double ToDouble() const;
```

Description

System::UnicodeString::ToDouble converts the string to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks in the string are ignored. The `DecimalSeparator` global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, an EConvertError exception is thrown.

35.1.23.6.45 UnicodeString::ToInt Method

Converts string to integer, throwing exception if string is invalid.

Pascal

```
function ToInt: Integer;
```

C++

```
__fastcall int ToInt() const;
```

Description

System::UnicodeString::ToInt converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, an EConvertError exception is thrown.

See Also

System::UnicodeString::ToIntDef (see page 3411)

35.1.23.6.46 UnicodeString::ToIntDef Method

Converts string to integer, returning default value if string is invalid.

Pascal

```
function ToIntDef(defaultValue: Integer): Integer;
```

C++

```
__fastcall int ToIntDef(int defaultValue) const;
```

Description

System::UnicodeString::ToIntDef converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, the value given by `defaultValue` is returned.

See Also

System::UnicodeString::ToInt (see page 3410)

35.1.23.6.47 UnicodeString::Trim Method

Returns new System::UnicodeString (see page 3381) without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim: String;
```

C++

```
__fastcall UnicodeString Trim() const;
```

Description

System::UnicodeString::Trim returns a new System::UnicodeString (see page 3381) instance, removing leading and trailing spaces and control characters. Use System::UnicodeString::Trim to remove blank space before and after the first printing character. The original System::UnicodeString (see page 3381) instance remains unchanged.

See Also

System::UnicodeString::TrimLeft (see page 3411)

System::UnicodeString::TrimRight (see page 3412)

35.1.23.6.48 UnicodeString::TrimLeft Method

Returns new System::UnicodeString (see page 3381) without leading spaces or control characters.

Pascal

```
function TrimLeft: String;
```

C++

```
__fastcall UnicodeString TrimLeft() const;
```

Description

System::UnicodeString::TrimLeft returns a new System::UnicodeString (see page 3381) instance, removing leading spaces and control characters. Use System::UnicodeString::TrimLeft to remove blank space before the first printing character. The original System::UnicodeString (see page 3381) instance remains unchanged.

See Also

System::UnicodeString::Trim (see page 3411)

System::UnicodeString::TrimRight (see page 3412)

35.1.23.6.49 UnicodeString::TrimRight Method

Returns new System::UnicodeString (see page 3381) without trailing spaces or control characters.

Pascal

```
function TrimRight: String;
```

C++

```
__fastcall UnicodeString TrimRight() const;
```

Description

System::UnicodeString::TrimRight returns a new System::UnicodeString (see page 3381) instance, removing trailing spaces and control characters. Use the System::UnicodeString::TrimRight function to remove blank space after the last printing character. The original System::UnicodeString (see page 3381) instance remains unchanged.

See Also

System::UnicodeString::Trim (see page 3411)

System::UnicodeString::TrimLeft (see page 3411)

35.1.23.6.50 UnicodeString::Unique Method

Makes System::UnicodeString (see page 3381) instance unique.

Pascal

```
function Unique: UnicodeString&;
```

C++

```
__fastcall UnicodeString& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::UnicodeString::Unique sets the reference count on the string for the System::UnicodeString (see page 3381) object to 1 so that it is the only object referencing that string.

See Also

System::UnicodeString::RefCount (see page 3407)

35.1.23.6.51 UnicodeString::UpperCase Method

Returns upper-case version of System::UnicodeString (see page 3381).

Pascal

```
function UpperCase: String;
```

C++

```
__fastcall UnicodeString UpperCase() const;
```

Description

System::UnicodeString::UpperCase returns a new System::UnicodeString (see page 3381) instance that contains all characters in this string, converted to upper case. The conversion uses the current locale where appropriate. The original System::UnicodeString (see page 3381) instance remains unchanged.

See Also

System::UnicodeString::LowerCase (see page 3406)

35.1.23.6.52 UnicodeString::vprintf Method

Sets value of System::UnicodeString (see page 3381) given format string and its arguments.

Pascal

```
function vprintf(const format: wchar_t*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(const wchar_t* format, va_list);
```

Description

Use System::UnicodeString::vprintf to set to the value of the System::UnicodeString (see page 3381) instance, given a standard C++ format specifier. Pass values to any arguments in the format specifier as a variable argument list that was created using `va_start`.

This method returns the length in characters of the final formatted string.

See Also

System::UnicodeString::Format (see page 3399)

System::UnicodeString::cat_vprintf (see page 3394)

System::UnicodeString::sprintf (see page 3408)

System::UnicodeString::printf (see page 3406)

35.1.23.6.53 UnicodeString::w_str Method

Returns System::UnicodeString::UnicodeString (see page 3381) data (see page 3396).

Pascal

```
function w_str: wchar_t*;
```

C++

```
__fastcall wchar_t* w_str() const;
```

Description

System::UnicodeString::w_str behaves the same as System::UnicodeString::c_str (see page 3392).

See Also

System::UnicodeString::c_str (see page 3392)

35.1.23.7 UnicodeString Operators

The operators of the UnicodeString class are listed here.

Public Operators

	Name	Description
	!= (see page 3414)	Compares two strings.
	[] (see page 3414)	This is the overview for the [] operator overload.

	+ (see page 3415)	Concatenates two System::UnicodeString (see page 3381) values.
	+= (see page 3416)	Append (see page 3520) System::UnicodeString (see page 3381).
	< (see page 3416)	Compares two strings.
	<= (see page 3417)	Compares two strings.
	= (see page 3418)	Assigns string `rhs` to System::UnicodeString (see page 3381).
	== (see page 3418)	Compares System::UnicodeString (see page 3381) with specified string.
	> (see page 3419)	Compares two strings.
	>= (see page 3419)	Compares two strings.

35.1.23.7.1 UnicodeString::!= Operator

Compares two strings.

Pascal

```
operator !=(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator !=(const UnicodeString& rhs) const;
```

Description

Returns true if the strings are not the same, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::!= performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.7.2 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	UnicodeString::[] (int) (see page 3414)	Returns character at specified index in string.
	UnicodeString::[] (int) (see page 3414)	Returns character at specified index in string.

35.1.23.7.2.1 UnicodeString::[] Operator (int)

Returns character at specified index in string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall wchar_t operator [](const int idx) const;
__fastcall wchar_t& operator [](const int idx);
```

Description

System::UnicodeString (see page 3381)::[] returns the character in the string at the character index value `idx`. The System::UnicodeString (see page 3381)::[] assumes a base index of 1.

See Also

System::UnicodeString::Substring

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

System::UnicodeString::+= (see page 3416)

35.1.23.7.3 UnicodeString::+ Operator

Concatenates two System::UnicodeString (see page 3381) values.

Pascal

```
operator +(const rhs: UnicodeString&);
```

C++

```
__fastcall UnicodeString operator +(const UnicodeString& rhs) const;
```

Description

The friend function returns a System::UnicodeString (see page 3381) instance that is the concatenation of strings `lhs` and `rhs`.

The member function returns a System::UnicodeString (see page 3381) instance that is the concatenation of this System::UnicodeString (see page 3381) instance and `rhs`.

See Also

System::AnsiStringBase

System::WideString

System::UnicodeString::[] (see page 3414)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+= (see page 3416)

35.1.23.7.4 UnicodeString::+= Operator

Append (see page 3520) System::UnicodeString (see page 3381).

Pascal

```
operator +=(const rhs: UnicodeString&);
```

C++

```
__fastcall UnicodeString& operator +=(const UnicodeString& rhs);
```

Description

System::UnicodeString (see page 3381)::+= concatenates this System::UnicodeString (see page 3381) instance and `rhs`, assigning the result to this System::UnicodeString (see page 3381) instance.

System::UnicodeString (see page 3381)::+= is not supported on a property with getter/setter functions.

See Also

System::AnsiStringBase

System::WideString

System::UnicodeString::[] (see page 3414)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.7.5 UnicodeString::< Operator

Compares two strings.

Pascal

```
operator <(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator <(const UnicodeString& rhs) const;
```

Description

Returns true if a System::UnicodeString (see page 3381) instance is less than `rhs`, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::< performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.7.6 UnicodeString::<= Operator

Compares two strings.

Pascal

```
operator <=(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator <=(const UnicodeString& rhs) const;
```

Description

Returns true if the System::UnicodeString (see page 3381) instance is less than or equal to `rhs`, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::<= performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::+ (see page 3415)

35.1.23.7.7 UnicodeString::= Operator

Assigns string `rhs` to System::UnicodeString (see page 3381).

Pascal

```
operator =(const rhs: UnicodeString&);
```

C++

```
__fastcall UnicodeString& operator =(const UnicodeString& rhs);
```

Description

Use System::UnicodeString (see page 3381)::= to assign the value of the System::UnicodeString (see page 3381) instance from another instance of System::UnicodeString (see page 3381).

See Also

System::AnsiStringBase

System::WideString

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

System::UnicodeString::+= (see page 3416)

35.1.23.7.8 UnicodeString::== Operator

Compares System::UnicodeString (see page 3381) with specified string.

Pascal

```
operator ==(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator ==(const UnicodeString& rhs) const;
```

Description

Returns true if this System::UnicodeString (see page 3381) instance is the same as `rhs`, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::== performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.7.9 UnicodeString::> Operator

Compares two strings.

Pascal

```
operator >(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator >(const UnicodeString& rhs) const;
```

Description

Returns true if this System::UnicodeString (see page 3381) instance is greater than `rhs`, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::> performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::>= (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.7.10 UnicodeString::>= Operator

Compares two strings.

Pascal

```
operator >=(const rhs: UnicodeString&);
```

C++

```
__fastcall bool operator >=(const UnicodeString& rhs) const;
```

Description

Returns true if this System::UnicodeString (see page 3381) instance is greater than or equal to `rhs`, false otherwise. The compare operation is controlled by the current Windows locale, when appropriate.

Note: System::UnicodeString (see page 3381)::>= performs a case sensitive comparison. To ignore case, use the CompareIC (see page 3395) method.

See Also

System::UnicodeString::CompareIC (see page 3395)

System::UnicodeString::= (see page 3418)

System::UnicodeString::== (see page 3418)

System::UnicodeString::!= (see page 3414)

System::UnicodeString::> (see page 3419)

System::UnicodeString::< (see page 3416)

System::UnicodeString::<= (see page 3417)

System::UnicodeString::+ (see page 3415)

35.1.23.8 UnicodeString Friends

The friends of the UnicodeString class are listed here.

Public Friends

Name	Description
UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs) (see page 3420)	This is friend UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs).
UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs) (see page 3420)	This is friend UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs).

35.1.23.8.1 friend UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs) Friend

Pascal

```
UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs)
```

C++

```
friend UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs);
```

Description

This is friend UnicodeString __fastcall operator +(const char*, const UnicodeString& rhs).

35.1.23.8.2 friend UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs) Friend

Pascal

```
UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs)
```

C++

```
friend UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs);
```

Description

This is friend UnicodeString __fastcall operator +(const wchar_t*, const UnicodeString& rhs).

35.1.24 Variant Class

System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.

Class Hierarchy

Pascal

```
Variant = class(TVarData);
```

C++

```
class Variant : public TVarData;
```

File

sysvari.h

Description

The System::Variant type is capable of representing values that change type dynamically. Whereas a variable of any other type is statically bound to that type, a variable of the System::Variant type can assume values of differing types at run-time. The System::Variant type is most commonly used in situations where the actual type to be operated upon varies or is unknown at compile-time. While variants offer great flexibility, they also consume more memory than regular variables, and operations on variants are substantially slower than operations on statically typed values.

System::Variants (see page 4973) can contain various numeric, string, Boolean, and date-time values. If COM is available (Windows only) variants can also contain OLE Automation objects. Finally, variants can contain arrays of any of the above types. The special System::Variant value Unassigned is used to indicate that a variant has not yet been assigned a value, and the special variant value Null is used to indicate unknown or missing data.

A variant can be constructed from the following data types:

short (see page 3462)

int (see page 3461)

float (see page 3460)

double (see page 3460)

Currency (see page 3459)

TDateTime (see page 3463)

bool (see page 3458)

WordBool

Byte

AnsiString (see page 3458)&

char (see page 3459) *

wchar_t * const

Ole2::IDispatch (see page 3494)* const (Windows only)

Ole2::IUnknown (see page 3756)* const (Windows only)

Note: When a System::Variant contains an OLE Automation object, the variant can be used to get and set properties of the

object, and to invoke methods on the object.

System::Variant variables are always initialized to be Unassigned when they are first created. This is true whether a variant variable is global, local, or part of a structure such as an array.

In C++ code, variant arrays are usually created using a System::Variant constructor in conjunction with the OPENARRAY macro:

```
Variant V(OPENARRAY(int,(0,HighVal,0,HighVal)),varInteger);
```

You can also use the VarArrayCreate function, but that function is designed for use in Delphi code, and makes for complex C++ code.

Note: Use only the operators declared within System::Variant. The compiler ignores any operators you overload yourself.

Note: For binary operators, if one operand is of type System::Variant, the other operand is automatically converted to type System::Variant.

See Also

System::AutoCmd

System::TVarRec (see page 3747)

TVarData (see page 3740)

35.1.24.1 Variant Members

The following tables list the members exposed by Variant.

Public Methods

	Name	Description
	~Variant (see page 3424)	Frees a System::Variant::Variant (see page 3421) object.
	ArrayDimCount (see page 3429)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 3429)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 3429)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 3430)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 3430)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 3430)	Unlocks a variant array that was previously locked by ArrayLock (see page 3429).
	AsType (see page 3431)	Casts a System::Variant::Variant (see page 3421) object to the type specified by the argument VarType.
	ChangeType (see page 3431)	Changes the data type of a System::Variant::Variant (see page 3421) object once it has been instantiated.
	Clear (see page 3431)	System::Variant::Clears the value of the System::Variant::Variant (see page 3421).
	Empty (see page 3431)	This is Empty, a member of class Variant.
	GetBaseVariant (see page 3432)	Returns the System::Variant (see page 3421) that is assigned as the value of this System::Variant (see page 3421) when Type (see page 3436) is varSystem::Variant (see page 3421).
	GetElement (see page 3432)	This is the overview for the GetElement method overload.
	GetError (see page 3433)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and returns the integer value.
	IsArray (see page 3433)	Queries the VType of the base class TVarData (see page 3740) for the varArray (see page 3861) bit.
	IsEmpty (see page 3433)	Queries the VType of the base class TVarData (see page 3740).
	IsNull (see page 3434)	Queries the VType of the base class TVarData (see page 3740) for the varNull (see page 3868) bit.
	NoParam (see page 3434)	This is NoParam, a member of class Variant.

	PutElement (see page 3434)	This is the overview for the PutElement method overload.
	Sanitized (see page 3435)	This is Sanitized, a member of class Variant.
	SetError (see page 3435)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and assigns the integer err as the value of the varError (see page 3866).
	Type (see page 3436)	Returns type code of a System::Variant (see page 3421) instance.
	Variant (see page 3424)	This is the overview for the Variant constructor overload.

Public Operators

	Name	Description
	- (see page 3439)	This is the overview for the - operator overload.
	! (see page 3439)	Returns a new System::Variant::Variant (see page 3421) that is the logical negation of this System::Variant::Variant (see page 3421).
	!= (see page 3440)	This is the overview for the != operator overload.
	% (see page 3440)	This is the overview for the % operator overload.
	%= (see page 3441)	Returns this System::Variant::Variant (see page 3421) as the remainder from dividing its original value and the System::Variant::Variant (see page 3421) specified by rhs.
	& (see page 3442)	This is the overview for the & operator overload.
	&= (see page 3442)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise and operation.
	* (see page 3443)	This is the overview for the * operator overload.
	*= (see page 3443)	Multiplies this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) specified by rhs.
	/ (see page 3444)	This is the overview for the / operator overload.
	/= (see page 3444)	Divides this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) rhs.
	^ (see page 3445)	This is the overview for the ^ operator overload.
	^= (see page 3445)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise xor operation.
	__int64 (see page 3446)	This is __int64, a member of class Variant.
	| (see page 3446)	This is the overview for the | operator overload.
	|= (see page 3446)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise or operation.
	+ (see page 3447)	This is the overview for the + operator overload.
	+= (see page 3447)	Adds the System::Variant::Variant (see page 3421) specified by rhs to this System::Variant::Variant (see page 3421) object.
	< (see page 3448)	This is the overview for the < operator overload.
	<< (see page 3448)	This is the overview for the << operator overload.
	<<= (see page 3449)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 3421).
	<= (see page 3449)	This is the overview for the <= operator overload.
	-= (see page 3454)	Subtracts the System::Variant::Variant (see page 3421) specified by rhs from this System::Variant::Variant (see page 3421) object.
	= (see page 3450)	This is the overview for the = operator overload.
	== (see page 3455)	This is the overview for the == operator overload.
	> (see page 3456)	This is the overview for the > operator overload.
	>= (see page 3456)	This is the overview for the >= operator overload.
	>> (see page 3457)	This is the overview for the >> operator overload.
	>>= (see page 3458)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 3421).
	AnsiString (see page 3458)	Converts the System::Variant::Variant (see page 3421) to an AnsiString object.
	bool (see page 3458)	Converts the System::Variant::Variant (see page 3421) to a boolean value.
	char (see page 3459)	This is char, a member of class Variant.
	Currency (see page 3459)	Converts the System::Variant::Variant (see page 3421) to a Currency object.
	Currency* (see page 3459)	This is Currency*, a member of class Variant.
	double (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a double value.
	double* (see page 3460)	This is double*, a member of class Variant.
	float (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a float value.

	float* (see page 3460)	This is float*, a member of class Variant.
	IDispatch* (see page 3461)	Converts the System::Variant (see page 3421) to an System::Variant::IDispatch (see page 3494)* interface pointer.
	IInterface* (see page 3461)	This is IInterface*, a member of class Variant.
	int (see page 3461)	Converts the System::Variant::Variant (see page 3421) to an integer value.
	int* (see page 3461)	This is int*, a member of class Variant.
	IUnknown* (see page 3462)	Converts the System::Variant (see page 3421) to an System::Variant::IUnknown (see page 3756)* interface pointer.
	long (see page 3462)	This is long, a member of class Variant.
	long* (see page 3462)	This is long*, a member of class Variant.
	short (see page 3462)	Converts the System::Variant::Variant (see page 3421) to a short value.
	short* (see page 3463)	This is short*, a member of class Variant.
	signed char (see page 3463)	This is signed char, a member of class Variant.
	signed char* (see page 3463)	This is signed char*, a member of class Variant.
	TDateTime (see page 3463)	Converts the System::Variant::Variant (see page 3421) to a TDateTime object.
	TDateTime* (see page 3464)	This is TDateTime*, a member of class Variant.
	UnicodeString (see page 3464)	This is UnicodeString, a member of class Variant.
	unsigned char (see page 3464)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value.
	unsigned char* (see page 3465)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value. And returns a reference.
	unsigned int (see page 3465)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 3465)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 3465)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 3466)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value.
	unsigned short* (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value and returns a reference to the value.
	WideString (see page 3466)	This is WideString, a member of class Variant.

35.1.24.2 Variant::~Variant Destructor

Frees a System::Variant::Variant (see page 3421) object.

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~Variant();
```

Description

System::Variant (see page 3421)::~Variant (see page 3421) is the destructor for System::Variant::Variant (see page 3421).

35.1.24.3 Variant Constructor

This is the overview for the Variant constructor overload.

Overload List

	Name	Description
	Variant::Variant () (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).

	Variant::Variant (__int64) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (__int64*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (AnsiString&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (bool) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (char) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (char*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (Currency&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (Currency*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (double) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (double*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (float) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (float*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (int) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (int*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (int*, int, Word) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (long) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (long double) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (long*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (short) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (short*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (signed char) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (signed char*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (System::DelphiInterface<IDispatch>&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).

	Variant::Variant (TDateTime&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (TDateTime*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (TVarData&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (UnicodeString&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned char) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned char*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned int) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned int*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned long) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned long*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned short) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (unsigned short*) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (Variant&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (Variant*, int) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (wchar_t*, bool) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).
	Variant::Variant (WideString&) (see page 3426)	Creates an instance of System::Variant::Variant (see page 3421).

35.1.24.3.1 Variant::Variant Constructor ()

Creates an instance of System::Variant::Variant (see page 3421).

Pascal

```
constructor Create;
constructor Create(const src: Variant&);
constructor Create(const src: TVarData&);
constructor Create(const src: bool);
constructor Create(const src: char);
constructor Create(const src: signed char);
constructor Create(const src: unsigned char);
constructor Create(const src: short);
constructor Create(const src: unsigned short);
constructor Create(const src: Integer);
constructor Create(const src: unsigned int);
constructor Create(const src: long);
```

```
constructor Create(const src: unsigned long);
constructor Create(const src: float);
constructor Create(const src: double);
constructor Create(const src: long double);
constructor Create(const src: __int64);
constructor Create(const src: AnsiString&);
constructor Create(const src: Currency&);
constructor Create(const src: TDateTime&);
constructor Create(const src: WideString&);
constructor Create(const src: UnicodeString&);
constructor Create(const src: char*);
constructor Create(var src: wchar_t; makeCopy: bool = true);
constructor Create(const src: System::DelphiInterface<IDispatch>&);
constructor Create(var src: signed char);
constructor Create(var src: unsigned char);
constructor Create(var src: short);
constructor Create(var src: unsigned short);
constructor Create(var src: Integer);
constructor Create(var src: unsigned int);
constructor Create(var src: long);
constructor Create(var src: unsigned long);
constructor Create(var src: float);
constructor Create(var src: double);
constructor Create(var src: __int64);
constructor Create(var src: Currency);
constructor Create(var src: TDateTime);
constructor Create(const bounds: int*; const boundsSize: Integer; varType: Word);
constructor Create(const values: Variant*; const valuesSize: Integer);
```

C++

```
__fastcall Variant();
__fastcall Variant(const Variant& src);
__fastcall Variant(const TVarData& src);
__fastcall Variant(const bool src);
__fastcall Variant(const char src);
__fastcall Variant(const signed char src);
__fastcall Variant(const unsigned char src);
__fastcall Variant(const short src);
__fastcall Variant(const unsigned short src);
__fastcall Variant(const int src);
__fastcall Variant(const unsigned int src);
__fastcall Variant(const long src);
__fastcall Variant(const unsigned long src);
__fastcall Variant(const float src);
__fastcall Variant(const double src);
__fastcall Variant(const long double src);
__fastcall Variant(const __int64 src);
__fastcall Variant(const AnsiString& src);
__fastcall Variant(const Currency& src);
__fastcall Variant(const TDateTime& src);
__fastcall Variant(const WideString& src);
__fastcall Variant(const UnicodeString& src);
__fastcall Variant(const char* src);
__fastcall Variant(wchar_t* src, bool makeCopy = true);
__fastcall Variant(const System::DelphiInterface<IDispatch>& src);
__fastcall Variant(signed char* src);
__fastcall Variant(unsigned char* src);
__fastcall Variant(short* src);
__fastcall Variant(unsigned short* src);
__fastcall Variant(int* src);
__fastcall Variant(unsigned int* src);
__fastcall Variant(long* src);
__fastcall Variant(unsigned long* src);
__fastcall Variant(float* src);
__fastcall Variant(double* src);
__fastcall Variant(__int64* src);
```

```
__fastcall Variant(Currency* src);
__fastcall Variant(TDateTime* src);
__fastcall Variant(const int* bounds, const int boundsSize, Word varType);
__fastcall Variant(const Variant* values, const int valuesSize);
```

Description

The first System::Variant::Variant (see page 3421) constructor above creates a variant instance with the value Unassigned.

The second System::Variant::Variant (see page 3421) constructor creates a System::Variant::Variant (see page 3421) array with the bounds given by bounds and the element type given by varType. The bounds parameter must contain an even number of values, and each pair of values must specify the upper and lower bounds of one dimension of the array. The boundsSize parameter is the index of the last element in bounds. The element type of the array, given by the varType parameter, must be one of the TVarData (see page 3740) type codes, and cannot include the varArray (see page 3861) or varByRef (see page 3862) bits. The element type cannot be varString (see page 3871). To create an array of strings, use the varOleStr (see page 3869) type code. If the element type is varSystem::Variant::Variant (see page 3421), the elements of the array are themselves System::Variant::Variants (see page 4973) and can, in turn, contain System::Variant::Variant (see page 3421) arrays.

The third System::Variant::Variant (see page 3421) constructor creates a one-dimensional System::Variant::Variant (see page 3421) array with the elements given by the values parameter. The low bound of the returned array is zero, the high bound is given by valuesSize (the index of the last value). The element type of the instantiated array is System::Variant::Variant (see page 3421).

The remaining System::Variant::Variant (see page 3421) constructors create a System::Variant::Variant (see page 3421) with the same value as the src argument, converting src as appropriate. Constructors that declare src as a const parameter copy src into the variant's internal representation. Constructors that do not declare src as a const create a reference to src and set the variant's varByRef (see page 3862) bit.

Unassigned (see page 5058)

TVarData (see page 3740)

35.1.24.4 Variant Methods

The methods of the Variant class are listed here.

Public Methods

	Name	Description
	ArrayDimCount (see page 3429)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 3429)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 3429)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 3430)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 3430)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 3430)	Unlocks a variant array that was previously locked by ArrayLock (see page 3429).
	AsType (see page 3431)	Casts a System::Variant::Variant (see page 3421) object to the type specified by the argument VarType.
	ChangeType (see page 3431)	Changes the data type of a System::Variant::Variant (see page 3421) object once it has been instantiated.
	Clear (see page 3431)	System::Variant::Clears the value of the System::Variant::Variant (see page 3421).
	Empty (see page 3431)	This is Empty, a member of class Variant.

	GetBaseVariant (see page 3432)	Returns the System::Variant (see page 3421) that is assigned as the value of this System::Variant (see page 3421) when Type (see page 3436) is varSystem::Variant (see page 3421).
	GetElement (see page 3432)	This is the overview for the GetElement method overload.
	GetError (see page 3433)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and returns the integer value.
	IsArray (see page 3433)	Queries the VType of the base class TVarData (see page 3740) for the varArray (see page 3861) bit.
	IsEmpty (see page 3433)	Queries the VType of the base class TVarData (see page 3740).
	IsNull (see page 3434)	Queries the VType of the base class TVarData (see page 3740) for the varNull (see page 3868) bit.
	NoParam (see page 3434)	This is NoParam, a member of class Variant.
	PutElement (see page 3434)	This is the overview for the PutElement method overload.
	Sanitized (see page 3435)	This is Sanitized, a member of class Variant.
	SetError (see page 3435)	Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and assigns the integer err as the value of the varError (see page 3866).
	Type (see page 3436)	Returns type code of a System::Variant (see page 3421) instance.

35.1.24.4.1 Variant::ArrayDimCount Method

Returns the number of dimensions of the given variant.

Pascal

```
function ArrayDimCount: Integer;
```

C++

```
__fastcall int ArrayDimCount() const;
```

Description

The resulting value is zero if the given variant is not a System::Variant::Variant (see page 3421) array.

35.1.24.4.2 Variant::ArrayHighBound Method

Returns the high bound of the given dimension in the given variant array.

Pascal

```
function ArrayHighBound(const dim: Integer = 1): Integer;
```

C++

```
__fastcall int ArrayHighBound(const int dim = 1) const;
```

Description

The dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An ESystem::Variant::VariantError exception is raised if the variant given by A is not an array, or if the dimension specified by dim does not exist.

35.1.24.4.3 Variant::ArrayLock Method

Locks the given variant array and returns a pointer to the data stored in the array.

Pascal

```
function ArrayLock: Pointer;
```

C++

```
__fastcall Pointer ArrayLock();
```

Description

While locked, a variant array can not be resized and any calls to ArrayRedim (see page 3430) will fail. Once locked, a variant array must later be unlocked using ArrayUnlock (see page 3430). An ESystem::Variant::VariantError exception is raised if the variant given by A is not an array.

The pointer returned by System::Variant::ArrayLock points to an array of elements in which the leftmost dimension increases first. In other words, the dimensions of the returned array pointer are reversed from the dimensions of the variant array.

Once it is verified that a variant array has the correct bounds and dimensions, System::Variant::ArrayLock can be used to gain direct access to the array data which results in much improved performance.

35.1.24.4.4 Variant::ArrayLowBound Method

Returns the low bound of the given dimension in the given variant array.

Pascal

```
function ArrayLowBound(const dim: Integer = 1): Integer;
```

C++

```
__fastcall int ArrayLowBound(const int dim = 1) const;
```

Description

The dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An ESystem::Variant::VariantError exception is raised if the variant given by A is not an array, or if the dimension specified by dim does not exist.

35.1.24.4.5 Variant::ArrayRedim Method

Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.

Pascal

```
procedure ArrayRedim(highBound: Integer);
```

C++

```
__fastcall void ArrayRedim(int highBound);
```

Description

Existing elements of the array are preserved, and new elements are set to zero or empty. An ESystem::Variant::VariantError exception is raised if the variant given by A is not an array, or if there is not enough memory to resize the array.

35.1.24.4.6 Variant::ArrayUnlock Method

Unlocks a variant array that was previously locked by ArrayLock (see page 3429).

Pascal

```
procedure ArrayUnlock;
```

C++

```
__fastcall void ArrayUnlock();
```

Description

System::Variant::ArrayUnlock invalidates the pointer returned by a call to the ArrayLock (see page 3429) method. An ESystem::Variant::VariantError exception is raised if the System::Variant::Variant (see page 3421) is not an array.

35.1.24.4.7 Variant::AsType Method

Casts a System::Variant::Variant (see page 3421) object to the type specified by the argument VarType.

Pascal

```
function AsType(VarType: Integer): Variant;
```

C++

```
__fastcall Variant AsType(int VarType) const;
```

Description

System::Variant::AsType returns a new System::Variant::Variant (see page 3421) with the same value as this System::Variant::Variant (see page 3421) but with the type specified by VarType. After the call to System::Variant::AsType there are two System::Variant::Variant (see page 3421) objects of the same type.

35.1.24.4.8 Variant::ChangeType Method

Changes the data type of a System::Variant::Variant (see page 3421) object once it has been instantiated.

Pascal

```
function ChangeType(VarType: Integer): Variant&;
```

C++

```
__fastcall Variant& ChangeType(int VarType);
```

Description

System::Variant::ChangeType converts the System::Variant::Variant (see page 3421) to the type specified by VarType.

See Also

System::Variant::Type (see page 3436)

35.1.24.4.9 Variant::Clear Method

System::Variant::Clears the value of the System::Variant::Variant (see page 3421).

Pascal

```
procedure Clear;
```

C++

```
__fastcall void Clear();
```

Description

System::Variant::Clear assigns the value Unassigned to this System::Variant::Variant (see page 3421).

See Also

Unassigned (see page 5058)

35.1.24.4.10 Variant::Empty Method

Pascal

```
function Empty: Variant&; static;
```

C++

```
static Variant& Empty();
```

Description

This is Empty, a member of class Variant.

35.1.24.4.11 Variant::GetBaseVariant Method

Returns the System::Variant (see page 3421) that is assigned as the value of this System::Variant (see page 3421) when Type (see page 3436) is varSystem::Variant (see page 3421).

Pascal

```
function GetBaseVariant: Variant*;
```

C++

```
__fastcall Variant* GetBaseVariant();
```

Description

Call System::Variant::GetBaseVariant to remove a level of indirection by accessing a System::Variant (see page 3421) that has been assigned as the value of this System::Variant (see page 3421). Check the Type (see page 3436) method to ensure that the variant is of type var System::Variant (see page 3421) before calling System::Variant::GetBaseVariant.

See Also

System::Variant (see page 3421)

35.1.24.4.12 GetElement Method

This is the overview for the GetElement method overload.

Overload List

	Name	Description
	Variant::GetElement (int) (see page 3432)	Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.
	Variant::GetElement (int, int) (see page 3432)	Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.
	Variant::GetElement (int, int, int) (see page 3432)	Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.
	Variant::GetElement (int, int, int, int) (see page 3432)	Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.
	Variant::GetElement (int, int, int, int, int) (see page 3432)	Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.

35.1.24.4.12.1 Variant::GetElement Method (int)

Returns the value of a specified element in a System::Variant::Variant (see page 3421) array.

Pascal

```
function GetElement(const i1: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer; const i3: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer; const i3: Integer; const i4:
```

```
  Integer): Variant;
  function GetElement(const i1: Integer; const i2: Integer; const i3: Integer; const i4:
  Integer; const i5: Integer): Variant;
```

C++

```
  __fastcall Variant GetElement(const int i1) const;
  __fastcall Variant GetElement(const int i1, const int i2) const;
  __fastcall Variant GetElement(const int i1, const int i2, const int i3) const;
  __fastcall Variant GetElement(const int i1, const int i2, const int i3, const int i4) const;
  __fastcall Variant GetElement(const int i1, const int i2, const int i3, const int i4, const
  int i5) const;
```

Description

Use System::Variant::GetElement to access one-dimensional or multi-dimensional System::Variant::Variant (see page 3421) arrays of up to 5 dimensions. The parameters specify the indexes of the desired element.

See Also

System::Variant::PutElement (see page 3435)

35.1.24.4.13 Variant::GetError Method

Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and returns the integer value.

Pascal

```
  function GetError: HResult;
```

C++

```
  __fastcall HResult GetError() const;
```

Description

See the base class TVarData (see page 3740) for more information about varError (see page 3866).

35.1.24.4.14 Variant::IsArray Method

Queries the VType of the base class TVarData (see page 3740) for the varArray (see page 3861) bit.

Pascal

```
  function IsArray: bool;
```

C++

```
  __fastcall bool IsArray() const;
```

Description

System::Variant::IsArray returns true if the given variant is an array, false otherwise.

See Also

TVarData (see page 3740)

35.1.24.4.15 Variant::IsEmpty Method

Queries the VType of the base class TVarData (see page 3740).

Pascal

```
  function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::Variant::IsEmpty returns true if the System::Variant::Variant (see page 3421) type code is varEmpty (see page 3865), false otherwise.

See Also

TVarData (see page 3740)

35.1.24.4.16 Variant::IsNull Method

Queries the VType of the base class TVarData (see page 3740) for the varNull (see page 3868) bit.

Pascal

```
function IsNull: bool;
```

C++

```
__fastcall bool IsNull() const;
```

Description

System::Variant::IsNull returns true if the System::Variant::Variant (see page 3421) type code is varNull (see page 3868), false otherwise.

See Also

TVarData (see page 3740)

35.1.24.4.17 Variant::NoParam Method

Pascal

```
function NoParam: Variant&; static;
```

C++

```
static Variant& NoParam();
```

Description

This is NoParam, a member of class Variant.

35.1.24.4.18 PutElement Method

This is the overview for the PutElement method overload.

Overload List

	Name	Description
	Variant::PutElement (Variant&, int) (see page 3435)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.
	Variant::PutElement (Variant&, int, int) (see page 3435)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.
	Variant::PutElement (Variant&, int, int, int) (see page 3435)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.

	Variant::PutElement (Variant&, int, int, int, int) (see page 3435)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.
	Variant::PutElement (Variant&, int, int, int, int, int) (see page 3435)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.

35.1.24.4.18.1 Variant::PutElement Method (Variant&, int)

Assigns an element as the value of an entry in a System::Variant::Variant (see page 3421) array.

Pascal

```
procedure PutElement(const data: Variant&; const i1: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer; const i4: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer; const i4: Integer; const i5: Integer);
```

C++

```
__fastcall void PutElement(const Variant& data, const int i1);
__fastcall void PutElement(const Variant& data, const int i1, const int i2);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3,
const int i4);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3,
const int i4, const int i5);
```

Description

Use System::Variant::PutElement to access one-dimensional and multi-dimensional System::Variant::Variant (see page 3421) arrays of up to 5 dimensions. The data parameter is the value to assign. The remaining parameters provide indexes into the dimensions of the array.

See Also

System::Variant::GetElement (see page 3432)

35.1.24.4.19 Variant::Sanitized Method

Pascal

```
function Sanitized: Variant;
```

C++

```
__fastcall Variant Sanitized() const;
```

Description

This is Sanitized, a member of class Variant.

35.1.24.4.20 Variant::SetError Method

Converts the System::Variant::Variant (see page 3421) to a varError (see page 3866) type and assigns the integer err as the value of the varError (see page 3866).

Pascal

```
procedure SetError(const err: HResult);
```

C++

```
__fastcall void SetError(const HResult err);
```

Description

See the base class TVarData (see page 3740) for more information about varError (see page 3866).

See Also

TVarData (see page 3740)

35.1.24.4.21 Variant::Type Method

Returns type code of a System::Variant (see page 3421) instance.

Pascal

```
function Type: Integer;
```

C++

```
__fastcall int Type() const;
```

Description

System::Variant::Type returns the type code of the given variant. The return value is constructed from the constants declared in the system.hpp header file.

The lower twelve bits of a variant type code (the bits defined by the varSystem::Variant::TypeMask bit mask) define the type of the variant. The varArray (see page 3861) bit is set if the variant is an array of the given type. The varByRef (see page 3862) bit is set if the variant is a reference to a value of the given type as opposed to an actual value.

The following table describes each of the variant type codes.

System::Variant (see page 3421) typeReturn valueContents of variant

Variant (see page 3421) type	Return value	Contents of variant
varEmpty (see page 3865)	0x0000	The variant is Unassigned.
varNull (see page 3868)	0x0001	The variant is Null.
varSmallint (see page 3870)	0x0002	16-bit signed integer (type short (see page 3462) int (see page 3461))
varInteger (see page 3867)	0x0003	32-bit signed integer (type int (see page 3461)).
varSingle (see page 3870)	0x0004	Single-precision floating-point value (type float (see page 3460))
varDouble (see page 3865)	0x0005	Double-precision floating-point value (type double (see page 3460)).
varCurrency (see page 3863)	0x0006	Currency (see page 3459) floating-point value (type Currency (see page 3459)).
varDate (see page 3864)	0x0007	Date and time value (type TDateTime (see page 3463)).
varOleStr (see page 3869)	0x0008	Reference to a dynamically allocated Unicode string.

varDispatch (see page 3864)	0x0009	Reference to an OLE automation object (an IDispatch (see page 3494) interface pointer).
varError (see page 3866)	0x000A	Operating system error code.
varBoolean (see page 3862)	0x000B	16-bit boolean (type WordBool).
varVariant (see page 3873)	0x000C	Indicates another Variant (see page 3421).
varUnknown (see page 3873)	0x000D	Reference to an unknown OLE object (an IUnknown (see page 3756) interface pointer).
varByte (see page 3863)	0x0011	Indicates an unsigned char (see page 3459).
varString (see page 3871)	0x0100	Reference to a dynamically allocated string (type AnsiString (see page 3458)).
varTypeMask (see page 3872)	0x0FFF	Indicates the type of each array element.
varArray (see page 3861)	0x2000	Indicates a Variant (see page 3421) array.
varByRef (see page 3862)	0x4000	Indicates that the variant contains a reference as opposed to a value.

The type of a System::Variant (see page 3421) can be changed using the ChangeSystem::Variant::Type member function.

See Also

System::Variant::ChangeType (see page 3431)

35.1.24.5 Variant Operators

The operators of the Variant class are listed here.

Public Operators

	Name	Description
	- (see page 3439)	This is the overview for the - operator overload.
	! (see page 3439)	Returns a new System::Variant::Variant (see page 3421) that is the logical negation of this System::Variant::Variant (see page 3421).
	!= (see page 3440)	This is the overview for the != operator overload.
	% (see page 3440)	This is the overview for the % operator overload.
	%= (see page 3441)	Returns this System::Variant::Variant (see page 3421) as the remainder from dividing its original value and the System::Variant::Variant (see page 3421) specified by rhs.
	& (see page 3442)	This is the overview for the & operator overload.
	&= (see page 3442)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise and operation.
	* (see page 3443)	This is the overview for the * operator overload.
	*= (see page 3443)	Multiplies this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) specified by rhs.
	/ (see page 3444)	This is the overview for the / operator overload.
	/= (see page 3444)	Divides this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) rhs.
	^ (see page 3445)	This is the overview for the ^ operator overload.
	^= (see page 3445)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise xor operation.

	__int64 (see page 3446)	This is __int64, a member of class Variant.
	| (see page 3446)	This is the overview for the | operator overload.
	|= (see page 3446)	Returns this System::Variant::Variant (see page 3421) after performing a bitwise or operation.
	+ (see page 3447)	This is the overview for the + operator overload.
	+= (see page 3447)	Adds the System::Variant::Variant (see page 3421) specified by rhs to this System::Variant::Variant (see page 3421) object.
	< (see page 3448)	This is the overview for the < operator overload.
	<< (see page 3448)	This is the overview for the << operator overload.
	<<= (see page 3449)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 3421).
	<= (see page 3449)	This is the overview for the <= operator overload.
	= (see page 3450)	This is the overview for the = operator overload.
	-= (see page 3454)	Subtracts the System::Variant::Variant (see page 3421) specified by rhs from this System::Variant::Variant (see page 3421) object.
	== (see page 3455)	This is the overview for the == operator overload.
	> (see page 3456)	This is the overview for the > operator overload.
	>= (see page 3456)	This is the overview for the >= operator overload.
	>> (see page 3457)	This is the overview for the >> operator overload.
	>>= (see page 3458)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 3421).
	AnsiString (see page 3458)	Converts the System::Variant::Variant (see page 3421) to an AnsiString object.
	bool (see page 3458)	Converts the System::Variant::Variant (see page 3421) to a boolean value.
	char (see page 3459)	This is char, a member of class Variant.
	Currency (see page 3459)	Converts the System::Variant::Variant (see page 3421) to a Currency object.
	Currency* (see page 3459)	This is Currency*, a member of class Variant.
	double (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a double value.
	double* (see page 3460)	This is double*, a member of class Variant.
	float (see page 3460)	Converts the System::Variant::Variant (see page 3421) to a float value.
	float* (see page 3460)	This is float*, a member of class Variant.
	IDispatch* (see page 3461)	Converts the System::Variant (see page 3421) to an System::Variant::IDispatch (see page 3494)* interface pointer.
	IInterface* (see page 3461)	This is IInterface*, a member of class Variant.
	int (see page 3461)	Converts the System::Variant::Variant (see page 3421) to an integer value.
	int* (see page 3461)	This is int*, a member of class Variant.
	IUnknown* (see page 3462)	Converts the System::Variant (see page 3421) to an System::Variant::IUnknown (see page 3756)* interface pointer.
	long (see page 3462)	This is long, a member of class Variant.
	long* (see page 3462)	This is long*, a member of class Variant.
	short (see page 3462)	Converts the System::Variant::Variant (see page 3421) to a short value.
	short* (see page 3463)	This is short*, a member of class Variant.
	signed char (see page 3463)	This is signed char, a member of class Variant.
	signed char* (see page 3463)	This is signed char*, a member of class Variant.
	TDateTime (see page 3463)	Converts the System::Variant::Variant (see page 3421) to a TDateTime object.
	TDateTime* (see page 3464)	This is TDateTime*, a member of class Variant.
	UnicodeString (see page 3464)	This is UnicodeString, a member of class Variant.
	unsigned char (see page 3464)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value.
	unsigned char* (see page 3465)	Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value. And returns a reference.
	unsigned int (see page 3465)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 3465)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 3465)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 3466)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value.
	unsigned short* (see page 3466)	Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value and returns a reference to the value.

	WideString (see page 3466)	This is WideString, a member of class Variant.

35.1.24.5.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	Variant::- (AnsiString&) (see page 3439)	Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).
	Variant::- () (see page 3439)	Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).
	Variant::- (double) (see page 3439)	Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).
	Variant::- (int) (see page 3439)	Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).
	Variant::- (Variant&) (see page 3439)	Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).

35.1.24.5.1.1 Variant::- Operator ()

Returns a new System::Variant (see page 3421) that has the negative value of this System::Variant (see page 3421).

Pascal

```
operator -(const rhs: Variant&);
operator -(const rhs: AnsiString&);
operator -(rhs: Integer);
operator -(rhs: double);
operator -;
```

C++

```
__fastcall Variant operator -(const Variant& rhs) const;
__fastcall Variant operator -(const AnsiString& rhs) const;
__fastcall Variant operator -(int rhs) const;
__fastcall Variant operator -(double rhs) const;
__fastcall Variant operator -() const;
```

Description

The unary - operator returns a new System::Variant (see page 3421) whose value has the opposite sign from this System::Variant (see page 3421) (effectively multiplying the System::Variant (see page 3421)'s value by –1).

35.1.24.5.2 Variant::! Operator

Returns a new System::Variant::Variant (see page 3421) that is the logical negation of this System::Variant::Variant (see page 3421).

Pascal

```
operator !;
```

C++

```
__fastcall Variant operator !() const;
```

Description

The System::Variant (see page 3421)::! returns 0 if the System::Variant::Variant (see page 3421) has a nonzero value and 1 if the value of the System::Variant::Variant (see page 3421) is 0 or NULL.

35.1.24.5.3 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	Variant::!= (char*) (see page 3440)	Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.
	Variant::!= (double) (see page 3440)	Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.
	Variant::!= (int) (see page 3440)	Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.
	Variant::!= (TDateTime) (see page 3440)	Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.
	Variant::!= (Variant&) (see page 3440)	Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.

35.1.24.5.3.1 Variant::!= Operator (TDateTime)

Compares the System::Variant::Variant (see page 3421) with another value, testing for inequality.

Pascal

```
operator !=(const rhs: Variant&);
operator !=(const rhs: char*);
operator !=(rhs: Integer);
operator !=(rhs: double);
operator !=(rhs: TDateTime);
```

C++

```
__fastcall bool operator !=(const Variant& rhs) const;
__fastcall bool operator !=(const char* rhs) const;
__fastcall bool operator !=(int rhs) const;
__fastcall bool operator !=(double rhs) const;
__fastcall bool operator !=(TDateTime rhs) const;
```

Description

The != System::Variant (see page 3421)::!= returns true if the System::Variant::Variant (see page 3421)'s value is not the same as the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.4 % Operator

This is the overview for the % operator overload.

Overload List

	Name	Description
	Variant::% (AnsiString&) (see page 3441)	Returns the remainder from dividing the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::% (double) (see page 3441)	Returns the remainder from dividing the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::% (int) (see page 3441)	Returns the remainder from dividing the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::% (Variant&) (see page 3441)	Returns the remainder from dividing the System::Variant::Variant (see page 3421)'s value by a specified value.

35.1.24.5.4.1 Variant::% Operator (AnsiString&)

Returns the remainder from dividing the System::Variant::Variant (see page 3421)'s value by a specified value.

Pascal

```
operator %(const rhs: Variant&);
operator %(const rhs: AnsiString&);
operator %(rhs: Integer);
operator %(rhs: double);
```

C++

```
__fastcall Variant operator %(const Variant& rhs) const;
__fastcall Variant operator %(const AnsiString& rhs) const;
__fastcall Variant operator %(int rhs) const;
__fastcall Variant operator %(double rhs) const;
```

Description

The System::Variant (see page 3421)::% returns a new System::Variant::Variant (see page 3421) that is the modulus of this System::Variant::Variant (see page 3421) and rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.5 Variant::%= Operator

Returns this System::Variant::Variant (see page 3421) as the remainder from dividing its original value and the System::Variant::Variant (see page 3421) specified by rhs.

Pascal

```
operator %=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator %=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an

ESystem::Variant::VariantError exception is thrown.

35.1.24.5.6 & Operator

This is the overview for the & operator overload.

Overload List

	Name	Description
	Variant::& (AnsiString&) (see page 3442)	Performs a bitwise and operation with a specified value.
	Variant::& (double) (see page 3442)	Performs a bitwise and operation with a specified value.
	Variant::& (int) (see page 3442)	Performs a bitwise and operation with a specified value.
	Variant::& (Variant&) (see page 3442)	Performs a bitwise and operation with a specified value.

35.1.24.5.6.1 Variant::& Operator (AnsiString&)

Performs a bitwise and operation with a specified value.

Pascal

```
operator &(const rhs: Variant&);
operator &(const rhs: AnsiString&);
operator &(rhs: Integer);
operator &(rhs: double);
```

C++

```
__fastcall Variant operator &(const Variant& rhs) const;
__fastcall Variant operator &(const AnsiString& rhs) const;
__fastcall Variant operator &(int rhs) const;
__fastcall Variant operator &(double rhs) const;
```

Description

The System::Variant (see page 3421)::& returns a new System::Variant::Variant (see page 3421) that is the result of a bitwise and operation on this System::Variant::Variant (see page 3421) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.7 Variant::&= Operator

Returns this System::Variant::Variant (see page 3421) after performing a bitwise and operation.

Pascal

```
operator &=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator &=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.8 * Operator

This is the overview for the * operator overload.

Overload List

	Name	Description
	Variant::* (AnsiString&) (see page 3443)	Multiplies the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::* (double) (see page 3443)	Multiplies the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::* (int) (see page 3443)	Multiplies the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::* (Variant&) (see page 3443)	Multiplies the System::Variant::Variant (see page 3421)'s value by a specified value.

35.1.24.5.8.1 Variant::* Operator (AnsiString&)

Multiplies the System::Variant::Variant (see page 3421)'s value by a specified value.

Pascal

```
operator *(const rhs: Variant&);
operator *(const rhs: AnsiString&);
operator *(rhs: Integer);
operator *(rhs: double);
```

C++

```
__fastcall Variant operator *(const Variant& rhs) const;
__fastcall Variant operator *(const AnsiString& rhs) const;
__fastcall Variant operator *(int rhs) const;
__fastcall Variant operator *(double rhs) const;
```

Description

The System::Variant (see page 3421)::* returns a new System::Variant::Variant (see page 3421) that is the result of multiplying this System::Variant::Variant (see page 3421) with rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.9 Variant::*= Operator

Multiplies this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) specified by rhs.

Pascal

```
operator *=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator *=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.10 / Operator

This is the overview for the / operator overload.

Overload List

	Name	Description
	Variant::/ (AnsiString&) (see page 3444)	Divides the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::/ (double) (see page 3444)	Divides the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::/ (int) (see page 3444)	Divides the System::Variant::Variant (see page 3421)'s value by a specified value.
	Variant::/ (Variant&) (see page 3444)	Divides the System::Variant::Variant (see page 3421)'s value by a specified value.

35.1.24.5.10.1 Variant::/ Operator (AnsiString&)

Divides the System::Variant::Variant (see page 3421)'s value by a specified value.

Pascal

```
operator /(const rhs: Variant&);
operator /(const rhs: AnsiString&);
operator /(rhs: Integer);
operator /(rhs: double);
```

C++

```
__fastcall Variant operator /(const Variant& rhs) const;
__fastcall Variant operator /(const AnsiString& rhs) const;
__fastcall Variant operator /(int rhs) const;
__fastcall Variant operator /(double rhs) const;
```

Description

The System::Variant (see page 3421)::/ returns a new System::Variant::Variant (see page 3421) that is the result of dividing this System::Variant::Variant (see page 3421) by rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.11 Variant::/= Operator

Divides this System::Variant::Variant (see page 3421) by the System::Variant::Variant (see page 3421) rhs.

Pascal

```
operator /=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator /=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.12 ^ Operator

This is the overview for the ^ operator overload.

Overload List

	Name	Description
	Variant::^ (AnsiString&) (see page 3445)	Performs a bitwise xor operation with a specified value.
	Variant::^ (double) (see page 3445)	Performs a bitwise xor operation with a specified value.
	Variant::^ (int) (see page 3445)	Performs a bitwise xor operation with a specified value.
	Variant::^ (Variant&) (see page 3445)	Performs a bitwise xor operation with a specified value.

35.1.24.5.12.1 Variant::^ Operator (AnsiString&)

Performs a bitwise xor operation with a specified value.

Pascal

```
operator ^(const rhs: Variant&);
operator ^(const rhs: AnsiString&);
operator ^(rhs: Integer);
operator ^(rhs: double);
```

C++

```
__fastcall Variant operator ^(const Variant& rhs) const;
__fastcall Variant operator ^(const AnsiString& rhs) const;
__fastcall Variant operator ^(int rhs) const;
__fastcall Variant operator ^(double rhs) const;
```

Description

The ^ System::Variant (see page 3421)::^ returns a new System::Variant::Variant (see page 3421) that is the result of a bitwise xor operation on this System::Variant::Variant (see page 3421) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.13 Variant::^= Operator

Returns this System::Variant::Variant (see page 3421) after performing a bitwise xor operation.

Pascal

```
operator ^=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator ^=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.14 Variant::__int64 Operator

Pascal

```
operator __int64;
```

C++

```
__fastcall operator __int64() const;
```

Description

This is __int64, a member of class Variant.

35.1.24.5.15 | Operator

This is the overview for the | operator overload.

Overload List

	Name	Description
	Variant::| (AnsiString&) (see page 3446)	Performs a bitwise or operation with a specified value.
	Variant::| (double) (see page 3446)	Performs a bitwise or operation with a specified value.
	Variant::| (int) (see page 3446)	Performs a bitwise or operation with a specified value.
	Variant::| (Variant&) (see page 3446)	Performs a bitwise or operation with a specified value.

35.1.24.5.15.1 Variant::| Operator (AnsiString&)

Performs a bitwise or operation with a specified value.

Pascal

```
operator |(const rhs: Variant&);
operator |(const rhs: AnsiString&);
operator |(rhs: Integer);
operator |(rhs: double);
```

C++

```
__fastcall Variant operator |(const Variant& rhs) const;
__fastcall Variant operator |(const AnsiString& rhs) const;
__fastcall Variant operator |(int rhs) const;
__fastcall Variant operator |(double rhs) const;
```

Description

The | System::Variant (see page 3421)::| returns a new System::Variant::Variant (see page 3421) that is the result of a bitwise or operation on this System::Variant::Variant (see page 3421) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.16 Variant::|= Operator

Returns this System::Variant::Variant (see page 3421) after performing a bitwise or operation.

Pascal

```
operator |=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator |=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.17 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	Variant::+ (double) (see page 3447)	Adds a specified value to the System::Variant::Variant (see page 3421).
	Variant::+ (int) (see page 3447)	Adds a specified value to the System::Variant::Variant (see page 3421).
	Variant::+ (Variant&) (see page 3447)	Adds a specified value to the System::Variant::Variant (see page 3421).

35.1.24.5.17.1 Variant::+ Operator (Variant&)

Adds a specified value to the System::Variant::Variant (see page 3421).

Pascal

```
operator +(const rhs: Variant&);
operator +(rhs: Integer);
operator +(rhs: double);
```

C++

```
__fastcall Variant operator +(const Variant& rhs) const;
__fastcall Variant operator +(int rhs) const;
__fastcall Variant operator +(double rhs) const;
```

Description

The + System::Variant (see page 3421)::+ returns a new System::Variant::Variant (see page 3421) that is the sum of this System::Variant::Variant (see page 3421) and rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.18 Variant::+= Operator

Adds the System::Variant::Variant (see page 3421) specified by rhs to this System::Variant::Variant (see page 3421) object.

Pascal

```
operator +=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator +=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.19 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	Variant::< (char*) (see page 3448)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.
	Variant::< (double) (see page 3448)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.
	Variant::< (int) (see page 3448)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.
	Variant::< (TDateTime) (see page 3448)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.
	Variant::< (Variant&) (see page 3448)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.

35.1.24.5.19.1 Variant::< Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 3421)'s value is less than a specified value.

Pascal

```
operator <(const rhs: Variant&);
operator <(const rhs: char*);
operator <(rhs: Integer);
operator <(rhs: double);
operator <(rhs: TDateTime);
```

C++

```
__fastcall bool operator <(const Variant& rhs) const;
__fastcall bool operator <(const char* rhs) const;
__fastcall bool operator <(int rhs) const;
__fastcall bool operator <(double rhs) const;
__fastcall bool operator <(TDateTime rhs) const;
```

Description

The < System::Variant (see page 3421)::< returns true if the System::Variant::Variant (see page 3421)'s value is less than the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.20 << Operator

This is the overview for the << operator overload.

Overload List

	Name	Description
	Variant::<< (AnsiString&) (see page 3449)	Writes the Variant (see page 3421) to a specified stream.
	Variant::<< (double) (see page 3449)	Writes the Variant (see page 3421) to a specified stream.
	Variant::<< (int) (see page 3449)	Writes the Variant (see page 3421) to a specified stream.
	Variant::<< (Variant&) (see page 3449)	Writes the Variant (see page 3421) to a specified stream.

35.1.24.5.20.1 Variant::<< Operator (AnsiString&)

Writes the Variant (see page 3421) to a specified stream.

Pascal

```
operator <<(const rhs: Variant&);
operator <<(const rhs: AnsiString&);
operator <<(rhs: Integer);
operator <<(rhs: double);
```

C++

```
__fastcall Variant operator <<(const Variant& rhs) const;
__fastcall Variant operator <<(const AnsiString& rhs) const;
__fastcall Variant operator <<(int rhs) const;
__fastcall Variant operator <<(double rhs) const;
```

Description

The << operator is a friend operator that writes out the Variant (see page 3421) specified by arg to the stream specified by os.

Note: This operator is only definedif you #include <iostream> or #define VCL_IOSTREAM before the include statement for sysvari.h (which is typically included indirectly via vcl.h).

35.1.24.5.21 Variant::<<= Operator

Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 3421).

Pascal

```
operator <<=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator <<=(const Variant& rhs);
```

Description

If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.22 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	Variant::<= (char*) (see page 3450)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.
	Variant::<= (double) (see page 3450)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.
	Variant::<= (int) (see page 3450)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.
	Variant::<= (TDateTime) (see page 3450)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.
	Variant::<= (Variant&) (see page 3450)	Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.

35.1.24.5.22.1 Variant::<= Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 3421)'s value is less than or equal to a specified value.

Pascal

```
operator <=(const rhs: Variant&);
operator <=(const rhs: char*);
operator <=(rhs: Integer);
operator <=(rhs: double);
operator <=(rhs: TDateTime);
```

C++

```
__fastcall bool operator <=(const Variant& rhs) const;
__fastcall bool operator <=(const char* rhs) const;
__fastcall bool operator <=(int rhs) const;
__fastcall bool operator <=(double rhs) const;
__fastcall bool operator <=(TDateTime rhs) const;
```

Description

The <= System::Variant (see page 3421)::<= returns true if the System::Variant::Variant (see page 3421)'s value is less than or equal to the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantErrorError exception is thrown.

35.1.24.5.23 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	Variant::= (__int64) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (__int64*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (AnsiString&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).

	Variant::= (bool) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (char) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (char*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (Currency&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (Currency*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (double) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (double*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (float) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (float*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IDispatch*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IDispatch**) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IInterface*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IInterface**) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (int) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (int*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IUnknown*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (IUnknown**) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).

	Variant::= (long) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (long*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (short) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (short*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (signed char) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (signed char*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (System::DelphiInterface<IDispatch>&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (TDateTime&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (TDateTime*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (UnicodeString&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned char) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned char*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned int) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned int*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned long) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned long*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (unsigned short) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).

	Variant::= (unsigned short*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (Variant&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (Variant*) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).
	Variant::= (WideString&) (see page 3453)	Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).

35.1.24.5.23.1 Variant::= Operator (AnsiString&)

Copies the System::Variant::Variant (see page 3421) specified by rhs into this System::Variant::Variant (see page 3421).

Pascal

```
operator =(const rhs: Variant&);
operator =(const src: bool);
operator =(const src: char);
operator =(const src: signed char);
operator =(const src: unsigned char);
operator =(const src: short);
operator =(const src: unsigned short);
operator =(const src: Integer);
operator =(const src: unsigned int);
operator =(const src: long);
operator =(const src: unsigned long);
operator =(const src: float);
operator =(const src: double);
operator =(const src: __int64);
operator =(const src: AnsiString&);
operator =(const src: Currency&);
operator =(const src: TDateTime&);
operator =(const src: WideString&);
operator =(const src: UnicodeString&);
operator =(const src: System::DelphiInterface<IDispatch>&);
operator =(var src: IUnknown);
operator =(var src: IInterface);
operator =(var src: IDispatch);

__fastcall Variant& operator =(long* src);
__fastcall Variant& operator =(unsigned long* src);
__fastcall Variant& operator =(float* src);
__fastcall Variant& operator =(double* src);
__fastcall Variant& operator =(__int64* src);
__fastcall Variant& operator =(IUnknown** src);
__fastcall Variant& operator =(IInterface** src);
__fastcall Variant& operator =(IDispatch** src);
__fastcall Variant& operator =(Currency* src);
__fastcall Variant& operator =(TDateTime* src);
__fastcall Variant& operator =(Variant* src);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.24 Variant::-= Operator

Subtracts the System::Variant::Variant (see page 3421) specified by rhs from this System::Variant::Variant (see page 3421) object.

Pascal

```
operator -=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator -=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 4973) determine the meaning of this operation. If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.25 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	Variant::== (AnsiString&) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.
	Variant::== (char*) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.
	Variant::== (double) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.
	Variant::== (int) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.
	Variant::== (TDateTime) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.
	Variant::== (Variant&) (see page 3455)	Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.

35.1.24.5.25.1 Variant::== Operator (AnsiString&)

Compares the System::Variant::Variant (see page 3421) with another value, testing for equality.

Pascal

```
operator ==(const rhs: Variant&);
operator ==(const rhs: char*);
operator ==(rhs: Integer);
operator ==(const rhs: AnsiString&);
operator ==(rhs: double);
operator ==(rhs: TDateTime);
```

C++

```
__fastcall bool operator ==(const Variant& rhs) const;
__fastcall bool operator ==(const char* rhs) const;
__fastcall bool operator ==(int rhs) const;
__fastcall bool operator ==(const AnsiString& rhs) const;
__fastcall bool operator ==(double rhs) const;
__fastcall bool operator ==(TDateTime rhs) const;
```

Description

The == System::Variant (see page 3421)::== returns true if the System::Variant::Variant (see page 3421)'s value is the same as the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.26 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	Variant::> (char*) (see page 3456)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.
	Variant::> (double) (see page 3456)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.
	Variant::> (int) (see page 3456)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.
	Variant::> (TDateTime) (see page 3456)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.
	Variant::> (Variant&) (see page 3456)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.

35.1.24.5.26.1 Variant::> Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 3421)'s value is greater than a specified value.

Pascal

```
operator >(const rhs: Variant&);
operator >(const rhs: char*);
operator >(rhs: Integer);
operator >(rhs: double);
operator >(rhs: TDateTime);
```

C++

```
__fastcall bool operator >(const Variant& rhs) const;
__fastcall bool operator >(const char* rhs) const;
__fastcall bool operator >(int rhs) const;
__fastcall bool operator >(double rhs) const;
__fastcall bool operator >(TDateTime rhs) const;
```

Description

The > System::Variant (see page 3421)::> returns true if the System::Variant::Variant (see page 3421)'s value is greater than the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.27 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	Variant::>= (char*) (see page 3457)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.
	Variant::>= (double) (see page 3457)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.

	Variant::>= (int) (see page 3457)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.
	Variant::>= (TDateTime) (see page 3457)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.
	Variant::>= (Variant&) (see page 3457)	Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.

35.1.24.5.27.1 Variant::>= Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 3421)'s value is greater than or equal to a specified value.

Pascal

```
operator >=(const rhs: Variant&);
operator >=(const rhs: char*);
operator >=(rhs: Integer);
operator >=(rhs: double);
operator >=(rhs: TDateTime);
```

C++

```
__fastcall bool operator >=(const Variant& rhs) const;
__fastcall bool operator >=(const char* rhs) const;
__fastcall bool operator >=(int rhs) const;
__fastcall bool operator >=(double rhs) const;
__fastcall bool operator >=(TDateTime rhs) const;
```

Description

The >= System::Variant (see page 3421)::>= returns true if the System::Variant::Variant (see page 3421)'s value is greater than or equal to the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.28 >> Operator

This is the overview for the >> operator overload.

Overload List

	Name	Description
	Variant::>> (AnsiString&) (see page 3457)	Returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation on this System::Variant (see page 3421).
	Variant::>> (double) (see page 3457)	Returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation on this System::Variant (see page 3421).
	Variant::>> (int) (see page 3457)	Returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation on this System::Variant (see page 3421).
	Variant::>> (Variant&) (see page 3457)	Returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation on this System::Variant (see page 3421).

35.1.24.5.28.1 Variant::>> Operator (AnsiString&)

Returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation on this System::Variant (see

page 3421).

Pascal

```
operator >>(const rhs: Variant&);
operator >>(const rhs: AnsiString&);
operator >>(rhs: Integer);
operator >>(rhs: double);
```

C++

```
__fastcall Variant operator >>(const Variant& rhs) const;
__fastcall Variant operator >>(const AnsiString& rhs) const;
__fastcall Variant operator >>(int rhs) const;
__fastcall Variant operator >>(double rhs) const;
```

Description

The >> operator returns a new System::Variant (see page 3421) that is the result of a shr (right shift) operation, shifting by the number of bits specified by rhs.

If the operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.29 Variant::>>= Operator

Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 3421).

Pascal

```
operator >>=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator >>=(const Variant& rhs);
```

Description

If the System::Variant::Variants (see page 4973) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.30 Variant::AnsiString Operator

Converts the System::Variant::Variant (see page 3421) to an AnsiString object.

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

This conversion System::Variant::AnsiString returns an AnsiString object that is a conversion of this System::Variant::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.31 Variant::bool Operator

Converts the System::Variant::Variant (see page 3421) to a boolean value.

Pascal

```
operator bool;
```

C++

```
__fastcall operator bool() const;
```

Description

This conversion System::Variant::bool returns a bool that is a conversion of this System::Variant::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.32 Variant::char Operator

Pascal

```
operator char;
```

C++

```
__fastcall operator char() const;
```

Description

This is char, a member of class Variant.

35.1.24.5.33 Variant::Currency Operator

Converts the System::Variant::Variant (see page 3421) to a Currency object.

Pascal

```
operator Currency;
```

C++

```
__fastcall operator Currency() const;
```

Description

The Currency conversion System::Variant::Currency returns a Currency or a reference to a Currency that is a conversion of this System::Variant::Variant (see page 3421). If the Currency* conversion is used, the System::Variant::Currency sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.34 Variant::Currency* Operator

Pascal

```
operator Currency*;
```

C++

```
__fastcall operator Currency*();
```

Description

This is Currency*, a member of class Variant.

35.1.24.5.35 Variant::double Operator

Converts the System::Variant::Variant (see page 3421) to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

The double conversion System::Variant::double returns a double or a reference to a double that is a conversion of this System::Variant::Variant (see page 3421). If the double* conversion is used, the System::Variant::double sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.36 Variant::double* Operator

Pascal

```
operator double*;
```

C++

```
__fastcall operator double*();
```

Description

This is double*, a member of class Variant.

35.1.24.5.37 Variant::float Operator

Converts the System::Variant::Variant (see page 3421) to a float value.

Pascal

```
operator float;
```

C++

```
__fastcall operator float() const;
```

Description

The float conversion System::Variant::float returns a float or a reference to a float that is a conversion of this System::Variant::Variant (see page 3421). If the float* conversion is used, the System::Variant::float sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.38 Variant::float* Operator

Pascal

```
operator float*;
```

C++

```
__fastcall operator float*();
```

Description

This is float*, a member of class Variant.

35.1.24.5.39 Variant::IDispatch* Operator

Converts the System::Variant (see page 3421) to an System::Variant::IDispatch (see page 3494)* interface pointer.

Pascal

```
operator IDispatch*;
```

C++

```
__fastcall operator IDispatch*();
```

Description

This conversion operator returns an OLE Automation object System::Variant::IDispatch (see page 3494)* interface pointer that is a conversion of this System::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::VariantError exception is thrown.

35.1.24.5.40 Variant::IInterface* Operator

Pascal

```
operator IInterface*;
```

C++

```
__fastcall operator IInterface*();
```

Description

This is IInterface*, a member of class Variant.

35.1.24.5.41 Variant::int Operator

Converts the System::Variant::Variant (see page 3421) to an integer value.

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

The int conversion System::Variant::int returns an integer or a reference to an integer that is a conversion of this System::Variant::Variant (see page 3421). If the int* conversion is used, the System::Variant::int sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown.

35.1.24.5.42 Variant::int* Operator

Pascal

```
operator int*;
```

C++

```
__fastcall operator int*();
```

Description

This is int*, a member of class Variant.

35.1.24.5.43 Variant::IUnknown* Operator

Converts the System::Variant (see page 3421) to an System::Variant::IUnknown (see page 3756)* interface pointer.

Pascal

```
operator IUnknown*;
```

C++

```
__fastcall operator IUnknown*();
```

Description

This conversion operator returns an OLE object System::Variant::IUnknown (see page 3756)* interface pointer that is a conversion of this System::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::VariantError exception is thrown.

35.1.24.5.44 Variant::long Operator

Pascal

```
operator long;
```

C++

```
__fastcall operator long() const;
```

Description

This is long, a member of class Variant.

35.1.24.5.45 Variant::long* Operator

Pascal

```
operator long*;
```

C++

```
__fastcall operator long*();
```

Description

This is long*, a member of class Variant.

35.1.24.5.46 Variant::short Operator

Converts the System::Variant::Variant (see page 3421) to a short value.

Pascal

```
operator short;
```

C++

```
__fastcall operator short() const;
```

Description

The short conversion System::Variant::short returns a short or a reference to a short that is a conversion of this System::Variant::Variant (see page 3421). If the short* conversion is used, the System::Variant::short sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.47 Variant::short* Operator

Pascal

```
operator short*;
```

C++

```
__fastcall operator short*();
```

Description

This is short*, a member of class Variant.

35.1.24.5.48 Variant::signed char Operator

Pascal

```
operator signed char;
```

C++

```
__fastcall operator signed char() const;
```

Description

This is signed char, a member of class Variant.

35.1.24.5.49 Variant::signed char* Operator

Pascal

```
operator signed char*;
```

C++

```
__fastcall operator signed char*();
```

Description

This is signed char*, a member of class Variant.

35.1.24.5.50 Variant::TDateTime Operator

Converts the System::Variant::Variant (see page 3421) to a TDateTime object.

Pascal

```
operator TDateTime;
```

C++

```
__fastcall operator TDateTime() const;
```

Description

The TDateTime conversion System::Variant::TDateTime returns a TDateTime or a reference to a TDateTime that is a conversion of this System::Variant::Variant (see page 3421). If the TDateTime* conversion is used, the System::Variant::TDateTime sets the varByRef (see page 3862) bit, meaning that the System::Variant::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError exception is thrown.

35.1.24.5.51 Variant::TDateTime* Operator

Pascal

```
operator TDateTime*;
```

C++

```
__fastcall operator TDateTime*();
```

Description

This is TDateTime*, a member of class Variant.

35.1.24.5.52 Variant::UnicodeString Operator

Pascal

```
operator UnicodeString;
```

C++

```
__fastcall operator UnicodeString() const;
```

Description

This is UnicodeString, a member of class Variant.

35.1.24.5.53 Variant::unsigned char Operator

Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value.

Pascal

```
operator unsigned char;
```

C++

```
__fastcall operator unsigned char() const;
```

Description

The System::Variant::unsigned char (see page 3459) conversion operator returns an unsigned char (see page 3459) that is a conversion of this System::Variant::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown. The System::Variant::unsigned char (see page 3459) operator replaces the Byte operator.

35.1.24.5.54 Variant::unsigned char* Operator

Converts the System::Variant (see page 3421) to an unsigned char (see page 3459) value. And returns a reference.

Pascal

```
operator unsigned char*;
```

C++

```
__fastcall operator unsigned char*();
```

Description

The System::Variant::unsigned char (see page 3459)* conversion operator returns a reference to an unsigned char (see page 3459) that is a conversion of this System::Variant::Variant (see page 3421). System::Variant::unsigned char (see page 3459)* sets the varByRef (see page 3862) bit, meaning that the System::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown. The System::Variant::unsigned char (see page 3459)* operator replaces the Byte* operator.

35.1.24.5.55 Variant::unsigned int Operator

Pascal

```
operator unsigned int;
```

C++

```
__fastcall operator unsigned int() const;
```

Description

This is unsigned int, a member of class Variant.

35.1.24.5.56 Variant::unsigned int* Operator

Pascal

```
operator unsigned int*;
```

C++

```
__fastcall operator unsigned int*();
```

Description

This is unsigned int*, a member of class Variant.

35.1.24.5.57 Variant::unsigned long Operator

Pascal

```
operator unsigned long;
```

C++

```
__fastcall operator unsigned long() const;
```

Description

This is unsigned long, a member of class Variant.

35.1.24.5.58 Variant::unsigned long* Operator

Pascal

```
operator unsigned long*;
```

C++

```
__fastcall operator unsigned long*();
```

Description

This is unsigned long*, a member of class Variant.

35.1.24.5.59 Variant::unsigned short Operator

Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value.

Pascal

```
operator unsigned short;
```

C++

```
__fastcall operator unsigned short() const;
```

Description

The System::Variant::unsigned short (see page 3462) conversion operator returns an unsigned short (see page 3462) that is a conversion of this System::Variant (see page 3421).

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown. The System::Variant::unsigned short (see page 3462) operator replaces the WordBool operator.

35.1.24.5.60 Variant::unsigned short* Operator

Converts the System::Variant (see page 3421) to an unsigned short (see page 3462) value and returns a reference to the value.

Pascal

```
operator unsigned short*;
```

C++

```
__fastcall operator unsigned short*();
```

Description

The System::Variant::unsigned short (see page 3462)* conversion operator returns a reference to an unsigned short (see page 3462) that is a conversion of this System::Variant (see page 3421). System::Variant::unsigned short (see page 3462)* sets the varByRef (see page 3862) bit, meaning that the System::Variant (see page 3421) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an EVariantError exception is thrown. The System::Variant::unsigned short (see page 3462)* operator replaces the WordBool* operator.

35.1.24.5.61 Variant::WideString Operator

Pascal

```
operator WideString;
```

C++

```
__fastcall operator WideString() const;
```

Description

This is WideString, a member of class Variant.

35.1.25 WideString Class

System::WideString represents strings of 16-bit characters.

Class Hierarchy

Pascal

```
WideString = class;
```

C++

```
class WideString;
```

File

wstring.h

Description

System::WideString represents strings of 16-bit characters. Each character is stored as a wchar_t value. The C++ class System::WideString is functionally equivalent to a Delphi intrinsic type, also called System::WideString.

Note: Although System::WideString is a platform-independent data (see page 3476) type and often appears in cross-platform code, System::WideString is also useful for working with Microsoft's Component Object Model (COM) System::WideString values are easily converted to or from the BSTR values used in COM.

35.1.25.1 WideString Members

The following tables list the members exposed by WideString.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3471)	This is record System::WideString::TStringFloatFormat.

Public Methods

	Name	Description
	~WideString (see page 3469)	Frees an instance ofSystem::WideString::WideString (see page 3467).
	c_bstr (see page 3473)	Returns the underlying BSTR that implements theSystem::WideString::WideString (see page 3467).
	cat_printf (see page 3473)	Appends to the value of the System::WideString (see page 3467) given a format string and its arguments.
	cat_sprintf (see page 3474)	Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).
	cat_vprintf (see page 3474)	Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).
	Copy (see page 3475)	Returns a copy of theSystem::WideString::WideString (see page 3467).
	CurrToStr (see page 3475)	Converts a currency value to its string representation.

	CurrToStrF (see page 3475)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 3476)	Returns a pointer to the underlying string System::WideString::data.
	Delete (see page 3476)	System::WideString::Deletes a substring from the System::WideString::WideString (see page 3467).
	FloatToStrF (see page 3477)	Returns the string representation of a floating-point value.
	Format (see page 3477)	System::WideString::Formats a string assembled from an System::WideString (see page 3467), format, and a series of array arguments, args.
	FormatFloat (see page 3478)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3479)	System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 3467).
	IntToHex (see page 3480)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3480)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3480)	Returns true if the System::WideString::WideString (see page 3467) is empty.
	IsPathDelimiter (see page 3481)	Returns true if the specified character is '\'.
	LastChar (see page 3481)	Returns a pointer to the last character in a string.
	LastDelimiter (see page 3481)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3481)	Returns the length of theSystem::WideString::WideString (see page 3467).
	LowerCase (see page 3482)	Returns a lower-case version of System::WideString (see page 3467).
	Pos (see page 3482)	Returns the index at which a specified substring begins.
	printf (see page 3482)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.
	SetLength (see page 3483)	Changes the length of theSystem::WideString::WideString (see page 3467).
	sprintf (see page 3483)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.
	StringOfChar (see page 3484)	Returns a string with the specified number of characters.
	SubString (see page 3484)	Returns a specified substring of theSystem::WideString::WideString (see page 3467).
	swap (see page 3484)	Swap string pointers.
	ToDouble (see page 3485)	Converts the string to a floating-point value.
	ToInt (see page 3485)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3485)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3486)	Returns a new System::WideString (see page 3467) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 3486)	Returns a new System::WideString (see page 3467) without leading spaces or control characters.
	TrimRight (see page 3486)	Returns a new System::WideString (see page 3467) without trailing spaces or control characters.
	UpperCase (see page 3486)	Returns an upper-case version of this System::WideString (see page 3467).
	vprintf (see page 3487)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.
	WideString (see page 3469)	This is the overview for the WideString constructor overload.

Public Operators

	Name	Description
	!= (see page 3487)	This is the overview for the != operator overload.
	[] (see page 3488)	This is the overview for the [] operator overload.
	+ (see page 3489)	Concatenates twoSystem::WideString::WideStrings (see page 6807).
	+= (see page 3489)	Concatenates this System::WideString::WideString (see page 3467) and rhs, and assigns the result to this System::WideString::WideString (see page 3467).
	< (see page 3489)	This is the overview for the < operator overload.
	<= (see page 3490)	This is the overview for the <= operator overload.
	= (see page 3490)	Assigns the value of theSystem::WideString::WideString (see page 3467) to equal a source string.
	== (see page 3491)	This is the overview for the == operator overload.
	> (see page 3491)	This is the overview for the > operator overload.

	>= (see page 3492)	This is the overview for the >= operator overload.

35.1.25.2 WideString::~WideString Destructor

Frees an instance ofSystem::WideString::WideString (see page 3467).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~WideString();
```

Description

System::WideString (see page 3467)::~WideString (see page 3467) is the destructor forSystem::WideString::WideString (see page 3467).

35.1.25.3 WideString Constructor

This is the overview for the WideString constructor overload.

Overload List

	Name	Description
	WideString::WideString () (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (__int64) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (AnsiStringT<codePage> &) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (char) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (char*) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (char*, int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (char16_t*, int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (char32_t*, int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (double) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (float) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (long) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (long double) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).

	WideString::WideString (short) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (UnicodeString&) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (unsigned __int64) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (unsigned int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (unsigned long) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (unsigned short) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (WideChar) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (WideChar*) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (WideChar*, int) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).
	WideString::WideString (WideString&) (see page 3470)	Creates an instance of System::WideString::WideString (see page 3467).

35.1.25.3.1 WideString::WideString Constructor ()

Creates an instance of System::WideString::WideString (see page 3467).

Pascal

```
constructor Create;
constructor Create(const src: char*);
constructor Create(const src: WideString&);
constructor Create(const src: WideChar*; len: Integer);
constructor Create(const src: char*; len: Integer);
constructor Create(const src: WideChar*);
constructor Create(const src: char16_t*; numChar16: Integer = -1);
constructor Create(const src: char32_t*; numChar32: Integer = -1);
constructor Create(const src: WideChar);
constructor Create(src: char);
constructor Create(src: short);
constructor Create(: unsigned short);
constructor Create(src: Integer);
constructor Create(: unsigned int);
constructor Create(: long);
constructor Create(: unsigned long);
constructor Create(: __int64);
constructor Create(: unsigned __int64);
constructor Create(src: float);
constructor Create(src: double);
constructor Create(src: long double);
constructor Create(const src: UnicodeString&);
constructor Create<unsigned short codePage>(const src: AnsiStringT<codePage> &);
```

C++

```
__fastcall WideString();
__fastcall WideString(const char* src);
__fastcall WideString(const WideString& src);
__fastcall WideString(const WideChar* src, int len);
```

```
__fastcall WideString(const char* src, int len);
__fastcall WideString(const WideChar* src);
__fastcall WideString(const char16_t* src, int numChar16 = -1);
__fastcall WideString(const char32_t* src, int numChar32 = -1);
__fastcall explicit WideString(const WideChar src);
__fastcall explicit WideString(char src);
__fastcall explicit WideString(short src);
__fastcall explicit WideString(unsigned short);
__fastcall explicit WideString(int src);
__fastcall explicit WideString(unsigned int);
__fastcall explicit WideString(long);
__fastcall explicit WideString(unsigned long);
__fastcall explicit WideString(__int64);
__fastcall explicit WideString(unsigned __int64);
__fastcall explicit WideString(float src);
__fastcall explicit WideString(double src);
__fastcall explicit WideString(long double src);
__fastcall WideString(const UnicodeString& src);
template <unsigned short codePage> __fastcall WideString(const AnsiStringT<codePage> & src);
```

Description

Call System::WideString::WideString (see page 3467) to create and initialize a wide string. If the constructor is given no arguments, the resulting System::WideString::WideString (see page 3467) is an empty string. If the constructor is passed a single wide character, the resulting System::WideString::WideString (see page 3467) has length one, and contains that character. All other versions of the constructor copy the string passed as an argument, converting characters to wchar_t if necessary. When constructing a System::WideString::WideString (see page 3467) from an array of char or wchar_t, the src string should be null terminated, unless a second argument is given that indicates the number of characters in the array.

35.1.25.4 WideString Enumerations

The enumerations of the WideString class are listed here.

Enumerations

	Name	Description
	TStringFloatFormat (see page 3471)	This is record System::WideString::TStringFloatFormat.

35.1.25.4.1 System::WideString::TStringFloatFormat Enumeration

Pascal

```
TStringFloatFormat = (
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
);
```

C++

```
enum TStringFloatFormat {
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
};
```

File

wstring.h

Description

This is record System::WideString::TStringFloatFormat.

35.1.25.5 WideString Methods

The methods of the WideString class are listed here.

Public Methods

	Name	Description
	c_bstr (see page 3473)	Returns the underlying BSTR that implements theSystem::WideString::WideString (see page 3467).
	cat_printf (see page 3473)	Appends to the value of the System::WideString (see page 3467) given a format string and its arguments.
	cat_sprintf (see page 3474)	Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).
	cat_vprintf (see page 3474)	Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).
	Copy (see page 3475)	Returns a copy of theSystem::WideString::WideString (see page 3467).
	CurrToStr (see page 3475)	Converts a currency value to its string representation.
	CurrToStrF (see page 3475)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 3476)	Returns a pointer to the underlying string System::WideString::data.
	Delete (see page 3476)	System::WideString::Deletes a substring from the System::WideString::WideString (see page 3467).
	FloatToStrF (see page 3477)	Returns the string representation of a floating-point value.
	Format (see page 3477)	System::WideString::Formats a string assembled from an System::WideString (see page 3467), format, and a series of array arguments, args.
	FormatFloat (see page 3478)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 3479)	System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 3467).
	IntToHex (see page 3480)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 3480)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 3480)	Returns true if the System::WideString::WideString (see page 3467) is empty.
	IsPathDelimiter (see page 3481)	Returns true if the specified character is '\'.
	LastChar (see page 3481)	Returns a pointer to the last character in a string.
	LastDelimiter (see page 3481)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 3481)	Returns the length of theSystem::WideString::WideString (see page 3467).
	LowerCase (see page 3482)	Returns a lower-case version of System::WideString (see page 3467).
	Pos (see page 3482)	Returns the index at which a specified substring begins.
	printf (see page 3482)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.
	SetLength (see page 3483)	Changes the length of theSystem::WideString::WideString (see page 3467).
	sprintf (see page 3483)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.
	StringOfChar (see page 3484)	Returns a string with the specified number of characters.
	SubString (see page 3484)	Returns a specified substring of theSystem::WideString::WideString (see page 3467).
	swap (see page 3484)	Swap string pointers.
	ToDouble (see page 3485)	Converts the string to a floating-point value.
	ToInt (see page 3485)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 3485)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 3486)	Returns a new System::WideString (see page 3467) without leading spaces, trailing spaces, or control characters.

	TrimLeft (see page 3486)	Returns a new System::WideString (see page 3467) without leading spaces or control characters.
	TrimRight (see page 3486)	Returns a new System::WideString (see page 3467) without trailing spaces or control characters.
	UpperCase (see page 3486)	Returns an upper-case version of this System::WideString (see page 3467).
	vprintf (see page 3487)	Sets the value of the System::WideString (see page 3467) given a format string and its arguments.

35.1.25.5.1 WideString::c_bstr Method

Returns the underlying BSTR that implements theSystem::WideString::WideString (see page 3467).

Pascal

```
function c_bstr: WideChar*;
```

C++

```
__fastcall WideChar* c_bstr() const;
```

Description

Use c_System::WideString::c_bstr to access the BSTR that implements theSystem::WideString::WideString (see page 3467).

Note: BSTR values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Window.

See Also

System::WideString::c_bstr

System::WideString::Copy (see page 3475)

System::WideString::&

35.1.25.5.2 WideString::cat_printf Method

Appends to the value of the System::WideString (see page 3467) given a format string and its arguments.

Pascal

```
function cat_printf(const format: wchar_t*; : ...): Integer; cdecl;
```

C++

```
__cdecl int cat_printf(const wchar_t* format, ...);
```

Description

Use System::WideString::cat_printf to modify the value of the System::WideString (see page 3467) by appending the result of using a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the number of bytes appended to the System::WideString (see page 3467).

See Also

System::WideString::Format (see page 3477)

System::WideString::cat_sprintf (see page 3474)

System::WideString::cat_vprintf (see page 3474)

35.1.25.5.3 WideString::cat_sprintf Method

Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).

Pascal

```
function cat_sprintf(const format: wchar_t*; : ...): WideString&; cdecl;
```

C++

```
__cdecl WideString& cat_sprintf(const wchar_t* format, ...);
```

Description

Use cat_System::WideString::cat_sprintf to append to the value of the System::WideString (see page 3467) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

For example, the following code

```
WideString Salutation = "Mr."
WideString s = "";
s.cat_sprintf("Dear %s ", Salutation);
s.cat_sprintf("%s,", "Smith");
```

results in an System::WideString (see page 3467) with the value

```
Dear Mr. Smith,
```

This method returns a reference to the System::WideString (see page 3467) (*this) with the resulting value.

See Also

System::WideString::Format (see page 3477)

System::WideString::cat_vprintf (see page 3474)

35.1.25.5.4 WideString::cat_vprintf Method

Appends the result of a given format string and its arguments to the end of the System::WideString (see page 3467).

Pascal

```
function cat_vprintf(const format: wchar_t*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(const wchar_t* format, va_list);
```

Description

Use cat_System::WideString::cat_vprintf to append to the value of the System::WideString (see page 3467) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the number of bytes appended to the System::WideString (see page 3467).

See Also

System::WideString::Format (see page 3477)

System::WideString::cat_printf (see page 3473)

System::WideString::cat_sprintf (see page 3474)

35.1.25.5.5 WideString::Copy Method

Returns a copy of theSystem::WideString::WideString (see page 3467).

Pascal

```
function Copy(var : wchar_t; len: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* Copy(wchar_t *, int len) const;
```

Description

Use System::WideString::Copy to copy theSystem::WideString::WideString (see page 3467) into an array of wchar_t. Use the Length (see page 3481) method to ensure that the destination buffer is large enough to hold the contents of theSystem::WideString::WideString (see page 3467).

WideString (see page 3467) also supports a static copy method that copies an arbitrary source string.

See Also

System::WideString::bstr

System::WideString::c_bstr (see page 3473)

System::WideString::&

System::WideString::Length (see page 3481)

35.1.25.5.6 WideString::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency): WideString; static;
```

C++

```
static __fastcall WideString CurrToStr(Currency value);
```

Description

System::WideString::CurrToStr converts the currency value given by value to its string representation. The conversion using the sffGeneral floating-point conversion rules. For further details, see System::WideString::CurrToStrF (see page 3475).

See Also

System::WideString::CurrToStrF (see page 3475)

35.1.25.5.7 WideString::CurrToStrF Method

Converts a currency value to its string representation using the indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer): WideString;
static;
```

C++

```
static __fastcall WideString CurrToStrF(Currency value, TStringFloatFormat format, int digits);
```

Description

System::WideString::CurrToStrF converts the currency value given by value to its string representation using the indicated float format convention. A call to System::WideString::CurrToStrF corresponds to a call to FloatToStrF (see page 3477) with an implied precision of 19 digits.

35.1.25.5.8 WideString::data Method

Returns a pointer to the underlying string System::WideString::data.

Pascal

```
function data: WideChar*;
```

C++

```
__fastcall WideChar* data();
```

Description

System::WideString::data returns a pointer to a null-terminated character array that the System::WideString (see page 3467) uses to store its value. This is the same value as the one returned by the System::WideString::c_str method, except that System::WideString::data returns a NULL pointer when the value is an empty string.

Note: Because System::WideString::data returns NULL instead of an empty string, it is useful for C++ functions that expect either a valid (non-empty) char* or NULL. The following example assumes that TCHAR mapping is not set to wchar_t:

```
WideString x;
    ShellExecute(0, static_cast<const char*>(x.data()), "File.txt", NULL, NULL, SW_SHOW);
```

If TCHAR mapping is set to wchar_t, ShellExecute becomes the wide version, ShellExecuteW. If you want to use the Ansi version of ShellExecute when TCHAR mapping is set to wchar_t, you should specify ShellExecuteA.

See Also

System::WideString::c_str

TCHAR Mapping

35.1.25.5.9 WideString::Delete Method

System::WideString::Deletes a substring from the System::WideString::WideString (see page 3467).

Pascal

```
procedure Delete(index: Integer; count: Integer);
```

C++

```
__fastcall void Delete(int index, int count);
```

Description

System::WideString::Delete removes count characters from theSystem::WideString::WideString (see page 3467), beginning with the character at position index.

See Also

System::WideString::Insert (see page 3479)

System::WideString::[] (see page 3488)

35.1.25.5.10 WideString::FloatToStrF Method

Returns the string representation of a floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer): WideString; static;
```

C++

```
static __fastcall WideString FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits);
```

Description

The format parameter controls the format of the resulting string. The precision parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the digits parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 3235) Format (see page 3477) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator and ThousandSeparator global variables.

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

35.1.25.5.11 WideString::Format Method

System::WideString::Formats a string assembled from an System::WideString (see page 3467), format, and a series of array arguments, args.

Pascal

```
function Format(const format: WideString&; const args: TVarRec *; size: Integer): WideString;
static;
```

C++

```
static __fastcall WideString Format(const WideString& format, const TVarRec * args, int size);
```

Description

Use System::WideString::Format to obtain an System::WideString (see page 3467) whose value is the result of applying an array of arguments (args) to a given a format string (format). The last parameter (size) is the index of the last element in args (one less than the number of arguments).

Note that System::WideString::Format is a static method. The returned value is a newly allocated System::WideString (see page 3467), even if the method is called from an existing System::WideString (see page 3467) instance.

For information on how System::WideString::Format assembles a final string from its format string and arguments, see System::WideString::Format Strings.

See Also

System::WideString::printf (see page 3482)

System::WideString::sprintf (see page 3483)

35.1.25.5.12 WideString::FormatFloat Method

Formats the floating-point value given by value using the format string given by format.

Pascal

```
function FormatFloat(const format: WideString&; const value: long double&): WideString; static;
```

C++

```
static __fastcall WideString FormatFloat(const WideString& format, const long double& value);
```

Description

The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the DecimalSeparator global variable, whose default value is specified in the Number Format (see page 3477) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the ThousandSeparator global variable, whose default value is specified in the Number Format (see page 3477) of the International section in the Windows Control Panel.

E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 3477) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 3477) string-1234-12340.50

Format (see page 3477) string-	**1234**	**-1234**	**0.5**	**0**
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	
#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

35.1.25.5.13 WideString::Insert Method

System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 3467).

Pascal

```
procedure Insert(const str: WideString&; index: Integer);
```

C++

```
__fastcall void Insert(const WideString& str, int index);
```

Description

Call System::WideString::Insert to inserts the string str into thisSystem::WideString::WideString (see page 3467) beginning at the position index.

See Also

System::WideString::Delete (see page 3476)

System::WideString::[] (see page 3488)

35.1.25.5.14 WideString::IntToHex Method

Converts a number into a string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer): WideString; static;
```

C++

```
static __fastcall WideString IntToHex(int value, int digits);
```

Description

Value is the number to convert. Digits indicates the minimum number of hexadecimal digits.

35.1.25.5.15 WideString::IsDelimiter Method

Returns true if the specified character matches any character in the delimiters string.

Pascal

```
function IsDelimiter(const delimiters: WideString&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const WideString& delimiters, int index) const;
```

Description

System::WideString::IsDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character contained in delimiters. If the byte is part of a multi-byte character or not in delimiters, System::WideString::IsDelimiter returns false.

35.1.25.5.16 WideString::IsEmpty Method

Returns true if the System::WideString::WideString (see page 3467) is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

Call System::WideString::IsEmpty to determine whether the System::WideString::WideString (see page 3467) represents an

empty string.

35.1.25.5.17 WideString::IsPathDelimiter Method

Returns true if the specified character is '\'.

Pascal

```
function IsPathDelimiter(index: Integer): bool;
```

C++

```
__fastcall bool IsPathDelimiter(int index) const;
```

Description

System::WideString::IsPathDelimiter returns true if the byte indicated by index (counting from 1) is a single-byte character containing the path delimiter ('\' on Windows, '/' on Linux).

35.1.25.5.18 WideString::LastChar Method

Returns a pointer to the last character in a string.

Pascal

```
function LastChar: wchar_t*;
```

C++

```
__fastcall wchar_t* LastChar() const;
```

Description

Call System::WideString::LastChar to obtain a pointer to the last character in a string. This function supports multi-byte character sets (MBCS).

35.1.25.5.19 WideString::LastDelimiter Method

Returns the index of the rightmost character that matches any character in the delimiters string.

Pascal

```
function LastDelimiter(const delimiters: WideString&): Integer;
```

C++

```
__fastcall int LastDelimiter(const WideString& delimiters) const;
```

Description

System::WideString::LastDelimiter returns the byte index in this System::WideString (see page 3467) of the rightmost whole character that matches any character in delimiters except NULL The System::WideString (see page 3467) may contain multibyte characters; delimiters must contain only single byte non-NULL characters.

35.1.25.5.20 WideString::Length Method

Returns the length of theSystem::WideString::WideString (see page 3467).

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::WideString::Length returns the number of characters in thisSystem::WideString::WideString (see page 3467).

35.1.25.5.21 WideString::LowerCase Method

Returns a lower-case version of System::WideString (see page 3467).

Pascal

```
function LowerCase: WideString;
```

C++

```
__fastcall WideString LowerCase() const;
```

Description

System::WideString::LowerCase returns a new System::WideString (see page 3467) that contains all characters in this string, converted to lower case. The conversion uses the current locale . The original System::WideString (see page 3467) remains unchanged.

35.1.25.5.22 WideString::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: WideString&): Integer;
```

C++

```
__fastcall int Pos(const WideString& subStr) const;
```

Description

Use System::WideString::Pos to locate a substring of theSystem::WideString::WideString (see page 3467). System::WideString::Pos returns the index of the first character in subStr. If subStr is not contained in theSystem::WideString::WideString (see page 3467), System::WideString::Pos returns 0.

See Also

System::WideString::Length (see page 3481)

System::WideString::SubString (see page 3484)

35.1.25.5.23 WideString::printf Method

Sets the value of the System::WideString (see page 3467) given a format string and its arguments.

Pascal

```
function printf(const format: wchar_t*; : ...): Integer; cdecl;
```

C++

```
__cdecl int printf(const wchar_t* format, ...);
```

Description

Use System::WideString::printf to set the value of the System::WideString (see page 3467) given a standard C++ format

specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the length of the final formatted string.

See Also

System::WideString::Format (see page 3477)

System::WideString::sprintf (see page 3483)

System::WideString::cat_printf (see page 3473)

System::WideString::vprintf (see page 3487)

35.1.25.5.24 WideString::SetLength Method

Changes the length of theSystem::WideString::WideString (see page 3467).

Pascal

```
procedure SetLength(newLength: Integer);
```

C++

```
__fastcall void SetLength(int newLength);
```

Description

System::WideString::SetLength changes theSystem::WideString::WideString (see page 3467)'s length to newLength, truncating if necessary.

System::WideString::SetLength reallocates the underlying array of characters that stores the value of theSystem::WideString::WideString (see page 3467). Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate theSystem::WideString::WideString (see page 3467), an EOutOfMemory exception is thrown. Following a call to System::WideString::SetLength, theSystem::WideString::WideString (see page 3467) is guaranteed to reference a unique string — that is a string with a reference count of one.

See Also

System::WideString::Length (see page 3481)

35.1.25.5.25 WideString::sprintf Method

Sets the value of the System::WideString (see page 3467) given a format string and its arguments.

Pascal

```
function sprintf(const format: wchar_t*; : ...): WideString&; cdecl;
```

C++

```
__cdecl WideString& sprintf(const wchar_t* format, ...);
```

Description

Use System::WideString::sprintf to set to the value of the System::WideString (see page 3467) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

This method returns a reference to the System::WideString (see page 3467) (*this) with the resulting value.

See Also

System::WideString::Format (see page 3477)

System::WideString::cat_sprintf (see page 3474)

System::WideString::printf (see page 3482)

System::WideString::vprintf (see page 3487)

35.1.25.5.26 WideString::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: WideChar; count: Integer): WideString; static;
```

C++

```
static __fastcall WideString StringOfChar(WideChar ch, int count);
```

Description

System::WideString::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::WideString (see page 3467) s = System::WideString::System::WideString::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

35.1.25.5.27 WideString::SubString Method

Returns a specified substring of theSystem::WideString::WideString (see page 3467).

Pascal

```
function SubString(index: Integer; count: Integer): WideString;
```

C++

```
__fastcall WideString SubString(int index, int count) const;
```

Description

System::WideString::SubString returns a newSystem::WideString::WideString (see page 3467) that is a substring of thisSystem::WideString::WideString (see page 3467). The substring contains count characters beginning at index.

See Also

System::WideString::Length (see page 3481)

System::WideString::Pos (see page 3482)

35.1.25.5.28 WideString::swap Method

Swap string pointers.

Pascal

```
function swap(var other: WideString): WideString&;
```

C++

```
WideString& swap(WideString& other);
```

Description

System::WideString::swap swaps two System::WideString (see page 3467) strings. Pointers to the data (see page 3476) are swapped, and the data (see page 3476) is not copied. This makes the swap operation efficient for sorting.

35.1.25.5.29 WideString::ToDouble Method

Converts the string to a floating-point value.

Pascal

```
function ToDouble: double;
```

C++

```
__fastcall double ToDouble() const;
```

Description

System::WideString::ToDouble converts the string to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks in the string are ignored. The DecimalSeparator global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, an EConvertError exception is thrown.

35.1.25.5.30 WideString::ToInt Method

Converts a string to an integer, throwing an exception if the string is invalid.

Pascal

```
function ToInt: Integer;
```

C++

```
__fastcall int ToInt() const;
```

Description

System::WideString::ToInt converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, an EConvertError exception is thrown.

See Also

System::WideString::ToIntDef (see page 3485)

35.1.25.5.31 WideString::ToIntDef Method

Converts the string to an integer, returning a default value if the string is invalid.

Pascal

```
function ToIntDef(defaultValue: Integer): Integer;
```

C++

```
__fastcall int ToIntDef(int defaultValue) const;
```

Description

System::WideString::ToIntDef converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, the value given by defaultValue is returned.

See Also

System::WideString::ToInt (see page 3485)

35.1.25.5.32 WideString::Trim Method

Returns a new System::WideString (see page 3467) without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim: WideString;
```

C++

```
__fastcall WideString Trim() const;
```

Description

System::WideString::Trim returns a new System::WideString (see page 3467) removing leading and trailing spaces and control characters. Use System::WideString::Trim to remove blank space before and after the first printing character.

35.1.25.5.33 WideString::TrimLeft Method

Returns a new System::WideString (see page 3467) without leading spaces or control characters.

Pascal

```
function TrimLeft: WideString;
```

C++

```
__fastcall WideString TrimLeft() const;
```

Description

System::WideString::TrimLeft returns a new System::WideString (see page 3467) removing leading spaces and control characters. Use System::WideString::TrimLeft to remove blank space before the first printing character.

35.1.25.5.34 WideString::TrimRight Method

Returns a new System::WideString (see page 3467) without trailing spaces or control characters.

Pascal

```
function TrimRight: WideString;
```

C++

```
__fastcall WideString TrimRight() const;
```

Description

System::WideString::TrimRight returns a new System::WideString (see page 3467) removing trailing spaces and control characters. Use the System::WideString::TrimRight function to remove blank space after the last printing character.

35.1.25.5.35 WideString::UpperCase Method

Returns an upper-case version of this System::WideString (see page 3467).

Pascal

```
function UpperCase: WideString;
```

C++

```
__fastcall WideString UpperCase() const;
```

Description

System::WideString::UpperCase returns a new System::WideString (see page 3467) that contains all characters in this string, converted to upper case. The conversion uses the current locale . The original System::WideString (see page 3467) remains unchanged.

35.1.25.5.36 WideString::vprintf Method

Sets the value of the System::WideString (see page 3467) given a format string and its arguments.

Pascal

```
function vprintf(const format: wchar_t*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(const wchar_t* format, va_list);
```

Description

Use System::WideString::vprintf to set to the value of the System::WideString (see page 3467) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the length of the final formatted string.

See Also

System::WideString::Format (see page 3477)

System::WideString::sprintf (see page 3483)

System::WideString::printf (see page 3482)

System::WideString::cat_vprintf (see page 3474)

35.1.25.6 WideString Operators

The operators of the WideString class are listed here.

Public Operators

	Name	Description
	!= (see page 3487)	This is the overview for the != operator overload.
	[] (see page 3488)	This is the overview for the [] operator overload.
	+ (see page 3489)	Concatenates twoSystem::WideString::WideStrings (see page 6807).
	+= (see page 3489)	Concatenates this System::WideString::WideString (see page 3467) and rhs, and assigns the result to this System::WideString::WideString (see page 3467).
	< (see page 3489)	This is the overview for the < operator overload.
	<= (see page 3490)	This is the overview for the <= operator overload.
	= (see page 3490)	Assigns the value of theSystem::WideString::WideString (see page 3467) to equal a source string.
	== (see page 3491)	This is the overview for the == operator overload.
	> (see page 3491)	This is the overview for the > operator overload.
	>= (see page 3492)	This is the overview for the >= operator overload.

35.1.25.6.1 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	WideString::!= (char*) (see page 3488)	Tests whether theSystem::WideString::WideString (see page 3467) is different from anotherSystem::WideString::WideString (see page 3467).
	WideString::!= (WideString&) (see page 3488)	Tests whether theSystem::WideString::WideString (see page 3467) is different from anotherSystem::WideString::WideString (see page 3467).

35.1.25.6.1.1 WideString::!= Operator (WideString&)

Tests whether theSystem::WideString::WideString (see page 3467) is different from anotherSystem::WideString::WideString (see page 3467).

Pascal

```
operator !=(const rhs: WideString&);
operator !=(const s: char*);
```

C++

```
__fastcall bool operator !=(const WideString& rhs) const;
__fastcall bool operator !=(const char* s) const;
```

Description

The != System::WideString (see page 3467)::!= returns true if the strings are not the same, false otherwise.

See Also

System::WideString::== (see page 3491)

35.1.25.6.2 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	WideString::[] (int) (see page 3488)	Returns the character at a specified index in the string.
	WideString::[] (int) (see page 3488)	Returns the character at a specified index in the string.

35.1.25.6.2.1 WideString::[] Operator (int)

Returns the character at a specified index in the string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall WideChar & operator [](const int idx);
__fastcall const WideChar& operator [](const int idx) const;
```

Description

The System::WideString (see page 3467)::[] returns the character in the string at index value idx. The System::WideString (

see page 3467)::[] assumes a base index of 1. For example, given the string “Hello” and an index value of 2, the character returned would be ‘e’.

35.1.25.6.3 WideString::+ Operator

Concatenates twoSystem::WideString::WideStrings (see page 6807).

Pascal

```
operator +(const rhs: WideString&);
```

C++

```
__fastcall WideString operator +(const WideString& rhs) const;
```

Description

The + System::WideString (see page 3467)::+ returns aSystem::WideString::WideString (see page 3467) that has the value passed as rhs concatenated to the end. A related friend System::WideString (see page 3467)::+ takes two arguments and returns the concatenation of lhs with rhs.

35.1.25.6.4 WideString::+= Operator

Concatenates this System::WideString::WideString (see page 3467) and rhs, and assigns the result to this System::WideString::WideString (see page 3467).

Pascal

```
operator +=(const rhs: WideString&);
```

C++

```
__fastcall WideString& operator +=(const WideString& rhs);
```

Description

Use += to concatenate rhs to the end of the System::WideString::WideString (see page 3467). This System::WideString (see page 3467)::+= is not supported when the System::WideString::WideString (see page 3467) is a property value.

35.1.25.6.5 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	WideString::< (char*) (see page 3489)	Compares two strings.
	WideString::< (WideString&) (see page 3489)	Compares two strings.

35.1.25.6.5.1 WideString::< Operator (WideString&)

Compares two strings.

Pascal

```
operator <(const rhs: WideString&);
operator <(const s: char*);
```

C++

```
__fastcall bool operator <(const WideString& rhs) const;
```

```
__fastcall bool operator <(const char* s) const;
```

Description

The < System::WideString (see page 3467)::< returns true if thisSystem::WideString::WideString (see page 3467) is less than rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::<= (see page 3490)

System::WideString::> (see page 3491)

35.1.25.6.6 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	WideString::<= (char*) (see page 3490)	Compares two strings.
	WideString::<= (WideString&) (see page 3490)	Compares two strings.

35.1.25.6.6.1 WideString::<= Operator (WideString&)

Compares two strings.

Pascal

```
operator <=(const rhs: WideString&);
operator <=(const s: char*);
```

C++

```
__fastcall bool operator <=(const WideString& rhs) const;
__fastcall bool operator <=(const char* s) const;
```

Description

The <= System::WideString (see page 3467)::<= returns true if thisSystem::WideString::WideString (see page 3467) is less than or equal to rhs, false otherwise. The strings are compared using their numerical value of each character, with case sensitivity.

See Also

System::WideString::>= (see page 3492)

System::WideString::< (see page 3489)

35.1.25.6.7 WideString::= Operator

Assigns the value of theSystem::WideString::WideString (see page 3467) to equal a source string.

Pascal

```
operator =(const rhs: WideString&);
```

C++

```
__fastcall WideString& operator =(const WideString& rhs);
```

Description

Use the assignment System::WideString (see page 3467)::= to set the value of theSystem::WideString::WideString (see

page 3467) to match the string given by rhs.

Note: BSTR values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Windows.

35.1.25.6.8 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	WideString::== (char*) (see page 3491)	Compares theSystem::WideString::WideString (see page 3467) with a specified string, returning true if they are the same.
	WideString::== (WideString&) (see page 3491)	Compares theSystem::WideString::WideString (see page 3467) with a specified string, returning true if they are the same.

35.1.25.6.8.1 WideString::== Operator (WideString&)

Compares theSystem::WideString::WideString (see page 3467) with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: WideString&);
operator ==(const s: char*);
```

C++

```
__fastcall bool operator ==(const WideString& rhs) const;
__fastcall bool operator ==(const char* s) const;
```

Description

The equality System::WideString (see page 3467)::== returns true if thisSystem::WideString::WideString (see page 3467) is the same as rhs, false otherwise.

See Also

System::WideString::!= (see page 3488)

35.1.25.6.9 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	WideString::> (char*) (see page 3491)	Compares two strings.
	WideString::> (WideString&) (see page 3491)	Compares two strings.

35.1.25.6.9.1 WideString::> Operator (WideString&)

Compares two strings.

Pascal

```
operator >(const rhs: WideString&);
operator >(const s: char*);
```

C++

```
__fastcall bool operator >(const WideString& rhs) const;
__fastcall bool operator >(const char* s) const;
```

Description

The System::WideString (see page 3467)::> returns true if thisSystem::WideString::WideString (see page 3467) is greater than rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::>= (see page 3492)

System::WideString::< (see page 3489)

35.1.25.6.10 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	WideString::>= (char*) (see page 3492)	Compares two strings.
	WideString::>= (WideString&) (see page 3492)	Compares two strings.

35.1.25.6.10.1 WideString::>= Operator (WideString&)

Compares two strings.

Pascal

```
operator >=(const rhs: WideString&);
operator >=(const s: char*);
```

C++

```
__fastcall bool operator >=(const WideString& rhs) const;
__fastcall bool operator >=(const char* s) const;
```

Description

The System::WideString (see page 3467)::>= returns true if thisSystem::WideString::WideString (see page 3467) is greater than or equal to rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::<= (see page 3490)

System::WideString::> (see page 3491)

35.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IComparable (see page 3493)	IComparable is the generic interface used to compare two objects.
	IDispatch (see page 3494)	IDispatch is the interface used to support Automation.
	IEnumerable (see page 3497)	IEnumerable is the generic interface for enumerable containers.
	IEnumerator (see page 3498)	IEnumerator is the generic interface for container enumerators.
	IEquatable (see page 3500)	IEquatable is the generic interface used to check the equality of two objects.
	IInterface (see page 3502)	IInterface is the base class for all interfaces defined in Delphi code.
	IInvokable (see page 3504)	IInvokable is the base class for invokable interfaces.

35.2.1 IComparable Interface

IComparable is the generic interface used to compare two objects.

Class Hierarchy

Pascal

```
IComparable<T> = interface;
```

C++

```
template <T>
__interface IComparable;
```

File

System

Description

IComparable is implemented by classes that have to support a comparison between instances. IComparable exposes a single method called CompareTo (see page 3494). CompareTo (see page 3494) can be used later to compare two instances of the same class.

See Also

CompareTo (see page 3494)

IEquatable (see page 3500)

35.2.1.1 IComparable Members

The following tables list the members exposed by IComparable.

Public Methods

	Name	Description
	CompareTo (see page 3494)	CompareTo is a generic method used to compare two instances of a class.

35.2.1.2 IComparable Methods

The methods of the IComparable class are listed here.

Public Methods

	Name	Description
	CompareTo (see page 3494)	CompareTo is a generic method used to compare two instances of a class.

35.2.1.2.1 IComparable.CompareTo Method

CompareTo is a generic method used to compare two instances of a class.

Pascal

```
function CompareTo(Value: T): Integer;
```

C++

```
__fastcall int CompareTo(T Value);
```

Description

Use the CompareTo method to compare two instances of the same class. Any class that implements the IComparable (see page 3493) interface should provide an implementation for the CompareTo method.

The return value of Compare must be in the following ranges.

Return value	Description
Result is less than zero (<0)	The object is less than `Value`.
Result is equal to zero(=0)	The object is equal to `Value`.
Result is greater than zero(>0)	The object is greater than `Value`.

See Also

IEquatable (see page 3500)

Equals (see page 3501)

35.2.2 IDispatch Interface

IDispatch is the interface used to support Automation.

Class Hierarchy

Pascal

```
IDispatch = interface(IUnknown);
```

C++

```
__interface IDispatch : public IUnknown;
```

File

System

Description

Implement the IDispatch interface in COM-enabled classes that have to act as Automation controllers. The IDispatch interface exposes a number of methods for Automation clients that require late-binding (such as scripting languages).

See Also

IInterface (see page 3502)

Dispatch Interfaces

IDispatch Interface (MSDN)

35.2.2.1 IDispatch Members

The following tables list the members exposed by IDispatch.

Public Methods

	Name	Description
	GetIDsOfNames (see page 3495)	GetIDsOfNames returns a set of dispatch identifiers (**dispid**s) for a given member name.
	GetTypeInfo (see page 3496)	GetTypeInfo returns the object's type information.
	GetTypeInfoCount (see page 3496)	GetTypeInfoCount returns the count of type information interfaces.
	Invoke (see page 3497)	Invoke performs a call to a late-binded property or method.

35.2.2.2 IDispatch Methods

The methods of the IDispatch class are listed here.

Public Methods

	Name	Description
	GetIDsOfNames (see page 3495)	GetIDsOfNames returns a set of dispatch identifiers (**dispid**s) for a given member name.
	GetTypeInfo (see page 3496)	GetTypeInfo returns the object's type information.
	GetTypeInfoCount (see page 3496)	GetTypeInfoCount returns the count of type information interfaces.
	Invoke (see page 3497)	Invoke performs a call to a late-binded property or method.

35.2.2.2.1 IDispatch.GetIDsOfNames Method

GetIDsOfNames returns a set of dispatch identifiers (**dispid**s) for a given member name.

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

GetIDsOfNames returns a set of dispatch identifiers (**dispid**s) for a given member name. GetIDsOfNames is used primarily to obtain dispatch identifiers for the late-binded methods exposed by the COM object through the IDispatch (see page 3494) interface.

See Also

GetTypeInfoCount (see page 3496)

GetTypeInfo (see page 3496)

Invoke (see page 3497)

35.2.2.2.2 IDispatch.GetTypeInfo Method

GetTypeInfo returns the object's type information.

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

GetTypeInfo returns the type information for a specified index. The index is previously obtained by a call to the GetTypeInfoCount (see page 3496) method. If the method returns S_OK (see page 3860), the `TypeInfo` parameter is set to point to the requested type information; otherwise an error code is returned.

See Also

GetTypeInfoCount (see page 3496)

GetIDsOfNames (see page 3495)

Invoke (see page 3497)

35.2.2.2.3 IDispatch.GetTypeInfoCount Method

GetTypeInfoCount returns the count of type information interfaces.

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

GetTypeInfoCount returns the count of type information interfaces supported by the implementing COM object. If the method returns S_OK (see page 3860), the `Count` parameter is set to the number of type information interfaces, which is either 1 (if the object supports type information) or 0 (if the object does not support type information). A return value of E_NOTIMPL (see page 3846) means that the method is not implemented in the COM object.

See Also

GetTypeInfo (see page 3496)

GetIDsOfNames (see page 3495)

Invoke (see page 3497)

35.2.2.2.4 IDispatch.Invoke Method

Invoke performs a call to a late-binded property or method.

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

Invoke actually calls a method or a property exposed by the COM object through IDispatch (see page 3494). Invoke requires a previously obtained dispatch identifier. The identifier uniquely identifies a method, a property, and a list of parameters to be passed to the called method and exception information. The dispatch identifier of a method or property (also known as **dispid**) can be obtained by a calling the GetIDsOfNames (see page 3495) method.

See Also

GetTypeInfoCount (see page 3496)

GetTypeInfo (see page 3496)

GetIDsOfNames (see page 3495)

35.2.3 IEnumerable Interface

IEnumerable is the generic interface for enumerable containers.

Class Hierarchy

Pascal

```
IEnumerable<T> = interface(IEnumerable);
```

C++

```
template <T>
__interface IEnumerable : public IEnumerable;
```

File

System

Description

To make your container enumerable, implement the IEnumerable interface. IEnumerable exposes a single method called GetEnumerator (see page 3498), that must return a reference to an IEnumerator (see page 3498) interface.

Classes that implement the IEnumerable interface are considered enumerable in Delphi language and can be used in **for..in** statements.

Note: It is not required that IEnumerable be actually implemented by a class in order to be considered enumerable. It is enough to export a public method called GetEnumerator (see page 3498) that returns an enumerator object. Still, we recommend that

you implement the IEnumerable interface.

See Also

IEnumerator (see page 3498)

GetEnumerator (see page 3498)

35.2.3.1 IEnumerable Members

The following tables list the members exposed by IEnumerable.

Public Methods

	Name	Description
	GetEnumerator (see page 3498)	Returns an enumerator used to iterate over a collection.

35.2.3.2 IEnumerable Methods

The methods of the IEnumerable class are listed here.

Public Methods

	Name	Description
	GetEnumerator (see page 3498)	Returns an enumerator used to iterate over a collection.

35.2.3.2.1 IEnumerable.GetEnumerator Method

Returns an enumerator used to iterate over a collection.

Pascal

```
function GetEnumerator: IEnumerator<T>;
```

C++

```
__fastcall IEnumerator<T> GetEnumerator();
```

Description

Call GetEnumerator to obtain an enumerator to iterate over a collection. Delphi language supports the **for..in** statement, which automatically uses GetEnumerator to obtain a reference to the enumerator object.

See Also

IEnumerator (see page 3498)

35.2.4 IEnumerator Interface

IEnumerator is the generic interface for container enumerators.

Class Hierarchy

Pascal

```
IEnumerator<T> = interface(IEnumerator);
```

C++

```
template <T>
__interface IEnumerator : public IEnumerator;
```

File

System

Description

Implement the IEnumerator interface in the class that has to act as an enumerator for a container. An IEnumerator is usually obtained by a call to the container's GetEnumerator method.

Classes that implement the IEnumerator interface are considered enumerators in Delphi language and are used automatically by the **for..in** statement.

Note: It is not required that IEnumerator be actually implemented by a class in order to be considered an enumerator. It is enough to simply implement the required methods in your class. Still, we recommend that you implement the IEnumerator interface.

See Also

IEnumerable (see page 3497)

35.2.4.1 IEnumerator Members

The following tables list the members exposed by IEnumerator.

Public Methods

	Name	Description
	GetCurrent (see page 3499)	Returns the currently focused element in the container.

Public Properties

	Name	Description
	Current (see page 3500)	Returns the currently focused element in the container.

35.2.4.2 IEnumerator Methods

The methods of the IEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 3499)	Returns the currently focused element in the container.

35.2.4.2.1 IEnumerator.GetCurrent Method

Returns the currently focused element in the container.

Pascal

```
function GetCurrent: T;
```

C++

```
__fastcall T GetCurrent();
```

Description

GetCurrent is a method that returns the currently focused element in the container.

See Also

Current (see page 3500)

35.2.4.3 IEnumerator Properties

The properties of the IEnumerator class are listed here.

Public Properties

	Name	Description
	Current (see page 3500)	Returns the currently focused element in the container.

35.2.4.3.1 IEnumerator.Current Property

Returns the currently focused element in the container.

Pascal

```
property Current: T;
```

C++

```
__property T Current;
```

Description

Current is a read-only property that gives the currently focused element in the container.

See Also

GetCurrent (see page 3499)

35.2.5 IEquatable Interface

IEquatable is the generic interface used to check the equality of two objects.

Class Hierarchy

System.IEquatable

Pascal

```
IEquatable<T> = interface;
```

C++

```
template <T>
__interface IEquatable;
```

File

System

Description

IEquatable is implemented by classes that have to support equality checking. IEquatable exposes a single method, called Equals (see page 3501). Equals (see page 3501) can be used later to check the equality of two instances of the same class.

See Also

Equals (see page 3501)

IComparable (see page 3493)

35.2.5.1 IEquatable Members

The following tables list the members exposed by IEquatable.

Public Methods

	Name	Description
	Equals (see page 3501)	Equals is a generic method used to check the equality of objects.

35.2.5.2 IEquatable Methods

The methods of the IEquatable class are listed here.

Public Methods

	Name	Description
	Equals (see page 3501)	Equals is a generic method used to check the equality of objects.

35.2.5.2.1 IEquatable.Equals Method

Equals is a generic method used to check the equality of objects.

Pascal

```
function Equals(Value: T): Boolean;
```

C++

```
__fastcall Boolean Equals(T Value);
```

Description

Use the Equals to check the equality of two objects of the same class. Any class that implements the IEquatable (see page 3500) interface is expected to provide the implementation for the Equals method.

The return value of Equals must be one of the following.

Return value	Description
False	The object is different from `Value`.
True	The object is equal to `Value`.

See Also

IComparable (see page 3493)

CompareTo (see page 3494)

35.2.6 IInterface Interface

IInterface is the base class for all interfaces defined in Delphi code.

Class Hierarchy

Pascal

```
IInterface = interface;
```

C++

```
__interface IInterface;
```

File

System

Description

IInterface is the base interface for interfaces defined in Delphi code. When used in C++ code, IInterface is considered a child interface of IUnknown (see page 3756) and IUnknown (see page 3756) is considered the base interface for all interfaces.

Note: IInterface introduces the QueryInterface (see page 3504) method, which is useful for discovering and using other interfaces implemented by the same object. IInterface also introduces the reference counting methods, _AddRef (see page 3503) and _Release (see page 3503). The Delphi compiler automatically provides calls to these methods when interfaces are used. The System::TInterfacedObject (see page 3342) class is provided as a base class for objects that implement interfaces. Use of System::TInterfacedObject (see page 3342) is not mandatory, but will often be easier than designing an implementer class from scratch.

Note: C++ method declarations that use IInterface refer to the _di_IInterface type instead. This is a DelphiInterface (see page 3256) wrapper around the IInterface interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IInterface > _di_IInterface;
```

See Also

System::TInterfacedObject (see page 3342)

IInvokable (see page 3504)

IUnknown (see page 3756)

System::DelphiInterface (see page 3256)

35.2.6.1 IInterface Members

The following tables list the members exposed by IInterface.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.

	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

35.2.6.2 IInterface Methods

The methods of the IInterface class are listed here.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

35.2.6.2.1 IInterface._AddRef Method

Increments the reference count for this interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

The Delphi compiler automatically generates a call to __AddRef for every reference to this interface. For most implementations, __AddRef increments the reference count for the interface and returns the new reference count. When the caller is through with the interface, the compiler generates a call to the _Release (see page 3503) method, which decrements the reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __AddRef and _Release (see page 3503) so that they do not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_Release (see page 3503)

35.2.6.2.2 IInterface._Release Method

Decrements the reference count for this interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

The Delphi compiler automatically generates a call to __Release whenever a reference to this interface goes out of scope. For most implementations, __Release decrements the reference count for the interface and returns the new reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __Release so that it does not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_AddRef (see page 3503)

35.2.6.2.3 IInterface.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the object that implements this interface supports the interface specified by IID. If so, QueryInterface

increments the reference count.

sets the Obj parameter so that it points to an instance of the specified interface.

returns 0 to indicate success.

If the object does not support the interface, QueryInterface returns a nonzero error code such as E_NoInterface.

See Also

_AddRef (see page 3503)

35.2.7 IInvokable Interface

IInvokable is the base class for invokable interfaces.

Class Hierarchy

Pascal

```
IInvokable = interface(IInterface);
```

C++

```
__interface IInvokable : public IInterface;
```

File

System

Description

Use IInvokable as a base interface when defining invokable interfaces. IInvokable does not add any properties or methods to the methods it inherits from IInterface (see page 3502). It exists, rather, to ensure that the interface an all its descendants are compiled with runtime type information (RTTI). This RTTI can be used by Web Service applications or the clients of Web Service applications for translating between the code that implements a method and the symbolic encoding of that method call that is sent between client and server applications.

35.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Abs (see page 3511)	Returns an absolute value.
	AcquireExceptionObject (see page 3512)	Retains access to exception object.
	AddModuleUnloadProc (see page 3514)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	AddModuleUnloadProc (see page 3514)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	Addr (see page 3514)	Returns a pointer to a specified object.
	AllocMem (see page 3515)	AllocMem allocates a memory block and initializes each byte to zero.
	AnsiToUtf8 (see page 3517)	Converts a string encoded in Ansi to UTF-8.
	Append (see page 3520)	Prepares an existing file for adding text to the end.
	ArcTan (see page 3521)	Calculates the arctangent of a given number.
	Assert (see page 3522)	Tests whether a Boolean expression is true.
	Assert (see page 3522)	Tests whether a Boolean expression is true.
	Assigned (see page 3524)	Tests for a nil (unassigned) pointer or procedural variable.
	AssignFile (see page 3525)	Associates the name of an external file with a file variable.
	AttemptToUseSharedMemoryManager (see page 3527)	Attempts to use a shared memory manager.
	BeginThread (see page 3527)	Spawns a separate thread of execution.
	BlockRead (see page 3528)	Reads one or more records from an open file into a variable.
	BlockRead (see page 3528)	Reads one or more records from an open file into a variable.
	BlockWrite (see page 3530)	Writes one or more records from a variable to an open file.
	BlockWrite (see page 3530)	Writes one or more records from a variable to an open file.
	Break (see page 3531)	Causes the flow of control to exit a for, while, or repeat statement.
	ChDir (see page 3534)	Changes the current directory.
	ChDir (see page 3534)	Changes the current directory.
	CheckSafecallResult (see page 3536)	This is function System::CheckSafecallResult.
	Chr (see page 3536)	Returns the character for a specified ASCII value.
	Close (see page 3538)	Terminates the association between a file variable and an external file.
	CloseFile (see page 3539)	Terminates the association between file variable and an external disk file.
	CompToCurrency (see page 3542)	Converts a **Comp** value to a Currency (see page 3235) value.
	CompToDouble (see page 3543)	Converts a Comp value to a double value.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Concat (see page 3545)	Concatenates two or more strings into one.
	Continue (see page 3546)	Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.
	Copy (see page 3547)	Returns a substring of a string or a segment of a dynamic array.
	Cos (see page 3549)	Calculates the cosine of an angle.
	CurrencyToComp (see page 3550)	Converts a Currency (see page 3235) value to a Comp value.
	Dec (see page 3550)	Decrements a variable by 1 or N.
	Dec (see page 3550)	Decrements a variable by 1 or N.
	Delete (see page 3552)	Removes a substring from a string.
	Dispose (see page 3553)	Releases memory allocated for a dynamic variable.
	DoubleToComp (see page 3555)	Converts a double value to a Comp.
	DynArrayClear (see page 3555)	This is function System.DynArrayClear.
	DynArrayDim (see page 3555)	This is function System.DynArrayDim.

	DynArraySetLength (see page 3556)	This is function System.DynArraySetLength.
	EndThread (see page 3556)	Terminates the execution of a thread.
	EnumModules (see page 3556)	Executes a callback for all the modules in an application.
	EnumModules (see page 3556)	Executes a callback for all the modules in an application.
	EnumResourceModules (see page 3557)	Executes a callback for all resource modules in an application.
	EnumResourceModules (see page 3557)	Executes a callback for all resource modules in an application.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eof (see page 3558)	Tests whether the file position is at the end of a file.
	Eoln (see page 3559)	Tests whether the file pointer is at the end of a line.
	Eoln (see page 3559)	Tests whether the file pointer is at the end of a line.
	Erase (see page 3560)	Deletes an external file.
	Error (see page 3560)	Error is used to generate a run-time exception.
	ExceptAddr (see page 3562)	Returns the address at which the current exception was raised.
	ExceptObject (see page 3562)	Returns current exception object.
	Exclude (see page 3564)	Removes an element from a Delphi set or removes an event handler in .NET applications.
	Exit (see page 3565)	Exits from the current procedure.
	Exp (see page 3567)	Returns the exponential of X.
	Exp (see page 3567)	Returns the exponential of X.
	FilePos (see page 3567)	Returns the current file position.
	FileSize (see page 3569)	Returns the number of records in a file.
	FillChar (see page 3570)	Fills contiguous bytes with a specified value.
	Finalize (see page 3572)	Uninitializes a dynamically allocated variable.
	Finalize (see page 3572)	Uninitializes a dynamically allocated variable.
	FindClassHInstance (see page 3573)	Returns the instance handle for the module in which a class type is defined.
	FindDynaInst (see page 3573)	This is function System::FindDynaInst.
	FindHInstance (see page 3574)	Returns the instance handle of the module that contains a specified address.
	FindResourceHInstance (see page 3574)	Returns the instance handle of the resource module associated with a specified `HInstance`.
	Flush (see page 3575)	Empties the buffer of a text file opened for output.
	FPower10 (see page 3576)	This is function System.FPower10.
	Frac (see page 3576)	Returns the fractional part of a real number.
	FreeMem (see page 3577)	FreeMem frees a memory block.
	FreeMem (see page 3577)	FreeMem frees a memory block.
	FreeMemory (see page 3579)	FreeMemory frees a memory block.
	Get8087CW (see page 3580)	Returns the value of the 8087 code word.
	GetDir (see page 3580)	Returns the current directory.
	GetHeapStatus (see page 3581)	Returns the current status of the memory manager.
	GetLastError (see page 3582)	Returns the last error reported by an operating system API call.
	GetMem (see page 3584)	GetMem allocates a memory block.
	GetMemory (see page 3585)	GetMemory allocates a memory block.
	GetMemoryManager (see page 3587)	Returns the entry points of the currently installed memory manager.
	GetMemoryManager (see page 3587)	Returns the entry points of the currently installed memory manager.
	GetMemoryManagerState (see page 3591)	Fetches state information for the Memory Manager.
	GetMemoryMap (see page 3592)	Fetches the memory map.
	GetMinimumBlockAlignment (see page 3592)	Gets the minimum memory block alignment.
	GetModuleFileName (see page 3593)	Returns the fully qualified name for a module, given its handle.
	GetVariantManager (see page 3594)	Returns the entry points of the routines that define variant behavior.
	Halt (see page 3594)	Initiates abnormal termination of a program.
	Halt (see page 3594)	Initiates abnormal termination of a program.
	Hi (see page 3595)	Returns the high-order byte of X as an unsigned value.
	High (see page 3596)	Returns the highest value in the range of an argument.
	Inc (see page 3597)	Increments an ordinal value by one or N.
	Inc (see page 3597)	Increments an ordinal value by one or N.

	Include (see page 3598)	Adds an element to a Delphi set or adds an event handler in .NET applications.
	Initialize (see page 3599)	Initializes a dynamically allocated variable.
	Initialize (see page 3599)	Initializes a dynamically allocated variable.
	Insert (see page 3601)	Inserts a substring into a string beginning at a specified point.
	Int (see page 3602)	Returns the integer part of a real number.
	IOResult (see page 3602)	Returns the status of the last I/O operation performed.
	IsMemoryManagerSet (see page 3604)	Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 3660) procedure.
	IsVariantManagerSet (see page 3606)	Indicates whether variant support is implemented in an application.
	Length (see page 3607)	Returns the number of characters in a string or elements in an array.
	Ln (see page 3608)	Returns the natural log of a real expression.
	Lo (see page 3609)	Returns the low order Byte of argument X.
	LoadResourceModule (see page 3609)	This is function System.LoadResourceModule.
	LoadResourceString (see page 3610)	This is function System::LoadResourceString.
	LoadResString (see page 3610)	This is function System.LoadResString.
	Low (see page 3610)	Returns the lowest value in a range.
	Mark (see page 3612)	This is function System.Mark.
	MemoryBarrier (see page 3612)	This is function System.MemoryBarrier.
	MkDir (see page 3612)	Creates a new subdirectory.
	MkDir (see page 3612)	Creates a new subdirectory.
	MonitorEnter (see page 3614)	Prohibits the access of all other threads but the calling one to the specified object.
	MonitorExit (see page 3614)	Releases a lock of the calling thread on the specified object.
	MonitorPulse (see page 3615)	Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases it.
	MonitorPulseAll (see page 3615)	Signals all threads in the waiting queue that either one of them will be able to lock the specified object as soon as the calling thread releases it.
	MonitorTryEnter (see page 3616)	Attempts to lock the specified object, so that only the calling thread is able to access it.
	MonitorWait (see page 3616)	Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.
	Move (see page 3617)	Copies bytes from a source to a destination.
	MoveChars (see page 3618)	Copies bytes from a source to a destination.
	New (see page 3619)	Creates a new dynamic variable and sets P to point to it.
	Odd (see page 3621)	Returns true if argument is an odd number.
	OleStrToString (see page 3622)	Copies data received from a COM interface to a string.
	OleStrToStrVar (see page 3622)	Copies a string from its COM representation to an existing Delphi string.
	OleStrToStrVar (see page 3622)	Copies a string from its COM representation to an existing Delphi string.
	Ord (see page 3623)	Returns the ordinal value of an ordinal-type expression.
	ParamCount (see page 3623)	Returns the number of parameters passed on the command line.
	ParamStr (see page 3625)	Returns a specified parameter from the command-line.
	Pi (see page 3626)	Returns 3.1415926535897932385.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 3627)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pred (see page 3628)	Returns the predecessor of the argument.
	Ptr (see page 3630)	Converts a specified address to a pointer.
	PUCS4Chars (see page 3632)	Converts a UCS4 string to a null-terminated array of UCS4 characters.
	RaiseList (see page 3632)	This is function System.RaiseList.
	Random (see page 3632)	Generates random numbers within a specified range.
	Random (see page 3632)	Generates random numbers within a specified range.
	Randomize (see page 3633)	Initializes the random number generator with a random value.
	Read (see page 3634)	Read reads data from a file.
	Read (see page 3634)	Read reads data from a file.
	Read (see page 3634)	Read reads data from a file.

	Read (see page 3634)	Read reads data from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReadLn (see page 3636)	Reads a line of text from a file.
	ReallocMem (see page 3637)	ReallocMem reallocates a memory block.
	ReallocMemory (see page 3638)	ReallocMemory resizes a memory block.
	RegisterExpectedMemoryLeak (see page 3640)	Registers an expected memory leak.
	RegisterModule (see page 3640)	Registers the specified module.
	Release (see page 3641)	This is function System.Release.
	ReleaseExceptionObject (see page 3641)	Releases exception object acquired by AcquireExceptionObject (see page 3512).
	RemoveModuleUnloadProc (see page 3641)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	RemoveModuleUnloadProc (see page 3641)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	Rename (see page 3642)	Changes the name of an external file.
	Rename (see page 3642)	Changes the name of an external file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Reset (see page 3643)	Opens an existing file.
	Rewrite (see page 3645)	Creates a new file and opens it.
	Rewrite (see page 3645)	Creates a new file and opens it.
	RmDir (see page 3647)	Deletes an empty subdirectory.
	RmDir (see page 3647)	Deletes an empty subdirectory.
	Round (see page 3648)	Returns the value of X rounded to the nearest whole number.
	RunError (see page 3649)	Stops execution and generates a runtime error.
	RunError (see page 3649)	Stops execution and generates a runtime error.
	Seek (see page 3650)	Moves the current position of a file to a specified component.
	SeekEof (see page 3651)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEof (see page 3651)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEoln (see page 3652)	Returns the end-of-line status of a file, ignoring whitespace.
	SeekEoln (see page 3652)	Returns the end-of-line status of a file, ignoring whitespace.
	Set8087CW (see page 3653)	Sets both the control word in the floating point unit and the variable NoErrMsg (see page 3832) declared in the system unit.
	SetCodePage (see page 3655)	This is function System.SetCodePage.
	SetInOutRes (see page 3655)	This is function System.SetInOutRes.
	SetLastError (see page 3656)	SetLastError sets the last API error code.
	SetLength (see page 3657)	Sets the length of a string or dynamic-array variable.
	SetLineBreakStyle (see page 3659)	Determines the end-of-line and end-of-file conventions for text file I/O.
	SetMemoryManager (see page 3660)	Sets entry points of the memory manager.
	SetMemoryManager (see page 3660)	Sets entry points of the memory manager.
	SetMinimumBlockAlignment (see page 3664)	Sets the minimum memory block alignment.
	SetMultiByteConversionCodePage (see page 3665)	Sets the code page used internally whenever multibyte characters are converted to/from WideChar.
	SetRaiseList (see page 3665)	This is function System.SetRaiseList.
	SetString (see page 3665)	Sets the contents and length of the given string.
	SetTextBuf (see page 3667)	Assigns an I/O buffer to a text file.
	SetTextBuf (see page 3667)	Assigns an I/O buffer to a text file.
	SetVariantManager (see page 3668)	Sets the entry points of routines that define variant behavior.
	ShareMemoryManager (see page 3668)	Shares the module's memory manager.
	Sin (see page 3669)	Returns the sine of the angle in radians.
	SizeOf (see page 3670)	Returns the number of bytes occupied by a variable or type.
	Slice (see page 3671)	Returns a sub-section of an array.
	Sqr (see page 3674)	Returns the square of a number.

	Sqr (see page 3674)	Returns the square of a number.
	Sqrt (see page 3675)	Returns the square root of X.
	Str (see page 3676)	Formats a string and returns it to a variable.
	Str (see page 3676)	Formats a string and returns it to a variable.
	StringCodePage (see page 3676)	Returns the code page associated with the string.
	StringCodePage (see page 3676)	Returns the code page associated with the string.
	StringElementSize (see page 3677)	Returns the number of bytes that represent a character in the string.
	StringElementSize (see page 3677)	Returns the number of bytes that represent a character in the string.
	StringOfChar (see page 3677)	Returns a string with a specified number of repeating characters.
	StringOfChar (see page 3677)	Returns a string with a specified number of repeating characters.
	StringRefCount (see page 3678)	Returns the reference count of a string.
	StringRefCount (see page 3678)	Returns the reference count of a string.
	StringToOleStr (see page 3678)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToOleStr (see page 3678)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToWideChar (see page 3679)	Returns a UNICODE string from an AnsiString.
	Succ (see page 3680)	Returns the successor of an argument.
	Swap (see page 3680)	Exchanges high order byte with the low order byte of an integer or word.
	SysAllocMem (see page 3681)	This is function System.SysAllocMem.
	SysFreeMem (see page 3681)	Frees the memory pointed to by a specified pointer.
	SysGetMem (see page 3682)	Allocates a specified number of bytes and returns a pointer to them.
	SysReallocMem (see page 3683)	Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.
	SysRegisterExpectedMemoryLeak (see page 3683)	This is function System.SysRegisterExpectedMemoryLeak.
	SysUnregisterExpectedMemoryLeak (see page 3684)	This is function System.SysUnregisterExpectedMemoryLeak.
	TextStart (see page 3684)	This is function System.TextStart.
	Trunc (see page 3684)	Truncates a real number to an integer.
	Truncate (see page 3685)	Deletes all the records after the current file position.
	UCS4StringToUnicodeString (see page 3686)	Converts an UCS-4 encoded string to an Unicode string.
	UCS4StringToWideString (see page 3687)	Converts a string of 4-byte Unicode characters into a WideString (see page 3467) value.
	UnicodeStringToUCS4String (see page 3689)	Converts an Unicode string to its UCS-4 encoded representation.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 3690)	Converts a string of Unicode characters into a UTF-8 string.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UniqueString (see page 3693)	Ensures that a given string has a reference count of one.
	UnregisterExpectedMemoryLeak (see page 3694)	Unregisters an expected memory leak.
	UnregisterModule (see page 3694)	Unregisters the specified module.
	UpCase (see page 3695)	Converts a character to uppercase.
	UpCase (see page 3695)	Converts a character to uppercase.
	UTF8Decode (see page 3696)	Converts a UTF8 string to a Unicode string (WideString (see page 3467)).
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8Encode (see page 3696)	Converts a WideString (see page 3467) value to a UTF8 string.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	UTF8EncodeToShortString (see page 3697)	Converts a string to its UTF-8 encoded representation.
	Utf8ToAnsi (see page 3698)	Converts a UTF8 string to a string of Ansi characters.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	UTF8ToString (see page 3698)	Converts an UTF-8 encoded string to a string.
	Utf8ToUnicode (see page 3699)	Converts a string of UTF-8 characters to a Unicode string.

	Utf8ToUnicode (see page 3699)	Converts a string of UTF-8 characters to a Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToUnicodeString (see page 3700)	Converts an UTF-8 encoded string to an Unicode string.
	UTF8ToWideString (see page 3700)	Converts an UTF-8 encoded string to a WideString (see page 3467).
	Val (see page 3701)	Converts a string to a numeric representation.
	VarArrayRedim (see page 3702)	Resizes a Variant (see page 3421) array.
	VarClear (see page 3704)	Empties a Variant (see page 3421), so that it is unassigned.
	WideCharLenToString (see page 3705)	Converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)**.
	WideCharLenToStrVar (see page 3706)	WideCharLenToStrVar converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)** or **AnsiString**.
	WideCharLenToStrVar (see page 3706)	WideCharLenToStrVar converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)** or **AnsiString**.
	WideCharToString (see page 3706)	Converts null-terminated **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.
	WideCharToStrVar (see page 3707)	Converts **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.
	WideStringToUCS4String (see page 3707)	Converts a WideString (see page 3467) value to a string of 4-byte Unicode characters.
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	Write (see page 3707)	Writes to either a typed file or a text file
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 3710)	Writes to a text file and adds an end-of-line marker.
	YieldProcessor (see page 3711)	This is function System.YieldProcessor.

35.3.1 System.Abs Function

Returns an absolute value.

Pascal

```
procedure Abs(X);
```

C++

```
Abs( X);
```

File

System

Description

Abs returns the absolute value of the argument, X.

X is an integer-type or real-type expression.

Delphi Examples:

```
{
This example converts negative floating point numbers and
integers to postive.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
```

```
  Edit1.Text := '-2.3';
  Edit3.Text := FloatToStr(Abs(StrToFloat(Edit1.Text)));    { 2.3 }
  Edit2.Text := '-157';
  Edit4.Text := IntToStr(Abs(StrToInt(Edit2.Text)));    { 157 }
end;
```

35.3.2 System.AcquireExceptionObject Function

Retains access to exception object.

Pascal

```
function AcquireExceptionObject: Pointer;
```

C++

```
void * AcquireExceptionObject();
```

File

System

Description

AcquireExceptionObject returns a pointer to the current exception object and prevents the exception object from being deallocated when the current exception handler exits.

Note: AcquireExceptionObject increments the exception object's reference count. Make sure that the reference count is decremented when the exception object is no longer needed. This happens automatically if you use the exception object to re-raise the exception. In all other cases, every call to AcquireExceptionObject must have a matching call to ReleaseExceptionObject (see page 3641). AcquireExceptionObject/ReleaseExceptionObject (see page 3641) sequences can be nested.

Delphi Examples:

```
{
This example demonstrates exception handling to catch runtime
errors.
}

procedure TForm2.btIOErrorClick(Sender: TObject);
var
  ExceptionObj : TObject;
begin
  {
  Try to write something onto the console - will raise an
  exception.
  }
  try
  WriteLn('This will generate an error because there is no' +
          ' console attached!');
  except
    ExceptionObj := ExceptObject;
    if ExceptionObj = nil then
      MessageDlg('No exception', mtError, [mbOK], 0)
    else
    begin
      MessageDlg(ExceptionObj.ToString, mtError, [mbOK], 0);
    end;
  end;
end;
```

```
{$OVERFLOWCHECKS ON}
{$OPTIMIZATION OFF}
{$HINTS OFF}
procedure TForm2.btOverflowErrClick(Sender: TObject);
var
  b : Cardinal;
  ExceptionPtr : Pointer;
begin
  {
  Simulate an overflow: Note, enabled the overflow
  checking and disabled optimizations because Delphi's
  compiler will not compile this code otherwise.
  }
  ExceptionPtr := nil;
  try
    b := $FFFFFFFF;
    b := b * b;
  except
    ExceptionPtr := AcquireExceptionObject;
  end;

  // Check exception
  if ExceptionPtr = nil then
    MessageDlg('No exception', mtError, [mbOK], 0)
  else
  begin
    MessageDlg(TObject(ExceptionPtr).ToString, mtError, [mbOK], 0);
    ReleaseExceptionObject;
  end;
end;
{$HINTS ON}
{$OPTIMIZATION ON}
{$OVERFLOWCHECKS OFF}

procedure TForm2.btRuntimeErrorClick(Sender: TObject);
var

  ExceptionObj : TObject;
  begin
  { Simulate an access violation }
  try
    System.Error(reAccessViolation);
  except
    ExceptionObj := ExceptObject;
    if ExceptionObj = nil then
      MessageDlg('No exception', mtError, [mbOK], 0)
    else
    begin
      MessageDlg(ExceptionObj.ToString, mtError, [mbOK], 0);
    end;
  end;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin

end;
```

See Also

ReleaseExceptionObject (see page 3641)

ExceptObject (see page 3562)

35.3.3 System.AddModuleUnloadProc Function

AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.

Pascal

```
procedure AddModuleUnloadProc(Proc: TModuleUnloadProc); overload;
procedure AddModuleUnloadProc(Proc: TModuleUnloadProcLW); overload;
```

C++

```
AddModuleUnloadProc(TModuleUnloadProc Proc);
AddModuleUnloadProc(TModuleUnloadProcLW Proc);
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your **Proc** routine. In essence, AddModuleUnloadProc adds your callback routine to the head of the list of internal routines that Delphi invokes to perform the unload.

Use RemoveModuleUnloadProc (see page 3641) to reverse the effect of AddModuleUnloadProc.

See Also

RemoveModuleUnloadProc (see page 3641)

TModuleUnloadProc (see page 3792)

35.3.4 System.Addr Function

Returns a pointer to a specified object.

Pascal

```
function Addr(var X): Pointer;
```

C++

```
void * Addr( X);
```

File

System

Description

The Addr function returns the address of a specified object. X is any variable, procedure or function identifier. The result is a pointer to X.

The result of Addr is of the predefined type Pointer, which means that it is assignment-compatible with all pointer types but can't be dereferenced directly without a typecast.

Note: Addr is equivalent to the @ operator except that it is unaffected by the $T compiler directive.

Delphi Examples:

```
{
This example uses the Addr function to get the address of a
numeric value that is stored as custom data in a tree node.
Once the assignment has been made, changes to the entries in
the NodeNumbers array can be read by dereferencing the
pointers that are stored in the Data property of the Tree
nodes.  This example requires a populated TreeView.
}

var
  NodeNumbers: array [0 .. 200] of String;

procedure TForm1.Button1Click(Sender: TObject);
var
  I : Integer;
 begin
  with TreeView1 do
  begin
    for I := 0 to Items.Count - 1 do
    begin
      NodeNumbers[I] := Items[I].Text;
      Items[I].Data := Addr(NodeNumbers[I]);
      StringGrid1.Cells[0, I + 1] := IntToStr(I);
      StringGrid1.Cells[1, I + 1] := IntToStr(Integer(Items[I].Data));
      StringGrid1.Cells[2, I + 1] := NodeNumbers[I];
    end;
  end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  I : Integer;
  addr : Pointer;
begin
  I := StrToInt(Edit2.Text);
  addr := TreeView1.Items[I].Data;
  string(addr^) := Edit1.Text;  // NodeNumbers has been altered
  TreeView1.Items[I].Text := NodeNumbers[I]; // Update TreeView
  StringGrid1.Cells[2, I + 1] := NodeNumbers[I];  // Update StringGrid
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[0, 0] := 'Node index';
  StringGrid1.Cells[1, 0] := 'Node addr';
  StringGrid1.Cells[2, 0] := 'Node text';
end;
```

See Also

Ptr (see page 3630)

35.3.5 System.AllocMem Function

AllocMem allocates a memory block and initializes each byte to zero.

Pascal

```
function AllocMem(Size: Cardinal): Pointer;
```

C++

```
void * AllocMem(unsigned Size);
```

File

System

Description

AllocMem allocates a block of the given **Size** on the heap, and returns the address of this memory. Each byte in the allocated buffer is set to zero. To dispose of the buffer, use FreeMem (see page 3577). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory does not need to be zero-initialized, it is more efficient to use GetMem (see page 3584) instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int iFileHandle;
  int iFileLength;
  int iBytesRead;
  char *pszBuffer;
  if (OpenDialog1->Execute())
  {
    try
    {
      iFileHandle = FileOpen(OpenDialog1->FileName, fmOpenRead);
      iFileLength = FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
//    pszBuffer = PChar(AllocMem(iFileLength+1));
      std::auto_ptr<char> pszBuffer(new char[iFileLength+1]);
      iBytesRead = FileRead(iFileHandle, pszBuffer.get(), iFileLength);
      FileClose(iFileHandle);
      for (int i=0;i<iBytesRead;i++)
      {
        StringGrid1->RowCount += 1;
        StringGrid1->Cells[1][i+1] = pszBuffer.get()[i];
        StringGrid1->Cells[2][i+1] = IntToStr((int)pszBuffer.get()[i]);
      }
    }
    catch(...)
    {
      Application->MessageBox(
        L"Can't perform one of the following file operations: Open, Seek, Read, Close.",
        L"File Error", IDOK);
    }
  }
}
```

Delphi Examples:

```
{
The following example uses a button, a string grid, and an
```

```
  Open dialog box on a form. When the button is clicked, the
  user is prompted for a filename. When the user clicks OK,
  the specified file is opened, read into a buffer, and closed.
  Then the buffer is displayed in two columns of the string
  grid. The first column contains the character values in the
  buffer. The second column contains the numeric values of the
  characters in the buffer.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    iFileHandle: Integer;
    iFileLength: Integer;
    iBytesRead: Integer;
    Buffer: PAnsiChar;
    i: Integer;
  begin
    if OpenDialog1.Execute then
    begin
      try
        iFileHandle := SysUtils.FileOpen(OpenDialog1.FileName, fmOpenRead);
        iFileLength := SysUtils.FileSeek(iFileHandle,0,2);
        FileSeek(iFileHandle,0,0);
        Buffer := System.AllocMem(iFileLength + 1);
        iBytesRead := SysUtils.FileRead(iFileHandle, Buffer^, iFileLength);
        FileClose(iFileHandle);
        for i := 0 to iBytesRead-1 do
        begin
          StringGrid1.RowCount := StringGrid1.RowCount + 1;
          StringGrid1.Cells[1,i+1] := Buffer[i];
          StringGrid1.Cells[2,i+1] := IntToStr(Integer(Buffer[i]));
        end;
      finally
        FreeMem(Buffer);
      end;
    end;
  end;
```

ReallocMemory (see page 3638)

35.3.6 System.AnsiToUtf8 Function

Converts a string encoded in Ansi to UTF-8.

Pascal

```
function AnsiToUtf8(const S: string): RawByteString;
```

C++

```
RawByteString AnsiToUtf8(const UnicodeString S);
```

File

System

Description

AnsiToUtf8 converts the string specified by **S**, which uses the ANSI encoding system, to UTF-8.

Delphi Examples:

```
{
This example converts various string formats to and from Unicode.
This example requires two text edits and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
  LFileStream: TFileStream;
  LOffset: Integer;
  LEncoding, DestEncoding: TEncoding;
  ComboIndex: Integer;
  ByteString: RawByteString;
  FileText: string;
  ucs4Text: UCS4String;
  wideStringText: WideString;
  utf8Text: UTF8String;
  L: Cardinal;

begin
  LEncoding:= nil;
  ComboIndex := ComboBox1.ItemIndex;
  LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
  try
    // Read file into buffer
    SetLength(LBuffer, LFileStream.Size);
    LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));
    // Get data encoding of data read
    LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
  finally
    LFileStream.Free;
  end;

  // Process various types
  case ComboIndex of

    // AnsiToUtf8
    0:
    begin
      // Identify encoding and convert buffer to Ansi
      DestEncoding := TEncoding.ASCII;
      LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
        LOffset, Length(LBuffer) - LOffset);
      LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
      FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);

35.3.7 System.Append Function

Prepares an existing file for adding text to the end.

Pascal

```
procedure Append(var F: Text);
```

C++

```
Append(Text F);
```

File

System

Description

Call Append to ensure that a file is opened with write-only access with the file pointer positioned at the end of the file. F is a text file variable and must be associated with an external file using AssignFile (see page 3525). If no external file of the given name exists, an error occurs. If F is already open, it is closed, then reopened. The current file position is set to the end of the file.

Note: If a Ctrl+Z (ASCII 26) is present in the last 128-byte block of the file, the current file position is set so that the next character added to the file overwrites the first Ctrl+Z in the block. In this way, text can be appended to a file that terminates with a Ctrl+Z.

If F was not assigned a name, then, after the call to Append, F refers to the standard output file.

Delphi Examples:

```
{
Click the button and select a file to append a string to the bottom of the file.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  f: TextFile;
begin
  if OpenDialog1.Execute then
  begin                    { open a text file }
```

```
    AssignFile(f, OpenDialog1.FileName);
    Append(f);
    Writeln(f, 'I am appending some stuff to the end of the file.');
    { insert code here that would require a Flush before closing the file }
    Flush(f);  { ensures that the text was actually written to file }
    CloseFile(f);
    MessageDlg(OpenDialog1.FileName + ' has been altered, please validate.', mtInformation,
[mbOK], 0)
  end;
end;
```

35.3.8 System.ArcTan Function

Calculates the arctangent of a given number.

Pascal

```
function ArcTan(const X: Extended): Extended;
```

C++

```
Extended ArcTan(const Extended X);
```

File

System

Description

In Delphi code, ArcTan returns the arctangent of X.

X is a real-type expression that gives an angle in radians.

C++ Examples:

```
/*
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Extended ex = 16 * ArcTan(1.0/5.0) - 4.0 * ArcTan(1.0/239.0); // Machin's formula
  String mystring = FloatToStr(ex);
  Edit2->Text = mystring;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Text = "3.14159265358979";
}
```

Delphi Examples:

```
{
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit3.Text := mystring;
  Str(ex:25:23, mystring);
  Edit4.Text := mystring;
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit2.Text := mystring;
  mystring := SysUtils.FormatFloat('#,##0.00000000000000000000000000;;Zero', ex);
  Edit5.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
//  mystring := FloatToStr(ex);
//  Str(ex:25:23, mystring);
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit1.Text := mystring;
end;

35.3.9 System.Assert Function

Tests whether a Boolean expression is true.

Pascal

```
procedure Assert(expr: Boolean); overload;
procedure Assert(expr: Boolean; const msg: string); overload;
```

C++

```
Assert(Boolean expr);
Assert(Boolean expr, const UnicodeString msg);
```

File

System

Description

In Delphi code, use Assert as a debugging tool to test that conditions assumed to be true are never violated. Assert provides an opportunity to intercept an unexpected condition and halt a program rather than allow execution to continue under unanticipated

conditions.

Assert takes a Boolean expression and an optional message string as parameters. If the Boolean test fails, Assert raises an EAssertionFailed exception. If a message string was passed to Assert, the exception object is created with that string. Otherwise it is created with a default string indicating that the assertion failed. The message is displayed along with the complete path, filename, and the line number on which Assert failed.

The SysUtils (see page 3901) unit causes runtime errors to be turned into exceptions. If SysUtils (see page 3901) is not used anywhere in your application, you will get a runtime error 227 rather than an EAssertionFailed exception. This runtime error will halt the program.

Because assertions are not usually used in shipping versions of a product, compiler directives are provided to disable the generation of assertion code:

$ASSERTIONS ON/OFF(long form)

$C +/-(short form)

These are global switches that affect the entire source file where they occur, regardless of their position in the file. It is not possible to enable and disable assertions for something smaller than a source file. Assertions are on by default.

Delphi Examples:

```
{
This example exercises the System Assert function.  The first
call passes and the second call fails.
}

type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TStorage = class(TObject)
    FData: string;
    property Data: string read FData write FData;
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  var
  Form1: TForm1;

implementation

{$R *.dfm}

procedure ModifyStorage(AStorage: TStorage; const s: string);
begin
  Assert(AStorage <> nil, '');
  AStorage.Data := s;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  Storage: TStorage;
begin
  Storage := TStorage.Create;
```

```
    try
      ModifyStorage(Storage, 'Hello world');
    finally
      Storage.Free;
    end;

    // The following call is buggy and triggers the Assert
    ModifyStorage(nil, 'Ooops');
  end;
```

See Also

EAssertionFailed (see page 3918)

35.3.10 System.Assigned Function

Tests for a nil (unassigned) pointer or procedural variable.

Pascal

```
function Assigned(const P): Boolean;
```

C++

```
Boolean Assigned(const  P);
```

File

System

Description

Use Assigned to determine whether the pointer or procedure referenced by P is nil. P must be a variable reference of a pointer or procedural type. Assigned(P) corresponds to the test P<> nil for a pointer variable, and @P <> nil for a procedural variable.

Assigned returns false if P is nil, true otherwise.

Note: Assigned can't detect a dangling pointer--that is, one that isn't nil but no longer points to valid data. For example, in the code example for Assigned, Assigned won't detect the fact that P isn't valid.

Delphi Examples:

```
{
This example demonstrates the System Assigned function succeeds.
}
procedure TForm1.Button1Click(Sender: TObject);
var P: Pointer;
begin
  P := nil;
  if Assigned (P) then
    MessageDlg('You won''t see this', mtInformation, [mbOK], 0);
  GetMem(P, 1024);  {P valid}
  FreeMem(P, 1024); {P no longer valid and still not nil}
  if Assigned (P) then
    MessageDlg('You''ll see this', mtInformation, [mbOK], 0);
end;
```

35.3.11 System.AssignFile Function

Associates the name of an external file with a file variable.

Pascal

```
procedure AssignFile(var F; FileName: string);
```

C++

```
AssignFile( F, UnicodeString FileName);
```

File

System

Description

Call AssignFile to initialize a file variable in Delphi code. F is a file variable of any file type. FileName is a string-type expression or an expression of type PChar if extended syntax is enabled.

After calling AssignFile, F is associated with the external file until F is closed. All further operations on the file variable F operate on the external file named by FileName.

When the FileName parameter is empty, AssignFile associates F with the standard input or standard output file. If assigned an empty name, after a call to Reset (see page 3643) (F), F refers to the standard input file, and after a call to Rewrite (see page 3645) (F), F refers to the standard output file.

Do not use AssignFile on a file variable that is already open.

Note: To avoid scope conflicts, AssignFile replaces the Assign procedure that was available in early versions of the Delphi product. However, for backward compatibility Assign is still available.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], fmOpenWrite);
```

```
        if (filehandle = -1) then
        begin
          MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                     ' cannot be opened with access mode fmOpenWrite.', mtError, [mbOk], 0);
          Continue;
        end
        else
          FileClose(filehandle);

        AssignFile(F, FileListBox1.Items.Strings[i]);
        Reset(F, 1);
        ListBox1.Items.Add(
          FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
        CloseFile(F);
      end;
     finally
     { do something here }
     end;
    end;
  end;
  {
  Use a TOpenDialog to select a file.  Place the first line of
  the file into a TEdit.  Click on the text edit to open the
  open dialog box.
  }
  procedure TForm1.Edit1Click(Sender: TObject);
  var
    F: TextFile;
    S: string;
  begin
    if OpenDialog1.Execute then            { Display Open dialog box }
    begin
      AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
      Reset(F);
      Readln(F, S);                        { Read first line of file }
      Edit1.Text := S;                     { Put string in a TEdit control }
      CloseFile(F);
    end;
  end;
  {
  Click the button to open a TOpenDialog, then select a file
  to delete.
  }

  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: Textfile;
  begin
    OpenDialog1.Title := 'Delete File';
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      try
        Reset(F);
        if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
          mtConfirmation, [mbYes, mbNo], 0) = mrYes then
        begin
          CloseFile(F);
          Erase(F);
        end;
      except
        on EInOutError do
          MessageDlg('File I/O error.', mtError, [mbOk], 0);
      end;
    end;
  end;
```

35.3.12 System.AttemptToUseSharedMemoryManager Function

Attempts to use a shared memory manager.

Pascal

```
function AttemptToUseSharedMemoryManager: Boolean;
```

C++

```
Boolean AttemptToUseSharedMemoryManager();
```

File

System

Description

AttemptToUseSharedMemoryManager searches the current process for a shared memory manager. If no memory has been allocated using this module's memory manager, it will switch to using the shared memory manager. It will return **True** if it found a shared memory manager to which it could switch. It will return **False** otherwise.

Note: The memory manager cannot be changed once memory has been allocated, since the new memory manager cannot free the pointers allocated through a different memory manager. This function is not thread safe.

Configuring the Memory Manager

Sharing Memory

35.3.13 System.BeginThread Function

Spawns a separate thread of execution.

Pascal

```
function BeginThread(SecurityAttributes: Pointer; StackSize: LongWord; ThreadFunc:
TThreadFunc; Parameter: Pointer; CreationFlags: LongWord; var ThreadId: LongWord): Integer;
```

C++

```
int BeginThread(void * SecurityAttributes, LongWord StackSize, TThreadFunc ThreadFunc, void *
Parameter, LongWord CreationFlags, LongWord ThreadId);
```

File

System

Description

Use this routine or a TThread object to spawn separate threads of execution. BeginThread spawns a new thread of execution and sets the global IsMultiThread (see page 3829) variable, thereby making the heap thread-safe.

ThreadFunc is the thread function. This is the code that executes in the new thread of execution. ThreadFunc should handle all of its own exceptions. However, because BeginThread sets up an execution frame, the system's default exception handler will catch any exceptions that escape ThreadFunc.

Parameter points to a single 32-bit parameter that is passed, uninterpreted, to ThreadFunc.

ThreadId returns the unique identifier for the new thread. This ID appears in the Thread Status box of the debugger.

SecurityAttributes is a pointer to a Windows SecurityAttributes record (structure). For details on security attributes, see the Microsoft documentation.

StackSize is the size of the stack reserved for the new thread when CreationFlags includes STACK_SIZE_IS_A_RESERVATION. Otherwise, this parameter is ignored.

CreationFlags is a set of bits or'ed together that are drawn from the following:

Value	Meaning
CREATE_SUSPENDED	The thread is created in a suspended state and does not run until the Windows API ResumeThread function is called. If this flag is not included, the new thread starts running as soon as it is created.
STACK_SIZE_PARAM_IS_A_RESERVATION	The StackSize parameter specifies the stack size for the thread. If this flag is not included, the new thread is assigned a default stack size by the linker.

On Windows, BeginThread returns the Windows thread handle. A return value of 0 indicates failure.

Attribute is a structure containing information about the thread such as its priority, its schedule policy, and its stack size.

On Linux, Begin Thread returns 0 if the thread is successfully spawned, an error code otherwise.

EndThread (see page 3556)

IsMultiThread (see page 3829)

Defining Thread Objects

35.3.14 System.BlockRead Function

Reads one or more records from an open file into a variable.

Pascal

```
procedure BlockRead(var F: File; var Buf; Count: Integer); overload;
procedure BlockRead(var F: File; var Buf; Count: Integer; var AmtTransferred: Integer);
overload;
```

C++

```
BlockRead(File F,  Buf, int Count);
BlockRead(File F,  Buf, int Count, int AmtTransferred);
```

File

System

Description

F is an untyped file variable, Buf is any variable, Count is an expression of type Integer, and AmtTransferred is an optional variable of type Integer.

BlockRead reads Count or fewer records from the file F into memory, starting at the first byte occupied by Buf. The actual number of complete records read (less than or equal to Count) is returned in AmtTransferred.

The entire transferred block occupies at most Count * RecSize bytes. RecSize is the record size specified when the file was opened (or 128 if the record size was not specified).

If the entire block was transferred, AmtTransferred is equal to Count.

If AmtTransferred is less than Count, ReadBlock reached the end of the file before the transfer was complete. If the file's record size is greater than 1, AmtTransferred returns the number of complete records read.

If AmtTransferred isn't specified, an I/O error occurs if the number of records read isn't equal to Count. If the $I+ compiler directive is in effect, errors raise an EInOutError exception.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.  Validate
the saved file contents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      // Use CloseFile rather than Close; Close provided for backward compatibility
      CloseFile(FromF);
      CloseFile(ToF);
      Canvas.TextOut(120, 10, ' done.');
    end;
  end;
end;
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  F: file;
  Size: Integer;
  Buffer: PAnsiChar;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    Reset(F, 1);
    try
      Size := FileSize(F);
      GetMem(Buffer, Size);
      try
        BlockRead(F, Buffer^, Size);
        Memo1.Lines.Add(AnsiString(Buffer));
      finally
        FreeMem(Buffer);
      end;
    finally
      CloseFile(F);
    end;
  end;
end;
```

See Also

TFileStream

EInOutError (see page 3929)

35.3.15 System.BlockWrite Function

Writes one or more records from a variable to an open file.

Pascal

```
procedure BlockWrite(var f: File; var Buf; Count: Integer); overload;
procedure BlockWrite(var f: File; var Buf; Count: Integer; var AmtTransferred: Integer);
overload;
```

C++

```
BlockWrite(File f,  Buf, int Count);
BlockWrite(File f,  Buf, int Count, int AmtTransferred);
```

File

System

Description

F is an untyped file variable, Buf is any variable, Count is an expression of type Integer, and AmtTransferred is an optional variable of type Integer.

BlockWrite writes Count or fewer records to the file F from memory, starting at the first byte occupied by Buf. The actual number of complete records written (less than or equal to Count) is returned in AmtTransferred.

The entire block transferred occupies at most Count * RecSize bytes. RecSize is the record size specified when the file was opened (or 128 if the record size was unspecified).

If the entire block is transferred, AmtTransferred is equal to Count on return.

If AmtTransferred is less than Count, the disk became full before the transfer was complete. In this case, if the file's record size is greater than 1, AmtTransferred returns the number of complete records written.

BlockWrite advances the current file position by AmtTransferred records.

If AmtTransferred isn't specified, an I/O error occurs if the number written isn't equal to Count. If the $I+ compiler directive is in effect, errors raise an EInOutError exception.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.  Validate
the saved file contents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      // Use CloseFile rather than Close; Close provided for backward compatibility
      CloseFile(FromF);
      CloseFile(ToF);
      Canvas.TextOut(120, 10, ' done.');
    end;
  end;
end;
```

35.3.16 System.Break Function

Causes the flow of control to exit a for, while, or repeat statement.

Pascal

```
procedure Break;
```

C++

```
Break();
```

File

System

Description

The Break procedure causes the flow of control in Delphi code to exit a for, while, or repeat statement and continue at the next

statement following the loop statement.

A call to Break must be contained in a for, while, or repeat statement, or the compiler reports an error.

Note: Break does not violate the flow of control dictated by a try..finally construct. If a break occurs inside the try clause, the finally clause is entered.

Delphi Examples:

```
{
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
}
procedure TForm1.FindDialog1Find(Sender: TObject);
var
  I, J, PosReturn, SkipChars: Integer;
begin
  for I := 0 to Memo1.Lines.Count do
  begin
    PosReturn := Pos(FindDialog1.FindText,Memo1.Lines[I]);
    if PosReturn <> 0 then {found!}
    begin
      SkipChars := 0;
      for J := 0 to I - 1 do
        SkipChars := SkipChars + Length(Memo1.Lines[J]);
      SkipChars := SkipChars + (I*2);
      SkipChars := SkipChars + PosReturn - 1;
      Memo1.SetFocus;
      Memo1.SelStart := SkipChars;
      Memo1.SelLength := Length(FindDialog1.FindText);
      Break;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'country.list';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off

}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
```

```
    TmpStr: string;
  begin
    { first, process the keystroke to obtain the current string }
    { This code requires all items in list to be uppercase}
    if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
    ct := (Sender as TComboBox).Items.Count;
    with (Sender as TComboBox) do
    begin
      SelSt := SelStart;
      if (Key = Chr(vk_Back)) and (SelLength <> 0) then
       TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
      else if Key = Chr(vk_Back) then {SelLength = 0}
       TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
      else {Key in ['A'..'Z', etc]}
       TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
      if TmpStr = '' then Exit;
      { update SelSt to the current insertion point }
      if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
      else if Key <> Chr(vk_Back) then Inc(SelSt);
      Key := #0; { indicate that key was handled }
      if SelSt = 0 then
      begin
        Text:= '';
        Exit;
      end;
     {Now that TmpStr is the currently typed string, see if we can locate a match }
      Found := False;
      for i := 1 to ct do
      begin
        if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
        begin
          Text := Items[i-1]; { update to the match that was found }
          ItemIndex := i-1;
          Found := True;
          Break;
        end;
      end;
      if Found then { select the untyped end of the string }
      begin
        SelStart := SelSt;
        SelLength := Length(Text) - SelSt;
      end
      else Beep;
    end;
  end;

  var
    CharSetList : TStringList;

  procedure TForm1.AddCharacterSet(const S: string);
  begin
    CharSetList.Add(S);
  end;

  procedure TForm1.FormCreate(Sender: TObject);

35.3.17 System.ChDir Function

Changes the current directory.

Pascal

```
procedure ChDir(const S: string); overload;
procedure ChDir(P: PChar); overload;
```

C++

```
ChDir(const UnicodeString S);
ChDir(const char * P);
```

File

System

Description

Note: ChDir changes the current directory to the path specified by S or P. If this operation fails, EInOutError is raised.

Note: On Windows, the path can include a drive specifier, which causes the current drive to be changed as well.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for an I/O error.

C++ Examples:

```
/*
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
*/
void __fastcall TMyChDir::Button1Click(TObject *Sender)
{
  try
  {
    System::ChDir(Edit1->Text);
  }
  catch (...)
  {
    MessageDlg("Cannot find directory", mtWarning, TMsgDlgButtons() << mbOK, 0);
  }
  Edit2->Text = GetCurrentDir();
  FileListBox1->Directory = GetCurrentDir();
  DirectoryListBox1->Directory = GetCurrentDir();
}

void __fastcall TMyChDir::DirectoryListBox1Change(TObject *Sender)
{
```

```
  FileListBox1->Directory = DirectoryListBox1->Directory;
  Edit2->Text = GetCurrentDir();
}

void __fastcall TMyChDir::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
  Edit2->Text = GetCurrentDir();
}
```

Delphi Examples:

```
{
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
}

35.3.18 System::CheckSafecallResult Function

Pascal

```
procedure CheckSafecallResult(hr: HRESULT);
```

C++

```
__fastcall void CheckSafecallResult(HRESULT hr);
```

File

sysclass.h

Description

This is function System::CheckSafecallResult.

35.3.19 System.Chr Function

Returns the character for a specified ASCII value.

Pascal

```
function Chr(X: Byte): Char;
```

C++

```
Char Chr(Byte X);
```

File

System

Description

Chr returns the character with the ordinal value (ASCII value) of the byte-type expression, X.

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do

35.3.20 System.Close Function

Terminates the association between a file variable and an external file.

Pascal

```
procedure Close(var F);
```

C++

```
Close( F);
```

File

System

Description

Close is provided for backward compatibility with existing code. When writing new applications in Delphi, use CloseFile (see page 3539) instead.

F is a file variable of any file type opened using Reset (see page 3643), Rewrite (see page 3645), or Append (see page 3520). The external file associated with F is completely updated and then closed, freeing the file handle for reuse.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.  Validate
the saved file contents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      // Use CloseFile rather than Close; Close provided for backward compatibility
      CloseFile(FromF);
      CloseFile(ToF);
      Canvas.TextOut(120, 10, ' done.');
    end;
  end;
end;
```

CloseFile (see page 3539)

35.3.21 System.CloseFile Function

Terminates the association between file variable and an external disk file.

Pascal

```
procedure CloseFile(var F);
```

C++

```
CloseFile( F);
```

File

System

Description

Due to naming conflicts, CloseFile replaces the Close (see page 3538) procedure. Use the CloseFile procedure instead of Close (see page 3538) to terminate the association between a file variable and an external disk file.

F is a file variable of any file type opened using Reset (see page 3643), Rewrite (see page 3645), or Append (see page 3520). The external file associated with F is completely updated and then closed, freeing the file handle for reuse.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.  Validate
the saved file contents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      // Use CloseFile rather than Close; Close provided for backward compatibility
      CloseFile(FromF);
      CloseFile(ToF);
      Canvas.TextOut(120, 10, ' done.');
    end;
  end;
end;
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: AnsiChar;
begin
```

```
    if OpenDialog1.Execute then begin
      AssignFile(F1, OpenDialog1.Filename);
      Reset(F1);
      if SaveDialog1.Execute then begin
        AssignFile(F2, SaveDialog1.Filename);
        Rewrite(F2);
        while not Eof(F1) do
        begin
          Read(F1, Ch);
          Write(F2, Ch);
        end;
        CloseFile(F2);
      end;
      CloseFile(F1);
    end;

35.3.22 System.CompToCurrency Function

Converts a **Comp** value to a Currency (see page 3235) value.

Pascal

```
function CompToCurrency(Value: Comp): Currency; cdecl;
```

C++

```
__cdecl Currency CompToCurrency(Comp Value);
```

File

System

Description

CompToCurrency converts a Comp value into a Currency (see page 3235) value containing the decimal representation of that number.

C++ Examples:

```
/*
This example demonstrates Comp conversion functions.
*/

void __fastcall TForm2::Button1Click(TObject *Sender)
{
    Comp CompValue;
    Currency CurrencyValue;

    try {
        CompValue = StrToInt64(Edit1->Text);
        CurrencyValue = CompToCurrency(CompValue);
        Edit2->Text = CurrToStr(CurrencyValue);
        }
    catch (...) {
        MessageDlg("Enter a signed integer with abs value <= 9 * 10**18", mtError,
            TMsgDlgButtons() << mbOK, 0);
    }
}
//---------------------------------------------------------------------------

void __fastcall TForm2::Button2Click(TObject *Sender)
{
    Comp CompValue;
    Double DoubleValue;

    try {
        CompValue = StrToInt64(Edit3->Text);
        DoubleValue = CompToDouble(CompValue);
        Edit4->Text = FloatToStr(DoubleValue);
        }
    catch (...) {
        MessageDlg("Enter a signed integer with abs value <= 9 * 10**18", mtError,
            TMsgDlgButtons() << mbOK, 0);
    }
}
```

Delphi Examples:

```
{
This example demonstrates Comp conversion functions.
```

```
}

procedure TForm2.Button1Click(Sender: TObject);
var
  CompValue: Comp;
  CurrencyValue: Currency;
begin
  try
    CompValue := StrToInt64(Edit1.Text);
    CurrencyValue := CompToCurrency(CompValue);
    Edit2.Text := CurrToStr(CurrencyValue);
  except
    MessageDlg('Enter a signed integer with abs value <= 9 * 10**18', mtError, [mbOK], 0);
  end;
end;

procedure TForm2.Button2Click(Sender: TObject);
var
  CompValue: Comp;
  DoubleValue: Double;
begin
  try
    CompValue := StrToInt64(Edit3.Text);
    DoubleValue := CompToDouble(CompValue);
    Edit4.Text := FloatToStr(DoubleValue);
  except
    MessageDlg('Enter a signed integer with abs value <= 9 * 10**18', mtError, [mbOK], 0);
  end;
end;
```

35.3.23 System.CompToDouble Function

Converts a Comp value to a double value.

Pascal

```
function CompToDouble(Value: Comp): Double; cdecl;
```

C++

```
__cdecl Double CompToDouble(Comp Value);
```

File

System

Description

CompToDouble converts a Comp value into a double value containing the decimal representation of that number.

C++ Examples:

```
/*
This example demonstrates Comp conversion functions.
*/

void __fastcall TForm2::Button1Click(TObject *Sender)
```

```
{
    Comp CompValue;
    Currency CurrencyValue;

    try {
        CompValue = StrToInt64(Edit1->Text);
        CurrencyValue = CompToCurrency(CompValue);
        Edit2->Text = CurrToStr(CurrencyValue);
        }
    catch (...) {
        MessageDlg("Enter a signed integer with abs value <= 9 * 10**18", mtError,
            TMsgDlgButtons() << mbOK, 0);
    }
}
//---------------------------------------------------------------------------

void __fastcall TForm2::Button2Click(TObject *Sender)
{
    Comp CompValue;
    Double DoubleValue;

    try {
        CompValue = StrToInt64(Edit3->Text);
        DoubleValue = CompToDouble(CompValue);
        Edit4->Text = FloatToStr(DoubleValue);
        }
    catch (...) {
        MessageDlg("Enter a signed integer with abs value <= 9 * 10**18", mtError,
            TMsgDlgButtons() << mbOK, 0);
    }
}
```

Delphi Examples:

```
{
This example demonstrates Comp conversion functions.
}

procedure TForm2.Button1Click(Sender: TObject);
var
  CompValue: Comp;
  CurrencyValue: Currency;
begin
  try
    CompValue := StrToInt64(Edit1.Text);
    CurrencyValue := CompToCurrency(CompValue);
    Edit2.Text := CurrToStr(CurrencyValue);
  except
    MessageDlg('Enter a signed integer with abs value <= 9 * 10**18', mtError, [mbOK], 0);
  end;
end;

procedure TForm2.Button2Click(Sender: TObject);
var
  CompValue: Comp;
  DoubleValue: Double;
begin
  try
    CompValue := StrToInt64(Edit3.Text);
    DoubleValue := CompToDouble(CompValue);
    Edit4.Text := FloatToStr(DoubleValue);
  except
    MessageDlg('Enter a signed integer with abs value <= 9 * 10**18', mtError, [mbOK], 0);
  end;
end;
```

35.3.24 System.Concat Function

Concatenates two or more strings into one.

Pascal

```
function Concat(s1: string): string; overload;
function Concat(s1: string; s2: string): string; overload;
function Concat(s1: string; s2: string; s3: string): string; overload;
```

C++

```
UnicodeString Concat(UnicodeString s1);
UnicodeString Concat(UnicodeString s1, UnicodeString s2);
UnicodeString Concat(UnicodeString s1, UnicodeString s2, UnicodeString s3);
```

File

System

Description

In Delphi code, use Concat to concatenate an arbitrary number of strings. Each parameter is a string-type expression. The result is the concatenation of all the string parameters.

The syntax shown here for Concat demonstrates that the procedure can take a variable number of arguments.

Using the plus (+) operator has the same effect on two strings as using the Concat function:

S := 'ABC' + 'DEF';

Tip: The plus operator is faster than Concat.

Delphi Examples:

```
{
This example requires a button and three text fields.
Select the button to concatenate the two texts into
the third.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
begin
  Edit3.Text := Concat(Edit1.Text, Edit2.Text);     { 'ABCDEF' }
end;
```

35.3.25 System.Continue Function

Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.

Pascal

```
procedure Continue;
```

C++

```
Continue();
```

File

System

Description

In Delphi code, the Continue procedure causes the flow of control to proceed to the next iteration of the enclosing for, while, or repeat statement.

The compiler reports an error if a call to Continue isn't enclosed by a for, while, or repeat statement.

Note: Continue does not violate the flow of control dictated by a try..finally construct. If a call to Continue causes control to leave the try clause, the finally clause is entered.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], fmOpenWrite);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode fmOpenWrite.', mtError, [mbOk], 0);
        Continue;
      end
```

```
        else
          FileClose(filehandle);

        AssignFile(F, FileListBox1.Items.Strings[i]);
        Reset(F, 1);
        ListBox1.Items.Add(
          FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
        CloseFile(F);
      end;
    finally
    { do something here }
    end;
  end;
end;
```

Abort (see page 4047)

35.3.26 System.Copy Function

Returns a substring of a string or a segment of a dynamic array.

Pascal

```
function Copy(S; Index: Integer; Count: Integer): array; overload;
```

C++

```
array Copy( S, int Index, int Count);
```

File

System

Description

S is an expression of a string or dynamic-array type. Index and Count are integer-type expressions. Copy returns a substring or subarray containing Count characters or elements starting at S[Index]. The substring or subarray is a unique copy (that is, it does not share memory with S, although if the elements of the array are pointers or objects, these are not copied as well.)

If Index is larger than the length of S, Copy returns an empty string or array.

If Count specifies more characters or array elements than are available, only the characters or elements from S[Index] to the end of S are returned.

Note: When S is a dynamic array, you can omit the Index and Count parameters and Copy copies the entire array.

Delphi Examples:

```
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
```

```
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off
default auto completion.
}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
  TmpStr: string;
begin
  { first, process the keystroke to obtain the current string }
  { This code requires all items in list to be uppercase}
  if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
  ct := (Sender as TComboBox).Items.Count;
  with (Sender as TComboBox) do
  begin
    SelSt := SelStart;
    if (Key = Chr(vk_Back)) and (SelLength <> 0) then
     TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
    else if Key = Chr(vk_Back) then {SelLength = 0}
     TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
    else {Key in ['A'..'Z', etc]}
     TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
    if TmpStr = '' then Exit;
    { update SelSt to the current insertion point }
    if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
    else if Key <> Chr(vk_Back) then Inc(SelSt);
    Key := #0; { indicate that key was handled }
    if SelSt = 0 then
    begin
      Text:= '';
      Exit;
    end;
   {Now that TmpStr is the currently typed string, see if we can locate a match }
    Found := False;
    for i := 1 to ct do
    begin
      if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
      begin
        Text := Items[i-1]; { update to the match that was found }
        ItemIndex := i-1;
        Found := True;
        Break;
      end;
    end;
    if Found then { select the untyped end of the string }
    begin
      SelStart := SelSt;
      SelLength := Length(Text) - SelSt;
    end
    else Beep;
  end;
end;

var
  CharSetList : TStringList;

procedure TForm1.AddCharacterSet(const S: string);
begin
  CharSetList.Add(S);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
  CharSetList := TStringList.Create;
  Graphics.GetCharsetValues(AddCharacterSet);
  ComboBox1.Items := CharSetList;
end;
```

Parameters

35.3.27 System.Cos Function

Calculates the cosine of an angle.

Pascal

```
function Cos(const X: Extended): Extended;
```

C++

```
Extended Cos(const Extended X);
```

File

System

Description

In Delphi code, Cos returns the cosine of the angle X.

X is a real-type expression that represents an angle in radians.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
  ScrollBar1.Position := new;
  Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
```

```
  Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
end;

procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
  var ScrollPos: Integer);
begin
  Edit1.Text := FloatToStr(ScrollPos/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
end;
```

35.3.28 System.CurrencyToComp Function

Converts a Currency (see page 3235) value to a Comp value.

Pascal

```
procedure CurrencyToComp(Value: Currency; var Result: Comp); cdecl;
```

C++

```
__cdecl CurrencyToComp(Currency Value, Comp Result);
```

File

System

Description

CurrencyToComp converts a Currency (see page 3235) value into a Comp.

See Also

CompToDouble (see page 3543)

CompToCurrency (see page 3542)

DoubleToComp (see page 3555)

35.3.29 System.Dec Function

Decrements a variable by 1 or N.

Pascal

```
procedure Dec(var X); overload;
procedure Dec(var X; N: Longint); overload;
```

C++

```
Dec( X);
Dec( X, Longint N);
```

File

System

Description

In Delphi code, Dec subtracts one or N from a variable.

X is a variable of an ordinal type (including Int64), or a pointer type if the extended syntax is enabled.

N is an integer-type expression.

X decrements by 1, or by N if N is specified; that is, Dec(X) corresponds to the statement X := X - 1, and Dec(X, N) corresponds to the statement X := X - N. On some platforms, Dec may generate optimized code, especially useful in tight loops.

If X is a pointer type, it decrements X by N times the size of the type pointed to. Thus, given

```
type
  PMyType = ^TMyType;
```

and

```
var
  P: PMyType;
```

the statement `Dec(P)` decrements `P` by `SizeOf (` see page 3670`)(TMyType)`.

Warning: Do not use Dec on ordinal-type properties if the property uses a write procedure.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
  ScrollBar1.Position := new;
  Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
end;

procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
  var ScrollPos: Integer);
begin
  Edit1.Text := FloatToStr(ScrollPos/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
end;
```

See Also

Inc (see page 3597)

35.3.30 System.Delete Function

Removes a substring from a string.

Pascal

```
procedure Delete(var S: string; Index: Integer; Count: Integer);
```

C++

```
Delete(UnicodeString S, int Index, int Count);
```

File

System

Description

In Delphi code, Delete removes a substring of Count characters from string S starting with S[Index]. S is a string-type variable. Index and Count are integer-type expressions.

If index is larger than the length of the string or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, Delete removes the rest of the string. If count is less than or equal to 0, no characters are deleted.

Delphi Examples:

```
{
This example uses the Delete function to edit a string.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  s: string;
begin
  s := 'Honest Abe Lincoln';
  Canvas.TextOut(10, 10, s);
  Delete(s,8,4);
  Canvas.TextOut(10, 40, s);    { 'Honest Lincoln' }
end;
```

35.3.31 System.Dispose Function

Releases memory allocated for a dynamic variable.

Pascal

```
procedure Dispose(var P: Pointer);
```

C++

```
Dispose(void * P);
```

File

System

Description

Use Dispose in Delphi code to free the memory which a pointer addresses. After a call to Dispose, the value of P is undefined and it is an error to reference P.

Note: If compiling with {$I+}, use exceptions to handle this error. When an invalid pointer is passed to Dispose it raises an EInvalidPointer exception.

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
{
The following code adds an object to MyList if it isn't
already in the list.
}
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  Form1: TForm1;
  MyList: TList;
  ARecord1, ARecord2: PMyList;

implementation

{$R *.dfm}

procedure DisplayTList(TheList: TList);
var
```

```
    ARecord: PMyList;
    B: Byte;
    Y: Word;
  begin
      { Now paint the items onto the paintbox}
      Y := 10;             {Variable used in TextOut function}
      for B := 0 to (TheList.Count - 1) do
      begin
        ARecord := TheList.Items[B];
        Form1.PaintBox1.Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
        Y := Y + 30;  {Increment Y Value again}
        Form1.PaintBox1.Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
        Y := Y + 30;  {Increment Y Value}
      end;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    if (MyList.IndexOf(ARecord1) = -1) then MyList.Add(ARecord1);
    DisplayTList(MyList);
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (MyList.IndexOf(ARecord2) = -1) then MyList.Add(ARecord2);
    DisplayTList(MyList);
  end;

  procedure TForm1.Button3Click(Sender: TObject);
  var
    ARecord: PMyList;
    B: Integer;
  begin
    if (MyList.Count <> 0) then
    begin
      for B := (MyList.Count - 1) downto 0 do
      begin
        ARecord := MyList.Items[B];
        MyList.Remove(ARecord);
      end;
    end;
    Form1.PaintBox1.Repaint;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    MyList := TList.Create;
    New(ARecord1);
    ARecord1^.I := 100;
    ARecord1^.C := 'Z';
    New(ARecord2);
    ARecord2^.I := 200;
    ARecord2^.C := 'X';
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    Dispose(ARecord1);
    Dispose(ARecord2);
    MyList.Free;
  end;
```

35.3.32 System.DoubleToComp Function

Converts a double value to a Comp.

Pascal

```
procedure DoubleToComp(Value: Double; var Result: Comp); cdecl;
```

C++

```
__cdecl DoubleToComp(Double Value, Comp Result);
```

File

System

Description

DoubleToComp converts a Double value into a Comp.

See Also

CompToDouble (see page 3543)

CompToCurrency (see page 3542)

35.3.33 System.DynArrayClear Function

Pascal

```
procedure DynArrayClear(var a: Pointer; typeInfo: Pointer);
```

C++

```
DynArrayClear(void * a, void * typeInfo);
```

File

System

Description

This is function System.DynArrayClear.

35.3.34 System.DynArrayDim Function

Pascal

```
function DynArrayDim(typeInfo: PDynArrayTypeInfo): Integer;
```

C++

```
int DynArrayDim(PDynArrayTypeInfo typeInfo);
```

File

System

Description

This is function System.DynArrayDim.

35.3.35 System.DynArraySetLength Function

Pascal

```
procedure DynArraySetLength(var a: Pointer; typeInfo: Pointer; dimCnt: Longint; lengthVec:
PLongint);
```

C++

```
DynArraySetLength(void * a, void * typeInfo, Longint dimCnt, PLongint lengthVec);
```

File

System

Description

This is function System.DynArraySetLength.

35.3.36 System.EndThread Function

Terminates the execution of a thread.

Pascal

```
procedure EndThread(ExitCode: Integer);
```

C++

```
EndThread(int ExitCode);
```

File

System

Description

EndThread terminates execution of a thread with the specified ExitCode (see page 3823).

Note: On Windows, EndThread calls the ExitThread WinAPI with the specified ExitCode (see page 3823).

See Also

BeginThread (see page 3527)

System::TThreadFunc (see page 3797)

35.3.37 System.EnumModules Function

Executes a callback for all the modules in an application.

Pascal

```
procedure EnumModules(Func: TEnumModuleFunc; Data: Pointer); overload;
procedure EnumModules(Func: TEnumModuleFuncLW; Data: Pointer); overload;
```

C++

```
EnumModules(TEnumModuleFunc Func, void * Data);
EnumModules(TEnumModuleFuncLW Func, void * Data);
```

File

System

Description

EnumModules enumerates the executable and all packages in an application by passing the handle of the executable and then of each package, in turn, to a user-defined callback function. EnumModules continues until the last module in the application is enumerated, or until the callback function returns false. The parameters to EnumModules areas follows:

Parameter	Meaning
Func	The procedure-instance address of the callback function.
Data	A 32-bit user-defined value that is passed to the callback function.

See Also

EnumResourceModules (see page 3557)

LibModuleList (see page 3830)

35.3.38 System.EnumResourceModules Function

Executes a callback for all resource modules in an application.

Pascal

```
procedure EnumResourceModules(Func: TEnumModuleFunc; Data: Pointer); overload;
procedure EnumResourceModules(Func: TEnumModuleFuncLW; Data: Pointer); overload;
```

C++

```
EnumResourceModules(TEnumModuleFunc Func, void * Data);
EnumResourceModules(TEnumModuleFuncLW Func, void * Data);
```

File

System

Description

EnumResourceModules executes the callback specified by the Func parameter for all of the instance handles associated with resources of the current program. The instance handle (HInstance) of each resource is passed to Func. EnumResourceModules continues until the last resource module in the application is enumerated, or until the callback returns false. The parameters to EnumResourceModules are as follows:

Parameter	Meaning
Func	The procedure-instance address of the callback function.
Data	A 32-bit user-defined value that is passed to the callback function.

See Also

EnumModules (see page 3556)

LibModuleList (see page 3830)

35.3.39 System.Eof Function

Tests whether the file position is at the end of a file.

Pascal

```
function Eof: Boolean; overload;
function Eof(var F): Boolean; overload;
function Eof(var F: Text): Boolean; overload;
```

C++

```
Boolean Eof();
Boolean Eof( F);
Boolean Eof(Text F);
```

File

System

Description

In Delphi code, Eof tests whether the current file position is the end-of-file. F is a file variable that has been opened for reading. If F is omitted, the standard file variable Input (see page 3827) is assumed.

Eof(F) returns true if the current file position is beyond the last character of the file or if the file is empty; otherwise, Eof(F) returns false.

Note: Eof fails if the file F has been opened in write-only mode. For example, you can't use Eof with files opened using the Append (see page 3520) or Rewrite (see page 3645), which open a file in write-only mode.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: AnsiChar;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
      begin
        Read(F1, Ch);
        Write(F2, Ch);
      end;
      CloseFile(F2);
    end;
```

```
    CloseFile(F1);
  end;
end;
```

35.3.40 System.Eoln Function

Tests whether the file pointer is at the end of a line.

Pascal

```
function Eoln: Boolean; overload;
function Eoln(var F: Text): Boolean; overload;
```

C++

```
Boolean Eoln();
Boolean Eoln(Text F);
```

File

System

Description

In Delphi code, Eoln tests whether the current file position is the end-of-line of a text file. F, if specified, is a text file variable. If F is omitted, the standard file variable Input (see page 3827) is assumed.

Eoln(F) returns true if the current file position is at an end-of-line or if Eof (see page 3558)(F) is true; otherwise, Eoln(F) returns false.

Delphi Examples:

```
{
This example waits for keyboard input before continuing.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   WriteLn('Type something on the console and hit return');
   Eoln;
   WriteLn('Write this after you type something');
   Readln;
end;
```

35.3.41 System.Erase Function

Deletes an external file.

Pascal

```
procedure Erase(var F);
```

C++

```
Erase( F);
```

File

System

Description

In Delphi code, Erase deletes the external file associated with F. F is a file variable of any file type.

Always close a file before erasing it.

Delphi Examples:

```
{
Click the button to open a TOpenDialog, then select a file
to delete.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  F: Textfile;
begin
  OpenDialog1.Title := 'Delete File';
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    try
      Reset(F);
      if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
        mtConfirmation, [mbYes, mbNo], 0) = mrYes then
      begin
        CloseFile(F);
        Erase(F);
      end;
    except
      on EInOutError do
        MessageDlg('File I/O error.', mtError, [mbOk], 0);
    end;
  end;
end;
```

35.3.42 System.Error Function

Error is used to generate a run-time exception.

Pascal

```
procedure Error(errorCode: TRuntimeError);
```

C++

```
Error(TRuntimeError errorCode);
```

File

System

Description

Error should be invoked when you want to generate an exception. **errorCode** defines the type of error to be reported.

Delphi Examples:

```
{
This example demostrates the use of ErrorProc and how to catch runtime
errors.
}
procedure MyErrorProc(ErrorCode : Byte; ErrorPtr : Pointer);
var
  ErrorName : String;
begin
  { Get the "name" of the enum value using RTTI }
  ErrorName := GetEnumName(TypeInfo(TRuntimeError), ErrorCode);

  { Show an error box }
  MessageDlg(Format('Error with code %d (%s) risen at $%X.',
      [ErrorCode, ErrorName, Integer(ErrorPtr)]), mtError, [mbOK], 0);
end;

procedure TForm2.btIOErrorClick(Sender: TObject);
begin
  {
  Try to write something onto the console - will raise an
  exception.
  }
  WriteLn('This will generate an error because there is no' +
          ' console attached!');
end;

{$OVERFLOWCHECKS ON}
{$OPTIMIZATION OFF}
{$HINTS OFF}
procedure TForm2.btOverflowErrClick(Sender: TObject);
var
  b : Cardinal;
begin
  {
  Simulate an overflow: Note, enabled the overflow
  checking and disabled optimizations because Delphi's
  compiler will not compile this code otherwise.
  }
  b := $FFFFFFFF;
  b := b * b;
end;
{$HINTS ON}
{$OPTIMIZATION ON}
{$OVERFLOWCHECKS OFF}

procedure TForm2.btRuntimeErrorClick(Sender: TObject);
begin
  { Simulate an access violation }
  System.Error(reAccessViolation);
end;
```

```
procedure TForm2.FormCreate(Sender: TObject);
begin
  { Register my System error proc }
  ErrorProc := MyErrorProc;
end;
```

TRuntimeError (see page 3734)

35.3.43 System.ExceptAddr Function

Returns the address at which the current exception was raised.

Pascal

```
function ExceptAddr: Pointer;
```

C++

```
void * ExceptAddr();
```

File

System

Description

Use ExceptAddr to obtain the address at which an exception was raised. If there is no current exception, ExceptAddr returns nil (Delphi) or NULL (C++).

See Also

ExceptionErrorMessage (see page 4107)

ExceptObject (see page 3562)

35.3.44 System.ExceptObject Function

Returns current exception object.

Pascal

```
function ExceptObject: TObject;
```

C++

```
TObject * ExceptObject();
```

File

System

Description

ExceptObject returns the current exception object. This is the Exception object that represents the exception currently being handled. If no exception is currently being handled, ExceptObject returns nil (Delphi) or NULL (C++).

ExceptObject is useful when the exception variable (declared in the Delphi on block or C++ catch statement) is not accessible. This can occur when the exception handler calls a procedure, putting the exception variable is out of scope. This is also true in the Delphi else exception handler, which cannot declare an exception variable.

Note: The object returned by ExceptObject may not exist after the exception handler finishes. Thus you cannot use ExceptObject to retain a reference to the exception object, or to re-raise the exception. If you need to do either of these things, call AcquireExceptionObject (see page 3512).

Delphi Examples:

```
{
This example demonstrates exception handling to catch runtime
errors.
}

procedure TForm2.btIOErrorClick(Sender: TObject);
var
  ExceptionObj : TObject;
begin
  {
  Try to write something onto the console - will raise an
  exception.
  }
  try
  WriteLn('This will generate an error because there is no' +
          ' console attached!');
  except
    ExceptionObj := ExceptObject;
    if ExceptionObj = nil then
      MessageDlg('No exception', mtError, [mbOK], 0)
    else
    begin
      MessageDlg(ExceptionObj.ToString, mtError, [mbOK], 0);
    end;
  end;
end;

{$OVERFLOWCHECKS ON}
{$OPTIMIZATION OFF}
{$HINTS OFF}
procedure TForm2.btOverflowErrClick(Sender: TObject);
var
  b : Cardinal;
  ExceptionPtr : Pointer;
begin
  {
  Simulate an overflow: Note, enabled the overflow
  checking and disabled optimizations because Delphi's
  compiler will not compile this code otherwise.
  }
  ExceptionPtr := nil;
  try
    b := $FFFFFFFF;
    b := b * b;
  except
    ExceptionPtr := AcquireExceptionObject;
  end;

  // Check exception
  if ExceptionPtr = nil then
    MessageDlg('No exception', mtError, [mbOK], 0)
  else
  begin
    MessageDlg(TObject(ExceptionPtr).ToString, mtError, [mbOK], 0);
    ReleaseExceptionObject;
  end;
end;
{$HINTS ON}
```

```
{$OPTIMIZATION ON}
{$OVERFLOWCHECKS OFF}

procedure TForm2.btRuntimeErrorClick(Sender: TObject);
var

  ExceptionObj : TObject;
  begin
  { Simulate an access violation }
  try
    System.Error(reAccessViolation);
  except
    ExceptionObj := ExceptObject;
    if ExceptionObj = nil then
      MessageDlg('No exception', mtError, [mbOK], 0)
    else
    begin
      MessageDlg(ExceptionObj.ToString, mtError, [mbOK], 0);
    end;
  end;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin

end;
```

35.3.45 System.Exclude Function

Removes an element from a Delphi set or removes an event handler in .NET applications.

Pascal

```
procedure Exclude(var S: set of T; I: T);
```

C++

```
Exclude(set of T S, T I);
```

File

System

Description

When the first argument of Include (see page 3598) is a set type variable, the Exclude procedure removes an element from the set. If S is a set type variable, and I is an expression of a type compatible with the base type of S. then `Exclude(S,I)` corresponds to `S := S - [I]` but the Exclude procedure generates more efficient code.

On the .NET platform, Exclude is overloaded. When the first argument of Exclude is a multicast event and the second argument is an event handler, Include (see page 3598) removes the event handler from the event's listeners.

Delphi Examples:

```
{
This example demonstrates the use of Include and Exclude routines.
The example assumes a form with three checkboxes and a button. Also
a field called FMsgButtons of type TMsgDlgButtons is declared in the form.
```

```
}
procedure TOptionsForm.btShowMessageClick(Sender: TObject);
begin
  //Creates a Message Dialog with the Selected Buttons
  MessageDlg('Hello World!', mtInformation, FMsgButtons, 0);
end;

procedure TOptionsForm.CheckBoxClick(Sender: TObject);
begin
  { Check wether an option is selected and add an element into a set,
    or exclude it from the set}

  if cbYes.Checked then
    Include(FMsgButtons, mbYes)
  else
    Exclude(FMsgButtons, mbYes);

  if cbNo.Checked then
    Include(FMsgButtons, mbNo)
  else
    Exclude(FMsgButtons, mbNo);

  if cbCancel.Checked then
    Include(FMsgButtons, mbCancel)
  else
    Exclude(FMsgButtons, mbCancel);
end;
```

See Also

Include (see page 3598)

35.3.46 System.Exit Function

Exits from the current procedure.

Pascal

```
procedure Exit;
```

C++

```
Exit();
```

File

System

Description

In Delphi, the Exit procedure immediately passes control away from the current procedure. If the current procedure is the main program, Exit causes the program to terminate.

Exit will cause the calling procedure to continue with the statement after the point at which the procedure was called.

Note: Exit passes control away from the current procedure, not merely the current block. But Exit does not violate the flow of control dictated by a try..finally construct; if Exit is called inside the try clause, the finally clause is still executed.

Beginning in Delphi 2009, Exit can take a parameter specifying a result. The parameter must be of the same type as the result of the function. For example:

```
function DoSomething(aInteger: integer): string
begin
if aInteger < 0 then
```

```
                begin
                   Exit('Negative');
                end;
                Result := 'Positive';
             end;
```

Delphi Examples:

```
{
This example uses a memo and six buttons on a form. This
example illustrates the different ways to exit a function.
}
function GetAString(input: string): string;
var
  mystring : string;
begin
  mystring := DateToStr(Date);
  if (input = 'date') then
    Exit(mystring);
  if (input = 'Tuesday') then
  begin
    Result := 'Tuesday';
    Exit;
  end;
  Result := 'nothing';
end;

function GetANumber(input: string): Integer;
var
  myInt : Integer;
begin
  myInt := Round(Date);
  if (input = 'date') then
    Exit(myInt);
  if (input = 'Tuesday') then
  begin
    Result := 2;
    Exit;
  end;
  Result := 0;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.Add(GetAString('date'));
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Memo1.Lines.Add(GetAString('babble'));
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  Memo1.Lines.Add(GetAString('Tuesday'));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  Memo1.Lines.Add(IntToStr(GetANumber('date')));
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  Memo1.Lines.Add(IntToStr(GetANumber('nothing')));
end;
```

```
procedure TForm1.Button6Click(Sender: TObject);
begin
  Memo1.Lines.Add(IntToStr(GetANumber('Tuesday')));
end;
```

Break (see page 3531)

Halt (see page 3594)

Continue (see page 3546)

35.3.47 System.Exp Function

Returns the exponential of X.

Pascal

```
function Exp(X: Real): Real;
function Exp(const X: Extended): Extended;
```

C++

```
Real Exp(Real X);
Extended Exp(const Extended X);
```

File

System

Description

In Delphi code, Exp returns the value of e raised to the power of X, where e is the base of the natural logarithms.

Delphi Examples:

```
{
This example calculated the exponential of 1.0 and then calculates
the natural log of that quantity to show that the natural log
function is the inverse of the exponential function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   e : real;
   S : string;
begin
   e := Exp(1.0);
   Str(ln(e):3:2, S);
   S := 'e = ' + FloatToStr(e) + '; ln(e) = ' + S;
   Canvas.TextOut(10, 10, S);
end;
```

See Also

Ln (see page 3608)

35.3.48 System.FilePos Function

Returns the current file position.

Pascal

```
function FilePos(var F): Longint;
```

C++

```
Longint FilePos( F);
```

File

System

Description

In Delphi code, use FilePos on the file variable of an open file to determine the current position in the file. If the current position in the file is at the very beginning, FilePos returns 0. Otherwise, FilePos returns the byte offset from the beginning of the current position.

FilePos will not work on a file that is not open.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example displays a open dialog when the user clicks a
button. When the user selects the file, it reports the size
of the file, seeks to halfway through the file, and reports
the file position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON
($I+). That is, it expects errors to generate exceptions
rather than checking IOResult to be sure that I/O routines
succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Byte;
   size: Longint;
   S: string;
   y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      S := 'Seeking halfway into file...';
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      Seek(f, size div 2);
      S := 'Position is now ' + IntToStr(FilePos(f));
      Canvas.TextOut(5, y, S);
    finally
      CloseFile(f);
    end;
  end;
end;
```

See Also

FileSize (see page 3569)

Seek (see page 3650)

35.3.49 System.FileSize Function

Returns the number of records in a file.

Pascal

```
function FileSize(var F): Integer;
```

C++

```
int FileSize( F);
```

File

System

Description

In Delphi code, call FileSize to determine the size of the file specified by the file variable F. The size is expressed as the number of records in a record file. Thus:

If the file is declared as a file of byte, then the record size defaults to one byte, and FileSize returns the number of bytes in the file.

The Reset (see page 3643) procedure can set the record size (in bytes) when it opens the file. In this case, FileSize returns the number of records in the file.

Note: If the file is declared as an untyped file and you don't specify a record size when you call Reset (see page 3643), then FileSize assumes a record size of 128. That is, FileSize gives the number of bytes divided by 128.

To use FileSize, the file must be open. If the file is empty, FileSize(F) returns 0.

Delphi Examples:

```
{
This example displays a open dialog when the user clicks a
button. When the user selects the file, it reports the size
of the file, seeks to halfway through the file, and reports
the file position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON
($I+). That is, it expects errors to generate exceptions
rather than checking IOResult to be sure that I/O routines
succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Byte;
   size: Longint;
   S: string;
   y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
```

```
        S := 'Seeking halfway into file...';
        Canvas.TextOut(5, y, S);
        y := y + Canvas.TextHeight(S) + 5;
        Seek(f, size div 2);
        S := 'Position is now ' + IntToStr(FilePos(f));
        Canvas.TextOut(5, y, S);
      finally
        CloseFile(f);
      end;
    end;
  end;
  {
  The following example opens a file of your choice and reads
  the entire file into a dynamically allocated buffer. The
  buffer and the size of the file are then passed to a routine
  that processes the text, and finally the dynamically
  allocated buffer is freed and the file is closed.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: file;
    Size: Integer;
    Buffer: PAnsiChar;
  begin
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      Reset(F, 1);
      try
        Size := FileSize(F);
        GetMem(Buffer, Size);
        try
          BlockRead(F, Buffer^, Size);
          Memo1.Lines.Add(AnsiString(Buffer));
        finally
          FreeMem(Buffer);
        end;
      finally
        CloseFile(F);
      end;
    end;
  end;
```

FilePos (see page 3567)

Reset (see page 3643)

35.3.50 System.FillChar Function

Fills contiguous bytes with a specified value.

Pascal

```
procedure FillChar(var X; Count: Integer; Value: Byte);
```

C++

```
FillChar( X, int Count, Byte Value);
```

File

System

Description

In Delphi, FillChar fills **Count** contiguous bytes (referenced by **X**) with the value specified by **Value** (**Value** can be type **Byte** or **Char**).

Note that if **X** is a **UnicodeString (see page 3381)**, this may not work as expected because FillChar expects a byte count, which not be the same as the character count.

In addition, the fill character is a single byte character. Therefore, when `Buf` is a **UnicodeString (see page 3381)**, the code `FillChar(Buf, Length (see page 3607)(Buf), #9);` fills `Buf` with the code point $0909, not $09. For such cases, you probably want to use the function StringOfChar (see page 3677).

Warning: This function does not perform any range checking.

Delphi Examples:

```
{
This example creates a rotated font and displays it on the
form by assigning the handle of the rotated to the Form's
Canvas Font via the Font's Handle property.  Rotating fonts
is a straightforward process, so long as the Windows Font
Mapper can supply a rotated font based on the font you
request. If you are using a TrueType font there is virtually
no reason for failure.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  lf: LOGFONT; // Windows native font structure
begin
  Canvas.Brush.Style := bsClear; // set the brush style to transparent
  FillChar(lf, SizeOf(lf), Byte(0));
  lf.lfHeight := 20;
  lf.lfEscapement := 10 * 45; // degrees to rotate
  lf.lfOrientation := 10 * 45;
  lf.lfCharSet := DEFAULT_CHARSET;
  StrCopy(lf.lfFaceName, 'Tahoma');

  Canvas.Font.Handle := CreateFontIndirect(lf);
  Canvas.TextOut(10, 100, 'Rotated text'); // output the rotated font
end;
{
This example fills a char array with characters and then
assigns the array to a text edit.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: array[0..79] of AnsiChar;
begin
  { Set to all Xs }
  FillChar(S, SizeOf(S), Ord('X'));
  Edit1.Text := S;
end;
```

See Also

Move (see page 3617)

StringOfChar (see page 3677)

35.3.51 System.Finalize Function

Uninitializes a dynamically allocated variable.

Pascal

```
procedure Finalize(var V); overload;
procedure Finalize(var V; Count: Integer); overload;
```

C++

```
Finalize( V);
Finalize( V, int Count);
```

File

System

Description

Finalize should be used only in Delphi code where a dynamically allocated variable is deallocated by other means than the Dispose (see page 3553) procedure. Dynamic arrays can never be deallocated using the Dispose (see page 3553) procedure, but can be freed by passing them to Finalize.

For global variables, local variables, objects, and dynamic variables deallocated using Dispose (see page 3553), the compiler generates code that finalizes all long strings, variants, and interfaces contained by the variable when the instance is destroyed.

If a dynamic variable meets the following two conditions, a call to Finalize is required to finalize the variable before it can be deallocated.

The variable is deallocated by other means than the Dispose (see page 3553) standard procedure (for example using FreeMem (see page 3577)).

The variable contains long strings, variants, or interfaces, not all of which are empty or Unassigned.

Finalize simply sets all long strings to empty and all variants and interfaces to Unassigned, thus properly releasing any memory that was referenced by the long strings and variants.

In cases where several variables are deallocated in a contiguous memory block such as a dynamically allocated array of strings, the additional Count parameter can be specified to finalize all variables in one operation.

If the variable specified in a call to Finalize contains no long strings, variants, or interfaces, the compiler eliminates the call and generates no code for it.

Delphi Examples:

```
{
This example demonstrates the use of Initialize and Finalize functions
used to initialize and finalize a RTTI-enabled structure.
}
type
  { Declaring a data type that needs initilization }
  PPerson = ^TPerson;
  TPerson = record
    FFirstName: String;
    FLastName: String;
    FAge: Integer;
  end;

procedure TForm1.Button1Click(Sender: TObject);
var
  Person: PPerson;
```

```
begin
  {
    Allocate a block of memory for the structure
    We're using an "unsafe" function: GetMem
    which doesn't use RTTI to initialize the
    strings inside the structure.
  }
  GetMem(Person, SizeOf(TPerson));

  { Initialize the structure in the Heap - RTTI will be used }
  Initialize(Person^);

  { Assign some data to the structure }
  Person.FFirstName := 'John';
  Person.FLastName := 'Smith';
  Person.FAge := 31;

  { Use RTTI to cleanup the internals of the structure }
  Finalize(Person^);
  FreeMem(Person);
end;
```

Initialize (see page 3599)

35.3.52 System.FindClassHInstance Function

Returns the instance handle for the module in which a class type is defined.

Pascal

```
function FindClassHInstance(ClassType: TClass): LongWord;
```

C++

```
LongWord FindClassHInstance(TClass ClassType);
```

File

System

Description

FindClassHInstance finds the `HInstance` of the executable or library that "owns", or contains, the runtime type information (RTTI) and the Virtual Method Table (VMT) for the specified class passed in as the Class Type parameter. When reading a component (which is a type), this information is needed in order to be able to load the form file (resources) associated with that component. The component streaming system uses FindClassHInstance for this purpose.

FindClassHInstance returns 0 if the instance is not found. Otherwise it returns the class owner's `HInstance`.

See Also

FindResourceHInstance (see page 3574)

35.3.53 System::FindDynaInst Function

Pascal

```
function FindDynaInst(var vmt; ID: Integer): Pointer;
```

C++

```
__fastcall void * FindDynaInst(void * vmt, int ID);
```

File

sysclass.h

Description

This is function System::FindDynaInst.

35.3.54 System.FindHInstance Function

Returns the instance handle of the module that contains a specified address.

Pascal

```
function FindHInstance(Address: Pointer): LongWord;
```

C++

```
LongWord FindHInstance(void * Address);
```

File

System

Description

Use FindHInstance to obtain the `HInstance` of the module that "owns", or contains, the address specified by the Address parameter. If no `HInstance` is found for that address, FindHInstance returns 0.

See Also

FindClassHInstance (see page 3573)

FindResourceHInstance (see page 3574)

MainInstance (see page 3830)

35.3.55 System.FindResourceHInstance Function

Returns the instance handle of the resource module associated with a specified `HInstance`.

Pascal

```
function FindResourceHInstance(Instance: LongWord): LongWord;
```

C++

```
LongWord FindResourceHInstance(LongWord Instance);
```

File

System

Description

FindResourceHInstance finds and returns the instance handle of the resource module associated with the executable, library, or package identified by the Instance parameter.

FindResourceHInstance returns 0 upon failure.

Note: The Instance parameter must be a valid instance handle.

See Also

FindClassHInstance (see page 3573)

FindHInstance (see page 3574)

35.3.56 System.Flush Function

Empties the buffer of a text file opened for output.

Pascal

```
function Flush(var t: Text): Integer;
```

C++

```
int Flush(Text t);
```

File

System

Description

F is a text file variable.

When a text file is opened for output using Rewrite (see page 3645) or Append (see page 3520), Flush empties the file's buffer. This guarantees that all characters written to the file at that time have actually been written to the external file. Flush has no effect on files opened for input.

Flush returns 0 if the operation succeeded. Otherwise, it returns the error code. When compiled using the {$I-} flag, the IOResult (see page 3602) method returns this value.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
Click the button and select a file to append a string to the bottom of the file.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  f: TextFile;
begin
  if OpenDialog1.Execute then
  begin                    { open a text file }
    AssignFile(f, OpenDialog1.FileName);
    Append(f);
    Writeln(f, 'I am appending some stuff to the end of the file.');
    { insert code here that would require a Flush before closing the file }
    Flush(f);  { ensures that the text was actually written to file }
    CloseFile(f);
    MessageDlg(OpenDialog1.FileName + ' has been altered, please validate.', mtInformation,
[mbOK], 0)
  end;
end;
```

See Also

Append (see page 3520)

Rewrite (see page 3645)

35.3.57 System.FPower10 Function

Pascal

```
procedure FPower10;
```

C++

```
FPower10();
```

File

System

Description

This is function System.FPower10.

35.3.58 System.Frac Function

Returns the fractional part of a real number.

Pascal

```
function Frac(const X: Extended): Extended;
```

C++

```
Extended Frac(const Extended X);
```

File

System

Description

In Delphi code, the Frac function returns the fractional part of the argument X.

X is a real-type expression. The result is the fractional part of X; that is, Frac(X) = X - Int (see page 3602)(X).

Delphi Examples:

```
{
This example illustrates the use of the System Frac function.
The number in the text edit can be a negative or positive
real number.
Notice how the type passed (R) matters.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 R: Extended;
begin
  R := StrToFloat(Edit1.Text);
  ListBox1.Items.Add(FloatToStr(Frac(R)));
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
 R: Real;
begin
  R := StrToFloat(Edit1.Text);
  ListBox1.Items.Add(FloatToStr(Frac(R)));
end;
```

See Also

Int (see page 3602)

35.3.59 System.FreeMem Function

FreeMem frees a memory block.

Pascal

```
procedure FreeMem(var P: Pointer); overload;
procedure FreeMem(var P: Pointer; Size: Integer); overload;
```

C++

```
FreeMem(void * P);
FreeMem(void * P, int Size);
```

File

System

Description

GetMem (see page 3584) allocates a block on the heap. To dispose of the buffer, use FreeMem.

Note: FreeMemory (see page 3579) is the C++ compatible version of FreeMem.

Delphi Examples:

```
{
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  iFileHandle: Integer;
  iFileLength: Integer;
  iBytesRead: Integer;
  Buffer: PAnsiChar;
  i: Integer;
begin
  if OpenDialog1.Execute then
  begin
    try
      iFileHandle := SysUtils.FileOpen(OpenDialog1.FileName, fmOpenRead);
      iFileLength := SysUtils.FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      Buffer := System.AllocMem(iFileLength + 1);
```

```
        iBytesRead := SysUtils.FileRead(iFileHandle, Buffer^, iFileLength);
        FileClose(iFileHandle);
        for i := 0 to iBytesRead-1 do
        begin
          StringGrid1.RowCount := StringGrid1.RowCount + 1;
          StringGrid1.Cells[1,i+1] := Buffer[i];
          StringGrid1.Cells[2,i+1] := IntToStr(Integer(Buffer[i]));
        end;
      finally
        FreeMem(Buffer);
      end;
    end;
  end;
  {
  The following example opens a file of your choice and reads
  the entire file into a dynamically allocated buffer. The
  buffer and the size of the file are then passed to a routine
  that processes the text, and finally the dynamically
  allocated buffer is freed and the file is closed.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: file;
    Size: Integer;
    Buffer: PAnsiChar;
  begin
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      Reset(F, 1);
      try
        Size := FileSize(F);
        GetMem(Buffer, Size);
        try
          BlockRead(F, Buffer^, Size);
          Memo1.Lines.Add(AnsiString(Buffer));
        finally
          FreeMem(Buffer);
        end;
      finally
        CloseFile(F);
      end;
    end;
  end;
```

35.3.60 System.FreeMemory Function

FreeMemory frees a memory block.

Pascal

```
function FreeMemory(P: Pointer): Integer; cdecl;
```

C++

```
__cdecl int FreeMemory(void * P);
```

File

System

Description

GetMemory (see page 3585) allocates a block on the heap. To dispose of the buffer, use FreeMemory.

Note: FreeMemory is the C++ compatible version of FreeMem (see page 3577).

C++ Examples:

```
/*
The following code demostrates the use of memory management functions in C++. Three
edit boxes and a button are expected onthe form.
*/
String __fastcall FastStrCat(String s1, String s2)
{
  /*
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  */
  wchar_t* finalStr = (wchar_t *)GetMemory((s1.Length() + 1) * sizeof(wchar_t));

  // Copy the contents of the first string
  MoveChars(s1.data(), finalStr, s1.Length() + 1);

  // And now expand the final string + $00 character
  finalStr = (wchar_t *)ReallocMemory(finalStr, (s1.Length() + s2.Length() + 1) *
sizeof(wchar_t));

  // Copy the contents of the second string
  MoveChars(s2.data(), finalStr + s1.Length(), s2.Length() + 1);

  // Get the result in String
  String result = String(finalStr);
  FreeMemory(finalStr);

  return result;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Concatenate 2 string
  Edit3->Text = FastStrCat(Edit1->Text, Edit2->Text);
}
```

35.3.61 System.Get8087CW Function

Returns the value of the 8087 code word.

Pascal

```
function Get8087CW: Word;
```

C++

```
Word Get8087CW();
```

File

System

Description

Use Get8087CW to determine the current value of the floating-point unit control word. This control word controls the precision of floating point calculations, the rounding mode, and whether certain floating-point operations trigger exceptions. See Intel's processor documentation for details.

See Also

NoErrMsg (see page 3832)

SetPrecisionMode

SetRoundMode

Set8087CW (see page 3653)

35.3.62 System.GetDir Function

Returns the current directory.

Pascal

```
procedure GetDir(D: Byte; var S: string);
```

C++

```
GetDir(Byte D, UnicodeString S);
```

File

System

Description

Note: On Windows, GetDir sets the S parameter to the current directory on the drive specified by the D parameter. D can be set to any of the following values:

Value	Drive
0	Default
1	A
2	B
3	C

Note: GetDir performs no error checking. For example, if the invalid value 5 (J) were specified, S would return J:\ as if it were the root directory of the invalid drive.

Note: On Linux, GetDir returns the current working directory using the S parameter. The first parameter is ignored.

Delphi Examples:

```
{
This example reports the current directory and drive.  Set
Help on GetDir for reporting information on other drives.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  GetDir(0,s); { 0 = Current drive }
  MessageDlg('Current drive and directory: ' + s, mtInformation, [mbOk] , 0);
end;
```

GetCurrentDir (see page 4202)

35.3.63 System.GetHeapStatus Function

Returns the current status of the memory manager.

Pascal

```
function GetHeapStatus: THeapStatus; deprecated; platform;
```

C++

```
THeapStatus GetHeapStatus();
```

File

System

Description

GetHeapStatus returns the current status of the memory manager in a THeapStatus (see page 3720) type. If the ShareMem unit is not included in the current project, GetHeapStatus returns information about the global heap. If the ShareMem unit is included, GetHeapStatus returns information about memory that can be shared between between the current project and other binary modules (such as DLLs) that also make use of the ShareMem unit. GetHeapStatus can only return useful information if the built-in memory manager is used. For example, when using CodeGuard, the memory manager is replaced and GetHeapStatus always returns nil (Delphi) or NULL (C++).

If you want information about the memory manager that is shared between modules, make sure to call the function GetHeapStatus provided in the ShareMem unit. The function GetHeapStatus in the System (see page 3159) unit returns no values for a project that uses shared memory.

Note: Since GetHeapStatus is deprecated, use GetMemoryManagerState (see page 3591) routine instead.

Warning: ShareMem must be the first unit included in the project file to prevent mixing of memory management models.

See Also

GetMemoryManagerState (see page 3591)

35.3.64 System.GetLastError Function

Returns the last error reported by an operating system API call.

Pascal

```
function GetLastError: Integer; stdcall;
```

C++

```
__stdcall int GetLastError();
```

File

System

Description

GetLastError returns the last error reported by an API call into the operating system. Calling this function usually resets the operating system error state.

C++ Examples:

```
//
//This code demonstrates the use of system error codes
//and how to use transform them into C++ exceptions.
//
void __fastcall TForm2::btRaiseLastClick(TObject *Sender)
{
    /* Set the last OS error to a bogus value */
    System::SetLastError(ERROR_ACCESS_DENIED);
```

```
    try
    {
        RaiseLastOSError();
    }
    catch(EOSError* ex)
    {
        MessageDlg(String("Caught an OS error with code: ") +
            IntToStr((int)ex->ErrorCode), mtError,
            TMsgDlgButtons() << mbOK, 0);
    }

    /* Let the Delphi's Exception dialog pop-up */
    RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

    /* Finally set the last error to none */
    System::SetLastError(ERROR_SUCCESS);

    if (GetLastError() != ERROR_SUCCESS)
        MessageDlg(String("Whoops, something went wrong ") +
          " in the mean time!", mtError, TMsgDlgButtons() << mbOK, 0);

    /* No exception should be thrown here */
    RaiseLastOSError();
}
```

Delphi Examples:

```
{
This code demonstrates the use of system error codes
and how to transform them into Delphi exceptions.
}
procedure TForm2.btRaiseLastClick(Sender: TObject);
begin
  { Set the last OS error to a bogus value }
  System.SetLastError(ERROR_ACCESS_DENIED);

  try
    RaiseLastOSError();
  except
    on Ex : EOSError do
       MessageDlg('Caught an OS error with code: ' +
          IntToStr(Ex.ErrorCode), mtError, [mbOK], 0);
  end;

  { Let the Delphi's Exception dialog pop-up }
  RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

  { Finally set the last error to none }
  System.SetLastError(ERROR_SUCCESS);

  if GetLastError() <> ERROR_SUCCESS then
     MessageDlg('Whoops, something went wrong in the ' +
                'mean time!', mtError, [mbOK], 0);

  { No exception should be thrown here }
  RaiseLastOSError();
end;
```

See Also

Win32Check (see page 4318)

35.3.65 System.GetMem Function

GetMem allocates a memory block.

Pascal

```
procedure GetMem(var P: Pointer; Size: Integer);
```

C++

```
GetMem(void * P, int Size);
```

File

System

Description

GetMem allocates a block of the given **Size** on the heap, and returns the address of this memory in parameter **P**. The bytes of the allocated buffer are not set to zero. To dispose of the buffer, use FreeMem (see page 3577). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory needs to be zero-initialized, use AllocMem (see page 3515) instead.

Delphi Examples:

```
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: file;
  Size: Integer;
  Buffer: PAnsiChar;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    Reset(F, 1);
    try
      Size := FileSize(F);
      GetMem(Buffer, Size);
      try
        BlockRead(F, Buffer^, Size);
        Memo1.Lines.Add(AnsiString(Buffer));
      finally
        FreeMem(Buffer);
      end;
    finally
      CloseFile(F);
    end;
  end;
end;
```

ReallocMem (see page 3637)

ReallocMemory (see page 3638)

35.3.66 System.GetMemory Function

GetMemory allocates a memory block.

Pascal

```
function GetMemory(Size: Integer): Pointer; cdecl;
```

C++

```
__cdecl void * GetMemory(int Size);
```

File

System

Description

GetMemory allocates a block of the given **Size** on the heap, and returns the address of this memory. The bytes of the allocated buffer are not set to zero. To dispose of the buffer, use FreeMem (see page 3577). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory needs to be zero-initialized, use AllocMem (see page 3515) instead.

Note: GetMemory is the C++ compatible version of GetMem (see page 3584).

C++ Examples:

```
/*
The following code demostrates the use of memory management functions in C++. Three
edit boxes and a button are expected onthe form.
*/
String __fastcall FastStrCat(String s1, String s2)
{
  /*
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  */
  wchar_t* finalStr = (wchar_t *)GetMemory((s1.Length() + 1) * sizeof(wchar_t));

  // Copy the contents of the first string
  MoveChars(s1.data(), finalStr, s1.Length() + 1);

  // And now expand the final string + $00 character
  finalStr = (wchar_t *)ReallocMemory(finalStr, (s1.Length() + s2.Length() + 1) *
sizeof(wchar_t));

  // Copy the contents of the second string
```

```
  MoveChars(s2.data(), finalStr + s1.Length(), s2.Length() + 1);

  // Get the result in String
  String result = String(finalStr);
  FreeMemory(finalStr);

  return result;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Concatenate 2 string
  Edit3->Text = FastStrCat(Edit1->Text, Edit2->Text);
}
```

Delphi Examples:

```
{
This example requires a button, a test edit, and a populated
ClientDataSet.  Pipe the ClientDataSet through a DataSource
to a DGGrid or DBNavigator to control the current field.
Cast the data correctly according to the field type when
assigning to the test edit.
}

{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button1Click(Sender: TObject);
var MyBuffer: Pointer;
begin
{ Retrieve the "raw" data from Field1 }
with CDS.Fields[0] do
  begin
    if not IsBlob then { this does not work for BLOB fields }
    begin
      { Allocate space }
      MyBuffer:= GetMemory(DataSize);
      try
        if not GetData(MyBuffer) then
          MessageDlg(DisplayName + ' is NULL', mtInformation, [mbOK], 0)
        else
          { Do something with the data };
          Edit1.Text:= string(PAnsiChar(MyBuffer)); // for a stringfield
      finally
        { Free the space }
        FreeMem(MyBuffer, DataSize);
      end;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;
```

35.3.67 System.GetMemoryManager Function

Returns the entry points of the currently installed memory manager.

Pascal

```
procedure GetMemoryManager(var MemMgr: TMemoryManager); overload; deprecated;
procedure GetMemoryManager(var MemMgrEx: TMemoryManagerEx); overload;
```

C++

```
GetMemoryManager(TMemoryManager MemMgr);
GetMemoryManager(TMemoryManagerEx MemMgrEx);
```

File

System

Description

GetMemoryManager returns the entry points of the currently installed memory manager in a TMemoryManager (see page 3724) record.

C++ Examples:

```
/*
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
*/

bool isMyMemMgr;
TMemoryManagerEx oldMemMgr;
volatile long getMemCalls;
volatile long freeMemCalls;
volatile long reallocMemCalls;
volatile long allocMemCalls;

void* __fastcall myGetMem(int size)
{
    //safely increment the counter
    InterlockedIncrement(&getMemCalls);

    //route the call
    return oldMemMgr.GetMem(size);
}

int __fastcall myFreeMem(void* p)
{
    //safely increment the counter
    InterlockedIncrement(&freeMemCalls);

    //route the call
    return oldMemMgr.FreeMem(p);
```

```
}

void* __fastcall myReallocMem(void* p, int size)
{
    //safely increment the counter
    InterlockedIncrement(&reallocMemCalls);

    //route the call
    return oldMemMgr.ReallocMem(p, size);
}

void* __fastcall myAllocMem(int size)
{
    //safely increment the counter
    InterlockedIncrement(&allocMemCalls);

    //route the call
    return oldMemMgr.AllocMem(size);
}

void __fastcall TForm3::btUseSysMemMgrClick(TObject *Sender)

    btUseMyMemMgr->Enabled = false;
```

```
    //get the old memory manager
    GetMemoryManager(oldMemMgr);

    //create out instance
    myMemMgr.GetMem = myGetMem;
    myMemMgr.FreeMem = myFreeMem;
    myMemMgr.AllocMem = myAllocMem;
    myMemMgr.ReallocMem = myReallocMem;

    //use defaults for this - not important
    myMemMgr.RegisterExpectedMemoryLeak = oldMemMgr.RegisterExpectedMemoryLeak;
    myMemMgr.UnregisterExpectedMemoryLeak = oldMemMgr.UnregisterExpectedMemoryLeak;

    //clear out the variables
    getMemCalls     = 0;
    freeMemCalls    = 0;
    reallocMemCalls = 0;
    allocMemCalls   = 0;

    //install the new memory manager
    SetMemoryManager(myMemMgr);

    isMyMemMgr = true;
}

void __fastcall TForm3::btDoSomethingClick(TObject *Sender)
{
    void *ptr;
    //perform some new and delete
    for (int i=0; i < 1000; ++i)
    {
        ptr = GetMemory(4);
        FreeMemory(ptr);
    }
}
```

Delphi Examples:

```
{
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
}
var
  OldMemMgr       : TMemoryManagerEx;
  GetMemCalls     : Integer;
  FreeMemCalls    : Integer;
  ReallocMemCalls : Integer;
  AllocMemCalls   : Integer;

function MyGetMem(Size: Integer): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.GetMem(Size);

  { Safely increment the counter }
  InterlockedIncrement(GetMemCalls);
end;

function MyFreeMem(P: Pointer): Integer;
begin
  { Route the call }
  Result := OldMemMgr.FreeMem(P);

  { Safely increment the counter }
  InterlockedIncrement(FreeMemCalls);
end;
```

```
function MyReallocMem(P: Pointer; Size: Integer): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.ReallocMem(P, Size);

  { Safely increment the counter }
  InterlockedIncrement(ReallocMemCalls);
end;

function MyAllocMem(Size: Cardinal): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.AllocMem(Size);

  { Safely increment the counter }
  InterlockedIncrement(AllocMemCalls);
end;

procedure TForm2.btPerformSomethingClick(Sender: TObject);
var
  X : Integer;
  I : ^Integer;
begin
  { Perform some allocations and frees }
  for X := 0 to 999 do
  begin
    New(I);
    Dispose(I);
  end;
end;

procedure TForm2.btUseMyMemMgrClick(Sender: TObject);
var
  MyMemMgr : TMemoryManagerEx;
begin
  { Switch button states }
  btUseSystemMemMgr.Enabled := true;
  btUseMyMemMgr.Enabled := false;

  { Get the old memory manager }
  GetMemoryManager(OldMemMgr);

  { Create our instance }
  MyMemMgr.GetMem := MyGetMem;
  MyMemMgr.FreeMem := MyFreeMem;
  MyMemMgr.ReallocMem := MyReallocMem;
  MyMemMgr.AllocMem := MyAllocMem;

  { Use the defaults for this - not important }
  MyMemMgr.RegisterExpectedMemoryLeak := OldMemMgr.RegisterExpectedMemoryLeak;
  MyMemMgr.UnregisterExpectedMemoryLeak := OldMemMgr.UnregisterExpectedMemoryLeak;

  { Clear out the count variables }
  GetMemCalls := 0;
  FreeMemCalls := 0;
  ReallocMemCalls := 0;
  AllocMemCalls := 0;

  { Install the new memory manager }
  SetMemoryManager(MyMemMgr);
end;

procedure TForm2.btUseSystemMemMgrClick(Sender: TObject);
begin
  { Switch button states }
```

```
    btUseSystemMemMgr.Enabled := false;
    btUseMyMemMgr.Enabled := true;

    { Set the old memory manager back! }
    SetMemoryManager(OldMemMgr);

    GetMemCalls := 0;
    FreeMemCalls := 0;
    ReallocMemCalls := 0;
    AllocMemCalls := 0;
  end;

  procedure TForm2.FormDestroy(Sender: TObject);

35.3.68 System.GetMemoryManagerState Function

Fetches state information for the Memory Manager.

Pascal

```
procedure GetMemoryManagerState(var AMemoryManagerState: TMemoryManagerState);
```

C++

```
GetMemoryManagerState(TMemoryManagerState AMemoryManagerState);
```

File

System

Description

GetMemoryManagerState returns a structure containing memory usage statistics for each block type - small, medium and large blocks. In the current implementation, small blocks are blocks that are smaller than roughly 2.5K, large blocks are blocks that are larger than roughly 256K, and medium blocks are the sizes in between. It provides additional detail for the small block type (which is usually the most frequently used block type) down to each individual block size.

The structure returned by this procedure makes a distinction between the reserved address space and the allocated address space for each block type. The allocated address space is that part of the address space that is currently in use by the application, i.e. memory that was allocated through GetMem (see page 3584) and not yet freed. The reserved address space

is the amount of address space that was obtained from the operating system for current and future use by the application, i.e. the allocated address space plus all overhead.

35.3.69 System.GetMemoryMap Function

Fetches the memory map.

Pascal

```
procedure GetMemoryMap(var AMemoryMap: TMemoryMap);
```

C++

```
GetMemoryMap(TMemoryMap AMemoryMap);
```

File

System

Description

GetMemoryMap returns a map of the address space of the process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. GetMemoryMap obtains a status value for each of them in the TMemoryMap (see page 3791) array. The sum of the number of blocks with the status of **csUnallocated** multiplied by the chunk size (64K) gives an indication of how much more memory the application can allocate before it will run out of address space.

Status Value	Description
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

35.3.70 System.GetMinimumBlockAlignment Function

Gets the minimum memory block alignment.

Pascal

```
function GetMinimumBlockAlignment: TMinimumBlockAlignment;
```

C++

```
TMinimumBlockAlignment GetMinimumBlockAlignment();
```

File

System

Description

GetMinimumBlockAlignment fetches the Memory Manager's minimum block alignment.

35.3.71 System.GetModuleFileName Function

Returns the fully qualified name for a module, given its handle.

Pascal

```
function GetModuleFileName(Module: HMODULE; Buffer: PChar; BufLen: Integer): Integer;
```

C++

```
int GetModuleFileName(HMODULE Module, const char * Buffer, int BufLen);
```

File

System

Description

Call GetModuleFileName to obtain the fully qualified name of a module, given its handle. The version of GetModuleFileName defined in the System (see page 3159) unit is available only on Linux. On Windows, use the Windows API with the same name instead.

Module is the handle of the module whose file name is required.

Buffer is a buffer that receives the file name.

BufLen is the number of bytes in Buffer.

GetModuleFileName returns the number of bytes written to Buffer.

Warning: GetModuleFileName is not always successful. Depending on the way the application is called, the presence of the /proc file system, and other factors, there are times when GetModuleFileName may return a name that is not fully qualified or in some cases, no file name at all. Be sure to check the results of this function before using the returned value.

GetModuleName (see page 4207)

35.3.72 System.GetVariantManager Function

Returns the entry points of the routines that define variant behavior.

Pascal

```
procedure GetVariantManager(var VarMgr: TVariantManager); deprecated;
```

C++

```
GetVariantManager(TVariantManager VarMgr);
```

File

System

Description

GetVariantManager returns the entry points of the routines that perform variant type conversion and define other variant behavior.

Note: Although GetVariantManager is defined in System.hpp, do not use this procedure in C++ code. Working directly with the Variant (see page 3421) manger is not guaranteed to work in C++.

See Also

SetVariantManager (see page 3668)

IsVariantManagerSet (see page 3606)

35.3.73 System.Halt Function

Initiates abnormal termination of a program.

Pascal

```
procedure Halt; overload;
procedure Halt(Exitcode: Integer); overload;
```

C++

```
Halt();
Halt(int Exitcode);
```

File

System

Description

Halt performs an abnormal termination of a program and returns to the operating system.

To perform a normal termination of a Delphi application, call the Terminate method on the global Application object. If the application does not use a unit that provides an Application object, call the Exit (see page 3565) procedure from the main Program block.

Exitcode is an optional expression that specifies an exit code for the program.

Delphi Examples:

```
{
```

```
This example halts before the TextOut and terminates the
application.  Do not expect to one step this procedure.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   if 1 = 1 then
     begin
       if 2 = 2 then
         begin
           if 3 = 3 then
             begin
               Halt(1); { Halt right here! }
             end;
         end;
     end;
   Canvas.TextOut(10, 10, 'This will not be executed');
 end;
```

35.3.74 System.Hi Function

Returns the high-order byte of X as an unsigned value.

Pascal

```
function Hi(X): Byte;
```

C++

```
Byte Hi( X);
```

File

System

Description

In Delphi code, use Hi to obtain the high-order byte of an expression of type Word or Integer.

Note: Hi treats Integer as a 16-bit value, even if it is 32-bit.

Delphi Examples:

```
{
This example demonstrate use of the System Hi function to
store the high byte of a word or integer into a byte.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  B : Byte;
begin
  B := Hi($1234);
  ShowMessage(Format('High byte of $1234 = $%x', [B]));
end;
```

See Also

Lo (see page 3609)

35.3.75 System.High Function

Returns the highest value in the range of an argument.

Pascal

```
procedure High(X);
```

C++

```
High( X);
```

File

System

Description

In Delphi code, call High to obtain the upper limit of an Ordinal, Array, or ShortString value. The result type is X, or the index type of X.

X is either a type identifier or a variable reference. The type denoted by X, or the type of the variable denoted by X, must be one of the following:

For this type	High returns
Ordinal type (includes Int64)	The highest value in the range of the type
Array type	The highest value within the range of the index type of the array. For empty arrays, High returns –1.
short string type	The declared size of the string
Open array	The value, of type Integer, giving the number of elements in the actual parameter minus one
short string parameter	The value, of type Integer, giving the number of elements in the actual parameter minus one

Delphi Examples:

```
{
This example requires a button and two list boxes.  Two lists
of floating point numbers are generated initially and
displayed in the list boxes. Clicking the button sums the lists.
Notice that the range of the list arrays can be any integers,
as long as Low is less than High.
}
var
  List1: array[0..3] of Double;
  List2: array[5..17] of Double;

function Sum( var X: array of Double): Double;
var
  I: Word;
  S: Real;
begin
  S := 0; { Note that open array index range is always zero-based. }
  for I := 0 to High(X) do S := S + X[I];
  Sum := S;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  S, TempStr: string;
begin
```

```
    Str(Sum(List1):4:2, S);
    S := 'Sum of List1: ' + S + #13#10;
    S := S + 'Sum of List2: ';
    Str(Sum(List2):4:2, TempStr);
    S := S + TempStr;
    MessageDlg(S, mtInformation, [mbOk], 0);

  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    X: Word;
  begin
    for X := Low(List1) to High(List1) do
    begin
        List1[X] := X * 3.4;
        ListBox1.Items.Add(FloatToStr(List1[X]));
    end;
    for X := Low(List2) to High(List2) do
    begin
        List2[X] := X * 0.0123;
        ListBox2.Items.Add(FloatToStr(List2[X]));
    end;
  end;
```

See Also

Low (see page 3610)

35.3.76 System.Inc Function

Increments an ordinal value by one or N.

Pascal

```
procedure Inc(var X); overload;
procedure Inc(var X; N: Longint); overload;
```

C++

```
Inc( X);
Inc( X, Longint N);
```

File

System

Description

In Delphi code, Inc adds one or N to the variable X.

X is a variable of an ordinal type (including Int64), or a pointer type if the extended syntax is enabled.

N is an integer-type expression.

X increments by 1, or by N if N is specified; that is, Inc(X) corresponds to the statement X := X + 1, and Inc(X, N) corresponds to the statement X := X + N. On some platforms, Inc may generate optimized code, especially useful in tight loops.

If X is a pointer type, it increments X by N times the size of the type pointed to. Thus, given

```
type
  PMyType = ^TMyType;
```

and

```
var
  P: PMyType;
```

the statement `Inc(P)` increments `P` by `SizeOf (` see page 3670`)(TMyType)`.

Warning: You can't use Inc on properties because it modifies the parameter.

Note: Inc(S, I) where S is a ShortInt and I is a number greater than 127 will cause an EIntOverFlow exception to be raised if range and overflow checking are on. In Delphi 1.0, this did not raise an exception.

Delphi Examples:

```
{
This example requires two buttons and two text fields.  The
text fields can be set to any integer and long integer value.
Click the buttons to execute Inc.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  IntVar: Integer;
begin
  IntVar := StrToInt(Edit1.Text);
  Inc(IntVar);
  Edit1.Text := IntToStr(IntVar);       { IntVar := IntVar + 1 }
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  LongintVar: Longint;
begin
  LongintVar := StrToInt(Edit2.Text);
  Inc(LongintVar, 5);
  Edit2.Text := IntToStr(LongintVar);   { LongintVar := LongintVar + 5 }
end;
```

35.3.77 System.Include Function

Adds an element to a Delphi set or adds an event handler in .NET applications.

Pascal

```
procedure Include(var S: set of T; I: T);
```

C++

```
Include(set of T S, T I);
```

File

System

Description

When the first argument of Include is a set type variable, Include adds an element to the set. The expression `Include(S,I)` corresponds to `S := S + [I]`, where S is a set type variable, and I is an expression of a type compatible with the base type of

S. The Include procedure generates more efficient code than using the + operator.

On the .NET platform, Include is overloaded. When the first argument of Include is a multicast event, and the second argument is an event handler, Include adds the event handler as a listener to the event.

Delphi Examples:

```
{
This example demonstrates the use of Include and Exclude routines.
The example assumes a form with three checkboxes and a button. Also
a field called FMsgButtons of type TMsgDlgButtons is declared in the form.
}
procedure TOptionsForm.btShowMessageClick(Sender: TObject);
begin
  //Creates a Message Dialog with the Selected Buttons
  MessageDlg('Hello World!', mtInformation, FMsgButtons, 0);
end;

procedure TOptionsForm.CheckBoxClick(Sender: TObject);
begin
  { Check wether an option is selected and add an element into a set,
    or exclude it from the set}

  if cbYes.Checked then
    Include(FMsgButtons, mbYes)
  else
    Exclude(FMsgButtons, mbYes);

  if cbNo.Checked then
    Include(FMsgButtons, mbNo)
  else
    Exclude(FMsgButtons, mbNo);

  if cbCancel.Checked then
    Include(FMsgButtons, mbCancel)
  else
    Exclude(FMsgButtons, mbCancel);
end;
```

See Also

Exclude (see page 3564)

35.3.78 System.Initialize Function

Initializes a dynamically allocated variable.

Pascal

```
procedure Initialize(var V); overload;
procedure Initialize(var V; Count: Integer); overload;
```

C++

```
Initialize( V);
Initialize( V, int Count);
```

File

System

Description

Initialize should be used only in Delphi code where a variable is dynamically allocated by other means than the New (see page

3619) standard procedure.

For global variables, local variables, objects, and dynamic variables allocated using New (see page 3619), the compiler generates code that initializes all long strings and variants contained by a variable upon creation of the variable. A call to Initialize is required to initialize a variable before it can be used if:

- the dynamic variable is created by other means than the New (see page 3619) standard function (for example using GetMem (see page 3584) or ReallocMem (see page 3637)).
- the variable contains long strings, variants, or interfaces.
- the dynamic variable is created by other means than the New (see page 3619) standard function (for example using GetMem (see page 3584) or ReallocMem (see page 3637)).
- the variable contains long strings, variants, or interfaces.
- the memory allocated for the variable is not initialized to zeros.

Initialize simply zeros out the memory occupied by long strings, variants, and interfaces, causing long strings to be empty and variants and interfaces to be Unassigned.

In cases where several variables are allocated in a contiguous memory block, the additional Count parameter can be specified to initialize all variables in one operation.

If the variable specified in a call to Initialize contains no long strings, variants, or interfaces, the compiler eliminates the call and generates no code for it.

Delphi Examples:

```
{
This example demonstrates the use of Initialize and Finalize functions
used to initialize and finalize a RTTI-enabled structure.
}
type
  { Declaring a data type that needs initilization }
  PPerson = ^TPerson;
  TPerson = record
    FFirstName: String;
    FLastName: String;
    FAge: Integer;
  end;

procedure TForm1.Button1Click(Sender: TObject);
var
  Person: PPerson;
begin
  {
    Allocate a block of memory for the structure
    We're using an "unsafe" function: GetMem
    which doesn't use RTTI to initialize the
    strings inside the structure.
  }
  GetMem(Person, SizeOf(TPerson));

  { Initialize the structure in the Heap - RTTI will be used }
  Initialize(Person^);

  { Assign some data to the structure }
  Person.FFirstName := 'John';
  Person.FLastName := 'Smith';
  Person.FAge := 31;

  { Use RTTI to cleanup the internals of the structure }
  Finalize(Person^);
  FreeMem(Person);
end;
```

See Also

Finalize (see page 3572)

New (see page 3619)

35.3.79 System.Insert Function

Inserts a substring into a string beginning at a specified point.

Pascal

```
procedure Insert(Source: string; var S: string; Index: Integer);
```

C++

```
Insert(UnicodeString Source, UnicodeString S, int Index);
```

File

System

Description

In Delphi code, Insert merges Source into S at the position S[index].

Source is a string-type expression. S is a string-type variable of any length. Index is an integer-type expression. It is a character index and not a byte index.

If Index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to the length of the string, turning the operation into an append.

If the Source parameter is an empty string, Insert does nothing.

Insert throws an EOutOfMemory exception if it is unable to allocate enough memory to accomodate the new returned string.

Delphi Examples:

```
{
This example uses the Insert function to edit a string.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
begin
  S := 'Honest Lincoln';
  Canvas.TextOut(10, 10, S);
  Insert('Abe ', S, 8);                    { 'Honest Abe Lincoln' }
  Canvas.TextOut(10, 40, S);
end;
```

35.3.80 System.Int Function

Returns the integer part of a real number.

Pascal

```
function Int(const X: Extended): Extended;
```

C++

```
Extended Int(const Extended X);
```

File

System

Description

In Delphi code, Int returns the integer part of X; that is, X rounded toward zero. X is a real-type expression.

Delphi Examples:

```
{
Click the button to display the integer part of any positive or
negative real number.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  R: Real;
begin
  R := StrToFloat(Edit1.Text);     { 123.456 }
  R := Int(R);                     { 123.0 }
  Edit2.Text := FloatToStr(R);
end;
```

Round (see page 3648)

Trunc (see page 3684)

35.3.81 System.IOResult Function

Returns the status of the last I/O operation performed.

Pascal

```
function IOResult: Integer;
```

C++

```
int IOResult();
```

File

System

Description

IOResult returns the result of the last Delphi I/O routine when I/O-checking is off (that is, when using the {$I-} compiler option). If

IOResult returns 0, the last I/O operation succeeded. Otherwise, IOResult returns an error code.

If an I/O error occurs and I/O-checking is off, all subsequent I/O operations are ignored until the internal error flag is cleared. Calling IOResult clears the internal error flag.

An alternative way to handle I/O errors is to use exception handling with the {$I+} compiler option.

The following table lists all I/O errors, numbers, and descriptions.

Number	Name	Description
100	Disk read error	Reported by Read (see page 3634) on a typed file if you attempt to read past the end of the file.
101	Disk write error	Reported by CloseFile (see page 3539), Write (see page 3707), WriteIn, or Flush (see page 3575) if the disk becomes full.
102	File not assigned	Reported by Reset (see page 3643), Rewrite (see page 3645), Append (see page 3520), Rename (see page 3642), or Erase (see page 3560) if the file variable has not been assigned a name through a call to Assign or AssignFile (see page 3525).
103	File not open	Reported by CloseFile (see page 3539), Read (see page 3634) Write (see page 3707), Seek (see page 3650), Eof (see page 3558), FilePos (see page 3567), FileSize (see page 3569), Flush (see page 3575), BlockRead (see page 3528), or BlockWrite (see page 3530) if the file is not open.
104	File not open for input	Reported by Read (see page 3634), Readln, Eof (see page 3558), Eoln (see page 3559), SeekEof (see page 3651), or SeekEoln (see page 3652) on a text file if the file is not open for input.
105	File not open for output	Reported by Write (see page 3707) or Writeln on a text file if you do not generate a Console application.
106	Invalid numeric format	Reported by Read (see page 3634) or Readln if a numeric value read from a text file does not conform to the proper numeric format.

Delphi Examples:

```
{
This example illustrates how to use IOResult to check the success of the Reset
method. If the call to Reset is successful, a message dialog displays the size
of the file that the user selects in an Open dialog. If the call to Reset fails,
a message warns the user that there was a file access error. To test the failure
part of this example, just misspell a file name in the open dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File of Byte;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    {$I-}
    Reset(F);
    {$I+}
    if IOResult = 0 then
    begin
      MessageDlg('File size in bytes: ' + IntToStr(FileSize(F)),
        mtInformation, [mbOk], 0);
      CloseFile(F);
    end
    else
      MessageDlg('File access error', mtWarning, [mbOk], 0);
  end;
end;
```

I/O errors

35.3.82 System.IsMemoryManagerSet Function

Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 3660) procedure.

Pascal

```
function IsMemoryManagerSet: Boolean;
```

C++

```
Boolean IsMemoryManagerSet();
```

File

System

Description

Call IsMemoryManagerSet to determine whether the default system memory management has been changed by a call to SetMemoryManager (see page 3660). IsMemoryManagerSet returns false if the default system memory management is in place, true otherwise.

Note: In C++, IsMemoryManagerSet always returns true, since C++ Builder automatically loads a custom memory manager.

Delphi Examples:

```
{
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
}
var
  OldMemMgr       : TMemoryManagerEx;
  GetMemCalls     : Integer;
  FreeMemCalls    : Integer;
  ReallocMemCalls : Integer;
  AllocMemCalls   : Integer;

function MyGetMem(Size: Integer): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.GetMem(Size);

  { Safely increment the counter }
  InterlockedIncrement(GetMemCalls);
end;

function MyFreeMem(P: Pointer): Integer;
begin
  { Route the call }
  Result := OldMemMgr.FreeMem(P);

  { Safely increment the counter }
  InterlockedIncrement(FreeMemCalls);
end;

function MyReallocMem(P: Pointer; Size: Integer): Pointer;
```

```
begin
  { Route the call }
  Result := OldMemMgr.ReallocMem(P, Size);

  { Safely increment the counter }
  InterlockedIncrement(ReallocMemCalls);
end;

function MyAllocMem(Size: Cardinal): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.AllocMem(Size);

  { Safely increment the counter }
  InterlockedIncrement(AllocMemCalls);
end;

procedure TForm2.btPerformSomethingClick(Sender: TObject);
var
  X : Integer;
  I : ^Integer;
begin
  { Perform some allocations and frees }
  for X := 0 to 999 do
  begin
    New(I);
    Dispose(I);
  end;
end;

procedure TForm2.btUseMyMemMgrClick(Sender: TObject);
var
  MyMemMgr : TMemoryManagerEx;

  MyMemMgr.ReallocMem := MyReallocMem;
  MyMemMgr.AllocMem := MyAllocMem;

  { Use the defaults for this - not important }
  MyMemMgr.RegisterExpectedMemoryLeak := OldMemMgr.RegisterExpectedMemoryLeak;
  MyMemMgr.UnregisterExpectedMemoryLeak := OldMemMgr.UnregisterExpectedMemoryLeak;

  { Clear out the count variables }
  GetMemCalls := 0;
  FreeMemCalls := 0;
  ReallocMemCalls := 0;
  AllocMemCalls := 0;

  { Install the new memory manager }
  SetMemoryManager(MyMemMgr);
end;

procedure TForm2.btUseSystemMemMgrClick(Sender: TObject);
begin
  { Switch button states }
  btUseSystemMemMgr.Enabled := false;
  btUseMyMemMgr.Enabled := true;
```

```
    { Set the old memory manager back! }
    SetMemoryManager(OldMemMgr);

    GetMemCalls := 0;
    FreeMemCalls := 0;
    ReallocMemCalls := 0;
    AllocMemCalls := 0;
  end;

  procedure TForm2.FormDestroy(Sender: TObject);
  begin
    { Set the old memory manager back }
    if IsMemoryManagerSet then
       SetMemoryManager(OldMemMgr);
  end;

  procedure TForm2.Timer1Timer(Sender: TObject);
  begin
    {
    Note that IntToStr calls will also Allocate/Free
    memory so at each timer tick the counts will be increased;
    }
    Form2.edtGetMemCalls.Text := IntToStr(GetMemCalls);
    Form2.edtFreeMemCalls.Text := IntToStr(FreeMemCalls);
    Form2.edtReallocMemCalls.Text := IntToStr(ReallocMemCalls);
    Form2.edtAllocMemCalls.Text := IntToStr(AllocMemCalls);
  end;
```

SetMemoryManager (see page 3660)

35.3.83 System.IsVariantManagerSet Function

Indicates whether variant support is implemented in an application.

Pascal

```
function IsVariantManagerSet: Boolean; deprecated;
```

C++

```
Boolean IsVariantManagerSet();
```

File

System

Description

Use IsVariantManagerSet in Delphi code to determine whether the compiler knows the locations of functions that define variant behavior. In any program or unit that uses the Variants (see page 4973) unit (directly or indirectly), IsVariantManagerSet should return true.

Note: Although IsVariantManagerSet is defined in System.hpp, do not use this function in C++ code. Working directly with the Variant (see page 3421) manger is not guaranteed to work in C++.

See Also

GetVariantManager (see page 3594)

SetVariantManager (see page 3668)

35.3.84 System.Length Function

Returns the number of characters in a string or elements in an array.

Pascal

```
function Length(S): Integer;
```

C++

```
int Length( S);
```

File

System

Description

In Delphi code, Length returns the number of characters actually used in the string or the number of elements in the array. In C++ code, use the method of the same name on the AnsiString or DynamicArray (see page 3261) class.

For single-byte and multibyte strings, Length returns the number of bytes used by the string. For Unicode (WideString (see page 3467)) strings, Length returns the number of bytes divided by two.

S is a string- or array-valued expression.

Delphi Examples:

```
{
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  Label1.Caption := '';
  for i := 1 to Length(Edit1.Text) do
  begin
    try
      Label1.Caption :=
        Label1.Caption +
        SysUtils.IntToHex(Byte(Edit1.Text[i]),2) + ' ';
    except
      Beep;
    end;
  end;
end;
{
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
}
```

```
procedure TForm1.FindDialog1Find(Sender: TObject);
var
  I, J, PosReturn, SkipChars: Integer;
begin
  for I := 0 to Memo1.Lines.Count do
  begin
    PosReturn := Pos(FindDialog1.FindText,Memo1.Lines[I]);
    if PosReturn <> 0 then {found!}
    begin
      SkipChars := 0;
      for J := 0 to I - 1 do
        SkipChars := SkipChars + Length(Memo1.Lines[J]);
      SkipChars := SkipChars + (I*2);
      SkipChars := SkipChars + PosReturn - 1;
      Memo1.SetFocus;
      Memo1.SelStart := SkipChars;
      Memo1.SelLength := Length(FindDialog1.FindText);
      Break;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'country.list';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
```

35.3.85 System.Ln Function

Returns the natural log of a real expression.

Pascal

```
function Ln(const X: Extended): Extended;
```

C++

```
Extended Ln(const Extended X);
```

File

System

Description

In Delphi code, Ln returns the natural logarithm (Ln(e) = 1) of the real-type expression X.

Delphi Examples:

```
{
This example calculated the exponential of 1.0 and then calculates
the natural log of that quantity to show that the natural log
```

```
function is the inverse of the exponential function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   e : real;
   S : string;
begin
   e := Exp(1.0);
   Str(ln(e):3:2, S);
   S := 'e = ' + FloatToStr(e) + '; ln(e) = ' + S;
   Canvas.TextOut(10, 10, S);
end;
```

Exp (see page 3567)

LnXP1

35.3.86 System.Lo Function

Returns the low order Byte of argument X.

Pascal

```
function Lo(X): Byte;
```

C++

```
Byte Lo( X);
```

File

System

Description

In Delphi code, Lo returns the low-order Byte of the argument X as an unsigned value. X is an expression of type Integer.

Delphi Examples:

```
{
This example demonstrate use of the System Lo function to
store the low byte of a word or integer into a byte.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  B : Byte;
begin
  B := Lo($1234);
  ShowMessage(Format('Low byte of $1234 = $%x', [B]));
end;
```

35.3.87 System.LoadResourceModule Function

Pascal

```
function LoadResourceModule(ModuleName: PChar; CheckOwner: Boolean = True): LongWord;
```

C++

```
LongWord LoadResourceModule(const char * ModuleName, Boolean CheckOwner = True);
```

File

System

Description

This is function System.LoadResourceModule.

35.3.88 System::LoadResourceString Function

Pascal

```
function LoadResourceString(rsrc: ResourceString const * const): String;
```

C++

```
__fastcall String LoadResourceString(ResourceString const * const rsrc);
```

File

sysclass.h

Description

This is function System::LoadResourceString.

35.3.89 System.LoadResString Function

Pascal

```
function LoadResString(ResStringRec: PResStringRec): string;
```

C++

```
UnicodeString LoadResString(PResStringRec ResStringRec);
```

File

System

Description

This is function System.LoadResString.

35.3.90 System.Low Function

Returns the lowest value in a range.

Pascal

```
procedure Low(X);
```

C++

```
Low( X);
```

File

System

Description

In Delphi code, call Low to obtain the lowest value or first element of an Ordinal, Array or ShortString. Result type is X, or the index type of X where X is either a type identifier or a variable reference.

Type	Low returns
Ordinal type (includes Int64)	The lowest value in the range of the type
Array type	The lowest value within the range of the index type of the array
short string type	Returns 0
Open array	Returns 0
short string parameter	Returns 0

Delphi Examples:

```
{
This example requires a button and two list boxes.  Two lists
of floating point numbers are generated initially and
displayed in the list boxes. Clicking the button sums the lists.
Notice that the range of the list arrays can be any integers,
as long as Low is less than High.
}
var
  List1: array[0..3] of Double;
  List2: array[5..17] of Double;

function Sum( var X: array of Double): Double;
var
  I: Word;
  S: Real;
begin
  S := 0; { Note that open array index range is always zero-based. }
  for I := 0 to High(X) do S := S + X[I];
  Sum := S;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  S, TempStr: string;
begin
  Str(Sum(List1):4:2, S);
  S := 'Sum of List1: ' + S + #13#10;
  S := S + 'Sum of List2: ';
  Str(Sum(List2):4:2, TempStr);
  S := S + TempStr;
  MessageDlg(S, mtInformation, [mbOk], 0);

end;

procedure TForm1.FormCreate(Sender: TObject);
var
  X: Word;
begin
  for X := Low(List1) to High(List1) do
  begin
      List1[X] := X * 3.4;
      ListBox1.Items.Add(FloatToStr(List1[X]));
  end;
  for X := Low(List2) to High(List2) do
```

```
  begin
      List2[X] := X * 0.0123;
      ListBox2.Items.Add(FloatToStr(List2[X]));
  end;
end;
```

35.3.91 System.Mark Function

Pascal

```
procedure Mark; deprecated;
```

C++

```
Mark();
```

File

System

Description

This is function System.Mark.

35.3.92 System.MemoryBarrier Function

Pascal

```
procedure MemoryBarrier;
```

C++

```
MemoryBarrier();
```

File

System

Description

This is function System.MemoryBarrier.

35.3.93 System.MkDir Function

Creates a new subdirectory.

Pascal

```
procedure MkDir(const S: string); overload;
procedure MkDir(P: PChar); overload;
```

C++

```
MkDir(const UnicodeString S);
MkDir(const char * P);
```

File

System

Description

MkDir creates a new subdirectory with the path specified by string S or P. The last item in the path cannot be an existing file name.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for an I/O error.

Delphi Examples:

```
{
The following sample code sets the directory of
DirectoryListBox1 to C:\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
mytemp is added to C:\WINDOWS, but note that it is not
updated in DirectoryListBox1 until Button2 is pressed
and Update is called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current path to see the magic happen.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  MkDir(Edit1.Text);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  DirectoryListBox1.Update;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  DirectoryListBox1.Directory := 'c:\WINDOWS';
end;
{
This example creates a directory using the path and directory name
entered in the text edit.  The path is relative to the project
directory.  Type in the name of an existing directory to induce the
error.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  {$I-}
  { Get directory name from TEdit control }
  MkDir(Edit1.Text);
  if IOResult <> 0 then
    MessageDlg('Cannot create directory', mtWarning, [mbOk], 0, mbOk)
  else
    MessageDlg('New directory created', mtInformation, [mbOk], 0, mbOk);
end;
```

RmDir (see page 3647)

ForceDirectories (see page 4186)

35.3.94 System.MonitorEnter Function

Prohibits the access of all other threads but the calling one to the specified object.

Pascal

```
function MonitorEnter(AObject: TObject; Timeout: Cardinal = INFINITE): Boolean;
```

C++

```
Boolean MonitorEnter(TObject * AObject, unsigned Timeout = INFINITE);
```

File

System

Description

Use the MonitorEnter function to prohibit `AObject` from being accessed by threads, other than the calling one.

Before attempting to lock the specified object, MonitorEnter tests whether the thread that is currently locking the object, if any, has made an equal number of calls to MonitorEnter and to MonitorExit (see page 3614). If not, the calling thread is blocked from accessing the object until the previous thread releases it.

MonitorEnter attempts to lock the specified object for the amount of time designated by the `Timeout` parameter. If the lock attempt is successful, MonitorEnter returns True, otherwise it returns False.

See Also

MonitorExit (see page 3614)

TMonitor (see page 3349)

Enter (see page 3350)

35.3.95 System.MonitorExit Function

Releases a lock of the calling thread on the specified object.

Pascal

```
procedure MonitorExit(AObject: TObject);
```

C++

```
MonitorExit(TObject * AObject);
```

File

System

Description

Use MonitorExit to release a lock of the calling thread on `AObject`, which is also owned by the thread. The object is released from all the locks of the calling thread as soon as the number of the thread's calls to MonitorExit is equal to the number of calls to

MonitorEnter (see page 3614).

See Also

MonitorEnter (see page 3614)

TMonitor (see page 3349)

Exit (see page 3351)

35.3.96 System.MonitorPulse Function

Notifies the next thread in the waiting queue that it will be able to lock the specified object as soon as the calling thread releases it.

Pascal

```
procedure MonitorPulse(AObject: TObject);
```

C++

```
MonitorPulse(TObject * AObject);
```

File

System

Description

MonitorPulse notifies the next thread in the waiting queue that it can move to the ready queue. Thus, as soon as the calling thread releases the lock on `AObject`, the next thread in the ready queue will lock it.

See Also

MonitorPulseAll (see page 3615)

TMonitor (see page 3349)

Pulse (see page 3352)

35.3.97 System.MonitorPulseAll Function

Signals all threads in the waiting queue that either one of them will be able to lock the specified object as soon as the calling thread releases it.

Pascal

```
procedure MonitorPulseAll(AObject: TObject);
```

C++

```
MonitorPulseAll(TObject * AObject);
```

File

System

Description

MonitorPulseAll notifies all threads in the waiting queue that they can move to the ready queue. As soon as the calling thread releases the lock on `AObject`, the first thread in the ready queue will lock it.

See Also

MonitorPulse (see page 3615)

TMonitor (see page 3349)

PulseAll (see page 3352)

35.3.98 System.MonitorTryEnter Function

Attempts to lock the specified object, so that only the calling thread is able to access it.

Pascal

```
function MonitorTryEnter(AObject: TObject): Boolean;
```

C++

```
Boolean MonitorTryEnter(TObject * AObject);
```

File

System

Description

The MonitorTryEnter function attempts to lock the object given as parameter, so that only the calling thread can access it.

MonitorTryEnter returns True if it manages to lock the object, or False otherwise.

As opposed to the MonitorEnter (see page 3614) method, MonitorTryEnter does not block the calling thread if the given object is currently owned by other threads.

See Also

MonitorEnter (see page 3614)

TMonitor (see page 3349)

Enter (see page 3350)

35.3.99 System.MonitorWait Function

Drops the lock on the specified object and puts the calling thread in the waiting queue for a specified amount of time.

Pascal

```
function MonitorWait(AObject: TObject; Timeout: Cardinal): Boolean;
```

C++

```
Boolean MonitorWait(TObject * AObject, unsigned Timeout);
```

File

System

Description

Use MonitorWait to drop the lock on the specified object and also to put the calling thread in the waiting queue for the amount of time specified in the `Timeout` parameter. Hence, the calling thread is blocked until it is again able to lock `AObject`.

See Also

TMonitor (see page 3349)

Wait (see page 3353)

35.3.100 System.Move Function

Copies bytes from a source to a destination.

Pascal

```
procedure Move(const Source; var Dest; Count: Integer);
```

C++

```
Move(const  Source,  Dest, int Count);
```

File

System

Description

Move copies Count bytes from Source to Dest. No range checking is performed. Move compensates for overlaps between the source and destination blocks.

Whenever possible, use the global SizeOf (see page 3670) function (Delphi) or the sizeof operator (C++) to determine the count.

Delphi Examples:

```
{
This example moves characters from a Char array into an integer.
Displaying the integer as a hex, you can see that 'W' (0x57) is
stored in the least significant byte of the integer.
}
var
  A: array[1..4] of Char;
  B: Integer;

procedure DisplayAB;
begin
  Form1.ListBox1.Items[0] := A[1];
  Form1.ListBox1.Items[1] := A[2];
  Form1.ListBox1.Items[2] := A[3];
  Form1.ListBox1.Items[3] := A[4];
  Form1.Edit1.Text := IntToHex(B, 1);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Move(A, B, SizeOf(B));  { SizeOf = safety! }
  DisplayAB;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I : Integer;
begin
  A[1] := 'W';
  A[2] := 'H';
  A[3] := 'A';
```

```
  A[4] := 'T';
  B := 5;
  DisplayAB;
end;
```

35.3.101 System.MoveChars Function

Copies bytes from a source to a destination.

Pascal

```
procedure MoveChars(const Source; var Dest; Length: Integer);
```

C++

```
MoveChars(const  Source,  Dest, int Length);
```

File

System

Description

MoveChars copies Length (see page 3607) bytes from Source to Dest. MoveChars compensates for overlaps between the source and destination blocks.

Note: MoveChars assumes that the size of Char is 2 Bytes (when Unicode is enabled). Use the Move (see page 3617) function to copy characters from a string that has character size different from SizeOf (see page 3670)(Char).

C++ Examples:

```
/*
The following code demostrates the use of memory management functions in C++. Three
edit boxes and a button are expected onthe form.
*/
String __fastcall FastStrCat(String s1, String s2)
{
  /*
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  */
  wchar_t* finalStr = (wchar_t *)GetMemory((s1.Length() + 1) * sizeof(wchar_t));

  // Copy the contents of the first string
  MoveChars(s1.data(), finalStr, s1.Length() + 1);

  // And now expand the final string + $00 character
  finalStr = (wchar_t *)ReallocMemory(finalStr, (s1.Length() + s2.Length() + 1) *
sizeof(wchar_t));

  // Copy the contents of the second string
  MoveChars(s2.data(), finalStr + s1.Length(), s2.Length() + 1);

  // Get the result in String
  String result = String(finalStr);
  FreeMemory(finalStr);

  return result;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Concatenate 2 string
```

```
  Edit3->Text = FastStrCat(Edit1->Text, Edit2->Text);
}
```

Delphi Examples:

```
{
The following code demostrates the use of ReallocMem function. Three
edit boxes and a button are expected onthe form.
}
function FastStrCat(const S1, S2: String): String;
var
  FinalStr: PChar;
begin
  {
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  }
  GetMem(FinalStr, (Length(S1) + 1) * SizeOf(Char));

  { Copy the contents of the first string }
  MoveChars(S1[1], FinalStr^, Length(S1) + 1);

  { And now expand the final string + $00 character }
  ReallocMem(FinalStr, (Length(S1) + Length(S2) + 1) * SizeOf(Char));

  { Copy the contents of the second string }
  MoveChars(S2[1], FinalStr[Length(S1)], Length(S2) + 1);

  { Get the result in String }
  SetString(Result, FinalStr, Length(S1) + Length(S2));
  FreeMem(FinalStr);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  { Concatenate 2 string }
  Edit3.Text := FastStrCat(Edit1.Text, Edit2.Text);
end;
```

See Also

Move (see page 3617)

35.3.102 System.New Function

Creates a new dynamic variable and sets P to point to it.

Pascal

```
procedure New(var P: Pointer);
```

C++

```
New(void * P);
```

File

System

Description

In Delphi code, the New procedure creates a new dynamic variable and sets a pointer variable to point to it. P is a variable of any pointer type. The size of the allocated memory block corresponds to the size of the type that P points to. The newly created variable can be referenced as P^. If there isn't enough memory available to allocate the dynamic variable, an EOutOfMemory

exception is raised.

When an application is finished using a dynamic variable created with New, it should dispose of the memory allocated for the variable using the Dispose (see page 3553) standard procedure.

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  type
  PMyRec = ^TMyRec;
  TMyRec = record
    FName: string;
    LName: string;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

{
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the selected node.
A TMyRec record is associated with the added item. The FName
```

```
  and LName fields are obtained from edit boxes Edit1 and
  Edit2.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    MyRecPtr: PMyRec;
    TreeViewIndex: LongInt;
  begin
    New(MyRecPtr);
    MyRecPtr^.FName := Edit1.Text;
    MyRecPtr^.LName := Edit2.Text;
    with TreeView1 do
    begin
      TreeViewIndex := Selected.AbsoluteIndex;
      if Items.Count = 0 then
        Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
      else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
        Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
    end;
  end;
  {
  After an item containing a TMyRec record has been added, the
  following code retrieves the FName and LName values
  associated with the item and displays the values in a label.
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
      Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                    PMyRec(TreeView1.Selected.Data)^.LName;
  end;
  procedure TForm1.Button3Click(Sender: TObject);
  begin
    Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
  end;
```

See Also

Dispose (see page 3553)

FreeMem (see page 3577)

GetMem (see page 3584)

35.3.103 System.Odd Function

Returns true if argument is an odd number.

Pascal

```
function Odd(X: Integer): Boolean;
```

C++

```
Boolean Odd(int X);
```

File

System

Description

In Delphi code, Odd tests if the argument is an odd number. It returns true if X is an odd number, false if X is even.

Delphi Examples:

```
{
This example requires a text edit and a button with some clear
canvas in the top left ocrner of the form.  Enter the number to be
tested in the text edit and click to button to test if the entry
is odd.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   Canvas.TextOut(10, 10, '                                          ');
   if Odd(StrToInt(Edit1.Text)) then
     Canvas.TextOut(10, 10, Edit1.Text + ' is odd.')
   else
     Canvas.TextOut(10, 10, Edit1.Text + ' is even.');
end;
```

35.3.104 System.OleStrToString Function

Copies data received from a COM interface to a string.

Pascal

```
function OleStrToString(Source: PWideChar): UnicodeString;
```

C++

```
UnicodeString OleStrToString(PWideChar Source);
```

File

System

Description

OleStrToString copies data from the format used by COM into a Delphi string.

See Also

OleStrToStrVar (see page 3622)

StringToOleStr (see page 3678)

35.3.105 System.OleStrToStrVar Function

Copies a string from its COM representation to an existing Delphi string.

Pascal

```
procedure OleStrToStrVar(Source: PWideChar; var Dest: AnsiString); overload;
procedure OleStrToStrVar(Source: PWideChar; var Dest: UnicodeString); overload;
```

C++

```
OleStrToStrVar(PWideChar Source, AnsiString Dest);
OleStrToStrVar(PWideChar Source, UnicodeString Dest);
```

File

System

Description

OleStrToStrVar converts a wide string (the format used by COM interfaces) into an existing string variable.

See Also

OleStrToString (see page 3622)

StringToOleStr (see page 3678)

35.3.106 System.Ord Function

Returns the ordinal value of an ordinal-type expression.

Pascal

```
procedure Ord(X);
```

C++

```
Ord( X);
```

File

System

Description

X is a Delphi ordinal-type expression. The result is the ordinal position of X; its type is the smallest standard integer type that can hold all values of X's type.

Ord cannot operate on Int64 values.

Delphi Examples:

```
{
This example displays the ordinal value for different enumerations.
}
procedure TForm1.Button1Click(Sender: TObject);
type
   Colors = (RED,BLUE,GREEN);
var
  S: string;
begin
  S := 'BLUE has an ordinal value of ' + IntToStr(Ord(BLUE)) + #13#10;
  S := S + 'The ASCII code for "c" is ' + IntToStr(Ord('c')) +  ' decimal';
  MessageDlg(S, mtInformation, [mbOk], 0, mbOK);
end;
```

See Also

Chr (see page 3536)

35.3.107 System.ParamCount Function

Returns the number of parameters passed on the command line.

Pascal

```
function ParamCount: Integer;
```

C++

```
int ParamCount();
```

File

System

Description

ParamCount returns the number of parameters passed to the program on the command line. Separate parameters with spaces or tabs. Use double quotes to wrap multiple words as one parameter (such as long file names containing spaces).

C++ Examples:

```
/*
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    "System ParamStr = " + AnsiString(System::ParamStr(i)),
//    mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  for (int i=1;i<=ParamCount();i++)
  {
    if (LowerCase(ParamStr(i)) == "beep")
      Beep();
    else if (LowerCase(ParamStr(i)) == "exit")
      Application->Terminate();
  }
}
```

Delphi Examples:

```
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    'System ParamCount = ' + IntToStr(System.ParamCount),
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

See Also

ParamStr (see page 3625)

CmdLine (see page 3812)

FindCmdLineSwitch (see page 4174)

35.3.108 System.ParamStr Function

Returns a specified parameter from the command-line.

Pascal

```
function ParamStr(Index: Integer): string;
```

C++

```
UnicodeString ParamStr(int Index);
```

File

System

Description

ParamStr returns the parameter from the command line that corresponds to Index, or an empty string if Index is greater than ParamCount (see page 3623). For example, an Index value of 2 returns the second command-line parameter.

Note: On Windows, ParamStr(0) returns the path and file name of the executing program (for example, C:\TEST\MYPROG.EXE).

Note: On Linux, ParamStr(0) returns the command used to execute the program, without parameters (for example, ./myprogram). This behavior is dependent on information returned by the shell program and may not be consistent among all shells.

Note: Use double quotes to wrap multiple words as one parameter (such as long file names containing spaces).

C++ Examples:

```
/*
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    "System ParamStr = " + AnsiString(System::ParamStr(i)),
//    mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  for (int i=1;i<=ParamCount();i++)
  {
    if (LowerCase(ParamStr(i)) == "beep")
      Beep();
    else if (LowerCase(ParamStr(i)) == "exit")
      Application->Terminate();
  }
}
```

Delphi Examples:

```
{
The following example beeps once for each "beep" passed in
```

```
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    'System ParamCount = ' + IntToStr(System.ParamCount),
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

FindCmdLineSwitch (see page 4174)

35.3.109 System.Pi Function

Returns 3.1415926535897932385.

Pascal

```
function Pi: Extended;
```

C++

```
Extended Pi();
```

File

System

Description

Use Pi in Delphi code to represent the mathematical value pi, the ratio of a circle's circumference to its diameter. Pi is approximated as 3.1415926535897932385.

Delphi Examples:

```
{
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
```

```
  Edit3.Text := mystring;
  Str(ex:25:23, mystring);
  Edit4.Text := mystring;
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit2.Text := mystring;
  mystring := SysUtils.FormatFloat('#,##0.00000000000000000000000000;;Zero', ex);
  Edit5.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
//  mystring := FloatToStr(ex);
//  Str(ex:25:23, mystring);
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit1.Text := mystring;
end;
```

35.3.110 System.Pos Function

Returns the index value of the first character in a specified substring that occurs in a given string.

Pascal

```
function Pos(const substr: UnicodeString; const str: UnicodeString): Integer; overload;
function Pos(const substr: RawByteString; const str: RawByteString): Integer; overload;
function Pos(const substr: WideString; const str: WideString): Integer; overload;
```

C++

```
int Pos(const UnicodeString substr, const UnicodeString str);
int Pos(const RawByteString substr, const RawByteString str);
int Pos(const BSTR substr, const BSTR str);
```

File

System

Description

In Delphi, Pos searches for a substring, Substr, in a string, S. Substr and S are string-type expressions.

Pos searches for Substr within S and returns an integer value that is the index of the first character of Substr within S. Pos is case-sensitive. If Substr is not found, Pos returns zero.

The PosEx function is similar to Pos, but provides additional features and can be used in C++ code.

Delphi Examples:

```
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
```

```
    begin
    for I := 0 to Source.Count - 1 do
    begin
      if Pos ('=', Source[I]) > 1 then
      begin
        DI := Dest.IndexOfName(Source.Names[I]);
        if DI > -1 then Dest[DI] := Source[I];
      end;
    end;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    MergeStrings(ListBox1.Items, ListBox2.Items);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Plants = 10');
    ListBox1.Items.Add('Animals = 20');
    ListBox1.Items.Add('Minerals = 15');
    ListBox2.Items.Add('Animals = 4');
    ListBox2.Items.Add('Plants = 3');
    ListBox2.Items.Add('Minerals = 78');
  end;
  {
  This example demonstrates how to edit particular elements of a string.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var S: string;
  begin
    S := Edit1.Text;
    { Convert spaces to zeros }
    while Pos(' ', S) > 0 do
      S[Pos(' ', S)] := '0';
    Edit1.Text := S;
  end;
```

35.3.111 System.Pred Function

Returns the predecessor of the argument.

Pascal

```
procedure Pred(X);
```

C++

```
Pred( X);
```

File

System

Description

X is an expression of a Delphi ordinal type (including Int64). The result, of the same type as X, is the predecessor of X.

Delphi Examples:

```
{
The following code is a self-contained unit that you can add to a project
that logs failed assertions to the event log rather than raising an
exception. If /Debug is passed to the application as a command-line
parameter, all failed Assert calls cause a call to OutputDebugString,
which sends a messages to the Event Log window if run from Delphi, or
does nothing if run outside the IDE (OutputDebugString is a no-op if not
run from within a debugger). A nice side benefit is that all the line
numbers and unit names can be stripped from the EXE by turning off
assertions and rebuilding the project. Build the executable in the IDE
by hitting "Run".  Then go to the debug directory for the project and
execute the command line "AssertErrorProc_proj /Debug".
Note: AssertErrorHandler should do as little as possible.  This routine
does no cleanup, so no variables, no compiler generated variables.
Procedure calls are OK.
Note:   This example was originally provided by Brian Long.
}
type
  TForm1 = class(TForm)
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TStorage = class(TObject)
    FData: string;
    property Data: string read FData write FData;
  private
    { Private declarations }
  public
    { Public declarations }
  end;

Pointer);

implementation

{$R *.dfm}

{$ASSERTIONS ON}

type
  EMyAssert = class(Exception);

procedure DoMessage(Message, Filename: String; LineNumber: Integer; ErrorAddr: Pointer);
var
  S: String;
begin
  S := Format('%s (%s, line %d, address $%x)',
    [Message, Filename, LineNumber, Pred(Integer(ErrorAddr))]);
  OutputDebugString(PChar(S));
end;
```

```
procedure AssertErrorHandler(const Message, Filename: string;  LineNumber: Integer; ErrorAddr:
Pointer);
{ No local variables.  Not compiler generated temporary variables. }
{ Using the call stack here will cause Access Violation errors. }
begin
  DoMessage(Message, Filename, LineNumber, ErrorAddr);
  raise EMyAssert.Create('Boom!');
end;

procedure AssertErrorNoHandler(const Message, Filename: string; LineNumber: Integer;
ErrorAddr: Pointer);
begin
end;

procedure ModifyStorage(AStorage: TStorage; const s: string);
begin
  Assert(AStorage <> nil, 'Value');
  AStorage.Data := s;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  ModifyStorage(nil, 'Oops');
end;

initialization
  if FindCmdLineSwitch('Debug', ['/', '-'], True) then
  begin
    MessageDlg('Command line switch found!', mtInformation, [mbOK], 0);
//    OldProc := System.AssertErrorProc;
    System.AssertErrorProc := @AssertErrorHandler
  end
  else
    System.AssertErrorProc := @AssertErrorNoHandler;

  ModifyStorage(nil, 'Ooops');
{
This example demonstrates how Pred and Succ can be used to
manage enumerations.
}
procedure TForm1.Button1Click(Sender: TObject);
type
  Colors = (RED,BLUE,GREEN);
var
  S: string;
begin
  S := 'The predecessor of 5 is ' + IntToStr(Pred(5)) + #13#10;
  S := S + 'The successor of 10 is ' + IntToStr(Succ(10)) + #13#10;
  if Succ(RED) = BLUE then
    S := S + 'In the type Colors, RED is the predecessor of BLUE.';
  MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

See Also

Succ (see page 3680)

35.3.112 System.Ptr Function

Converts a specified address to a pointer.

Pascal

```
function Ptr(Address: Integer): Pointer;
```

C++

```
void * Ptr(int Address);
```

File

System

Description

In Delphi code, Ptr converts the given **Address** to a pointer. A call to this function generates no code, but simply treats the 32-bit value given by Address as a pointer. Like nil, the result of Ptr is assignment compatible with all pointer types.

Delphi Examples:

```
{
The following code demostrates the use of Ptr function. The example
makes use of Ptr to simulate pointer arithmetics.
}
function FastUpperCase(const S: String): String;
var
  C: ^Char;
  I: Integer;
begin
  { Get the text in the edit box }
  Result := S;

  { Ensure the string reference stored in Result is unique,
    otherwise we may change the original string also.
    No copy-on-write is done if we're accesing the character
    directly.
  }
  UniqueString(Result);

  { Find the address of the first char in the string }
  C := Addr(Result[1]);

  for I := 0 to Length(Result) - 1 do
  begin
    { Up-case the character }
    C^ := UpCase(C^);

    { Move to the next character }
    C := Ptr(Integer(C) + SizeOf(Char));
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  { Uppercase the string in the edit box }
  Edit1.Text := FastUpperCase(Edit1.Text);
end;
```

See Also

Addr (see page 3514)

35.3.113 System.PUCS4Chars Function

Converts a UCS4 string to a null-terminated array of UCS4 characters.

Pascal

```
function PUCS4Chars(const S: UCS4String): PUCS4Char;
```

C++

```
PUCS4Char PUCS4Chars(const UCS4String S);
```

File

System

Description

PUCS4Chars converts the UCS-4 string specified by S to a null-terminated sequence of UCS4Char (see page 3802) values.

See Also

UCS4StringToWideString (see page 3687)

Utf8ToUnicode (see page 3699)

WideStringToUCS4String (see page 3707)

35.3.114 System.RaiseList Function

Pascal

```
function RaiseList: Pointer; deprecated;
```

C++

```
void * RaiseList();
```

File

System

Description

This is function System.RaiseList.

35.3.115 System.Random Function

Generates random numbers within a specified range.

Pascal

```
function Random(const ARange: Integer): Integer; overload;
function Random: Extended; overload;
```

C++

```
int Random(const int ARange);
Extended Random();
```

File

System

Description

In Delphi code, Random returns a random number within the range 0 <= X < Range. If Range is not specified, the result is a real-type random number within the range

`0 <= X < 1.`

To initialize the random number generator, add a single call Randomize (see page 3633) or assign a value to the RandSeed (see page 3834) variable before making any calls to Random.

Note: Because the implementation of the Random function may change between compiler versions, we do not recommend using Random for encryption or other purposes that require reproducible sequences of pseudo-random numbers.

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

See Also

RandSeed (see page 3834)

35.3.116 System.Randomize Function

Initializes the random number generator with a random value.

Pascal

```
procedure Randomize;
```

C++

```
Randomize();
```

File

System

Description

Randomize initializes the built-in random number generator with a random value (obtained from the system clock). The random number generator should be initialized by making a call to Randomize, or by assigning a value to RandSeed (see page 3834).

Do not combine the call to Randomize in a loop with calls to the Random (see page 3632) function. Typically, Randomize is called only once, before all calls to Random (see page 3632).

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

See Also

RandG

RandSeed (see page 3834)

Random (see page 3632)

35.3.117 System.Read Function

Read reads data from a file.

Pascal

```
procedure Read(F; V1); overload;
procedure Read(F; V1; Vn); overload;
procedure Read(F: Text; V1); overload;
procedure Read(F: Text; V1; Vn); overload;
```

C++

```
Read( F,  V1);
Read( F,  V1,  Vn);
Read(Text F,  V1);
Read(Text F,  V1,  Vn);
```

File

System

Description

The Read procedure can be used in Delphi code in the following ways.

For typed files, it reads a file component into a variable.

For text files, it reads one or more values into one or more variables.

The syntax shown here for Read demonstrates that the procedure can take a variable number of arguments.

Read reads all characters up to, but not including, the next end-of-line marker or until Eof (see page 3558)(F) becomes true; it does not skip to the next line after reading. If the resulting string is longer than the maximum length of the string variable, it is truncated.

After the first Read, each subsequent Read sees the end-of-line marker and returns a zero-length string.

Use multiple Readln calls to read successive string values.

When the extended syntax is enabled, Read can read null-terminated strings into zero-based character arrays.

Read reads one character from the file and assigns it to the variable. If CRLF mode is enabled and Eof (see page 3558)(F) was true before Read was executed, the value Chr (see page 3536)(26) (a Ctrl-Z character) is assigned to the variable. (To enable CRLF mode, use SetLineBreakStyle (see page 3659).)

Read skips any blanks, tabs, or end-of-line markers preceding the numeric string.

If the numeric string does not conform to the expected format, an I/O error occurs; otherwise, the value is assigned to the variable.

The next Read starts with the blank, tab, or end-of-line marker that terminated the numeric string.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: AnsiChar;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
```

```
        begin
          Read(F1, Ch);
          Write(F2, Ch);
        end;
        CloseFile(F2);
      end;
      CloseFile(F1);
    end;
  end;
```

See Also

Eof (see page 3558)

ReadLn (see page 3636)

Write (see page 3707)

WriteLn (see page 3710)

SetLineBreakStyle (see page 3659)

35.3.118 System.ReadLn Function

Reads a line of text from a file.

Pascal

```
procedure ReadLn(V1); overload;
procedure ReadLn(V1; Vn); overload;
procedure ReadLn(var F: Text; V1); overload;
procedure ReadLn(var F: Text; V1; Vn); overload;
```

C++

```
ReadLn( V1);
ReadLn( V1,  Vn);
ReadLn(Text F,  V1);
ReadLn(Text F,  V1,  Vn);
```

File

System

Description

In Delphi code, the ReadLn procedure reads a line of text and then skips to the next line of the file.

The syntax shown here for ReadLn demonstrates that the procedure can take a variable number of arguments.

ReadLn(F) with no parameters causes the current file position to advance to the beginning of the next line if there is one; otherwise, it goes to the end of the file.

If F is omitted, the global variable Input (see page 3827) is used, which accesses the processes standard input file. Use of Input (see page 3827) in GUI applications raises special issues.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example assumes you are compiling as a console
application.  Notice how the form deactivates when the button
click procedure exits.
}
```

```
{$APPTYPE CONSOLE}

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  Write('Enter a line of text: ');
  Readln(s);
  Writeln('You typed: ',s);
  Writeln('Hit <Enter> to exit');
  Readln;
end;
{
Use a TOpenDialog to select a file.  Place the first line of
the file into a TEdit.  Click on the text edit to open the
open dialog box.
}
procedure TForm1.Edit1Click(Sender: TObject);
var
  F: TextFile;
  S: string;
begin
  if OpenDialog1.Execute then            { Display Open dialog box }
  begin
    AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
    Reset(F);
    Readln(F, S);                        { Read first line of file }
    Edit1.Text := S;                     { Put string in a TEdit control }
    CloseFile(F);
  end;
end;
```

SetLineBreakStyle (see page 3659)

35.3.119 System.ReallocMem Function

ReallocMem reallocates a memory block.

Pascal

```
procedure ReallocMem(var P: Pointer; Size: Integer);
```

C++

```
ReallocMem(void * P, int Size);
```

File

System

Description

GetMem (see page 3584) allocates a block of the given **Size** on the heap. If you need to change the size of this memory block, call ReallocMem, passing the existing memory block pointer in **P**, and the revised block size in **Size**. If ReallocMem can't expand the memory block pointed to by **P**, it frees the referenced memory and copies the values to the newly allocated memory that is returned.

If there isn't enough memory available to extend the memory block to the desired size, an EOutOfMemory exception is raised.

Note: ReallocMemory (see page 3638) is the C++ compatible version of ReallocMem.

Delphi Examples:

```
{
The following code demostrates the use of ReallocMem function. Three
edit boxes and a button are expected onthe form.
}
function FastStrCat(const S1, S2: String): String;
var
  FinalStr: PChar;
begin
  {
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  }
  GetMem(FinalStr, (Length(S1) + 1) * SizeOf(Char));

  { Copy the contents of the first string }
  MoveChars(S1[1], FinalStr^, Length(S1) + 1);

  { And now expand the final string + $00 character }
  ReallocMem(FinalStr, (Length(S1) + Length(S2) + 1) * SizeOf(Char));

  { Copy the contents of the second string }
  MoveChars(S2[1], FinalStr[Length(S1)], Length(S2) + 1);

  { Get the result in String }
  SetString(Result, FinalStr, Length(S1) + Length(S2));
  FreeMem(FinalStr);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  { Concatenate 2 string }
  Edit3.Text := FastStrCat(Edit1.Text, Edit2.Text);
end;
```

35.3.120 System.ReallocMemory Function

ReallocMemory resizes a memory block.

Pascal

```
function ReallocMemory(P: Pointer; Size: Integer): Pointer; cdecl;
```

C++

```
__cdecl void * ReallocMemory(void * P, int Size);
```

File

System

Description

GetMem (see page 3584) allocates a block of the given **Size** on the heap. If you need to change the size of this memory block, call ReallocMemory, passing the existing memory block pointer in **P**, and the revised block size in **Size**. A pointer to the resized memory block is returned. If ReallocMemory can't expand the memory block pointed to by **P**, it frees the referenced memory and copies the values to the newly allocated memory that is returned.

If there isn't enough memory available to extend the memory block to the desired size, an EOutOfMemory exception is raised.

Note: ReallocMemory is the C++ compatible version of ReallocMem (see page 3637).

C++ Examples:

```
/*
The following code demostrates the use of memory management functions in C++. Three
edit boxes and a button are expected onthe form.
*/
String __fastcall FastStrCat(String s1, String s2)
{
  /*
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  */
  wchar_t* finalStr = (wchar_t *)GetMemory((s1.Length() + 1) * sizeof(wchar_t));

  // Copy the contents of the first string
  MoveChars(s1.data(), finalStr, s1.Length() + 1);

  // And now expand the final string + $00 character
  finalStr = (wchar_t *)ReallocMemory(finalStr, (s1.Length() + s2.Length() + 1) *
sizeof(wchar_t));

  // Copy the contents of the second string
  MoveChars(s2.data(), finalStr + s1.Length(), s2.Length() + 1);

  // Get the result in String
  String result = String(finalStr);
  FreeMemory(finalStr);

  return result;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Concatenate 2 string
  Edit3->Text = FastStrCat(Edit1->Text, Edit2->Text);
}
```

EOutOfMemory (see page 3942)

ReallocMem (see page 3637)

35.3.121 System.RegisterExpectedMemoryLeak Function

Registers an expected memory leak.

Pascal

```
function RegisterExpectedMemoryLeak(P: Pointer): boolean;
```

C++

```
boolean RegisterExpectedMemoryLeak(void * P);
```

File

System

Description

RegisterExpectedMemoryLeak registers a memory location that an application has allocated and does not expect to free.

See Also

Memory Management

Configuring the Memory Manager

Registering Memory Leaks

UnregisterExpectedMemoryLeak (see page 3694)

ReportMemoryLeaksOnShutdown (see page 3835)

35.3.122 System.RegisterModule Function

Registers the specified module.

Pascal

```
procedure RegisterModule(LibModule: PLibModule);
```

C++

```
RegisterModule(PLibModule LibModule);
```

File

System

Description

This is an internal function and should not be used directly.

See Also

UnregisterModule (see page 3694)

35.3.123 System.Release Function

Pascal

```
procedure Release; deprecated;
```

C++

```
Release();
```

File

System

Description

This is function System.Release.

35.3.124 System.ReleaseExceptionObject Function

Releases exception object acquired by AcquireExceptionObject (see page 3512).

Pascal

```
procedure ReleaseExceptionObject;
```

C++

```
ReleaseExceptionObject();
```

File

System

Description

ReleaseExceptionObject releases an exception object previously acquired by AcquireExceptionObject (see page 3512).

See Also

AcquireExceptionObject (see page 3512)

ExceptObject (see page 3562)

35.3.125 System.RemoveModuleUnloadProc Function

RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.

Pascal

```
procedure RemoveModuleUnloadProc(Proc: TModuleUnloadProc); overload;
procedure RemoveModuleUnloadProc(Proc: TModuleUnloadProcLW); overload;
```

C++

```
RemoveModuleUnloadProc(TModuleUnloadProc Proc);
RemoveModuleUnloadProc(TModuleUnloadProcLW Proc);
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your **Proc** routine. In essence, AddModuleUnloadProc (see page 3514) adds your routine to the head of the list of internal routines that Delphi invokes to perform the unload. RemoveModuleUnloadProc reverses the effect of AddModuleUnloadProc (see page 3514).

See Also

AddModuleUnloadProc (see page 3514)

TModuleUnloadProc (see page 3792)

35.3.126 System.Rename Function

Changes the name of an external file.

Pascal

```
procedure Rename(var F; Newname: string); overload;
procedure Rename(var F; Newname: PChar); overload;
```

C++

```
Rename( F, UnicodeString Newname);
Rename( F, const char * Newname);
```

File

System

Description

The external file associated with F is renamed Newname. Further operations on F operate on the external file with the new name.

F is a variable of any file type. Newname is a string-type expression or an expression of type PChar if the extended syntax is enabled.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example requires a button, an open dialog and a save
dialog.  Click the button to rename a file.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  f : file;
begin
  OpenDialog1.Title := 'Choose a file... ';
  if OpenDialog1.Execute then
  begin
    SaveDialog1.Title := 'Rename to...';
    if SaveDialog1.Execute then
    begin
```

```
        AssignFile(f, OpenDialog1.FileName);
        Canvas.TextOut(5, 10, 'Renaming ' + OpenDialog1.FileName +
                       ' to ' + SaveDialog1.FileName);
        Rename(f, SaveDialog1.FileName);
      end;
    end;
  end;
```

See Also

Rename File

35.3.127 System.Reset Function

Opens an existing file.

Pascal

```
procedure Reset(var F); overload;
procedure Reset(var F; RecSize: Word); overload;
procedure Reset(var F: File); overload;
procedure Reset(var F: File; RecSize: Word); overload;
```

C++

```
Reset( F);
Reset( F, Word RecSize);
Reset(File F);
Reset(File F, Word RecSize);
```

File

System

Description

In Delphi code, Reset opens the existing external file with the name assigned to F using the mode specified by the global FileMode (see page 3824) variable. An error results if no existing external file of the given name exists or if the file can't be opened with the current file mode. If F is already open, it is first closed and then reopened. The current file position is set to the beginning of the file.

Warning: The default value of FileMode (see page 3824) is 2 (Read (see page 3634)/Write (see page 3707) access). If this is not changed to a read-only file mode before calling Reset, attempts to open read-only files will fail.

F is a variable of any file type associated with an external file using AssignFile (see page 3525). RecSize is an optional expression, which can be specified only if F is an untyped file. If F is an untyped file, RecSize specifies the record size to be used in data transfers. If RecSize is omitted, a default record size of 128 bytes is assumed.

If F is assigned an empty name, such as AssignFile (see page 3525)(F, ''), then after the call to Reset, F refers to the standard input file.

If F is a text file, F becomes read-only.

After a call to Reset, Eof (see page 3558)(F) is true if the file is empty; otherwise, Eof (see page 3558)(F) is false.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
```

```
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], fmOpenWrite);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode fmOpenWrite.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
    end;
   finally
   { do something here }
   end;
  end;
end;
{
This example should be executed from a command line
formatted like this: "SystemReset_proj foo.txt".  The file
path is relative to the project directory.
}
function FileIsThere(FileName: string): Boolean;
{ Boolean function that returns True if the file exists; otherwise,
  it returns False. Closes the file if it exists. }
 var
  F: file;
begin
  {$I-}
  AssignFile(F, FileName);
  FileMode := 0;  {Set file access to read only }
  Reset(F);
  CloseFile(F);
  {$I+}
  FileIsThere := (IOResult = 0) and (FileName <> '');
end;  { FileIsThere }

procedure TForm1.Button1Click(Sender: TObject);
begin
```

```
    if FileIsThere(ParamStr(1)) then {Get file name from command line}
      Canvas.TextOut(10, 10, 'File exists')
    else
      Canvas.TextOut(10, 10, 'File not found');
  end;
  {
  Click the button to open a TOpenDialog, then select a file
  to delete.
  }

  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: Textfile;
  begin
    OpenDialog1.Title := 'Delete File';
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      try
        Reset(F);
        if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
          mtConfirmation, [mbYes, mbNo], 0) = mrYes then
        begin
          CloseFile(F);
          Erase(F);
        end;
      except
        on EInOutError do
          MessageDlg('File I/O error.', mtError, [mbOk], 0);
      end;
    end;
  end;
```

Truncate (see page 3685)

FileMode (see page 3824)

35.3.128 System.Rewrite Function

Creates a new file and opens it.

Pascal

```
procedure Rewrite(var F: File); overload;
procedure Rewrite(var F: File; Recsize: Word); overload;
```

C++

```
Rewrite(File F);
Rewrite(File F, Word Recsize);
```

File

System

Description

In Delphi code, Rewrite creates a new external file with the name assigned to F.

F is a variable of any file type associated with an external file using AssignFile (see page 3525). RecSize is an optional expression, which can be specified only if F is an untyped file. If F is an untyped file, RecSize specifies the record size to be used in data transfers. If RecSize is omitted, a default record size of 128 bytes is assumed.

If an external file with the same name already exists, it is deleted and a new empty file is created in its place.

If F is already open, it is first closed and then re-created. The current file position is set to the beginning of the empty file.

If F was assigned an empty name, such as AssignFile (see page 3525)(F,''), then after the call to Rewrite, F refers to the standard output file.

If F is a text file, F becomes write-only.

After calling Rewrite, Eof (see page 3558)(F) is always true.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.  Validate
the saved file contents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      // Use CloseFile rather than Close; Close provided for backward compatibility
      CloseFile(FromF);
      CloseFile(ToF);
      Canvas.TextOut(120, 10, ' done.');
    end;
  end;
end;
{
Rewrite example
}

procedure TForm1.Button1Click(Sender: TObject);
var F: TextFile;
begin
  AssignFile(F, 'NEWFILE.$$$');
  Rewrite(F);  // default record size is 128 bytes
```

```
  Writeln(F, 'Just created file with this text in it...');
  CloseFile(F);
  MessageDlg('NEWFILE.$$$ has been created in the ' + GetCurrentDir + ' directory.',
    mtInformation, [mbOk], 0, mbOK);
end;
```

35.3.129 System.RmDir Function

Deletes an empty subdirectory.

Pascal

```
procedure RmDir(const S: string); overload;
procedure RmDir(P: PChar); overload;
```

C++

```
RmDir(const UnicodeString S);
RmDir(const char * P);
```

File

System

Description

RmDir removes the subdirectory with the path specified by S or P. If the path does not exist, is non-empty, or is the currently logged directory, an I/O error occurs.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example requires a text edit and a button.  Enter the
folder to remove in the text edit and click the button.  The
path is relative to the project folder.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   {$I-}
   { Get directory name from TEdit control }
   RmDir(Edit1.Text);
   if IOResult <> 0 then
     MessageDlg('Cannot remove directory', mtWarning, [mbOk], 0, mbOk)
   else
     MessageDlg('Directory removed', mtInformation, [mbOk], 0, mbOk);
end;
```

See Also

ChDir (see page 3534)

GetDir (see page 3580)

MkDir (see page 3612)

RemoveDir (see page 4232)

35.3.130 System.Round Function

Returns the value of X rounded to the nearest whole number.

Pascal

```
function Round(X: Extended): Int64;
```

C++

```
Int64 Round(Extended X);
```

File

System

Description

In Delphi, the Round function rounds a real-type value to an integer-type value.

X is a real-type expression. Round returns an Int64 value that is the value of X rounded to the nearest whole number. If X is exactly halfway between two whole numbers, the result is always the even number. This method of rounding is often called "Banker's Rounding".

If the rounded value of X is not within the Int64 range, a runtime error is generated, which can be handled using the EInvalidOp exception.

Note: The behavior of Round can be affected by the Set8087CW (see page 3653) procedure or SetRoundMode function.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
  ScrollBar1.Position := new;
  Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
end;
```

```
procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
  var ScrollPos: Integer);
begin
  Edit1.Text := FloatToStr(ScrollPos/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
end;
{
This example illustrates the rules for rounding positive and
negative real numbers to integers.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   S, T: string;
begin
   Str(1.4:2:1, T);
   S := T + ' rounds to ' + IntToStr(Round(1.4)) + #13#10;
   Str(1.5:2:1, T);
   S := S + T + ' rounds to ' + IntToStr(Round(1.5)) + #13#10;
   Str(-1.4:2:1, T);
   S := S + T + ' rounds to ' + IntToStr(Round(-1.4)) + #13#10;
   Str(-1.5:2:1, T);
   S := S + T + ' rounds to ' + IntToStr(Round(-1.5));
   MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

SimpleRoundTo

35.3.131 System.RunError Function

Stops execution and generates a runtime error.

Pascal

```
procedure RunError; overload;
procedure RunError(Errorcode: Byte); overload;
```

C++

```
RunError();
RunError(Byte Errorcode);
```

File

System

Description

In Delphi, the RunError procedure stops program execution by generating a runtime error with the given number at the current statement. Errorcode is the runtime error number (0 if omitted).

Delphi Examples:

```
{
```

```
This example demonstrates how to set a run error, the behavior of
execution and the message that follows.
}
var P: Pointer;

procedure TForm1.Button1Click(Sender: TObject);
begin
{$IFDEF Debug}
  if P = nil then
    RunError(204);
{$ENDIF}
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  P:= nil;
end;
```

See Also

Halt (see page 3594)

35.3.132 System.Seek Function

Moves the current position of a file to a specified component.

Pascal

```
procedure Seek(var F; N: Longint);
```

C++

```
Seek( F, Longint N);
```

File

System

Description

Use Seek in Delphi code to move to a specified position in open typed or untyped files. The current file position of F moves to component number N, where the number of the first component of a file is 0.

In the above syntax, F is a typed or untyped file variable. The file specified by F must be open. N is an expression of type Longint

To expand a file, seek one component beyond the last component; that is, the statement Seek(F, FileSize (see page 3569)(F)) moves the current file position to the end of the file.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example displays a open dialog when the user clicks a
button. When the user selects the file, it reports the size
of the file, seeks to halfway through the file, and reports
the file position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON
($I+). That is, it expects errors to generate exceptions
rather than checking IOResult to be sure that I/O routines
succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
   f: file of Byte;
   size: Longint;
   S: string;
   y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      S := 'Seeking halfway into file...';
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      Seek(f, size div 2);
      S := 'Position is now ' + IntToStr(FilePos(f));
      Canvas.TextOut(5, y, S);
    finally
      CloseFile(f);
    end;
  end;
end;
```

See Also

FilePos (see page 3567)

35.3.133 System.SeekEof Function

Returns the end-of-file status of a file, ignoring whitespace.

Pascal

```
function SeekEof: Boolean; overload;
function SeekEof(var F: Text): Boolean; overload;
```

C++

```
Boolean SeekEof();
Boolean SeekEof(Text F);
```

File

System

Description

In Delphi code, call SeekEof to determine whether there is only whitespace between the file pointer and the end of a file. SeekEof moves the file pointer past any whitespace, leaving it positioned at the end of a file or on the next non-whitespace character, whichever comes first. If it leaves the file pointer at the end of the file, SeekEof returns true. Otherwise, it returns false.

SeekEof can only be used on open text files.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
This example creates a file TEST.TXT, puts some text in it
and then reads the file to EOF.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f : System.TextFile;
   j, Y : Integer;
 begin
   AssignFile(f,'TEST.TXT');
   Rewrite(f);
   { Create a file with 8 numbers and some
     whitespace at the ends of the lines }
   Writeln(f,'1 2 3 4 ');
   Writeln(f,'5 6 7 8 ');
   Reset(f);
   { Read the numbers back. SeekEof returns TRUE if there is no
     more text (other than whitespace) in the file. }
   Y := 5;
   while not SeekEof(f) do
   begin
     Read(f,j);
     Canvas.TextOut(5, Y, IntToStr(j));
     Y := Y + Canvas.TextHeight(IntToStr(j)) + 5;
   end;
 end;
```

SetLineBreakStyle (see page 3659)

35.3.134 System.SeekEoln Function

Returns the end-of-line status of a file, ignoring whitespace.

Pascal

```
function SeekEoln: Boolean; overload;
function SeekEoln(var F: Text): Boolean; overload;
```

C++

```
Boolean SeekEoln();
Boolean SeekEoln(Text F);
```

File

System

Description

In Delphi code, call SeekEoln to determine whether there is only whitespace between the file pointer and the end of the current line. SeekEoln moves the file pointer past any whitespace, leaving it positioned at the end of the current line, the end of the file, or on the next non-whitespace character (whichever comes first). If SeekEoln leaves the file pointer at the end of the current line or at the end of the file, it returns true. Otherwise, it returns false.

SeekEoln can be used only on open text files.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 3602) to check for I/O errors.

Delphi Examples:

```
{
Create data with white space at beginning and end of line to
demonstrate that SeekEoln is immune to this.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: System.TextFile;
   j, Y: Integer;
   s: string;
begin
   AssignFile(f,'TEST.TXT');
   Rewrite(f);

   Writeln(f, '    1 2 3 4      ');
   Writeln(f, 'Some text');

   Reset(f);
   Y := 5;

   while not SeekEoln(f) do // Will skip white space
   begin
     Read(f, j);
     Canvas.TextOut(5, Y, IntToStr(j));
     Y := Y + Canvas.TextHeight(IntToStr(j)) + 5;
   end;
   Readln(f); // Read line-end marker

   Readln(f, s); // Read string with line-end marker
   Canvas.TextOut(5, Y, s);
end;
```

35.3.135 System.Set8087CW Function

Sets both the control word in the floating point unit and the variable NoErrMsg (see page 3832) declared in the system unit.

Pascal

```
procedure Set8087CW(NewCW: Word);
```

C++

```
Set8087CW(Word NewCW);
```

File

System

Description

The floating-point unit control word controls the precision of floating point calculations, the rounding mode, and whether certain floating-point operations trigger exceptions. See Intel's processor documentation for details.

This routine allows the programmer to have direct access to the CW. Be aware that using this routine to change the value of the

8087CW will change the behavior of the program's FP calculations. It is the programmer's responsibility to reset it.

It is recommended that you disable all floating-point exceptions when using OpenGL to render 3D graphics. To do this, call Set8087CW(0x133f) in your main form's OnCreate event before calling any OpenGL functions.

C++ Examples:

```
/*
This example accesses the Floating Point Unit (FPU) control
register.  Try turning floating point exceptions off and on
and dividing a number by zero to test it.
*/
Word Saved8087CW;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit3->Text = FloatToStr(StrToFloat(Edit1->Text) / StrToFloat(Edit2->Text));
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "FPU Exceptions")
    System::Set8087CW(Saved8087CW);
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "No FPU Exceptions")
    System::Set8087CW(0x133f); // Disable all fpu exceptions
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("No FPU Exceptions");
  RadioGroup1->Items->Add("FPU Exceptions");
  RadioGroup1->ItemIndex = 2;
  Saved8087CW = Default8087CW;  // Save this because Set8087CW changes it!
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  System::Set8087CW(Saved8087CW); // Default value (with exceptions) is 0x1372
}
```

Delphi Examples:

```
{
This example accesses the Floating Point Unit (FPU) control
register.  Try turning floating point exceptions off and on
and dividing a number by zero to test it.
}
var
  Form1: TForm1;
  Saved8087CW: Word;

implementation

{$R *.dfm}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit3.Text := FloatToStr(StrToFloat(Edit1.Text) / StrToFloat(Edit2.Text));
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'FPU Exceptions' then
    System.Set8087CW(Saved8087CW);
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'No FPU Exceptions' then
    System.Set8087CW($133f); { Disable all fpu exceptions }
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('No FPU Exceptions');
  RadioGroup1.Items.Add('FPU Exceptions');
  RadioGroup1.ItemIndex := 2;
  Saved8087CW := Default8087CW;  // Save this because Set8087CW changes it!
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  System.Set8087CW(Saved8087CW); // Default value (with exceptions) is $1372
end;
```

35.3.136 System.SetCodePage Function

Pascal

```
procedure SetCodePage(var S: RawByteString; CodePage: Word; Convert: Boolean = True);
```

C++

```
SetCodePage(RawByteString S, Word CodePage, Boolean Convert = True);
```

File

System

Description

This is function System.SetCodePage.

35.3.137 System.SetInOutRes Function

Pascal

```
procedure SetInOutRes(NewValue: Integer);
```

C++

```
SetInOutRes(int NewValue);
```

File

System

Description

This is function System.SetInOutRes.

35.3.138 System.SetLastError Function

SetLastError sets the last API error code.

Pascal

```
procedure SetLastError(ErrorCode: Integer); stdcall;
```

C++

```
__stdcall SetLastError(int ErrorCode);
```

File

System

Description

GetLastError (see page 3582) returns the last API error code encountered. It then resets it to 0. SetLastError forces the API error code to the specified **ErrorCode** value. A call to GetLastError (see page 3582) will then return this value before again resetting the error code to 0.

C++ Examples:

```
//
//This code demonstrates the use of system error codes
//and how to use transform them into C++ exceptions.
//
void __fastcall TForm2::btRaiseLastClick(TObject *Sender)
{
    /* Set the last OS error to a bogus value */
    System::SetLastError(ERROR_ACCESS_DENIED);

    try
    {
        RaiseLastOSError();
    }
    catch(EOSError* ex)
    {
        MessageDlg(String("Caught an OS error with code: ") +
            IntToStr((int)ex->ErrorCode), mtError,
            TMsgDlgButtons() << mbOK, 0);
    }

    /* Let the Delphi's Exception dialog pop-up */
    RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

    /* Finally set the last error to none */
    System::SetLastError(ERROR_SUCCESS);

    if (GetLastError() != ERROR_SUCCESS)
        MessageDlg(String("Whoops, something went wrong ") +
          " in the mean time!", mtError, TMsgDlgButtons() << mbOK, 0);

    /* No exception should be thrown here */
    RaiseLastOSError();
}
```

Delphi Examples:

```
{
This code demonstrates the use of system error codes
and how to transform them into Delphi exceptions.
```

```
}
procedure TForm2.btRaiseLastClick(Sender: TObject);
begin
  { Set the last OS error to a bogus value }
  System.SetLastError(ERROR_ACCESS_DENIED);

  try
    RaiseLastOSError();
  except
    on Ex : EOSError do
       MessageDlg('Caught an OS error with code: ' +
          IntToStr(Ex.ErrorCode), mtError, [mbOK], 0);
  end;

  { Let the Delphi's Exception dialog pop-up }
  RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

  { Finally set the last error to none }
  System.SetLastError(ERROR_SUCCESS);

  if GetLastError() <> ERROR_SUCCESS then
     MessageDlg('Whoops, something went wrong in the ' +
                'mean time!', mtError, [mbOK], 0);

  { No exception should be thrown here }
  RaiseLastOSError();
end;
```

See Also

GetLastError (see page 3582)

35.3.139 System.SetLength Function

Sets the length of a string or dynamic-array variable.

Pascal

```
procedure SetLength(var S; NewLength: Integer);
```

C++

```
SetLength( S, int NewLength);
```

File

System

Description

S is a Delphi string or dynamic-array variable.

NewLength is the new number of characters or elements in S.

For a short-string variable, SetLength simply sets the length-indicator character (the character at S[0]) to the given value. In this case, NewLength must be a value between 0 and 255.

For a long-string or dynamic-array variable, SetLength reallocates the string or array referenced by S to the given length. Existing characters in the string or elements in the array are preserved, but the content of newly allocated space is undefined. The one exception is when increasing the length of a dynamic array in which the elements are types that must be initialized (strings, Variants (see page 4973), Variant (see page 3421) arrays, or records that contain such types). When S is a dynamic array of types that must be initialized, newly allocated space is set to 0 or nil.

For dynamic arrays, SetLength may take more than one length parameter (up to the number of array dimensions). Each parameter specifies the number of elements along a particular dimension.

Following a call to SetLength, S is guaranteed to reference a unique string or array—that is, a string or array with a reference count of one. If there is not enough memory available to reallocate the variable, SetLength raises an EOutOfMemory exception.

Delphi Examples:

```
{
This example determines the encoding of a source file and then
writes the file in any encoding chosen.  Use this project to
create files of any encoding.  This example requires two text edits
and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
  LOffset: Integer;
  LEncoding, DestEncoding: TEncoding;
  LFileStream: TFileStream;
  EncodingArray: array[0..5] of TEncoding;
begin
  LEncoding:= nil;
  EncodingArray[0]:= TEncoding.UTF8;
  EncodingArray[1]:= TEncoding.UTF7;
  EncodingArray[2]:= TEncoding.Unicode;
  EncodingArray[3]:= TEncoding.Default;
  EncodingArray[4]:= TEncoding.BigEndianUnicode;
  EncodingArray[5]:= TEncoding.ASCII;
  DestEncoding := EncodingArray[ComboBox1.ItemIndex];
  LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
  try
    // Read file into buffer
    SetLength(LBuffer, LFileStream.Size);
//    LFileStream.Read(LBuffer[0], Length(LBuffer));
    LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));

    // Identify encoding and convert buffer to UTF8
    LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
//    for I := 0 to Length(LBuffer) - 1 do
//      Memo1.Lines.Add((LBuffer[I]));
    LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
      LOffset, Length(LBuffer) - LOffset);
  finally
    LFileStream.Free;
  end;

  LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
  try
    // Write an encoding byte order mark and buffer to output file
    LByteOrderMark := DestEncoding.GetPreamble;
    LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
    LFileStream.Write(LBuffer[0], Length(LBuffer));
  finally
    LFileStream.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  StringList: TStrings;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
```

```
        Add('TEncoding.UTF8');
        Add('TEncoding.UTF7');
        Add('TEncoding.Unicode');
        Add('TEncoding.Default');
        Add('TEncoding.BigEndianUnicode');
        Add('TEncoding.ASCII');
      end;
      with ComboBox1 do begin
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

EOutOfMemory (see page 3942)

35.3.140 System.SetLineBreakStyle Function

Determines the end-of-line and end-of-file conventions for text file I/O.

Pascal

```
procedure SetLineBreakStyle(var T: Text; Style: TTextLineBreakStyle);
```

C++

```
SetLineBreakStyle(Text T, TTextLineBreakStyle Style);
```

File

System

Description

In Delphi, call SetLineBreakStyle to determine how text file routines find or mark the end of a line and the end of a file. Affected routines include Read (see page 3634), Write (see page 3707), ReadLn (see page 3636), WriteLn (see page 3710), Eof (see page 3558), Eoln (see page 3559), SeekEof (see page 3651), and SeekEoln (see page 3652).

T is the text file whose line break style is altered. It must be closed, or SetLineBreakStyle generates a runtime error.

Style indicates the style to use. When Style is tlbsLF, end-of-line is marked using only a linefeed character. When Style is tlbsCRLF, end-of-line is marked using a carriage return and linefeed.

35.3.141 System.SetMemoryManager Function

Sets entry points of the memory manager.

Pascal

```
procedure SetMemoryManager(const MemMgr: TMemoryManager); overload; deprecated;
procedure SetMemoryManager(const MemMgrEx: TMemoryManagerEx); overload;
```

C++

```
SetMemoryManager(const TMemoryManager MemMgr);
SetMemoryManager(const TMemoryManagerEx MemMgrEx);
```

File

System

Description

SetMemoryManager sets the entry points of the memory manager to the three functions encapsulated by the MemMgr parameter. Use SetMemoryManager to change the memory allocation routines that are used for:

Allocation and deallocation of dynamic strings and dynamic arrays.

The GetMem (see page 3584), ReallocMem (see page 3637), and FreeMem (see page 3577) standard procedures (Delphi only)

The New (see page 3619) and Dispose (see page 3553) standard procedures (Delphi only).

C++ Examples:

```
/*
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
*/

bool isMyMemMgr;
TMemoryManagerEx oldMemMgr;
volatile long getMemCalls;
volatile long freeMemCalls;
volatile long reallocMemCalls;
volatile long allocMemCalls;

void* __fastcall myGetMem(int size)
{
    //safely increment the counter
    InterlockedIncrement(&getMemCalls);

    //route the call
    return oldMemMgr.GetMem(size);
}

int __fastcall myFreeMem(void* p)
{
    //safely increment the counter
    InterlockedIncrement(&freeMemCalls);

    //route the call
    return oldMemMgr.FreeMem(p);
}
```

```
void* __fastcall myReallocMem(void* p, int size)
{
    //safely increment the counter
    InterlockedIncrement(&reallocMemCalls);

    //route the call
    return oldMemMgr.ReallocMem(p, size);
}

void* __fastcall myAllocMem(int size)
{
    //safely increment the counter
    InterlockedIncrement(&allocMemCalls);

    //route the call
    return oldMemMgr.AllocMem(size);
}

void __fastcall TForm3::btUseSysMemMgrClick(TObject *Sender)
{
    //switch button states
    btUseSysMemMgr->Enabled = false;
    btUseMyMemMgr->Enabled = true;

    //set the old memory manager back
    SetMemoryManager(oldMemMgr);

    isMyMemMgr = false;

    //clear out the variables
    getMemCalls     = 0;
    freeMemCalls    = 0;
    reallocMemCalls = 0;
    allocMemCalls   = 0;
}

void __fastcall TForm3::FormDestroy(TObject *Sender)
{
    //set the old memory manager back
    if (isMyMemMgr)
    {
        SetMemoryManager(oldMemMgr);
    }
}

void __fastcall TForm3::Timer1Timer(TObject *Sender)
{
    //Note that IntToStr calls will also Allocate/Free
    //memory so at each timer tick the counts will be +4;

    Form3->edGetMem->Text = IntToStr((int)getMemCalls);
    Form3->edFreeMem->Text = IntToStr((int)freeMemCalls);
    Form3->edReallocMem->Text = IntToStr((int)reallocMemCalls);
    Form3->edAllocMem->Text = IntToStr((int)allocMemCalls);
}

void __fastcall TForm3::btUseMyMemMgrClick(TObject *Sender)
{
    TMemoryManagerEx myMemMgr;

    //switch button states
    btUseSysMemMgr->Enabled = true;
    btUseMyMemMgr->Enabled = false;

    //get the old memory manager
```

```
    GetMemoryManager(oldMemMgr);

    //create out instance
    myMemMgr.GetMem = myGetMem;
    myMemMgr.FreeMem = myFreeMem;
    myMemMgr.AllocMem = myAllocMem;
    myMemMgr.ReallocMem = myReallocMem;

    //use defaults for this - not important
    myMemMgr.RegisterExpectedMemoryLeak = oldMemMgr.RegisterExpectedMemoryLeak;
    myMemMgr.UnregisterExpectedMemoryLeak = oldMemMgr.UnregisterExpectedMemoryLeak;

    //clear out the variables
    getMemCalls     = 0;
    freeMemCalls    = 0;
    reallocMemCalls = 0;
    allocMemCalls   = 0;

    //install the new memory manager
    SetMemoryManager(myMemMgr);

    isMyMemMgr = true;
}

void __fastcall TForm3::btDoSomethingClick(TObject *Sender)
{
    void *ptr;
    //perform some new and delete
    for (int i=0; i < 1000; ++i)
    {
        ptr = GetMemory(4);
        FreeMemory(ptr);
    }
}
```

Delphi Examples:

```
{
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
}
var
  OldMemMgr       : TMemoryManagerEx;
  GetMemCalls     : Integer;

35.3.142 System.SetMinimumBlockAlignment Function

Sets the minimum memory block alignment.

Pascal

```
procedure SetMinimumBlockAlignment(AMinimumBlockAlignment: TMinimumBlockAlignment);
```

C++

```
SetMinimumBlockAlignment(TMinimumBlockAlignment AMinimumBlockAlignment);
```

File

System

Description

SetMinimumBlockAlignment sets the Memory Manager's minimum block alignment. Existing allocations are not affected if this

setting is changed. The memory manager will enforce the new setting for all allocations made after the change.

Memory Management

Configuring the Memory Manager

35.3.143 System.SetMultiByteConversionCodePage Function

Sets the code page used internally whenever multibyte characters are converted to/from WideChar.

Pascal

```
procedure SetMultiByteConversionCodePage(CodePage: Integer);
```

C++

```
SetMultiByteConversionCodePage(int CodePage);
```

File

System

Description

SetMultiByteConversionCodePage sets the code page used internally whenever multibyte characters are converted to or from WideChar. The default is the active system code page. This function allows you to override the default.

35.3.144 System.SetRaiseList Function

Pascal

```
function SetRaiseList(NewPtr: Pointer): Pointer; deprecated;
```

C++

```
void * SetRaiseList(void * NewPtr);
```

File

System

Description

This is function System.SetRaiseList.

35.3.145 System.SetString Function

Sets the contents and length of the given string.

Pascal

```
procedure SetString(var s: string; buffer: PChar; len: Integer);
```

C++

```
SetString(UnicodeString s, const char * buffer, int len);
```

File

System

Description

In Delphi code, SetString sets the contents and length of the given string variable to the block of characters given by the Buffer and Len parameters.

For a short string variable, SetString sets the length indicator character (the character at **S**[0]) to the value given by **Len** and then, if the **Buffer** parameter is not nil, copies **Len** characters from **Buffer** into the string starting at **S**[1]. For a short string variable, the **Len** parameter must be a value between 0 and 255.

For a long string variable, SetString sets **S** to reference a newly allocated string of the given length. If the **Buffer** parameter is not nil, SetString then copies **Len** characters from **Buffer** into the string; otherwise, the contents of the new string is left uninitialized. If there is not enough memory available to create the string, an EOutOfMemory exception is raised. Following a call to SetString, **S** is guaranteed to reference a unique string, that is a string with a reference count of one.

Delphi Examples:

```
{
The following code demostrates the use of ReallocMem function. Three
edit boxes and a button are expected onthe form.
}
function FastStrCat(const S1, S2: String): String;
var
  FinalStr: PChar;
begin
  {
   Allocated enough space in FinalStr to copy the contents
   of the initial string + $00 character
  }
  GetMem(FinalStr, (Length(S1) + 1) * SizeOf(Char));

  { Copy the contents of the first string }
  MoveChars(S1[1], FinalStr^, Length(S1) + 1);

  { And now expand the final string + $00 character }
  ReallocMem(FinalStr, (Length(S1) + Length(S2) + 1) * SizeOf(Char));

  { Copy the contents of the second string }
  MoveChars(S2[1], FinalStr[Length(S1)], Length(S2) + 1);

  { Get the result in String }
  SetString(Result, FinalStr, Length(S1) + Length(S2));
  FreeMem(FinalStr);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  { Concatenate 2 string }
  Edit3.Text := FastStrCat(Edit1.Text, Edit2.Text);
end;
```

EOutOfMemory (see page 3942)

35.3.146 System.SetTextBuf Function

Assigns an I/O buffer to a text file.

Pascal

```
procedure SetTextBuf(var F: Text; var Buf); overload;
procedure SetTextBuf(var F: Text; var Buf; Size: Integer); overload;
```

C++

```
SetTextBuf(Text F,  Buf);
SetTextBuf(Text F,  Buf, int Size);
```

File

System

Description

In Delphi code, SetTextBuf changes the text file **F** to use the buffer specified by **Buf** instead of F's internal buffer. F is a text file variable, Buf is any variable, and Size is an optional expression.

Each Text file variable has an internal 128-byte buffer that buffers Read (see page 3634) and Write (see page 3707) operations. This buffer is adequate for most operations. However, heavily I/O-bound programs benefit from a larger buffer to reduce disk head movement and file system overhead.

Size specifies the size of the buffer in bytes. If Size is omitted, SizeOf (see page 3670)(Buf) is assumed. The new buffer remains in effect until F is next passed to AssignFile (see page 3525).

SetTextBuf can be called immediately after Reset (see page 3643), Rewrite (see page 3645), and Append (see page 3520), but never apply it to an open file.

When SetTextBuf is called on an open file once I/O operations have taken place, data could be lost because of the change of buffer.

The Delphi runtime library does not ensure that the buffer exists for the entire duration of I/O operations on the file. A common error is to install a local variable as a buffer, then use the file outside the procedure that declared the buffer.

Delphi Examples:

```
{
This example reads a file into a buffer and then dumps
the buffer into a new file WOOF.DOG
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F, FTwo: System.TextFile;
  Ch: Char;
  Buf: array[1..4096] of Char;  { 4K buffer }
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    { Larger buffer for faster reads }
    System.SetTextBuf(F, Buf);
    Reset(F);
    { Dump text file into another file }
    AssignFile(FTwo, 'WOOF.DOG');
    Rewrite(FTwo);
    while not Eof(f) do
    begin
```

```
      Read(F, Ch);
      Write(FTwo, Ch);
    end;
    System.CloseFile(F);
    System.CloseFile(FTwo);
  end;
```

SizeOf (see page 3670)

Write (see page 3707)

35.3.147 System.SetVariantManager Function

Sets the entry points of routines that define variant behavior.

Pascal

```
procedure SetVariantManager(const VarMgr: TVariantManager); deprecated;
```

C++

```
SetVariantManager(const TVariantManager VarMgr);
```

File

System

Description

SetVariantManager sets the entry points of the routines that perform variant type conversion and define other variant behavior.

Note: Although System.hpp defines the SetVariantManager procedure, do not use this routine in C++ code. Customized Variant (see page 3421) support is not fully supported in C++.

See Also

GetVariantManager (see page 3594)

IsVariantManagerSet (see page 3606)

35.3.148 System.ShareMemoryManager Function

Shares the module's memory manager.

Pascal

```
function ShareMemoryManager: Boolean;
```

C++

```
Boolean ShareMemoryManager();
```

File

System

Description

ShareMemoryManager makes the module's memory manager available for sharing to other modules in the same process. Only one memory manager may be shared per process. It returns **False** if another module in the process is already sharing its memory manager.

Note: This function is not thread safe.

See Also

Memory Management

Configuring the Memory Manager

Sharing Memory

35.3.149 System.Sin Function

Returns the sine of the angle in radians.

Pascal

```
function Sin(const X: Extended): Extended;
```

C++

```
Extended Sin(const Extended X);
```

File

System

Description

In Delphi code, the Sin function returns the sine of the argument.

X is a real-type expression. Sin returns the sine of the angle X in radians.

Delphi Examples:

```
{
This example uses the Sine trig function to compute
the sine of Pi.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  R: Extended;
  S: string;
begin
  R := Sin(Pi);
  Str(R:5:3, S);
  Canvas.TextOut(10, 10, 'The Sin of Pi is ' + S);
end;
```

See Also

ArcTan (see page 3521)

Cos (see page 3549)

35.3.150 System.SizeOf Function

Returns the number of bytes occupied by a variable or type.

Pascal

```
function SizeOf(X): Integer;
```

C++

```
int SizeOf( X);
```

File

System

Description

Pass a Delphi variable reference to SizeOf to determine the number of bytes used to represent the variable. Pass a type identifier to SizeOf to determine the number of bytes used to represent instances of that type. SizeOf is useful for determining the amount of memory to specify for the FillChar (see page 3570), Move (see page 3617), or GetMem (see page 3584) procedures.

SizeOf returns 0 when the argument is an untyped variable.

Delphi Examples:

```
{
This example fills a char array with characters and then
assigns the array to a text edit.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: array[0..79] of AnsiChar;
begin
  { Set to all Xs }
  FillChar(S, SizeOf(S), Ord('X'));
  Edit1.Text := S;
end;
{
This example makes a record.  Reports the size of the reocrd,
fills it and reports the contents.
}
type
  CustRec = record
    Name: string[30];
    Phone: string[14];
  end;

procedure TForm1.Button1Click(Sender: TObject);
 var
  P: ^CustRec;
  size: Integer;
begin
  GetMem(P, SizeOf(CustRec));
  Canvas.TextOut(10, 10, 'The size of the record is ' + IntToStr(SizeOf(CustRec)));
  P.Name := 'a12345678901234567890123456789';
  P.Phone := '9,1,4085551212';
  Canvas.TextOut(10, 40, 'Name was assigned this string: ' + P.Name);
  Canvas.TextOut(10, 70, 'Phone was assigned this string: ' + P.Phone);
  size := SizeOf(CustRec);
```

```
  FreeMem (P, size);
end;
```

See Also

FillChar (see page 3570)

GetMem (see page 3584)

Move (see page 3617)

35.3.151 System.Slice Function

Returns a sub-section of an array.

Pascal

```
function Slice(var A: array; Count: Integer): array;
```

C++

```
array Slice(array A, int Count);
```

File

System

Description

In Delphi code, use Slice to select a sub-section (slice) of an array to be passed as an open array parameter. Slice is only allowed as a parameter in a call to a procedure or function that expects an open array parameter. Slice selects the first **Count** elements of the array given by **A** to be passed as an open array parameter. A can be an open array parameter itself, allowing dynamically allocated arrays to be passed to open array parameters.

Delphi Examples:

```
{
This example demonstrates the use and the need for the TThread
Synchronize method by executing three sorting routines in three
separate threads with and without synchronizaiton.
This example is a snippet from the Threads demo in the the
Demos directory of your RAD Studio installation.  Please refer
to that demo for the remaining support code and all design
requirements. The UseSynchronize feature in not implemented
in the demo, but all the changes you need are here.
}
type

{ TSortThread }

  PThreadSortArray = ^TThreadSortArray;
  TThreadSortArray = array[0..MaxInt div SizeOf(Integer) - 1] of Integer;

  TSortThread = class(TThread)

SetLength (see page 3657)

35.3.152 System.Sqr Function

Returns the square of a number.

Pascal

```
function Sqr(X: Extended): Extended; overload;
function Sqr(X: Integer): Integer; overload;
```

C++

```
Extended Sqr(Extended X);
int Sqr(int X);
```

File

System

Description

In Delphi code, the Sqr function returns the square of the argument.

X is a floating-point expression. The result, of the same type as X, is the square of X, or X*X.

Delphi Examples:

```
{
This example uses the System Sqr and Sqrt functions to calculate
the some mathematical values.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  S, Temp: string;
begin
   Str(Sqr(5.5):3:1, Temp);
   S := '5.5 squared is ' + Temp + #13#10;
```

```
   MessageDlg(S, mtInformation, [mbOk], 0);
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  S, Temp: string;
begin
   Str(Sqrt(2.0):5:4, Temp);
   S := S + 'The square root of 2 is ' + Temp;
   MessageDlg(S, mtInformation, [mbOk], 0);
end;
```

Sqrt (see page 3675)

Power

35.3.153 System.Sqrt Function

Returns the square root of X.

Pascal

```
function Sqrt(const X: Extended): Extended;
```

C++

```
Extended Sqrt(const Extended X);
```

File

System

Description

X is a Delphi floating-point expression. The result is the square root of X.

Delphi Examples:

```
{
This example uses the System Sqr and Sqrt functions to calculate
the some mathematical values.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  S, Temp: string;
begin
   Str(Sqr(5.5):3:1, Temp);
   S := '5.5 squared is ' + Temp + #13#10;
   MessageDlg(S, mtInformation, [mbOk], 0);
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  S, Temp: string;
begin
   Str(Sqrt(2.0):5:4, Temp);
   S := S + 'The square root of 2 is ' + Temp;
   MessageDlg(S, mtInformation, [mbOk], 0);
end;
```

See Also

Sqr (see page 3674)

35.3.154 System.Str Function

Formats a string and returns it to a variable.

Pascal

```
procedure Str(X: Width; var S); overload;
procedure Str(X: Decimals; var S); overload;
```

C++

```
Str(Width X,  S);
Str(Decimals X,  S);
```

File

System

Description

In Delphi code, Str converts X to a string representation according to the Width and Decimals formatting parameters. The effect is like a call to Write (see page 3707) except the resulting string is stored in S instead of being written to a text file.

X is an integer-type or real-type expression. Width and Decimals are integer-type expressions. S is a string-type variable or a zero-based character array variable if extended syntax is enabled.

Delphi Examples:

```
{
This example makes a simple string conversion routine
and then prints an integer to the screen.
}

function MakeItAString(I: Longint): string;
{ Convert any integer type to a string }
var
  S: string[11];
begin
  Str(I, S);
  Result:= S;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Canvas.TextOut(10, 10, MakeItAString(-5322));
end;
```

See Also

Write (see page 3707)

35.3.155 System.StringCodePage Function

Returns the code page associated with the string.

Pascal

```
function StringCodePage(const S: UnicodeString): Word; overload;
function StringCodePage(const S: RawByteString): Word; overload;
```

C++

```
Word StringCodePage(const UnicodeString S);
Word StringCodePage(const RawByteString S);
```

File

System

Description

Call StringCodePage to obtain the code page of the string. Each string in RAD Studio is associated to a code page. The runtime library uses this information to safely convert and manipulate international character sets.

See Also

TEncoding (see page 3969)

StringElementSize (see page 3677)

35.3.156 System.StringElementSize Function

Returns the number of bytes that represent a character in the string.

Pascal

```
function StringElementSize(const S: UnicodeString): Word; overload;
function StringElementSize(const S: RawByteString): Word; overload;
```

C++

```
Word StringElementSize(const UnicodeString S);
Word StringElementSize(const RawByteString S);
```

File

System

Description

Call StringElementSize to obtain the number of bytes necessary to represent one character in the current string. Calling StringElementSize for Unicode strings always returns a result of 2.

See Also

TEncoding (see page 3969)

StringCodePage (see page 3676)

35.3.157 System.StringOfChar Function

Returns a string with a specified number of repeating characters.

Pascal

```
function StringOfChar(ch: AnsiChar; Count: Integer): AnsiString; overload;
function StringOfChar(ch: WideChar; Count: Integer): UnicodeString; overload;
```

C++

```
AnsiString StringOfChar(AnsiChar ch, int Count);
UnicodeString StringOfChar(WideChar ch, int Count);
```

File

System

Description

In Delphi code, StringOfChar returns a string containing **Count** characters with the character value given by **Ch**. For example,

S := StringOfChar('A', 10);

sets **S** to the string 'AAAAAAAAAA'.

Note that StringOfChar returns the same type as **ch**: either an **AnsiString** or **UnicodeString (see page 3381)**, so it works properly for both types.

See Also

FillChar (see page 3570)

DupeString (see page 3037)

35.3.158 System.StringRefCount Function

Returns the reference count of a string.

Pascal

```
function StringRefCount(const S: UnicodeString): Longint; overload;
function StringRefCount(const S: RawByteString): Longint; overload;
```

C++

```
Longint StringRefCount(const UnicodeString S);
Longint StringRefCount(const RawByteString S);
```

File

System

Description

Call StringRefCount to obtain the reference count of a string. Each string has an associated reference count. This value is used to detect how many references a string has.

To ensure that a string has a reference count of one, call UniqueString (see page 3693).

See Also

UniqueString (see page 3693)

35.3.159 System.StringToOleStr Function

Allocates memory and copies an AnsiStringa string to the OLE format.

Pascal

```
function StringToOleStr(const Source: AnsiString): PWideChar; overload;
function StringToOleStr(const Source: UnicodeString): PWideChar; overload;
```

C++

```
PWideChar StringToOleStr(const AnsiString Source);
PWideChar StringToOleStr(const UnicodeString Source);
```

File

System

Description

StringToOleStr allocates memory and copies string data from a native AnsiString into a format that can be passed to OLE functions.

See Also

OleStrToString (see page 3622)

OleStrToStrVar (see page 3622)

StringToWideChar (see page 3679)

35.3.160 System.StringToWideChar Function

Returns a UNICODE string from an AnsiString.

Pascal

```
function StringToWideChar(const Source: UnicodeString; Dest: PWideChar; DestSize: Integer):
PWideChar;
```

C++

```
PWideChar StringToWideChar(const UnicodeString Source, PWideChar Dest, int DestSize);
```

File

System

Description

StringToWideChar converts a string from ANSI to UNICODE and stores the result in a specified buffer.

Source is the string to convert. It must include at most DestSize – 1 characters.

Dest is the buffer into which StringToWideChar writes the corresponding UNICODE string. The caller allocates this memory to include at least DestSize wide characters. Following the call, Dest contains at most DestSize - 1 characters, terminated by a NULL wide character.

DestSize is the size of the buffer Dest.

StringToWideChar returns a pointer to Dest.

See Also

WideCharToString (see page 3706)

WideCharLenToString (see page 3705)

WideCharToStrVar (see page 3707)

WideCharLenToStrVar (see page 3706)

35.3.161 System.Succ Function

Returns the successor of an argument.

Pascal

```
procedure Succ(X);
```

C++

```
Succ( X);
```

File

System

Description

In Delphi code, Succ returns the successor of the argument, X.

X is an expression of an ordinal type (including Int64). The result, of the same type as X, is the successor of X.

Delphi Examples:

```
{
This example demonstrates how Pred and Succ can be used to
manage enumerations.
}
procedure TForm1.Button1Click(Sender: TObject);
type
  Colors = (RED,BLUE,GREEN);
var
  S: string;
begin
  S := 'The predecessor of 5 is ' + IntToStr(Pred(5)) + #13#10;
  S := S + 'The successor of 10 is ' + IntToStr(Succ(10)) + #13#10;
  if Succ(RED) = BLUE then
    S := S + 'In the type Colors, RED is the predecessor of BLUE.';
  MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

See Also

Pred (see page 3628)

35.3.162 System.Swap Function

Exchanges high order byte with the low order byte of an integer or word.

Pascal

```
procedure Swap(X);
```

C++

```
Swap( X);
```

File

System

Description

In Delphi code, Swap exchanges the high-order bytes with the low-order bytes of the argument. **X** is an expression of type SmallInt, as a 16-bit value, or Word. This is provided for backward compatibility only.

Delphi Examples:

```
{
This example demonstrate use of the System Swap function to
exchange the high and low portions of a word.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  W: Word;
begin
  W := Swap($1234);
  ShowMessage(Format('The swapped value of $1234 = $%x', [W]));
end;
```

35.3.163 System.SysAllocMem Function

Pascal

```
function SysAllocMem(Size: Cardinal): Pointer;
```

C++

```
void * SysAllocMem(unsigned Size);
```

File

System

Description

This is function System.SysAllocMem.

35.3.164 System.SysFreeMem Function

Frees the memory pointed to by a specified pointer.

Pascal

```
function SysFreeMem(P: Pointer): Integer;
```

C++

```
int SysFreeMem(void * P);
```

File

System

Description

When implementing a custom memory manager, use SysFreeMem to free the memory pointed to by the P parameter.

Note: On Windows, the System (see page 3159) unit provides a limited implementation of SysFreeMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysFreeMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 3159) unit provides an implementation of SysFreeMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

SysGetMem (see page 3682)

SetMemoryManager (see page 3660)

35.3.165 System.SysGetMem Function

Allocates a specified number of bytes and returns a pointer to them.

Pascal

```
function SysGetMem(Size: Integer): Pointer;
```

C++

```
void * SysGetMem(int Size);
```

File

System

Description

When implementing a custom memory manager, use SysGetMem to dynamically allocate Size bytes of memory.

Note: On Windows, the System (see page 3159) unit provides a limited implementation of SysGetMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysGetMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 3159) unit provides an implementation of SysGetMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

SetMemoryManager (see page 3660)

35.3.166 System.SysReallocMem Function

Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.

Pascal

```
function SysReallocMem(P: Pointer; Size: Integer): Pointer;
```

C++

```
void * SysReallocMem(void * P, int Size);
```

File

System

Description

When implementing a custom memory manager, use SysReallocMem to change the size of a dynamically allocated chunk of memory. If SysReallocMem can't expand the memory block point to by P, it frees the referenced memory and copies the values to the newly allocated memory that is returned. If Size is less than the number of bytes pointed to by P, only the first Size bytes are preserved. Otherwise, the entire value of the memory pointed to by P is preserved in the newly allocated memory.

Note: On Windows, the System (see page 3159) unit provides a limited implementation of SysReallocMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysReallocMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 3159) unit provides an implementation of SysReallocMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

35.3.167 System.SysRegisterExpectedMemoryLeak Function

Pascal

```
function SysRegisterExpectedMemoryLeak(P: Pointer): Boolean;
```

C++

```
Boolean SysRegisterExpectedMemoryLeak(void * P);
```

File

System

Description

This is function System.SysRegisterExpectedMemoryLeak.

35.3.168 System.SysUnregisterExpectedMemoryLeak Function

Pascal

```
function SysUnregisterExpectedMemoryLeak(P: Pointer): Boolean;
```

C++

```
Boolean SysUnregisterExpectedMemoryLeak(void * P);
```

File

System

Description

This is function System.SysUnregisterExpectedMemoryLeak.

35.3.169 System.TextStart Function

Pascal

```
procedure TextStart; deprecated;
```

C++

```
TextStart();
```

File

System

Description

This is function System.TextStart.

35.3.170 System.Trunc Function

Truncates a real number to an integer.

Pascal

```
function Trunc(X: Extended): Int64;
```

C++

```
Int64 Trunc(Extended X);
```

File

System

Description

In Delphi code, the Trunc function truncates a real-type value to an integer-type value. X is a real-type expression. Trunc returns an Int64 value that is the value of X rounded toward zero.

If the truncated value of X is not within the Int64 range, an EInvalidOp exception is raised.

Delphi Examples:

```
{
This example demonstrates how the Trunc function operates
on various real numbers.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   S, T: string;
begin
   Str(1.4:2:1, T);
   S := T + ' Truncs to ' + IntToStr(Trunc(1.4)) + #13#10;
   Str(1.5:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(1.5)) + #13#10;
   Str(1.6:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(1.6)) + #13#10;
   Str(-1.4:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(-1.4)) + #13#10;
   Str(-1.5:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(-1.5)) + #13#10;
   Str(-1.6:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(-1.6)) + #13#10;
   Str(2.5:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(2.5)) + #13#10;
   Str(-2.5:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(-2.5)) + #13#10;
   Str(-2.6:2:1, T);
   S := S + T + ' Truncs to ' + IntToStr(Trunc(-2.6));
   MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

35.3.171 System.Truncate Function

Deletes all the records after the current file position.

Pascal

```
procedure Truncate(var F);
```

C++

```
Truncate( F);
```

File

System

Description

In Delphi code, Call Truncate to cause the current file position to become end-of-file (Eof (see page 3558)(F) is true).

F is a file variable of any type except a text file. Truncate does not work on text files. F must be open.

Delphi Examples:

```
{
This example shows how to truncate a file after the position
set by the last read statement.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Integer;
   i,j: Integer;
 begin
   AssignFile(f,'TEST.INT');
   Rewrite(f);
   for i := 1 to 6 do
     Write(f,i);
   Writeln('File before truncation:');
   Reset(f);
   while not Eof(f) do
   begin
     Read(f,i);
     Writeln(i);
   end;
   Reset(f);
   for i := 1 to 3 do
     Read(f,j); { Read ahead 3 records }
   Truncate(f); { Cut file off here }
   Writeln;
   Writeln('File after truncation:');
   Reset(f);
   while not Eof(f) do
   begin
     Read(f,i);
     Writeln(i);
   end;
   CloseFile(f);
   Erase(f);
 end;
```

Seek (see page 3650)

35.3.172 System.UCS4StringToUnicodeString Function

Converts an UCS-4 encoded string to an Unicode string.

Pascal

```
function UCS4StringToUnicodeString(const S: UCS4String): UnicodeString;
```

C++

```
UnicodeString UCS4StringToUnicodeString(const UCS4String S);
```

File

System

Description

Call UCS4StringToUnicodeString to convert an UCS-4 encoded string to Unicode. S is a string that contains UCS-4 encoded

characters. The result of the function is the corresponding Unicode (UTF-16) string value.

See Also

UnicodeStringToUCS4String (see page 3689)

35.3.173 System.UCS4StringToWideString Function

Converts a string of 4-byte Unicode characters into a WideString (see page 3467) value.

Pascal

```
function UCS4StringToWideString(const S: UCS4String): WideString;
```

C++

```
BSTR UCS4StringToWideString(const UCS4String S);
```

File

System

Description

Call UCS4StringToWideString to convert a string of UCS4 (4-byte Unicode) characters into a WideString (see page 3467) value. UCS4 strings are returned by some Linux operating system calls.

Delphi Examples:

```
{
This example converts various string formats to and from Unicode.
This example requires two text edits and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
  LFileStream: TFileStream;
  LOffset: Integer;
  LEncoding, DestEncoding: TEncoding;
  ComboIndex: Integer;
  ByteString: RawByteString;
  FileText: string;
  ucs4Text: UCS4String;
  wideStringText: WideString;
  utf8Text: UTF8String;
  L: Cardinal;

begin
  LEncoding:= nil;
  ComboIndex := ComboBox1.ItemIndex;
  LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
  try
    // Read file into buffer
    SetLength(LBuffer, LFileStream.Size);
    LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));
    // Get data encoding of data read
    LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
  finally
    LFileStream.Free;
  end;

  // Process various types
  case ComboIndex of
```

```
    // AnsiToUtf8
    0:
    begin
      // Identify encoding and convert buffer to Ansi
      DestEncoding := TEncoding.ASCII;
      LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
        LOffset, Length(LBuffer) - LOffset);
      LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
      FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
      ByteString := AnsiToUtf8(FileText);
      ShowMessage(UTF8ToString(ByteString));

      // Write to file
      LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
      try
        // New destination encoding
        DestEncoding := TEncoding.UTF8;
        LByteOrderMark := DestEncoding.GetPreamble;
        LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
        LFileStream.Write(ByteString[1], Length(ByteString));
      finally
        LFileStream.Free;
      end;
    end;

    // UCS4StringToWideString
    1:
    begin
      // Identify encoding and convert buffer to UCS4
      DestEncoding := TEncoding.Unicode;
      LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
        LOffset, Length(LBuffer) - LOffset);
      LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
      FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
      ucs4Text := UnicodeStringToUCS4String(FileText);
      wideStringText := UCS4StringToWideString(ucs4Text);
      ShowMessage(wideStringText);

      // Write to file
      LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
      try
        // New destination encoding
//        DestEncoding := TEncoding.UTF8;
        LByteOrderMark := DestEncoding.GetPreamble;
        LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
        LFileStream.Write(wideStringText[1], Length(wideStringText) * SizeOf(Char));
      finally
        LFileStream.Free;
      end;
    end;

    // UnicodeToUtf8
    2:
    begin
      // Identify encoding and convert buffer to Unicode
      DestEncoding := TEncoding.Unicode;
      LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
        LOffset, Length(LBuffer) - LOffset);
      LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
      FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
      L := Length(FileText);
      SetLength(utf8Text, L * SizeOf(Char) + 1);
      L := UnicodeToUtf8(PAnsiChar(utf8Text), Length(utf8Text), PWideChar(FileText), L);
      ShowMessage(UTF8ToString(utf8Text));
```

```
        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(utf8Text[1], L);
        finally
          LFileStream.Free;
        end;
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    StringList: TStrings;
  begin
    Edit1.Text := 'Sample.txt';
    Edit2.Text := 'Dest.txt';
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('AnsiToUtf8');
        Add('UCS4StringToWideString');
        Add('UnicodeToUtf8');
      end;
      with ComboBox1 do begin
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

35.3.174 System.UnicodeStringToUCS4String Function

Converts an Unicode string to its UCS-4 encoded representation.

Pascal

```
function UnicodeStringToUCS4String(const S: UnicodeString): UCS4String;
```

C++

```
UCS4String UnicodeStringToUCS4String(const UnicodeString S);
```

File

System

Description

Call UnicodeStringToUCS4String to convert an Unicode string to its UCS-4 encoded representation. S is an Unicode string that contains UTF-16 characters. The result of the function is the corresponding UCS-4 string value.

See Also

UCS4StringToUnicodeString (see page 3686)

35.3.175 System.UnicodeToUtf8 Function

Converts a string of Unicode characters into a UTF-8 string.

Pascal

```
function UnicodeToUtf8(Dest: PChar; MaxDestBytes: Cardinal; Source: PWideChar; SourceChars:
Cardinal): Cardinal; overload;
function UnicodeToUtf8(Dest: PChar; Source: PWideChar; MaxBytes: Integer): Integer; overload;
deprecated;
function UnicodeToUtf8(Dest: PAnsiChar; Source: PWideChar; MaxBytes: Integer): Integer;
overload; deprecated;
function UnicodeToUtf8(Dest: PAnsiChar; MaxDestBytes: Cardinal; Source: PWideChar;
SourceChars: Cardinal): Cardinal; overload;
```

C++

```
unsigned UnicodeToUtf8(const char * Dest, unsigned MaxDestBytes, PWideChar Source, unsigned
SourceChars);
int UnicodeToUtf8(const char * Dest, PWideChar Source, int MaxBytes);
int UnicodeToUtf8(PAnsiChar Dest, PWideChar Source, int MaxBytes);
unsigned UnicodeToUtf8(PAnsiChar Dest, unsigned MaxDestBytes, PWideChar Source, unsigned
SourceChars);
```

File

System

Description

Call UnicodeToUtf8 to convert a Unicode string to a null-terminated sequence of UTF-8 characters. Use the second syntax. The deprecated syntax is included only for backward compatibility.

Dest receives the resulting null-terminated array of UTF-8 characters.

MaxDestBytes or **MaxBytes** indicates the number of bytes available in the buffer specified by **Dest**, including the byte for the null terminator.

Source is an array of Unicode characters.

SourceChars is the number of characters in **Source**. If **SourceChars** is not specified, **Source** must be null-terminated.

UnicodeToUtf8 returns the number of bytes written to **Dest**.

Delphi Examples:

```
{
This example converts various string formats to and from Unicode.
This example requires two text edits and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
```

```
    LFileStream: TFileStream;
    LOffset: Integer;
    LEncoding, DestEncoding: TEncoding;
    ComboIndex: Integer;
    ByteString: RawByteString;
    FileText: string;
    ucs4Text: UCS4String;
    wideStringText: WideString;
    utf8Text: UTF8String;
    L: Cardinal;

  begin
    LEncoding:= nil;
    ComboIndex := ComboBox1.ItemIndex;
    LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
    try
      // Read file into buffer
      SetLength(LBuffer, LFileStream.Size);
      LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));
      // Get data encoding of data read
      LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
    finally
      LFileStream.Free;
    end;

    // Process various types
    case ComboIndex of

      // AnsiToUtf8
      0:
      begin
        // Identify encoding and convert buffer to Ansi
        DestEncoding := TEncoding.ASCII;
        LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
          LOffset, Length(LBuffer) - LOffset);
        LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
        FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
        ByteString := AnsiToUtf8(FileText);
        ShowMessage(UTF8ToString(ByteString));

        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(ByteString[1], Length(ByteString));
        finally
          LFileStream.Free;
        end;
      end;

      // UCS4StringToWideString
      1:
      begin
        // Identify encoding and convert buffer to UCS4
        DestEncoding := TEncoding.Unicode;
        LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
          LOffset, Length(LBuffer) - LOffset);
        LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
        FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
        ucs4Text := UnicodeStringToUCS4String(FileText);
        wideStringText := UCS4StringToWideString(ucs4Text);
        ShowMessage(wideStringText);
```

```
        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
//          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(wideStringText[1], Length(wideStringText) * SizeOf(Char));
        finally
          LFileStream.Free;
        end;
      end;

      // UnicodeToUtf8
      2:
      begin
        // Identify encoding and convert buffer to Unicode
        DestEncoding := TEncoding.Unicode;
        LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
          LOffset, Length(LBuffer) - LOffset);
        LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
        FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
        L := Length(FileText);
        SetLength(utf8Text, L * SizeOf(Char) + 1);
        L := UnicodeToUtf8(PAnsiChar(utf8Text), Length(utf8Text), PWideChar(FileText), L);
        ShowMessage(UTF8ToString(utf8Text));

        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(utf8Text[1], L);
        finally
          LFileStream.Free;
        end;
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    StringList: TStrings;
  begin
    Edit1.Text := 'Sample.txt';
    Edit2.Text := 'Dest.txt';
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('AnsiToUtf8');
        Add('UCS4StringToWideString');
        Add('UnicodeToUtf8');
      end;
      with ComboBox1 do begin
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

35.3.176 System.UniqueString Function

Ensures that a given string has a reference count of one.

Pascal

```
procedure UniqueString(var str: AnsiString); overload;
procedure UniqueString(var str: WideString); overload;
procedure UniqueString(var str: UnicodeString); overload;
```

C++

```
UniqueString(AnsiString str);
UniqueString(BSTR str);
UniqueString(UnicodeString str);
```

File

System

Description

UniqueString forces the reference count on a string to one, copying the string in memory if necessary. For normal string handling, there is no need to call UniqueString. UniqueString is used only in cases where an application modifies the contents of a string after:

- casting the string to a **PAnsiChar** or **PWideChar** in Delphi.
- using the `c_str()`, `t_str()` or `data()` methods of **UnicodeString (see page 3381)** or **AnsiString** or the `c_bstr()` method of **WideString (see page 3467)** in C++. (It's better to use `data()` than `c_str()` because `c_str()` returns an empty string for a NULL **UnicodeString (see page 3381)** or **AnsiString**.)

Delphi Examples:

```
{
The following code demostrates the use of Ptr function. The example
makes use of Ptr to simulate pointer arithmetics.
}
function FastUpperCase(const S: String): String;
var
  C: ^Char;
  I: Integer;
begin
  { Get the text in the edit box }
  Result := S;

  { Ensure the string reference stored in Result is unique,
    otherwise we may change the original string also.
    No copy-on-write is done if we're accesing the character
    directly.
  }
  UniqueString(Result);

  { Find the address of the first char in the string }
  C := Addr(Result[1]);
```

```
    for I := 0 to Length(Result) - 1 do
    begin
      { Up-case the character }
      C^ := UpCase(C^);

      { Move to the next character }
      C := Ptr(Integer(C) + SizeOf(Char));
    end;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    { Uppercase the string in the edit box }
    Edit1.Text := FastUpperCase(Edit1.Text);
  end;
```

Pascal

```
procedure UnregisterModule(LibModule: PLibModule);
```

C++

```
UnregisterModule(PLibModule LibModule);
```

File

System

Description

This is an internal function and should not be used directly.

See Also

RegisterModule (see page 3640)

35.3.179 System.UpCase Function

Converts a character to uppercase.

Pascal

```
function UpCase(Ch: AnsiChar): AnsiChar; overload;
function UpCase(Ch: WideChar): WideChar; overload;
```

C++

```
AnsiChar UpCase(AnsiChar Ch);
WideChar UpCase(WideChar Ch);
```

File

System

Description

UpCase converts a character to uppercase. Ch is an expression of type Char. Character values not in the range a..z are unaffected.

C++ Examples:

```
/*
The following code uppercases every other character in the
text of an edit control when the user clicks the button.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Get string from TEdit control
  UnicodeString s = Edit1->Text;
  for (int i = 1; i <= s.Length(); i += 2)
    s[i] = System::UpCase(s[i]);
  Edit1->Text = s;
}
```

Delphi Examples:

```
{
The following code uppercases every other character in the
text of an edit control when the user clicks the button.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
  s : string;
  i : Integer;
begin
  { Get string from TEdit control }
  s := Edit1.Text;
  for i := 1 to Length(s) do
    if i mod 2 = 0 then s[i] := System.UpCase(s[i]);
  Edit1.Text := s;
end;
```

See Also

AnsiUpperCase (see page 4062)

StrUpper (see page 4292)

UpperCase (see page 4311)

35.3.180 System.UTF8Decode Function

Converts a UTF8 string to a Unicode string (WideString (see page 3467)).

Pascal

```
function UTF8Decode(const S: RawByteString): WideString; deprecated;
```

C++

```
BSTR UTF8Decode(const RawByteString S);
```

File

System

Description

Call UTF8Decode to convert a UTF-8 string to Unicode. S is a string encoded in UTF-8. UTF8Decode returns the corresponding WideString (see page 3467) value that represents the string in Unicode.

See Also

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

Utf8ToAnsi (see page 3698)

AnsiToUtf8 (see page 3517)

35.3.181 System.UTF8Encode Function

Converts a WideString (see page 3467) value to a UTF8 string.

Pascal

```
function UTF8Encode(const WS: WideString): RawByteString; overload;
function UTF8Encode(const US: UnicodeString): RawByteString; overload;
function UTF8Encode(const A: RawByteString): RawByteString; overload;
```

C++

```
RawByteString UTF8Encode(const BSTR WS);
RawByteString UTF8Encode(const UnicodeString US);
RawByteString UTF8Encode(const RawByteString A);
```

File

System

Description

Call UTF8Encode to convert a Unicode string to UTF-8. WS is the Unicode string to convert. Utf8Encode returns the corresponding UTF-8 string.

See Also

UnicodeToUtf8 (see page 3690)

UTF8Decode (see page 3696)

Utf8ToUnicode (see page 3699)

35.3.182 System.UTF8EncodeToShortString Function

Converts a string to its UTF-8 encoded representation.

Pascal

```
function UTF8EncodeToShortString(const WS: WideString): ShortString; overload;
function UTF8EncodeToShortString(const US: UnicodeString): ShortString; overload;
function UTF8EncodeToShortString(const A: RawByteString): ShortString; overload;
```

C++

```
ShortString UTF8EncodeToShortString(const BSTR WS);
ShortString UTF8EncodeToShortString(const UnicodeString US);
ShortString UTF8EncodeToShortString(const RawByteString A);
```

File

System

Description

Call UTF8EncodeToShortString to convert a string to its UTF-8 representation. S is the string to be converted. The result of the function is the corresponding UTF-8 encoded ShortString value.

See Also

UTF8ToWideString (see page 3700)

UTF8ToUnicodeString (see page 3700)

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

Utf8ToAnsi (see page 3698)

AnsiToUtf8 (see page 3517)

35.3.183 System.Utf8ToAnsi Function

Converts a UTF8 string to a string of Ansi characters.

Pascal

```
function Utf8ToAnsi(const S: RawByteString): string;
```

C++

```
UnicodeString Utf8ToAnsi(const RawByteString S);
```

File

System

Description

Call Utf8ToAnsi to convert a UTF-8 string to Ansi. S is a string encoded in UTF-8. Utf8ToAnsi returns the corresponding string that uses the Ansi character set.

See Also

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

UTF8Decode (see page 3696)

AnsiToUtf8 (see page 3517)

35.3.184 System.UTF8ToString Function

Converts an UTF-8 encoded string to a string.

Pascal

```
function UTF8ToString(const S: RawByteString): string;
function UTF8ToString(const S: ShortString): string;
function UTF8ToString(const S: PAnsiChar): string;
function UTF8ToString(const S: array of AnsiChar): string; overload;
```

C++

```
UnicodeString UTF8ToString(const RawByteString S);
UnicodeString UTF8ToString(const ShortString S);
UnicodeString UTF8ToString(const PAnsiChar S);
UnicodeString UTF8ToString(const array of AnsiChar S);
```

File

System

Description

Call UTF8ToString to convert an UTF-8 encoded string to a string. S is a string or an array of UTF-8 encoded characters. The result of the function is the corresponding decoded string value.

See Also

UTF8ToWideString (see page 3700)

UTF8ToUnicodeString (see page 3700)

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

Utf8ToAnsi (see page 3698)

AnsiToUtf8 (see page 3517)

35.3.185 System.Utf8ToUnicode Function

Converts a string of UTF-8 characters to a Unicode string.

Pascal

```
function Utf8ToUnicode(Dest: PWideChar; Source: PAnsiChar; MaxChars: Integer): Integer;
overload; deprecated;
function Utf8ToUnicode(Dest: PWideChar; MaxDestChars: Cardinal; Source: PAnsiChar;
SourceBytes: Cardinal): Cardinal; overload;
```

C++

```
int Utf8ToUnicode(PWideChar Dest, PAnsiChar Source, int MaxChars);
unsigned Utf8ToUnicode(PWideChar Dest, unsigned MaxDestChars, PAnsiChar Source, unsigned
SourceBytes);
```

File

System

Description

Call Utf8ToUnicode to convert a UTF-8 string to Unicode. Use the second syntax. The deprecated syntax is provided for backward compatibility only.

Dest receives the resulting null-terminated array of Unicode characters.

MaxDestChars or MaxChars indicates the maximum number of Unicode characters that the buffer specified by Dest can hold, not counting the null terminator.

Source is an array of UTF-8 characters.

SourceBytes is the number of bytes in Source. If SourceBytes is not specified, Source must be null-terminated.

Utf8ToUnicode returns the number of characters written to Dest.

In case of errors, the Utf8ToUnicode ... : Cardinal variant returns `Cardinal(-1) == $FFFFFFFF` and the Utf8ToUnicode ... : Integer returns `-1`.

UTF8Encode (see page 3696)

UTF8Decode (see page 3696)

UTF8String (see page 3804)

35.3.186 System.UTF8ToUnicodeString Function

Converts an UTF-8 encoded string to an Unicode string.

Pascal

```
function UTF8ToUnicodeString(const S: RawByteString): UnicodeString; overload;
function UTF8ToUnicodeString(const S: ShortString): UnicodeString; overload;
function UTF8ToUnicodeString(const S: PAnsiChar): UnicodeString; overload;
```

C++

```
UnicodeString UTF8ToUnicodeString(const RawByteString S);
UnicodeString UTF8ToUnicodeString(const ShortString S);
UnicodeString UTF8ToUnicodeString(const PAnsiChar S);
```

File

System

Description

Call UTF8ToUnicodeString to convert an UTF-8 encoded string to Unicode. S is a string that contains UTF-8 encoded characters. The result of the function is the corresponding Unicode string value.

See Also

UTF8ToWideString (see page 3700)

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

AnsiToUtf8 (see page 3517)

35.3.187 System.UTF8ToWideString Function

Converts an UTF-8 encoded string to a WideString (see page 3467).

Pascal

```
function UTF8ToWideString(const S: RawByteString): WideString;
```

C++

```
BSTR UTF8ToWideString(const RawByteString S);
```

File

System

Description

Call UTF8ToWideString to convert an UTF-8 encoded string to Unicode. S is a RawByteString (see page 3783) that contains

UTF-8 encoded characters. The result of the function is the corresponding WideString (see page 3467) value that represents the string in Unicode.

See Also

UTF8ToUnicodeString (see page 3700)

UnicodeToUtf8 (see page 3690)

UTF8Encode (see page 3696)

Utf8ToUnicode (see page 3699)

AnsiToUtf8 (see page 3517)

35.3.188 System.Val Function

Converts a string to a numeric representation.

Pascal

```
procedure Val(S; var V; var Code: Integer);
```

C++

```
Val( S,  V, int Code);
```

File

System

Description

In Delphi code, Val converts the string value S to its numeric representation, as if it were read from a text file with Read (see page 3634).

S is a string-type expression; it must be a sequence of characters that form a signed real number.

V is an integer-type or real-type variable. If V is an integer-type variable, S must form a whole number.

Code is a variable of type Integer.

If the string is invalid, the index of the offending character is stored in Code; otherwise, Code is set to zero. For a null-terminated string, the error position returned in Code is one larger than the actual zero-based index of the character in error.

Delphi Examples:

```
{
This example uses the System Val function to convert a string to
an integer.  Enter an integer in the text edit and then click the
button.  An error will occur if the value entered is not an integer.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, Code: Integer;
  mystr: string;
begin
  { Get text from TEdit control }
  mystr := Edit1.Text;
  Val(mystr, I, Code);
  { Error during conversion to integer? }
  if Code <> 0 then
```

```
    MessageDlg('Error at position: ' + IntToStr(Code), mtWarning, [mbOk], 0, mbOk)
  else
    Canvas.TextOut(10, 10, 'Value = ' + IntToStr(I));
end;
```

See Also

Str (see page 3676)

35.3.189 System.VarArrayRedim Function

Resizes a Variant (see page 3421) array.

Pascal

```
procedure VarArrayRedim(A: Variant; HighBound: Integer);
```

C++

```
VarArrayRedim(Variant A, int HighBound);
```

File

System

Description

VarArrayRedim resizes the given Variant (see page 3421) array by changing the high bound of the rightmost dimension to the given value. The A parameter can be a Variant (see page 3421) or an OleVariant (see page 3274), and it must be possible to assign a value to A (A must be an lvalue).

Existing elements of the array are preserved, and new elements are set to zero or empty. An EVariantArrayCreateError exception is thrown if the Variant (see page 3421) given by A is not an array, or if there is not enough memory to resize the array.

Note: A Variant (see page 3421) array can't be resized while it is locked.

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
```

```
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    VarArrayPut(Arr, I, [I]);
  end;

  { Now read the elements of the array }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    if VarArrayGet(Arr, [I]) <> I then
      MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
  end;

  { Clear the variant array }
  VarClear(Arr);
end;
```

See Also

VarArrayCreate (see page 5059)

VarArrayLock (see page 5067)

EVariantArrayCreateError (see page 4978)

35.3.190 System.VarClear Function

Empties a Variant (see page 3421), so that it is unassigned.

Pascal

```
procedure VarClear(V: Variant);
```

C++

```
VarClear(Variant V);
```

File

System

Description

Calling VarClear is equivalent to assigning the Unassigned constant to the Variant (see page 3421). V can be either a Variant (see page 3421) or an OleVariant (see page 3274), but it must be possible to assign a value to it (it must be an lvalue).

After calling VarClear, the VarIsEmpty function returns true, and the VarType function returns varEmpty (see page 3865). Using an unassigned variant in an expression causes an exception to be thrown. Likewise, if you attempt to convert an unassigned Variant (see page 3421) to another type (using VarAsType), an exception is thrown.

Note: Do not confuse clearing a Variant (see page 3421), which leaves it unassigned, with assigning a Null value. A Null Variant (see page 3421) is still assigned, but has the value Null. Unlike unassigned Variants (see page 4973), Null Variants (see page 4973) can be used in expressions and can be converted to other types of Variants (see page 4973).

C++ Examples:

```
/*
This example shows how to use the TVarData type in typecasts
of Variant variables to access the internals of a variable.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Variant V;
  AnsiString mystr;
  if (TVarData(V).VType == varEmpty)
    ListBox1->Items->Add("Variants start empty.");
  VarClear(V);
  TVarData(V).VType = varString;
  mystr = "Here is my string";
  std::auto_ptr<char> MyBuffer(new char[mystr.Length() + 1]);
  StrCopy(MyBuffer.get(), mystr.c_str());
  TVarData(V).VString  = MyBuffer.get();
  mystr = PAnsiChar(TVarData(V).VString);
  ListBox1->Items->Add("This variant is now a string: " + mystr);
  VarClear(V);
  TVarData(V).VType = varInteger;
  TVarData(V).VInteger = 1234567;
  ListBox1->Items->Add("This variant is now an integer: " + IntToStr(TVarData(V).VInteger));
}
```

Delphi Examples:

```
{{
This example shows how to use the TVarData type in typecasts
```

```
  of Variant variables to access the internals of a variable.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    V: Variant;
    mystr: string;
    MyBuffer: PChar;
  begin
    if TVarData(V).VType = varEmpty then
      ListBox1.Items.Add('Variants start empty.');
    VarClear(V);
    TVarData(V).VType := varString;
    mystr := 'Here is my string';
    MyBuffer:= GetMemory(Length(mystr));
    StrCopy(MyBuffer, PChar(mystr));
    TVarData(V).VString := MyBuffer;
    ListBox1.Items.Add('This variant is now a string: ' + PChar(TVarData(V).VString));
    VarClear(V);
    TVarData(V).VType := varInteger;
    TVarData(V).VInteger := 1234567;
    ListBox1.Items.Add('This variant is now an integer: ' + IntToStr(TVarData(V).VInteger));
  end;
```

35.3.191 System.WideCharLenToString Function

Converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)**.

Pascal

```
function WideCharLenToString(Source: PWideChar; SourceLen: Integer): UnicodeString;
```

C++

```
UnicodeString WideCharLenToString(PWideChar Source, int SourceLen);
```

File

System

Description

WideCharLenToString converts `SourceLen` **WideString (see page 3467)** characters from the buffer given by `Source` to a **UnicodeString (see page 3381)**.

See Also

StringToWideChar (see page 3679)

WideCharToString (see page 3706)

35.3.192 System.WideCharLenToStrVar Function

WideCharLenToStrVar converts **WideString (see page 3467)** characters to **UnicodeString (see page 3381)** or **AnsiString**.

Pascal

```
procedure WideCharLenToStrVar(Source: PWideChar; SourceLen: Integer; var Dest: UnicodeString);
overload;
procedure WideCharLenToStrVar(Source: PWideChar; SourceLen: Integer; var Dest: AnsiString);
overload;
```

C++

```
WideCharLenToStrVar(PWideChar Source, int SourceLen, UnicodeString Dest);
WideCharLenToStrVar(PWideChar Source, int SourceLen, AnsiString Dest);
```

File

System

Description

The WideCharLenToStrVar procedure converts `SourceLen` **WideString (see page 3467)** characters from `Source` into a **UnicodeString (see page 3381)** or **AnsiString**, and copies the result into `Dest`.

See Also

WideCharToString (see page 3706)

35.3.193 System.WideCharToString Function

Converts null-terminated **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.

Pascal

```
function WideCharToString(Source: PWideChar): UnicodeString;
```

C++

```
UnicodeString WideCharToString(PWideChar Source);
```

File

System

Description

WideCharToString converts the given null-terminated **WideString (see page 3467)** string to a **UnicodeString (see page 3381)**.

See Also

StringToWideChar (see page 3679)

WideCharLenToString (see page 3705)

35.3.194 System.WideCharToStrVar Function

Converts **WideString (see page 3467)** string to **UnicodeString (see page 3381)**.

Pascal

```
procedure WideCharToStrVar(Source: PWideChar; var Dest: UnicodeString);
```

C++

```
WideCharToStrVar(PWideChar Source, UnicodeString Dest);
```

File

System

Description

WideCharToStrVar converts the **WideString (see page 3467)** string `Source` into a **UnicodeString (see page 3381)**, and copies the result into `Dest`. The source must be null-terminated.

See Also

WideCharToString (see page 3706)

35.3.195 System.WideStringToUCS4String Function

Converts a WideString (see page 3467) value to a string of 4-byte Unicode characters.

Pascal

```
function WideStringToUCS4String(const S: WideString): UCS4String;
```

C++

```
UCS4String WideStringToUCS4String(const BSTR S);
```

File

System

Description

Call WideStringToUCS4String to convert a WideString (see page 3467) value to a string of UCS4 (4-byte Unicode) characters. UCS4 strings are used by some Linux operating system calls.

35.3.196 System.Write Function

Writes to either a typed file or a text file

Pascal

```
procedure Write(P1); overload;
procedure Write(P1; Pn); overload;
procedure Write(var F: Text; P1); overload;
procedure Write(var F: Text; P1; Pn); overload;
```

C++

```
Write( P1);
Write( P1,  Pn);
Write(Text F,  P1);
Write(Text F,  P1,  Pn);
```

File

System

Description

The syntax shown here for the Write procedure is an example that illustrates that Write can take a variable number of arguments.

Write procedure for typed files:

In Delphi code, Write writes a file to a file component. F is a file variable, and each V is a variable of the same type as the component type of F. For each variable written, the current file position is advanced to the next component. If the current file position is at the end of the file (that is, if Eof (see page 3558)(F) is true), the file is expanded.

Write procedure for text files:

In Delphi code, Write writes one or more values to a text file. F, if specified, is a text file variable. If F is omitted, the standard file variable Output (see page 3833) is assumed. Each P is a write parameter. Each write parameter includes an output expression whose value is to be written to the file. A write parameter can also contain the specifications of a field width and a number of decimal places. Each output expression must be of a type Char, one of the Integer types (Byte, Shortint, Word, Longint, Cardinal), one of the floating-point types (Single, Real, Double, Extended, Currency (see page 3235)), one of the string types (PChar, AnsiString, ShortString), a packed string, or one of the Boolean types (Boolean, Bool).

A write parameter has the form:

```
OutExpr [: MinWidth [: DecPlaces ] ]
```

where OutExpr is an output expression. MinWidth and DecPlaces are type integer expressions.

MinWidth specifies the minimum field width, which must be greater than 0. Exactly MinWidth characters are written (using leading blanks if necessary) except when OutExpr has a value that must be represented in more than MinWidth characters. In that case, enough characters are written to represent the value of OutExpr. Likewise, if MinWidth is omitted, then the necessary number of characters is written to represent the value of OutExpr.

DecPlaces specifies the number of decimal places in a fixed-point representation of one of the Real types. It can be specified only if OutExpr is one of the Real types, and if MinWidth is also specified. When MinWidth is specified, it must be greater than or equal to 0.

Write with a character-type value: If MinWidth is omitted, the character value of OutExpr is written to the file. Otherwise, MinWidth - 1 blanks followed by the character value of OutExpr is written.

Write with one of the integer type values: If MinWidth is omitted, the decimal representation of OutExpr is written to the file with no preceding blanks. If MinWidth is specified and its value is larger than the length of the decimal string, enough blanks are written before the decimal string to make the field width MinWidth.

Write with one of the real type values: If OutExpr has one of the real type values, its decimal representation is written to the file. The format of the representation depends on the presence or absence of DecPlaces. If DecPlaces is omitted (or if it's present but has a negative value), a floating-point decimal string is written. If MinWidth is also omitted, a default MinWidth of 17 is assumed; otherwise, if MinWidth is less than 8, it's assumed to be 8. The format of the floating-point string is:

```
[   | - ] <digit> . <decimals> E [ + | - ] <exponent>
```

The following table lists the components of the output string.

Component	Meaning
[| —]	" “ or “-”I, according to the sign of OutExpr
<digit>	Single digit, “0” only if OutExpr is 0
<decimals>	Digit string of MinWidth-7 (but at most 10) digits
E	Uppercase [E] character
[+ | —]	According to the sign of the exponent
<exponent>	Two-digit decimal exponent

If DecPlaces is present, a fixed-point decimal string is written. If DecPlaces is larger than 11, it's assumed to be 11. The format of the fixed-point string follows:

```
[<blanks>] [ - ] <digits> [.<decimals>]
```

The following table lists the components of the fixed-point string:

Component	Meaning
[<blanks>	Blanks to satisfy MinWidth
[-]	If OutExpr is negative
<digits>	At least one digit, but no leading zeros
[.<decimals>]	Decimals if DecPlaces > 0

Write with one of the string-type values: If MinWidth is omitted, the string value of OutExpr is written to the file with no leading blanks. If MinWidth is specified, and its value is larger than the length of OutExpr, enough blanks are written before the decimal string to make the field width MinWidth.

Write with a packed string-type value: If OutExpr is of packed string type, the effect is the same as writing a string whose length is the number of elements in the packed string type.

Write with one of the Boolean type values: If OutExpr is of type Boolean, the effect is the same as writing the strings true or false, depending on the value of OutExpr.

Note: When using Write the file must be open for output.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: AnsiChar;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
      begin
        Read(F1, Ch);
        Write(F2, Ch);
      end;
      CloseFile(F2);
```

```
    end;
    CloseFile(F1);
  end;
end;
```

WriteLn (see page 3710)

35.3.197 System.WriteLn Function

Writes to a text file and adds an end-of-line marker.

Pascal

```
procedure WriteLn(P1); overload;
procedure WriteLn(P1; Pn); overload;
procedure WriteLn(var F: Text; P1); overload;
procedure WriteLn(var F: Text; P1; Pn); overload;
```

C++

```
WriteLn( P1);
WriteLn( P1,  Pn);
WriteLn(Text F,  P1);
WriteLn(Text F,  P1,  Pn);
```

File

System

Description

WriteLn is an extension to the Write (see page 3707) procedure, as it is defined for text files.

The syntax shown here for the WriteLn procedure is an example that illustrates that WriteLn can take a variable number of arguments.

After executing Write (see page 3707), WriteLn writes an end-of-line marker (line feed or carriage return/line feed) to the file.

If F is omitted, the global variable Output (see page 3833) is used, which accesses the processes standard input file. Use of Output (see page 3833) in GUI applications raises special issues.

Delphi Examples:

```
{
This example assumes you are compiling as a console
application.  Notice how the form deactivates when the button
click procedure exits.
}

{$APPTYPE CONSOLE}

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  Write('Enter a line of text: ');
  Readln(s);
  Writeln('You typed: ',s);
  Writeln('Hit <Enter> to exit');
  Readln;
end;
```

See Also

Write (see page 3707)

SetLineBreakStyle (see page 3659)

Output (see page 3833)

35.3.198 System.YieldProcessor Function

Pascal

```
procedure YieldProcessor;
```

C++

```
YieldProcessor();
```

File

System

Description

This is function System.YieldProcessor.

35.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TChunkStatus (see page 3714)	TChunkStatus enumerates the possible states of a chunk of memory.
	TMinimumBlockAlignment (see page 3732)	TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.
	TRuntimeError (see page 3734)	TRuntimeError is an enumeration of internal runtime error codes.
	TTextLineBreakStyle (see page 3737)	TTextLineBreakStyle indicates the default set of characters used to divide lines in text.

Records

	Name	Description
	PackageInfoTable (see page 3713)	A variable of type PackageInfoTable provides information on initializing or finalizing a series of package units.
	PackageUnitEntry (see page 3713)	A variable of type PackageUnitEntry provides information on initializing or finalizing a package unit.
	TCallDesc (see page 3714)	TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 3758) is a pointer to this descriptior.
	TCVModInfo (see page 3715)	This is record System.TCVModInfo.
	TDispatchMessage (see page 3716)	This is record System.TDispatchMessage.
	TDispDesc (see page 3716)	This is record System.TDispDesc.
	TDynArrayTypeInfo (see page 3716)	This is record System.TDynArrayTypeInfo.
	TFileRec (see page 3717)	TFileRec is the internal format for typed and untyped files in the Delphi language.
	TGUID (see page 3718)	TGUID is a structured form of the value that uniquely identifies an interface.
	THeapStatus (see page 3720)	System::THeapStatus represents information about the global heap.
	TInitContext (see page 3721)	This is record System.TInitContext.
	TInterfaceEntry (see page 3722)	TInterfaceEntry encapsulates the information needed to dispatch interface calls.
	TInterfaceTable (see page 3723)	TInterfaceTable lists the interfaces that a class supports, and PInterfaceTable (see page 3766) points to this list.
	TLibModule (see page 3723)	System::TLibModule describes a module that is compiled with the application.
	TMemoryManager (see page 3724)	System::TMemoryManager defines the memory block entry points.
	TMemoryManagerEx (see page 3725)	System::TMemoryManagerEx defines extended memory block entry points.
	TMemoryManagerState (see page 3730)	System::TMemoryManagerState holds statistics about memory allocations.
	TMethod (see page 3731)	TMethod stores Code and Data fields to represent a method.
	TModuleUnloadRec (see page 3732)	This is record System::TModuleUnloadRec.
	TMonitorSupport (see page 3733)	This is record System.TMonitorSupport.
	TResStringRec (see page 3733)	This is record System::TResStringRec.
	TSmallBlockTypeState (see page 3736)	System::TSmallBlockTypeState holds statistics about a small memory block.
	TTextRec (see page 3738)	TTextRec is the internal format for text files.
	TVarArray (see page 3739)	This is the descriptor type for safe arrays.
	TVarArrayBound (see page 3740)	Gives bound information for one dimension of a safe array.
	TVarData (see page 3740)	TVarData represents Variant (see page 3421) information.
	TVariantManager (see page 3745)	System::TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.
	TVarRec (see page 3747)	System::TVarRec is used inside a function with an untyped array parameter.

Structures

	Name	Description
	THeapBlock (see page 3720)	This is record System::THeapBlock.
	TCallDesc (see page 3749)	This is type System::TCallDesc.

	TDispDesc (see page 3749)	This is type System::TDispDesc.

35.4.1 System.PackageInfoTable Record

A variable of type PackageInfoTable provides information on initializing or finalizing a series of package units.

Pascal

```
PackageInfoTable = packed record
  UnitCount: Integer;
  UnitInfo: PUnitEntryTable;
end;
```

C++

```
struct PackageInfoTable {
  int UnitCount;
  PUnitEntryTable UnitInfo;
};
```

File

System

Description

A variable of type PackageInfoTable provides information on initializing or finalizing a series of package units.

PackageInfoTable is a record containing a pointer to an array of type UnitEntryTable (see page 3804), as the field `UnitInfo`, and also the number of entries in this array, as the field `UnitCount`.

The value of `UnitCount` must always be greater than or equal to 1.

See Also

UnitEntryTable (see page 3804)

35.4.2 System.PackageUnitEntry Record

A variable of type PackageUnitEntry provides information on initializing or finalizing a package unit.

Pascal

```
PackageUnitEntry = packed record
  FInit: Pointer;
  Init: Pointer;
end;
```

C++

```
struct PackageUnitEntry {
  void * FInit;
  void * Init;
};
```

File

System

Description

PackageUnitEntry is a record containing the pointer fields `Init` and `FInit`. These fields provide information on initializing or

finalizing a package unit.

See Also

UnitEntryTable (see page 3804)

35.4.3 System.TCallDesc Record

TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 3758) is a pointer to this descriptior.

Pascal

```
TCallDesc = packed record
  CallType: Byte;
  ArgCount: Byte;
  NamedArgCount: Byte;
  ArgTypes: array[0..255] of Byte;
end;
```

C++

```
struct TCallDesc {
  Byte CallType;
  Byte ArgCount;
  Byte NamedArgCount;
  array[0..255] of Byte ArgTypes;
};
```

File

System

Description

TCallDesc identifies a method call that was made using a Variant (see page 3421).

CallType identifies the method that was called.

ArgCount indicates the total number of arguments passed to the method.

NamedArgCount

ArgTypes is an array giving the type codes for each argument.

See Also

System::PCallDesc (see page 3758)

35.4.4 System.TChunkStatus Enumeration

TChunkStatus enumerates the possible states of a chunk of memory.

Pascal

```
TChunkStatus = (
  csUnallocated,
  csAllocated,
  csReserved,
  csSysAllocated,
  csSysReserved
);
```

C++

```
enum TChunkStatus {
  csUnallocated,
  csAllocated,
  csReserved,
  csSysAllocated,
  csSysReserved
};
```

File

System

Description

GetMemoryMap (see page 3592) returns a map of the address space of the current process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. TMemoryMap (see page 3791) obtains a TChunkStatus status value for each of them in the TMemoryMap (see page 3791) array. TChunkStatus defines the following values :

Status value	Meaning
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

See Also

GetMemoryMap (see page 3592)

TMemoryMap (see page 3791)

35.4.5 System.TCVModInfo Record

Pascal

```
TCVModInfo = packed record
  ModName: PAnsiChar;
  LibName: PAnsiChar;
  UserData: Pointer;
end;
```

C++

```
struct TCVModInfo {
  PAnsiChar ModName;
  PAnsiChar LibName;
  void * UserData;
};
```

File

System

Description

This is record System.TCVModInfo.

35.4.6 System.TDispatchMessage Record

Pascal

```
TDispatchMessage = record
  MsgID: Word;
end;
```

C++

```
struct TDispatchMessage {
  Word MsgID;
};
```

File

System

Description

This is record System.TDispatchMessage.

35.4.7 System.TDispDesc Record

Pascal

```
TDispDesc = packed record
  DispID: Integer;
  ResType: Byte;
  CallDesc: TCallDesc;
end;
```

C++

```
struct TDispDesc {
  int DispID;
  Byte ResType;
  TCallDesc CallDesc;
};
```

File

System

Description

This is record System.TDispDesc.

35.4.8 System.TDynArrayTypeInfo Record

Pascal

```
TDynArrayTypeInfo = packed record
  kind: Byte;
  name: string[0];
  elSize: Longint;
  elType: ^PDynArrayTypeInfo;
```

```
    varType: Integer;
  end;
```

C++

```
  struct TDynArrayTypeInfo {
    Byte kind;
    string[0] name;
    Longint elSize;
    ^PDynArrayTypeInfo elType;
    int varType;
  };
```

File

System

Description

This is record System.TDynArrayTypeInfo.

35.4.9 System.TFileRec Record

TFileRec is the internal format for typed and untyped files in the Delphi language.

Pascal

```
  TFileRec = packed record
    Handle: Integer;
    Mode: Word;
    Flags: Word;
    case Byte of
      0: (RecSize: Cardinal;);
      1: (BufSize: Cardinal;
          BufPos: Cardinal;
          BufEnd: Cardinal;
          BufPtr: PAnsiChar;
          OpenFunc: Pointer;
          InOutFunc: Pointer;
          FlushFunc: Pointer;
          CloseFunc: Pointer;
          UserData: array[1..32] of Byte;
          Name: array[0..259] of WideChar;);
  end;
```

C++

```
  struct TFileRec {
    int Handle;
    Word Mode;
    Word Flags;
    unsigned RecSize;
    unsigned BufSize;
    unsigned BufPos;
    unsigned BufEnd;
    PAnsiChar BufPtr;
    void * OpenFunc;
    void * InOutFunc;
    void * FlushFunc;
    void * CloseFunc;
    array[1..32] of Byte UserData;
    array[0..259] of WideChar Name;
  };
```

File

System

Description

TFileRec is the internal format for typed and untyped files. TFileRec enables you to typecast a Delphi file variable to access its internal fields.

Note: You would normally never declare a variable of this type.

35.4.10 System.TGUID Record

TGUID is a structured form of the value that uniquely identifies an interface.

Pascal

```
TGUID = packed record
  D1: LongWord;
  D2: Word;
  D3: Word;
  D4: array[0..7] of Byte;
end;
```

C++

```
struct TGUID {
  LongWord D1;
  Word D2;
  Word D3;
  array[0..7] of Byte D4;
};
```

File

System

Description

An interface declaration can specify a globally unique identifier (GUID), represented by a string literal enclosed in brackets immediately preceding the member list. The GUID part of the declaration must have the form :

['{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}']

where each x is a hexadecimal digit (0 through 9 or A through F). On Windows, the Type Library editor automatically generates GUIDs for new interfaces. You can also generate GUIDs by pressing Ctrl+Shift+G in the Code editor.

TGUID provides a structured access to this GUID :

D1 maps to the first 8 hexadecimal digits.

D2 maps to the next 4 hexadecimal digits.

D3 maps to the next 4 hexadecimal digits.

D4 maps to the final 8 hexadecimal digits.

C++ Examples:

```
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
```

```
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
              "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
         ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
         myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
         myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7])));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));

    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));

  { Auto-generate a random GUID at runtime }
  if CreateGUID(MyGuid1) <> 0 then
     Memo1.Lines.Add('Creating GUID failed!')
  else
     Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

  { Generating second random GUID }
  CreateGUID(MyGuid0);

  { Testing if 2 guids are equal }
```

```
    if IsEqualGUID(MyGuid0, MyGuid1) then
       Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                       '2 randomly generated GUIDs cannot be equal!');
  end;
```

35.4.11 System::THeapBlock Structure

Pascal

```
  THeapBlock = record
    Start: Pointer;
    Size: unsigned int;
  end;
```

C++

```
  struct THeapBlock {
    void * Start;
    unsigned int Size;
  };
```

File

sysclass.h

Description

This is record System::THeapBlock.

35.4.12 System::THeapStatus Record

System::THeapStatus represents information about the global heap.

Pascal

```
  THeapStatus = record
    TotalAddrSpace: Cardinal;
    TotalUncommitted: Cardinal;
    TotalCommitted: Cardinal;
    TotalAllocated: Cardinal;
    TotalFree: Cardinal;
    FreeSmall: Cardinal;
    FreeBig: Cardinal;
    Unused: Cardinal;
    Overhead: Cardinal;
    HeapErrorCode: Cardinal;
  end;
```

C++

```
  struct THeapStatus {
    Cardinal TotalAddrSpace;
    Cardinal TotalUncommitted;
    Cardinal TotalCommitted;
    Cardinal TotalAllocated;
    Cardinal TotalFree;
    Cardinal FreeSmall;
    Cardinal FreeBig;
    Cardinal Unused;
    Cardinal Overhead;
    Cardinal HeapErrorCode;
  };
```

File

System.pas

Description

System::THeapStatus represents information about the current memory manager. These are the meanings of the values in each field:

Field	Meaning
TotalAddrSpace	The (current) total address space available to your program, in bytes. This will grow as your program's dynamic memory usage grows.
TotalUncommitted	The total number of bytes (of TotalAddrSpace) for which space has not been allocated in the swap file.
TotalCommitted	The total number of bytes (of TotalAddrSpace) for which space has been allocated in the swap file. Note : TotalUncommitted + TotalCommitted = TotalAddrSpace
TotalAllocated	The total number of bytes dynamically allocated by your program.
TotalFree	The total number of free bytes available in the (current) address space for allocation by your program. If this number is exceeded, and enough virtual memory is available, more address space will be allocated from the OS; TotalAddrSpace will be incremented accordingly.
FreeSmall	Total bytes of small memory blocks which are not currently allocated by your program.
FreeBig	Total bytes of big memory blocks which are not currently allocated by your program. Large free blocks can be created by coalescing smaller, contiguous, free blocks or by freeing a large dynamic allocation. (The exact size of the blocks is immaterial).
Unused	Total bytes which have never been allocated by your program. Note : Unused + FreeBig + FreeSmall = TotalFree These three fields (Unused, FreeBig, and FreeSmall) refer to dynamic allocation by the user program.
Overhead	The total number of bytes required by the heap manager to manage all the blocks dynamically allocated by your program.
HeapErrorCode	Indicates the current status of the heap, as internally determined.

Note: TotalAddrSpace, TotalUncommitted and TotalCommitted refer to OS memory used by the program, whereas TotalAllocated and TotalFree refer to the heap memory used within the program by dynamic allocations. Therefore, to monitor dynamic memory used in your program use TotalAllocated and TotalFree.

35.4.13 System.TInitContext Record

Pascal

```
TInitContext = record
  OuterContext: PInitContext;
  ExcFrame: Pointer;
  InitTable: PackageInfo;
  InitCount: Integer;
  Module: PLibModule;
  DLLSaveEBP: Pointer;
  DLLSaveEBX: Pointer;
  DLLSaveESI: Pointer;
  DLLSaveEDI: Pointer;
  ExitProcessTLS: procedure;
  DLLInitState: Byte;
  PkgLoaderLock: Pointer;
end;
```

C++

```
struct TInitContext {
  PInitContext OuterContext;
  void * ExcFrame;
  PackageInfo InitTable;
  int InitCount;
  PLibModule Module;
  void * DLLSaveEBP;
  void * DLLSaveEBX;
  void * DLLSaveESI;
  void * DLLSaveEDI;
  procedure ExitProcessTLS;
  Byte DLLInitState;
  void * PkgLoaderLock;
};
```

File

System

Description

This is record System.TInitContext.

35.4.14 System.TInterfaceEntry Record

TInterfaceEntry encapsulates the information needed to dispatch interface calls.

Pascal

```
TInterfaceEntry = packed record
  IID: TGUID;
  VTable: Pointer;
  IOffset: Integer;
  ImplGetter: Integer;
end;
```

C++

```
struct TInterfaceEntry {
  TGUID IID;
  void * VTable;
  int IOffset;
  int ImplGetter;
};
```

File

System

Description

PInterfaceEntry (see page 3766) is a pointer to a TInterfaceEntry value. TInterfaceEntry contains the following fields:

Field	Meaning
IID	The GUID that uniquely identifies the interface.
VTable	The VTable to use for dispatching interface calls.
IOffset	The offset of the interface in the implementing object.
ImplGetter	A method pointer for accessing the interface if IOffset is not available.

See Also

PInterfaceEntry (see page 3766)

35.4.15 System.TInterfaceTable Record

TInterfaceTable lists the interfaces that a class supports, and PInterfaceTable (see page 3766) points to this list.

Pascal

```
TInterfaceTable = packed record
  EntryCount: Integer;
  Entries: array[0..9999] of TInterfaceEntry;
end;
```

C++

```
struct TInterfaceTable {
  int EntryCount;
  array[0..9999] of TInterfaceEntry Entries;
};
```

File

System

Description

PInterfaceTable (see page 3766) is a pointer to a TInterfaceTable value. TInterfaceTable contains the following fields:

Field	Meaning
EntryCount	The number of interface descriptors in the table.
Entries	An array of interface descriptors.

See Also

PInterfaceTable (see page 3766)

35.4.16 System::TLibModule Record

System::TLibModule describes a module that is compiled with the application.

Pascal

```
TLibModule = record
  Next: PLibModule;
  Instance: LongWord;
  CodeInstance: LongWord;
  DataInstance: LongWord;
  ResInstance: LongWord;
  Reserved: Integer;
end;
```

C++

```
struct TLibModule {
  PLibModule Next;
  LongWord Instance;
```

```
    LongWord CodeInstance;
    LongWord DataInstance;
    LongWord ResInstance;
    Integer Reserved;
  };
```

File

System.pas

Description

System::TLibModule is an entry in a linked list of data structures that describe the modules in an application.

Next is a pointer to the next entry in the list.

The **Instance** field represents the instance handle of the executable or package and the instance handles of the text, data, and resource associated with that executable instance.

The additional fields on Linux are used internally to access information in the module header.

See Also

PLibModule (see page 3767)

35.4.17 System::TMemoryManager Record

System::TMemoryManager defines the memory block entry points.

Pascal

```
TMemoryManager = record
  GetMem: function(Size: Integer): Pointer;
  FreeMem: function(P: Pointer): Integer;
  ReallocMem: function(P: Pointer; Size: Integer): Pointer;
end;
```

C++

```
struct TMemoryManager {
  function(Size: Integer): Pointer GetMem;
  function(P: Pointer): Integer FreeMem;
  function(P: Pointer; Size: Integer): Pointer ReallocMem;
};
```

File

System.pas

Description

The System::TMemoryManager type is used by the GetMemoryManager (see page 3587) and SetMemoryManager (see page 3660) procedures. It defines the routines that allocate and free memory.

The GetMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the GetMemory (see page 3585) routine.

The Size parameter passed to the GetMem function will never be zero. If the GetMem function cannot allocate a block of the given size, it should return nil (Delphi) or NULL (C++).

The FreeMem field (Delphi) or method (C++) must specify a function that deallocates the given block. The pointer parameter passed to the FreeMem function will never be nil (Delphi) or NULL (C++). If the FreeMem function successfully deallocates the given block, it should return zero. Otherwise, it should return a non-zero value. As invoked by the FreeMemory (see page 3579) routine.

The ReallocMem field (Delphi) or method (C++) must specify a function that reallocates the given block to the given new size. The pointer parameter passed to the ReallocMem function will never be nil (Delphi) or NULL (C++), and the Size parameter will never be zero. The ReallocMem function must reallocate the given block to the given new size, possibly moving the block if it cannot be resized in place. Any existing contents of the block must be preserved, but newly allocated space can be uninitialized. The ReallocMem function must return a pointer to the reallocated block, or nil (Delphi) or NULL (C++) if the block cannot be reallocated. As invoked by the ReallocMem routine.

AllocMem (see page 3515)

FreeMemory (see page 3579)

GetMemoryManager (see page 3587)

ReallocMem (see page 3637)

SetMemoryManager (see page 3660)

35.4.18 System::TMemoryManagerEx Record

System::TMemoryManagerEx defines extended memory block entry points.

Pascal

```
TMemoryManagerEx = record
  GetMem: function(Size: Integer): Pointer;
  FreeMem: function(P: Pointer): Integer;
  ReallocMem: function(P: Pointer; Size: Integer): Pointer;
  AllocMem: function(Size: Cardinal): Pointer;
  RegisterExpectedMemoryLeak: function(P: Pointer): Boolean;
  UnregisterExpectedMemoryLeak: function(P: Pointer): Boolean;
end;
```

C++

```
struct TMemoryManagerEx {
  function(Size: Integer): Pointer GetMem;
  function(P: Pointer): Integer FreeMem;
  function(P: Pointer; Size: Integer): Pointer ReallocMem;
  function(Size: Cardinal): Pointer AllocMem;
  function(P: Pointer): Boolean RegisterExpectedMemoryLeak;
  function(P: Pointer): Boolean UnregisterExpectedMemoryLeak;
};
```

File

System.pas

Description

The RegisterExpectedMemoryLeak type is used by the GetMemoryManager (see page 3587) and SetMemoryManager (see page 3660) procedures. It defines the routines that allocate and free memory.

The GetMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the GetMemory (see page 3585) routine.

The Size parameter passed to the GetMem function will never be zero. If the GetMem function cannot allocate a block of the given size, it should return nil (Delphi) or NULL (C++).

The FreeMem field (Delphi) or method (C++) must specify a function that deallocates the given block. The pointer parameter passed to the FreeMem function will never be nil (Delphi) or NULL (C++). If the FreeMem function successfully deallocates the

given block, it should return zero. Otherwise, it should return a non-zero value. As invoked by the FreeMemory (see page 3579) routine.

The ReallocMem field (Delphi) or method (C++) must specify a function that reallocates the given block to the given new size. The pointer parameter passed to the ReallocMem function will never be nil (Delphi) or NULL (C++), and the Size parameter will never be zero. The ReallocMem function must reallocate the given block to the given new size, possibly moving the block if it cannot be resized in place. Any existing contents of the block must be preserved, but newly allocated space can be uninitialized. The ReallocMem function must return a pointer to the reallocated block, or nil (Delphi) or NULL (C++) if the block cannot be reallocated. As invoked by the ReallocMem routine.

The AllocMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the AllocMem routine.

The RegisterExpectedMemoryLeak field (Delphi) or method (C++) must specify a function that registers a memory location that an application has allocated and does not expect to free, as invoked by the RegisterExpectedMemoryLeak routine.

The UnregisterExpectedMemoryLeak field (Delphi) or method (C++) must specify a function that removes a memory location from the Memory Manager's list of expected memory leaks, as invoked by the UnregisterExpectedMemoryLeak routine.

C++ Examples:

```
/*
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
*/

bool isMyMemMgr;
TMemoryManagerEx oldMemMgr;
volatile long getMemCalls;
volatile long freeMemCalls;
volatile long reallocMemCalls;
volatile long allocMemCalls;

void* __fastcall myGetMem(int size)
{
    //safely increment the counter
    InterlockedIncrement(&getMemCalls);

    //route the call
    return oldMemMgr.GetMem(size);
}

int __fastcall myFreeMem(void* p)
{
    //safely increment the counter
    InterlockedIncrement(&freeMemCalls);

    //route the call
    return oldMemMgr.FreeMem(p);
}

void* __fastcall myReallocMem(void* p, int size)
{
    //safely increment the counter
    InterlockedIncrement(&reallocMemCalls);

    //route the call
    return oldMemMgr.ReallocMem(p, size);
}

void* __fastcall myAllocMem(int size)
{
    //safely increment the counter
```

```
    InterlockedIncrement(&allocMemCalls);

    //route the call
    return oldMemMgr.AllocMem(size);
}

void __fastcall TForm3::btUseSysMemMgrClick(TObject *Sender)
{
    //switch button states
    btUseSysMemMgr->Enabled = false;
    btUseMyMemMgr->Enabled = true;

    //set the old memory manager back
    SetMemoryManager(oldMemMgr);

    isMyMemMgr = false;

    //clear out the variables
    getMemCalls     = 0;
    freeMemCalls    = 0;
    reallocMemCalls = 0;
    allocMemCalls   = 0;
}

void __fastcall TForm3::FormDestroy(TObject *Sender)
{
    //set the old memory manager back
    if (isMyMemMgr)
    {
        SetMemoryManager(oldMemMgr);
    }
}

void __fastcall TForm3::Timer1Timer(TObject *Sender)
{
    //Note that IntToStr calls will also Allocate/Free
    //memory so at each timer tick the counts will be +4;

    Form3->edGetMem->Text = IntToStr((int)getMemCalls);
    Form3->edFreeMem->Text = IntToStr((int)freeMemCalls);
    Form3->edReallocMem->Text = IntToStr((int)reallocMemCalls);
    Form3->edAllocMem->Text = IntToStr((int)allocMemCalls);
}

void __fastcall TForm3::btUseMyMemMgrClick(TObject *Sender)
{
    TMemoryManagerEx myMemMgr;

    //switch button states
    btUseSysMemMgr->Enabled = true;
    btUseMyMemMgr->Enabled = false;

    //get the old memory manager
    GetMemoryManager(oldMemMgr);

    //create out instance
    myMemMgr.GetMem = myGetMem;
    myMemMgr.FreeMem = myFreeMem;
    myMemMgr.AllocMem = myAllocMem;
    myMemMgr.ReallocMem = myReallocMem;

    //use defaults for this - not important
    myMemMgr.RegisterExpectedMemoryLeak = oldMemMgr.RegisterExpectedMemoryLeak;
    myMemMgr.UnregisterExpectedMemoryLeak = oldMemMgr.UnregisterExpectedMemoryLeak;

    //clear out the variables
```

```
    getMemCalls     = 0;
    freeMemCalls    = 0;
    reallocMemCalls = 0;
    allocMemCalls   = 0;

    //install the new memory manager
    SetMemoryManager(myMemMgr);

    isMyMemMgr = true;
}

void __fastcall TForm3::btDoSomethingClick(TObject *Sender)
{
    void *ptr;
    //perform some new and delete
    for (int i=0; i < 1000; ++i)
    {
        ptr = GetMemory(4);
        FreeMemory(ptr);
    }
}
```

Delphi Examples:

```
{
This example demonstrates the use of SetMemoryManager and
GetMemoryManager routines. Note that this example is
thread safe.
}
var
  OldMemMgr       : TMemoryManagerEx;
  GetMemCalls     : Integer;
  FreeMemCalls    : Integer;
  ReallocMemCalls : Integer;
  AllocMemCalls   : Integer;

function MyGetMem(Size: Integer): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.GetMem(Size);

  { Safely increment the counter }
  InterlockedIncrement(GetMemCalls);
end;

function MyFreeMem(P: Pointer): Integer;
begin
  { Route the call }
  Result := OldMemMgr.FreeMem(P);

  { Safely increment the counter }
  InterlockedIncrement(FreeMemCalls);
end;

function MyReallocMem(P: Pointer; Size: Integer): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.ReallocMem(P, Size);

  { Safely increment the counter }
  InterlockedIncrement(ReallocMemCalls);
end;

function MyAllocMem(Size: Cardinal): Pointer;
begin
  { Route the call }
  Result := OldMemMgr.AllocMem(Size);
```

```
  { Safely increment the counter }
  InterlockedIncrement(AllocMemCalls);
end;

procedure TForm2.btPerformSomethingClick(Sender: TObject);
var
  X : Integer;
  I : ^Integer;
begin
  { Perform some allocations and frees }
  for X := 0 to 999 do
  begin
    New(I);
    Dispose(I);
  end;
end;

procedure TForm2.btUseMyMemMgrClick(Sender: TObject);
var
  MyMemMgr : TMemoryManagerEx;
begin
  { Switch button states }
  btUseSystemMemMgr.Enabled := true;
  btUseMyMemMgr.Enabled := false;

  { Get the old memory manager }
  GetMemoryManager(OldMemMgr);

  { Create our instance }
  MyMemMgr.GetMem := MyGetMem;
  MyMemMgr.FreeMem := MyFreeMem;
  MyMemMgr.ReallocMem := MyReallocMem;
  MyMemMgr.AllocMem := MyAllocMem;

  { Use the defaults for this - not important }
  MyMemMgr.RegisterExpectedMemoryLeak := OldMemMgr.RegisterExpectedMemoryLeak;
  MyMemMgr.UnregisterExpectedMemoryLeak := OldMemMgr.UnregisterExpectedMemoryLeak;

  { Clear out the count variables }
  GetMemCalls := 0;
  FreeMemCalls := 0;
  ReallocMemCalls := 0;
  AllocMemCalls := 0;

  { Install the new memory manager }
  SetMemoryManager(MyMemMgr);
end;

procedure TForm2.btUseSystemMemMgrClick(Sender: TObject);
begin
  { Switch button states }
  btUseSystemMemMgr.Enabled := false;
  btUseMyMemMgr.Enabled := true;

  { Set the old memory manager back! }
  SetMemoryManager(OldMemMgr);

  GetMemCalls := 0;
  FreeMemCalls := 0;
  ReallocMemCalls := 0;
  AllocMemCalls := 0;
end;

procedure TForm2.FormDestroy(Sender: TObject);
begin
```

```
    { Set the old memory manager back }
    if IsMemoryManagerSet then
       SetMemoryManager(OldMemMgr);
  end;

35.4.19 System::TMemoryManagerState Record

System::TMemoryManagerState holds statistics about memory allocations.

Pascal

```
  TMemoryManagerState = packed record
    SmallBlockTypeStates: TSmallBlockTypeStates;
    AllocatedMediumBlockCount: Cardinal;
    TotalAllocatedMediumBlockSize: Cardinal;
    ReservedMediumBlockAddressSpace: Cardinal;
    AllocatedLargeBlockCount: Cardinal;
    TotalAllocatedLargeBlockSize: Cardinal;
    ReservedLargeBlockAddressSpace: Cardinal;
  end;
```

C++

```
  struct TMemoryManagerState {
    TSmallBlockTypeStates SmallBlockTypeStates;
    Cardinal AllocatedMediumBlockCount;
    Cardinal TotalAllocatedMediumBlockSize;
    Cardinal ReservedMediumBlockAddressSpace;
    Cardinal AllocatedLargeBlockCount;
    Cardinal TotalAllocatedLargeBlockSize;
    Cardinal ReservedLargeBlockAddressSpace;
  };
```

File

System.pas

Description

GetMemoryManagerState (see page 3591) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a System::TMemoryManagerState record. AllocMem (see page 3515) and GetMemory (see page 3585) can be used to allocate memory blocks. The record holds the following information :

Field	Meaning
SmallBlockTypeStates	An array of small memory block information records.
AllocatedMediumBlockCount	The number of medium sized memory blocks (blocks less than 264,749 bytes in size).
TotalAllocatedMediumBlockSize	The total number of bytes oiccupied by the medium memory blocks.
ReservedMediumBlockAddressSpace	The amount of memory reserved for medium memory blocks.
AllocatedLargeBlockCount	The number of large sized memory blocks (blocks greater than 264,748 bytes in size).
TotalAllocatedLargeBlockSize	The total number of bytes oiccupied by the large memory blocks.
ReservedLargeBlockAddressSpace	The amount of memory reserved for large memory blocks.

35.4.20 System.TMethod Record

TMethod stores Code and Data fields to represent a method.

Pascal

```
TMethod = record
  Code: Pointer;
  Data: Pointer;
end;
```

C++

```
struct TMethod {
  void * Code;
  void * Data;
};
```

File

System

Description

The TMethod stores the Code and Data pointers for a method. This type can be used in a type cast of a method pointer to access the code and data parts of the method pointer.

You can also furnish a TMethod variable by assigning Data a pointer to an object, and assigning Code using System::TObject::MethodAddress (see page 3378), specifying the method name as a string parameter to that method.

See Also

System::TObject::MethodAddress (see page 3378)

35.4.21 System.TMinimumBlockAlignment Enumeration

TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.

Pascal

```
TMinimumBlockAlignment = (
  mba8Byte,
  mba16Byte
);
```

C++

```
enum TMinimumBlockAlignment {
  mba8Byte,
  mba16Byte
};
```

File

System

Description

The TMinimumBlockAlignment type defines either 8 byte (**mba8Byte**) or 16 byte (**mba16Byte**) block alignments. Namely, that the memory address is divisible exactly by 8 or 16 respectively.

See Also

AllocMem (see page 3515)

GetMemory (see page 3585)

35.4.22 System::TModuleUnloadRec Record

Pascal

```
TModuleUnloadRec = record
  Next: PModuleUnloadRec;
  Proc: TModuleUnloadProcLW;
end;
```

C++

```
struct TModuleUnloadRec {
  PModuleUnloadRec Next;
  TModuleUnloadProcLW Proc;
};
```

File

System.pas

Description

This is record System::TModuleUnloadRec.

35.4.23 System.TMonitorSupport Record

Pascal

```
TMonitorSupport = record
  NewSyncObject: function: Pointer;
  FreeSyncObject: procedure (SyncObject: Pointer);
  NewWaitObject: function: Pointer;
  FreeWaitObject: procedure (WaitObject: Pointer);
  WaitAndOrSignalObject: function (SignalObject, WaitObject: Pointer; Timeout: Cardinal):
Cardinal;
end;
```

C++

```
struct TMonitorSupport {
  function: Pointer NewSyncObject;
  procedure (SyncObject: Pointer) FreeSyncObject;
  function: Pointer NewWaitObject;
  procedure (WaitObject: Pointer) FreeWaitObject;
  function (SignalObject, WaitObject: Pointer; Timeout: Cardinal): Cardinal
WaitAndOrSignalObject;
};
```

File

System

Description

This is record System.TMonitorSupport.

35.4.24 System::TResStringRec Record

Pascal

```
TResStringRec = packed record
  Module: ^Cardinal;
  Identifier: Integer;
end;
```

C++

```
struct TResStringRec {
  ^Cardinal Module;
  Integer Identifier;
};
```

File

System.pas

Description

This is record System::TResStringRec.

35.4.25 System.TRuntimeError Enumeration

TRuntimeError is an enumeration of internal runtime error codes.

Pascal

```
TRuntimeError = (
  reNone,
  reOutOfMemory,
  reInvalidPtr,
  reDivByZero,
  reRangeError,
  reIntOverflow,
  reInvalidOp,
  reZeroDivide,
  reOverflow,
  reUnderflow,
  reInvalidCast,
  reAccessViolation,
  rePrivInstruction,
  reControlBreak,
  reStackOverflow,
  reVarTypeCast,
  reVarInvalidOp,
  reVarDispatch,
  reVarArrayCreate,
  reVarNotArray,
  reVarArrayBounds,
  reAssertionFailed,
  reExternalException,
  reIntfCastError,
  reSafeCallError,
  reMonitorNotLocked,
  reNoMonitorSupport
);
```

C++

```
enum TRuntimeError {
  reNone,
  reOutOfMemory,
  reInvalidPtr,
  reDivByZero,
  reRangeError,
  reIntOverflow,
  reInvalidOp,
  reZeroDivide,
  reOverflow,
  reUnderflow,
  reInvalidCast,
  reAccessViolation,
  rePrivInstruction,
  reControlBreak,
  reStackOverflow,
  reVarTypeCast,
  reVarInvalidOp,
  reVarDispatch,
  reVarArrayCreate,
  reVarNotArray,
  reVarArrayBounds,
  reAssertionFailed,
  reExternalException,
  reIntfCastError,
```

```
    reSafeCallError,
    reMonitorNotLocked,
    reNoMonitorSupport
  };
```

File

System

Description

The TRuntimeError type is used internally within Delphi when Error (see page 3560) is used to generate a run-time exception. It defines the type of run time error that has occured. The values are :

Constant	Meaning
reNone	Undefined error.
reOutOfMemory	Out of memory
reInvalidPtr	An attempt was made to use a nil or invalid pointer.
reDivByZero	An attempt was made to divide by zero.
reRangeError	A value out of range was encountered.
reIntOverflow	An integer variable exceeded its capacity.
reInvalidOp	An invalid operation was attempted.
reZeroDivide	An attempt was made to divide by zero.
reOverflow	A floating point number exceeded its positive capacity.
reUnderflow	A floating point number exceeded its negative capacity
reInvalidCast	An invalid type cast operation was attempted.
reAccessViolation	An attempt was made to access an invalid storage address.
rePrivInstruction	An attempt was made to execute a priveleged instruction.
reControlBreak	The user pressed Ctrl-Break (see page 3531) to interrupt an operation.
reStackOverflow	The internal stack exceeded its capacity.
reVarTypeCast	An invalid variable type cast operation was attempted.
reVarInvalidOp	An attempt was made to process an invalid variable type.
reVarDispatch	
reVarArrayCreate	
reVarNotArray	
reVarArrayBounds	
reAssertionFailed	
reExternalException	An external exception was encountered.
reIntfCastError	
reSafeCallError	

Delphi Examples:

```
{
This example demostrates the use of ErrorProc and how to catch runtime
errors.
}
procedure MyErrorProc(ErrorCode : Byte; ErrorPtr : Pointer);
var
```

```
    ErrorName : String;
  begin
    { Get the "name" of the enum value using RTTI }
    ErrorName := GetEnumName(TypeInfo(TRuntimeError), ErrorCode);

    { Show an error box }
    MessageDlg(Format('Error with code %d (%s) risen at $%X.',
        [ErrorCode, ErrorName, Integer(ErrorPtr)]), mtError, [mbOK], 0);
  end;

  procedure TForm2.btIOErrorClick(Sender: TObject);
  begin
    {
    Try to write something onto the console - will raise an
    exception.
    }
    WriteLn('This will generate an error because there is no' +
            ' console attached!');
  end;

  {$OVERFLOWCHECKS ON}
  {$OPTIMIZATION OFF}
  {$HINTS OFF}
  procedure TForm2.btOverflowErrClick(Sender: TObject);
  var
    b : Cardinal;
  begin
    {
    Simulate an overflow: Note, enabled the overflow
    checking and disabled optimizations because Delphi's
    compiler will not compile this code otherwise.
    }
    b := $FFFFFFFF;
    b := b * b;
  end;
  {$HINTS ON}
  {$OPTIMIZATION ON}
  {$OVERFLOWCHECKS OFF}

  procedure TForm2.btRuntimeErrorClick(Sender: TObject);
  begin
    { Simulate an access violation }
    System.Error(reAccessViolation);
  end;

  procedure TForm2.FormCreate(Sender: TObject);
  begin
    { Register my System error proc }
    ErrorProc := MyErrorProc;
  end;
```

See Also

Error (see page 3560)

35.4.26 System::TSmallBlockTypeState Record

System::TSmallBlockTypeState holds statistics about a small memory block.

Pascal

```
  TSmallBlockTypeState = packed record
    InternalBlockSize: Cardinal;
```

```
    UseableBlockSize: Cardinal;
    AllocatedBlockCount: Cardinal;
    ReservedAddressSpace: Cardinal;
  end;
```

C++

```
  struct TSmallBlockTypeState {
    Cardinal InternalBlockSize;
    Cardinal UseableBlockSize;
    Cardinal AllocatedBlockCount;
    Cardinal ReservedAddressSpace;
  };
```

File

System.pas

Description

GetMemoryManagerState (see page 3591) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a System::TMemoryManagerState (see page 3730) record. Within that record is held a System::TSmallBlockTypeStates (see page 3795) field - an array of System::TSmallBlockTypeState records. Each System::TSmallBlockTypeState record holds the following information :

Field	Meaning
InternalBlockSize	Actual memory allocated to each small memory block - at least 4 bytes of which are not available in the UseableBlockSize.
UseableBlockSize	The useable size of each allocated small memory block.
AllocatedBlockCount	The number of small memory blocks allocated of the given InternalBlockSize.
ReservedAddressSpace	The amount memory reserved for this group of small memory blocks.

See Also

System::TSmallBlockTypeStates (see page 3795)

GetMemoryManagerState (see page 3591)

35.4.27 System.TTextLineBreakStyle Enumeration

TTextLineBreakStyle indicates the default set of characters used to divide lines in text.

Pascal

```
  TTextLineBreakStyle = (
    tlbsLF,
    tlbsCRLF
  );
```

C++

```
  enum TTextLineBreakStyle {
    tlbsLF,
    tlbsCRLF
  };
```

File

System

Description

TTextLineBreakStyle can have one of the following values:

Value	Meaning
tlbsLF	Linefeed only
tlbsCRLF	Carriage return followed by Linefeed

35.4.28 System.TTextRec Record

TTextRec is the internal format for text files.

Pascal

```
TTextRec = packed record
  Handle: Integer;
  Mode: Word;
  Flags: Word;
  BufSize: Cardinal;
  BufPos: Cardinal;
  BufEnd: Cardinal;
  BufPtr: PAnsiChar;
  OpenFunc: Pointer;
  InOutFunc: Pointer;
  FlushFunc: Pointer;
  CloseFunc: Pointer;
  UserData: array[1..32] of Byte;
  Name: array[0..259] of WideChar;
  Buffer: TTextBuf;
end;
```

C++

```
struct TTextRec {
  int Handle;
  Word Mode;
  Word Flags;
  unsigned BufSize;
  unsigned BufPos;
  unsigned BufEnd;
  PAnsiChar BufPtr;
  void * OpenFunc;
  void * InOutFunc;
  void * FlushFunc;
  void * CloseFunc;
  array[1..32] of Byte UserData;
  array[0..259] of WideChar Name;
  TTextBuf Buffer;
};
```

File

System

Description

TTextRec is the internal format of a Delphi variable of type text. You would never declare a variable of this type. However, you can use TTextRec to typecast a text file variable to access the internal data fields, such as the file name.

TextBuf is the type of the Buffer entry in the TTextRec record, and indicates the size of the buffer used.

Note: Do not use this unless you are familiar with writing text file device drivers for the Delphi language.

35.4.29 System::TVarArray Record

This is the descriptor type for safe arrays.

Pascal

```
TVarArray = packed record
  DimCount: Word;
  Flags: Word;
  ElementSize: Integer;
  LockCount: Integer;
  Data: Pointer;
  Bounds: TVarArrayBoundArray;
end;
```

C++

```
struct TVarArray {
  Word DimCount;
  Word Flags;
  Integer ElementSize;
  Integer LockCount;
  Pointer Data;
  TVarArrayBoundArray Bounds;
};
```

File

System.pas

Description

A variable of type System::TVarArray stores all the necessary information about a safe array. The meaning of each field in the System::TVarArray record is given in the following table.

Field	Meaning
DimCount	The number of dimensions of the safe array.
Flags	Flags providing different kind of information about the safe array.
ElementSize	The size in bytes of a safe array element.
LockCount	The number of times the safe array has been locked.
Data	The actual data in the safe array.
Bounds	The bounds of the safe array corresponding to all its dimensions. This is an array of System::TVarArrayBoundArray (see page 3798) type.

See Also

System::TVarArrayBoundArray (see page 3798)

SafeArrayCreate (see page 5118)

SafeArrayDestroy (see page 5119)

SafeArrayGetElemSize (see page 5122)

SafeArrayGetLBound (see page 5122)

SafeArrayGetUBound (see page 5123)

35.4.30 System::TVarArrayBound Record

Gives bound information for one dimension of a safe array.

Pascal

```
TVarArrayBound = packed record
  ElementCount: Integer;
  LowBound: Integer;
end;
```

C++

```
struct TVarArrayBound {
  Integer ElementCount;
  Integer LowBound;
};
```

File

System.pas

Description

Declare a variable of System::TVarArrayBound type to store information about the array bounds, corresponding to one dimension of a safe array.

The following list describes each field in the System::TVarArrayBound type.

Field	Meaning
ElementCount	The number of elements in the corresponding dimension.
LowBound	The low bound of the index range, in the corresponding dimension.

See Also

TVarArrayBoundArray (see page 3798)

35.4.31 System.TVarData Record

TVarData represents Variant (see page 3421) information.

Pascal

```
TVarData = packed record
  case Integer of
    0: (VType: TVarType;
        Reserved1: Word;
        Reserved2: Word;
        Reserved3: Word;);
    1: (VLongs: array[0..2] of LongInt);
        RawData: array [0..3] of LongInt););
    2: (VWords: array [0..6] of Word);
        VBytes: array [0..13] of Byte););
    varAny: (VAny: Pointer;);
    varArray: (VArray: PVarArray;);
    varBoolean: (VBoolean: WordBool;);
    varByRef: (VPointer: Pointer;);
    varByte: (VByte: Byte;);
```

```
      varCurrency: (VCurrency: Currency;);

Description

TVarData is the base class for Variant (see page 3421).

Note: The internal structure of a Variant (see page 3421) as designated by TVarData is identical to the Variant (see page 3421) type used by OLE and the Win32 APIs.

struct TVarData

  {

```
  union
      {
        Word     VType;    // Delphi-compatible - Variant Type member
        VARTYPE  vt;       // tagVARIANT compatible member
      };
      Word Reserved1;
      Word Reserved2;
      Word Reserved3;
  union
      {
        // Delphi-compatible Variant members
        Smallint      VSmallint;    //  iVal
        Integer       VInteger;     //  lVal
        Single        VSingle;      //  fltVal
        Double        VDouble;      //  dblVal
        CurrencyBase  VCurrency;    //  cyVal
        TDateTimeBase VDate;        //  date
        PWideChar     VOleStr;      //  bstrVal
        IDispatch*    VDispatch;    //  pdispVal
        HResult       VError;       //  scode
        WordBool      VBoolean;     //  boolVal
        IUnknown*     VUnknown;     //  punkVal
        Byte          VByte;        //  bVal
        Pointer       VString;      //  ??????
        PVarArray     VArray;       //  parray
        Pointer       VPointer;     //  byref
        // tagVARIANT compatible members (from OAIDL.H)
        // Allowing all types marked as [V] (may appear in a VARIANT to be initialized
        LONG          lVal;
        BYTE          bVal;
        SHORT         iVal;
        FLOAT         fltVal;
        DOUBLE        dblVal;
        VARIANT_BOOL  boolVal;
        SCODE         scode;
        CY            cyVal;
        DATE          date;
        BSTR          bstrVal;
        IUnknown     *punkVal;
        IDispatch    *pdispVal;
        SAFEARRAY    *parray;
        BYTE         *pbVal;SHORT        *piVal;
        LONG         *plVal;
        FLOAT        *pfltVal;
        DOUBLE       *pdblVal;
        VARIANT_BOOL *pboolVal;
        SCODE        *pscode;
        CY           *pcyVal;
        DATE         *pdate;
        BSTR         *pbstrVal;
        IUnknown    **ppunkVal;
        IDispatch   **ppdispVal;
        SAFEARRAY   **pparray;
        VARIANT      *pvarVal;
        PVOID         byref;
        CHAR          cVal;
        USHORT        uiVal;
        ULONG         ulVal;
        INT           intVal;
        UINT          uintVal;
        DECIMAL      *pdecVal;
        CHAR         *pcVal;
        USHORT       *puiVal;
        ULONG        *pulVal;
        INT          *pintVal;
        UINT         *puintVal;
```

```
    };
  };
```

The VType of TVarData contains the type code of the variant in the lower twelve bits (the bits defined by varTypeMask (see page 3872)).

The following values are used for VType:

#define varEmpty (see page 3865) (Byte)(0)

```
#define varNull (ByteByte_Type)(1)
#define varSmallint (ByteByte_Type)(2)
#define varInteger (ByteByte_Type)(3)
#define varSingle (ByteByte_Type)(4)
#define varDouble (ByteByte_Type)(5)
#define varCurrency (ByteByte_Type)(6)
#define varDate (ByteByte_Type)(7)
#define varOleStr (ByteByte_Type)(8)
#define varDispatch (ByteByte_Type)(9)
#define varError (ByteByte_Type)(10)
#define varBoolean (ByteByte_Type)(11)
#define varVariant (ByteByte_Type)(12)
#define varUnknown (ByteByte_Type)(13)
#define varByte (ByteByte_Type)(17)
#define varString (WordWord_Type)(256)
#define varTypeMask (WordWord_Type)(4095)
#define varArray (WordWord_Type)(8192)
#define varByRef (WordWord_Type)(16384)
#define varStrArg (ByteByte_Type)(72)
#define vtInteger (ByteByte_Type)(0)
#define vtBoolean (ByteByte_Type)(1)
#define vtChar (ByteByte_Type)(2)
#define vtExtended (ByteByte_Type)(3)
#define vtString (ByteByte_Type)(4)
#define vtPointer (ByteByte_Type)(5)
#define vtPChar (ByteByte_Type)(6)
#define vtObject (ByteByte_Type)(7)
#define vtClass (ByteByte_Type)(8)
#define vtWideChar (ByteByte_Type)(9)
#define vtPWideChar (ByteByte_Type)(10)
#define vtAnsiString (ByteByte_Type)(11)
#define vtCurrency (ByteByte_Type)(12)
#define vtVariant (ByteByte_Type)(13)
```

In addition, the varArray (see page 3861) bit may be set to indicate that the variant is an array, and the varByRef (see page 3862) bit may be set to indicate that the variant contains a reference as opposed to a value.

Word Reserved1;

```
    Word Reserved2;
    Word Reserved3;
```

The Reserved1, Reserved2, and Reserved3 members of TVarData are unused.

union { Smallint VSmallint;

```
      Integer VInteger;
      Single VSingle;
      Double VDouble;
      CurrencyBase VCurrency;
      TDateTimeBase VDate;
      PWideChar VOleStr;
      Ole2::IDispatch* VDispatch;
      Integer VError;
      WordBool VBoolean;
      Ole2::IUnknown* VUnknown;
      Byte VByte;
```

```
      Pointer VString;
      PVarArray VArray;
      Pointer VPointer;
    };
};
```

The contents of the remaining eight bytes of TVarData depend on the VType field. If neither the varArray (see page 3861) nor the varByRef (see page 3862) bits are set, the variant contains a value of the given type.

If the varArray (see page 3861) bit is set, the variant contains a pointer to a TVarArray (see page 3739) structure that defines the specifics of the array. The type of each array element is given by the varTypeMask (see page 3872) bits in VType.

If the varByRef (see page 3862) bit is set, the variant contains a reference to a value of the type given by the varTypeMask (see page 3872) and varArray (see page 3861) bits in VType.

C++ Examples:

```
/*
This example shows how to use the TVarData type in typecasts
of Variant variables to access the internals of a variable.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Variant V;
  AnsiString mystr;
  if (TVarData(V).VType == varEmpty)
    ListBox1->Items->Add("Variants start empty.");
  VarClear(V);
  TVarData(V).VType = varString;
  mystr = "Here is my string";
  std::auto_ptr<char> MyBuffer(new char[mystr.Length() + 1]);
  StrCopy(MyBuffer.get(), mystr.c_str());
  TVarData(V).VString  = MyBuffer.get();
  mystr = PAnsiChar(TVarData(V).VString);
  ListBox1->Items->Add("This variant is now a string: " + mystr);
  VarClear(V);
  TVarData(V).VType = varInteger;
  TVarData(V).VInteger = 1234567;
  ListBox1->Items->Add("This variant is now an integer: " + IntToStr(TVarData(V).VInteger));
}
```

Delphi Examples:

```
{{
This example shows how to use the TVarData type in typecasts
of Variant variables to access the internals of a variable.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  V: Variant;
  mystr: string;
  MyBuffer: PChar;
begin
  if TVarData(V).VType = varEmpty then
    ListBox1.Items.Add('Variants start empty.');
  VarClear(V);
  TVarData(V).VType := varString;
  mystr := 'Here is my string';
  MyBuffer:= GetMemory(Length(mystr));
  StrCopy(MyBuffer, PChar(mystr));
  TVarData(V).VString := MyBuffer;
  ListBox1.Items.Add('This variant is now a string: ' + PChar(TVarData(V).VString));
  VarClear(V);
  TVarData(V).VType := varInteger;
  TVarData(V).VInteger := 1234567;
```

```
  ListBox1.Items.Add('This variant is now an integer: ' + IntToStr(TVarData(V).VInteger));
end;
```

35.4.32 System::TVariantManager Record

System::TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.

Pascal

```
TVariantManager = record
  VarClear: procedure(var V : Variant);
  VarCopy: procedure(var Dest: Variant; const Source: Variant);
  VarCopyNoInd: procedure;
  VarCast: procedure(var Dest: Variant; const Source: Variant; VarType: Integer);
  VarCastOle: procedure(var Dest: Variant; const Source: Variant; VarType: Integer);
  VarToInt: function(const V: Variant): Integer;
  VarToInt64: function(const V: Variant): Int64;
  VarToBool: function(const V: Variant): Boolean;
  VarToReal: function(const V: Variant): Extended;
  VarToCurr: function(const V: Variant): Currency;

  };
```

File

System.pas

Description

The System::TVariantManager type is used by the GetVariantManager (see page 3594) and SetVariantManager (see page 3668) procedures. It defines routines that perform Variant (see page 3421) type conversions and other tasks that implement Variant (see page 3421) behavior.

Note: Although a version of System::TVariantManager is declared in sysclass.h, it should not be used in C++ code. The use of a Variant (see page 3421) manager to customize the behavior of Variants (see page 4973) is not fully supported in C++.

See Also

GetVariantManager (see page 3594)

SetVariantManager (see page 3668)

35.4.33 System::TVarRec Record

System::TVarRec is used inside a function with an untyped array parameter.

Pascal

```
TVarRec = record
  case Byte of
    vtAnsiString: (VAnsiString: Pointer;);
    vtBoolean: (VBoolean: Boolean;);
    vtChar: (VChar: AnsiChar;);
    vtClass: (VClass: TClass;);
    vtCurrency: (VCurrency: PCurrency;);
    vtExtended: (VExtended: PExtended;);
    vtInt64: (VInt64: PInt64;);
    vtInteger: (VInteger: Integer;
                VType: Byte;);
    vtInterface: (VInterface: Pointer;);
    vtObject: (VObject: TObject;);
    vtPChar: (VPChar: PAnsiChar;);
    vtPointer: (VPointer: Pointer;);
    vtPWideChar: (VPWideChar: PWideChar;);
    vtString: (VString: PShortString;);
    vtUnicodeString: (VUnicodeString: Pointer;);
    vtVariant: (VVariant: PVariant;);
    vtWideChar: (VWideChar: WideChar;);
    vtWideString: (VWideString: Pointer;);
end;
```

C++

```
struct TVarRec {
  Integer VInteger;
  Byte VType;
  Boolean VBoolean;
  AnsiChar VChar;
  PExtended VExtended;
  PShortString VString;
  Pointer VPointer;
  PAnsiChar VPChar;
  TObject VObject;
  TClass VClass;
  WideChar VWideChar;
  PWideChar VPWideChar;
  Pointer VAnsiString;
  PCurrency VCurrency;
  PVariant VVariant;
  Pointer VInterface;
  Pointer VWideString;
  PInt64 VInt64;
  Pointer VUnicodeString;
};
```

File

System.pas

Description

The System::TVarRec type is used inside a function with a parameter type of array of const in Delphi. In Delphi, the compiler automatically translates each element in the array to a System::TVarRec value. In C++, the function parameter appears as an array of System::TVarRec values.

Use System::TVarRec to work with individual elements of the array when implementing the function that has an array of const parameter.

The VType field indicates the simple type of each System::TVarRec value. The variable type constants represent the values passed in the tag of the System::TVarRec structure. These constants, listed below, are defined in the System (see page 3159) unit.

Delphi constants :

vtInteger (see page 3886)	= 0;
vtBoolean (see page 3883)	= 1;
vtCharacter	= 2;
vtExtended (see page 3885)	= 3;
vtString (see page 3889)	= 4;
vtPointer (see page 3888)	= 5;
vtPChar (see page 3888)	= 6;
vtObject (see page 3887)	= 7;
vtClass (see page 3884)	= 8;
vtWideChar (see page 3890)	= 9;
vtPWideChar (see page 3889)	= 10;
vtAnsiString (see page 3883)	= 11;
vtCurrency (see page 3885)	= 12;
vtVariant (see page 3890)	= 13;
vtInterface (see page 3887)	= 14;
vtWideString (see page 3891)	= 15;
vtInt64 (see page 3886)	= 16;

C++ constants :

static const Shortint vtInteger (see page 3886)	= 0x0;
static const Shortint vtBoolean (see page 3883)	= 0x1;
static const Shortint vtCharacter	= 0x2;
static const Shortint vtExtended (see page 3885)	= 0x3;
static const Shortint vtString (see page 3889)	= 0x4;
static const Shortint vtPointer (see page 3888)	= 0x5;
static const Shortint vtPChar (see page 3888)	= 0x6;
static const Shortint vtObject (see page 3887)	= 0x7;
static const Shortint vtClass (see page 3884)	= 0x8;
static const Shortint vtWideChar (see page 3890)	= 0x9;
static const Shortint vtPWideChar (see page 3889)	= 0xa;
static const Shortint vtAnsiString (see page 3883)	= 0xb;
static const Shortint vtCurrency (see page 3885)	= 0xc;
static const Shortint vtVariant (see page 3890)	= 0xd;

static const Shortint vtInterface (see page 3887)	= 0xe;
static const Shortint vtWideString (see page 3891)	= 0xf;
static const Shortint vtInt64 (see page 3886)	= 0x10;

Note: In C++, you can create an array of System::TVarRec values using the ARRAYOFCONST macro, which is defined in sysopen.h.

35.4.34 System::TCallDesc Structure

Pascal

```
TCallDesc = struct TCallDesc@1;
```

C++

```
typedef struct {
  unsigned char CallType;
  unsigned char ArgCount;
  unsigned char NamedArgCount;
  unsigned char ArgTypes[256];
} TCallDesc, * PCallDesc;
```

File

systvar.h

Description

This is type System::TCallDesc.

35.4.35 System::TDispDesc Structure

Pascal

```
TDispDesc = struct TDispDesc@1;
```

C++

```
typedef struct {
  int DispID;
  unsigned char ResType;
  TCallDesc CallDesc;
} TDispDesc, * PDispDesc;
```

File

systvar.h

Description

This is type System::TDispDesc.

35.5 Types

The following table lists types in this documentation.

Types

Name	Description
CppLongInt (see page 3752)	This is type System.CppLongInt.
CppULongInt (see page 3753)	This is type System.CppULongInt.
GetPackageInfoTable (see page 3753)	This is type System.GetPackageInfoTable.
HGLOBAL (see page 3753)	This is type System.HGLOBAL.
HINST (see page 3754)	This is type System.HINST.
HMODULE (see page 3754)	This is type System.HMODULE.
HRESULT (see page 3754)	This is type System.HRESULT.
HRSRC (see page 3755)	This is type System.HRSRC.
Int16 (see page 3755)	Alias for `SmallInt`.
Int32 (see page 3755)	Alias for `Integer`.
Int8 (see page 3756)	Alias for `ShortInt`.
IntegerArray (see page 3756)	This is type System.IntegerArray.
IUnknown (see page 3756)	IUnknown is a special base interface.
PackageInfo (see page 3757)	PackageInfo is a pointer to a PackageInfoTable (see page 3713) variable.
PAnsiString (see page 3757)	PAnsiString is a pointer to an `AnsiString` variable.
PBoolean (see page 3758)	PBoolean is a pointer to a `Boolean` variable.
PByte (see page 3758)	PByte is a pointer to a `Byte` variable.
PCallDesc (see page 3758)	This is type System::PCallDesc.
PCardinal (see page 3759)	PCardinal is a pointer to a `Cardinal` variable.
PComp (see page 3759)	PComp is a pointer to a `Comp` variable.
PCurrency (see page 3759)	PCurrency is a pointer to a `Currency (see page 3235)` variable.
PCVModInfo (see page 3760)	This is type System.PCVModInfo.
PDate (see page 3760)	PDate is a pointer to a Date variable.
PDateTime (see page 3761)	PDateTime is a pointer to a TDateTime (see page 3323) variable.
PDispatch (see page 3761)	This is type System.PDispatch.
PDispDesc (see page 3761)	This is type System::PDispDesc.
PDouble (see page 3762)	PDouble is a pointer to a `Double` variable.
PDynArrayTypeInfo (see page 3762)	This is type System.PDynArrayTypeInfo.
PError (see page 3762)	This is type System.PError.
PExtended (see page 3763)	PExtended is a pointer to an `Extended` variable.
PGUID (see page 3763)	PGUID is a pointer to a TGUID (see page 3718) variable.
PInitContext (see page 3765)	This is type System.PInitContext.
PInt64 (see page 3765)	PInt64 is a pointer to an `Int64` variable.
PInteger (see page 3765)	PInteger is a pointer to an `Integer` variable.
PIntegerArray (see page 3766)	PIntegerArray is a pointer to an `IntegerArray (see page 3756)` variable.
PInterfaceEntry (see page 3766)	PInterfaceEntry is a pointer to a TInterfaceEntry (see page 3722) variable.
PInterfaceTable (see page 3766)	PInterfaceTable is a pointer to a TInterfaceTable (see page 3723) variable.
PLibModule (see page 3767)	PLibModule is a pointer to a System::TLibModule (see page 3723) variable.
PLongint (see page 3767)	PLongint is a pointer to a `LongInt` variable.
PLongWord (see page 3768)	PLongWord is a pointer to a `LongWord` variable.
PMemoryManager (see page 3768)	System::PMemoryManager is a pointer to a System::TMemoryManager (see page 3724) variable.
PMemoryManagerEx (see page 3768)	System::PMemoryManagerEx is a pointer to a System::TMemoryManagerEx (see page 3725) variable.

PModuleUnloadRec (see page 3769)	This is type System::PModuleUnloadRec.
PMonitor (see page 3769)	This is type System.PMonitor.
PMonitorSupport (see page 3769)	This is type System.PMonitorSupport.
PointerArray (see page 3770)	This is type System.PointerArray.
POleVariant (see page 3770)	POleVariant is a pointer to a System::OleVariant (see page 3274) variable.
PPAnsiChar (see page 3770)	This is type System.PPAnsiChar.
PPChar (see page 3771)	This is type System.PPChar.
PPCharArray (see page 3771)	This is type System.PPCharArray.
PPDispatch (see page 3771)	This is type System.PPDispatch.
PPMonitor (see page 3772)	This is type System.PPMonitor.
PPointer (see page 3772)	PPointer is a pointer to a `Pointer` variable.
PPointerArray (see page 3772)	PPointerArray is a pointer to a PointerArray (see page 3770) variable.
PPUnknown (see page 3773)	This is type System.PPUnknown.
PPWideChar (see page 3773)	This is type System.PPWideChar.
PRawByteString (see page 3773)	This is type System.PRawByteString.
PResStringRec (see page 3774)	This is type System::PResStringRec.
PShortInt (see page 3774)	PShortInt is a pointer to a `ShortInt` variable.
PShortString (see page 3774)	PShortString is a pointer to a `ShortString` variable.
PSingle (see page 3775)	PSingle is a pointer to a `Single` variable.
PSmallBlockTypeState (see page 3775)	This is type System::PSmallBlockTypeState.
PSmallInt (see page 3775)	PSmallInt is a pointer to a `SmallInt` variable.
PString (see page 3776)	PString is a pointer to a `String` variable.
PTextBuf (see page 3776)	This is type System.PTextBuf.
PUCS2Char (see page 3776)	This is type System.PUCS2Char.
PUCS4Char (see page 3777)	This is type System.PUCS4Char.
PUCS4CharArray (see page 3777)	This is type System.PUCS4CharArray.
PUInt64 (see page 3777)	This is type System.PUInt64.
PUnicodeString (see page 3778)	This is type System.PUnicodeString.
PUnitEntryTable (see page 3778)	PUnitEntryTable is a pointer to a UnitEntryTable (see page 3804) variable.
PUnknown (see page 3778)	PUnknown is a pointer to an IUnknown (see page 3756) variable.
PUTF8String (see page 3779)	This is type System.PUTF8String.
PVarArray (see page 3779)	Pointer type to a TVarArray (see page 3739).
PVarArrayBoundArray (see page 3779)	This is type System.PVarArrayBoundArray.
PVarArrayCoorArray (see page 3780)	Pointer type to a TVarArrayCoorArray (see page 3799).
PVarData (see page 3780)	This is type System.PVarData.
PVariant (see page 3780)	PVariant is a pointer to a System::Variant (see page 3421) variable.
PVariantManager (see page 3781)	This is type System::PVariantManager.
PVarRec (see page 3781)	System::PVarRec is a pointer to a System::TVarRec (see page 3747) variable.
PWideString (see page 3782)	PWideString is a pointer to a `WideString` (see page 3467) variable.
PWord (see page 3782)	PWord is a pointer to a `Word` variable.
PWordBool (see page 3782)	PWordBool is a pointer to a `WordBool` variable.
RawByteString (see page 3783)	RawByteString enables the passing of string data of any code page without doing any codepage conversions.
ResourceString (see page 3783)	This is type System::ResourceString.
TAssertErrorProc (see page 3783)	This is type System.TAssertErrorProc.
TBooleanDynArray (see page 3784)	This is type System::TBooleanDynArray.
TBoundArray (see page 3784)	This is type System.TBoundArray.
TByteDynArray (see page 3784)	This is type System::TByteDynArray.
TCardinalDynArray (see page 3785)	This is type System::TCardinalDynArray.
TClass (see page 3785)	TClass defines the metaclass for System::TObject (see page 3354).
TClassHelperBaseClass (see page 3786)	This is type System.TClassHelperBaseClass.
TDate (see page 3786)	TDate is used to represent a date.
TDateTime (see page 3787)	TDateTime represents a date-and-time value in the Delphi language.
TDLLProc (see page 3788)	This is type System.TDLLProc.
TDLLProcEx (see page 3788)	This is type System.TDLLProcEx.

TDoubleDynArray (see page 3788)	This is type System::TDoubleDynArray.
TEnumModuleFunc (see page 3789)	This is type System.TEnumModuleFunc.
TEnumModuleFuncLW (see page 3789)	This is type System.TEnumModuleFuncLW.
TFileIOFunc (see page 3789)	This is type System.TFileIOFunc.
THandle (see page 3790)	THandle is a general purpose data reference (handle).
TInt64DynArray (see page 3790)	This is type System::TInt64DynArray.
TIntegerDynArray (see page 3790)	This is type System::TIntegerDynArray.
TInterfacedClass (see page 3791)	TInterfacedClass defines the metaclass for System::TInterfacedObject (see page 3342).
TLongWordDynArray (see page 3791)	This is type System::TLongWordDynArray.
TMemoryMap (see page 3791)	TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 3714) values.
TModuleUnloadProc (see page 3792)	TModuleUnloadProc defines a procedure that can be called during package unload.
TModuleUnloadProcLW (see page 3793)	TModuleUnloadProcLW dehines a procedure that can be called during package unload.
TPCharArray (see page 3793)	This is type System.TPCharArray.
TResourceHandle (see page 3793)	This is type System.TResourceHandle.
TSafeCallErrorProc (see page 3794)	This is type System.TSafeCallErrorProc.
TShortIntDynArray (see page 3794)	This is type System::TShortIntDynArray.
TSingleDynArray (see page 3794)	This is type System::TSingleDynArray.
TSmallBlockTypeStates (see page 3795)	System::TSmallBlockTypeStates is an array of small memory block information records.
TSmallIntDynArray (see page 3795)	This is type System::TSmallIntDynArray.
TStringDynArray (see page 3796)	This is type System::TStringDynArray.
TSystemThreadEndProc (see page 3796)	This is type System.TSystemThreadEndProc.
TSystemThreadFuncProc (see page 3796)	This is type System.TSystemThreadFuncProc.
TTextBuf (see page 3797)	This is type System.TTextBuf.
TTextIOFunc (see page 3797)	This is type System.TTextIOFunc.
TThreadFunc (see page 3797)	System::TThreadFunc defines a new thread of execution.
TTime (see page 3798)	TTime is used to represent a time.
TUCS4CharArray (see page 3798)	This is type System.TUCS4CharArray.
TVarArrayBoundArray (see page 3798)	Gives bound information for all the dimensions of a safe array.
TVarArrayCoorArray (see page 3799)	Gives the position of an element in a safe array.
TVarOp (see page 3799)	TVarOp defines a Variant (see page 3421) operation.
TVarType (see page 3801)	This is type System.TVarType.
TWideStringDynArray (see page 3801)	This is type System::TWideStringDynArray.
TWordDynArray (see page 3801)	This is type System::TWordDynArray.
UCS2Char (see page 3802)	This is type System.UCS2Char.
UCS4Char (see page 3802)	UCS4Char is used for working with 4–byte Unicode characters.
UCS4String (see page 3802)	UCS4String is used for working with 4–byte Unicode characters.
UInt16 (see page 3803)	Alias for `Word`.
UInt32 (see page 3803)	Alias for `Cardinal`.
UInt8 (see page 3804)	Alias for `Byte`.
UnitEntryTable (see page 3804)	UnitEntryTable is an array type with entries of type PackageUnitEntry (see page 3713).
UTF8String (see page 3804)	UTF8String represents UTF-8 encoded Unicode strings.

35.5.1 System.CppLongInt Type

Pascal

```
CppLongInt = type LongInt;
```

C++

```
type LongInt CppLongInt;
```

File

System

Description

This is type System.CppLongInt.

35.5.2 System.CppULongInt Type

Pascal

```
CppULongInt = type LongWord;
```

C++

```
type LongWord CppULongInt;
```

File

System

Description

This is type System.CppULongInt.

35.5.3 System.GetPackageInfoTable Type

Pascal

```
GetPackageInfoTable = function : PackageInfo;
```

C++

```
: PackageInfo ( GetPackageInfoTable)();
```

File

System

Description

This is type System.GetPackageInfoTable.

35.5.4 System.HGLOBAL Type

Pascal

```
HGLOBAL = THandle;
```

C++

```
THandle HGLOBAL;
```

File

System

Description

This is type System.HGLOBAL.

35.5.5 System.HINST Type

Pascal

```
HINST = THandle;
```

C++

```
THandle HINST;
```

File

System

Description

This is type System.HINST.

35.5.6 System.HMODULE Type

Pascal

```
HMODULE = HINST;
```

C++

```
HINST HMODULE;
```

File

System

Description

This is type System.HMODULE.

35.5.7 System.HRESULT Type

Pascal

```
HRESULT = type Longint;
```

C++

```
type Longint HRESULT;
```

File

System

Description

This is type System.HRESULT.

35.5.8 System.HRSRC Type

Pascal

```
HRSRC = THandle;
```

C++

```
THandle HRSRC;
```

File

System

Description

This is type System.HRSRC.

35.5.9 System.Int16 Type

Alias for `SmallInt`.

Pascal

```
Int16 = SmallInt;
```

C++

```
SmallInt Int16;
```

File

System

Description

Int16 is an alias for a `SmallInt` variable.

See Also

Simple Types

35.5.10 System.Int32 Type

Alias for `Integer`.

Pascal

```
Int32 = Integer;
```

C++

```
int Int32;
```

File

System

Description

Int32 is an alias for a `Integer` variable.

See Also

Simple Types

35.5.11 System.Int8 Type

Alias for `ShortInt`.

Pascal

```
Int8 = ShortInt;
```

C++

```
ShortInt Int8;
```

File

System

Description

Int8 is an alias for a `ShortInt` variable.

See Also

Simple Types

35.5.12 System.IntegerArray Type

Pascal

```
IntegerArray = array[0..$efffffff] of Integer;
```

C++

```
array[0..$efffffff] of Integer IntegerArray;
```

File

System

Description

This is type System.IntegerArray.

35.5.13 System.IUnknown Type

IUnknown is a special base interface.

Pascal

```
IUnknown = IInterface;
```

C++

```
IInterface IUnknown;
```

File

System

Description

IUnknown is a base interface with features that are important to C++ programmers and also programmers who utilize COM objects.

Note: In Delphi code, IUnknown is simply another name for IInterface (see page 3502). Descending from IUnknown instead of IInterface (see page 3502) informs the Delphi compiler that the interface must be compatible with COM objects. Cross-platform applications can use interfaces descended from IUnknown, but must not use them to access COM objects, which are only available under Windows.

See Also

IInterface (see page 3502)

System::DelphiInterface (see page 3256)

35.5.14 System.PackageInfo Type

PackageInfo is a pointer to a PackageInfoTable (see page 3713) variable.

Pascal

```
PackageInfo = ^PackageInfoTable;
```

C++

```
^PackageInfoTable PackageInfo;
```

File

System

Description

PackageInfo is a pointer to a PackageInfoTable (see page 3713) variable.

See Also

PackageInfoTable (see page 3713)

35.5.15 System.PAnsiString Type

PAnsiString is a pointer to an `AnsiString` variable.

Pascal

```
PAnsiString = ^AnsiString;
```

C++

```
^AnsiString PAnsiString;
```

File

System

Description

PAnsiString is a pointer to an `AnsiString` variable.

35.5.16 System.PBoolean Type

PBoolean is a pointer to a `Boolean` variable.

Pascal

```
PBoolean = ^Boolean;
```

C++

```
^Boolean PBoolean;
```

File

System

Description

PBoolean is a pointer to a `Boolean` variable.

35.5.17 System.PByte Type

PByte is a pointer to a `Byte` variable.

Pascal

```
PByte = ^Byte;
```

C++

```
^Byte PByte;
```

File

System

Description

PByte is a pointer to a `Byte` variable.

35.5.18 System::PCallDesc Type

Pascal

```
PCallDesc = ^TCallDesc;
```

C++

```
^TCallDesc PCallDesc;
```

File

System.pas

Description

This is type System::PCallDesc.

35.5.19 System.PCardinal Type

PCardinal is a pointer to a `Cardinal` variable.

Pascal

```
PCardinal = ^Cardinal;
```

C++

```
^Cardinal PCardinal;
```

File

System

Description

PCardinal is a pointer to a `Cardinal` variable.

35.5.20 System.PComp Type

PComp is a pointer to a `Comp` variable.

Pascal

```
PComp = ^Comp;
```

C++

```
^Comp PComp;
```

File

System

Description

PComp is a pointer to a `Comp` variable.

Note: The `Comp` data type is deprecated.

35.5.21 System.PCurrency Type

PCurrency is a pointer to a `Currency` (see page 3235) variable.

Pascal

```
PCurrency = ^Currency;
```

C++

```
^Currency PCurrency;
```

File

System

Description

PCurrency is a pointer to a `Currency (see page 3235)` variable.

35.5.22 System.PCVModInfo Type

Pascal

```
PCVModInfo = ^TCVModInfo;
```

C++

```
^TCVModInfo PCVModInfo;
```

File

System

Description

This is type System.PCVModInfo.

35.5.23 System.PDate Type

PDate is a pointer to a Date variable.

Pascal

```
PDate = ^Double;
```

C++

```
^Double PDate;
```

File

System

Description

PDate is a pointer to a Date variable.

See Also

Date (see page 4087)

35.5.24 System.PDateTime Type

PDateTime is a pointer to a TDateTime (see page 3323) variable.

Pascal

```
PDateTime = ^TDateTime;
```

C++

```
^TDateTime PDateTime;
```

File

System

Description

PDateTime is a pointer to a TDateTime (see page 3323) variable.

See Also

TDateTime (see page 3787)

35.5.25 System.PDispatch Type

Pascal

```
PDispatch = ^IDispatch;
```

C++

```
^IDispatch PDispatch;
```

File

System

Description

This is type System.PDispatch.

35.5.26 System::PDispDesc Type

Pascal

```
PDispDesc = ^TDispDesc;
```

C++

```
^TDispDesc PDispDesc;
```

File

System.pas

Description

This is type System::PDispDesc.

35.5.27 System.PDouble Type

PDouble is a pointer to a `Double` variable.

Pascal

```
PDouble = ^Double;
```

C++

```
^Double PDouble;
```

File

System

Description

PDouble is a pointer to a `Double` variable.

35.5.28 System.PDynArrayTypeInfo Type

Pascal

```
PDynArrayTypeInfo = ^TDynArrayTypeInfo;
```

C++

```
^TDynArrayTypeInfo PDynArrayTypeInfo;
```

File

System

Description

This is type System.PDynArrayTypeInfo.

35.5.29 System.PError Type

Pascal

```
PError = ^LongWord;
```

C++

```
^LongWord PError;
```

File

System

Description

This is type System.PError.

35.5.30 System.PExtended Type

PExtended is a pointer to an Extended variable.

Pascal

```
PExtended = ^Extended;
```

C++

```
^Extended PExtended;
```

File

System

Description

PExtended is a pointer to an Extended variable.

35.5.31 System.PGUID Type

PGUID is a pointer to a TGUID (see page 3718) variable.

Pascal

```
PGUID = ^TGUID;
```

C++

```
^TGUID PGUID;
```

File

System

Description

PGUID is a pointer to a TGUID (see page 3718) variable.

C++ Examples:

```
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
              "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
         ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
         myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
```

```
          myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7])));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));

    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                "String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));

  { Auto-generate a random GUID at runtime }
  if CreateGUID(MyGuid1) <> 0 then
     Memo1.Lines.Add('Creating GUID failed!')
  else
     Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

  { Generating second random GUID }
  CreateGUID(MyGuid0);

  { Testing if 2 guids are equal }
  if IsEqualGUID(MyGuid0, MyGuid1) then
     Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                     '2 randomly generated GUIDs cannot be equal!');
end;
```

See Also

TGUID (see page 3718)

35.5.32 System.PInitContext Type

Pascal

```
PInitContext = ^TInitContext;
```

C++

```
^TInitContext PInitContext;
```

File

System

Description

This is type System.PInitContext.

35.5.33 System.PInt64 Type

PInt64 is a pointer to an `Int64` variable.

Pascal

```
PInt64 = ^Int64;
```

C++

```
^Int64 PInt64;
```

File

System

Description

PInt64 is a pointer to an `Int64` variable.

35.5.34 System.PInteger Type

PInteger is a pointer to an `Integer` variable.

Pascal

```
PInteger = ^Integer;
```

C++

```
^Integer PInteger;
```

File

System

Description

PInteger is a pointer to an `Integer` variable.

35.5.35 System.PIntegerArray Type

PIntegerArray is a pointer to an `IntegerArray (see page 3756)` variable.

Pascal

```
PIntegerArray = ^IntegerArray;
```

C++

```
^IntegerArray PIntegerArray;
```

File

System

Description

PIntegerArray is a pointer to an `IntegerArray (see page 3756)` variable.

See Also

IntegerArray (see page 3756)

35.5.36 System.PInterfaceEntry Type

PInterfaceEntry is a pointer to a TInterfaceEntry (see page 3722) variable.

Pascal

```
PInterfaceEntry = ^TInterfaceEntry;
```

C++

```
^TInterfaceEntry PInterfaceEntry;
```

File

System

Description

PInterfaceEntry is a pointer to a TInterfaceEntry (see page 3722) variable.

See Also

TInterfaceEntry (see page 3722)

35.5.37 System.PInterfaceTable Type

PInterfaceTable is a pointer to a TInterfaceTable (see page 3723) variable.

Pascal

```
PInterfaceTable = ^TInterfaceTable;
```

C++

```
^TInterfaceTable PInterfaceTable;
```

File

System

Description

PInterfaceTable is a pointer to a TInterfaceTable (see page 3723) variable.

See Also

TInterfaceTable (see page 3723)

35.5.38 System.PLibModule Type

PLibModule is a pointer to a System::TLibModule (see page 3723) variable.

Pascal

```
PLibModule = ^TLibModule;
```

C++

```
^TLibModule PLibModule;
```

File

System

Description

PLibModule is a pointer to a System::TLibModule (see page 3723) variable.

See Also

System::TLibModule (see page 3723)

35.5.39 System.PLongint Type

PLongint is a pointer to a `LongInt` variable.

Pascal

```
PLongint = ^Longint;
```

C++

```
^Longint PLongint;
```

File

System

Description

PLongint is a pointer to a PLongint variable.

See Also

PLongint (see page 4665)

35.5.40 System.PLongWord Type

PLongWord is a pointer to a `LongWord` variable.

Pascal

```
PLongWord = ^LongWord;
```

C++

```
^LongWord PLongWord;
```

File

System

Description

PLongWord is a pointer to a `LongWord` variable.

35.5.41 System::PMemoryManager Type

System::PMemoryManager is a pointer to a System::TMemoryManager (see page 3724) variable.

Pascal

```
PMemoryManager = ^TMemoryManager;
```

C++

```
^TMemoryManager PMemoryManager;
```

File

System.pas

Description

System::PMemoryManager is a pointer to a System::TMemoryManager (see page 3724) variable.

See Also

System::TMemoryManager (see page 3724)

35.5.42 System::PMemoryManagerEx Type

System::PMemoryManagerEx is a pointer to a System::TMemoryManagerEx (see page 3725) variable.

Pascal

```
PMemoryManagerEx = ^TMemoryManagerEx;
```

C++

```
^TMemoryManagerEx PMemoryManagerEx;
```

File

System.pas

Description

System::PMemoryManagerEx is a pointer to a System::TMemoryManagerEx (see page 3725) variable.

See Also

System::TMemoryManagerEx (see page 3725)

35.5.43 System::PModuleUnloadRec Type

Pascal

```
PModuleUnloadRec = ^TModuleUnloadRec;
```

C++

```
^TModuleUnloadRec PModuleUnloadRec;
```

File

System.pas

Description

This is type System::PModuleUnloadRec.

35.5.44 System.PMonitor Type

Pascal

```
PMonitor = ^TMonitor;
```

C++

```
^TMonitor PMonitor;
```

File

System

Description

This is type System.PMonitor.

35.5.45 System.PMonitorSupport Type

Pascal

```
PMonitorSupport = ^TMonitorSupport;
```

C++

```
^TMonitorSupport PMonitorSupport;
```

File

System

Description

This is type System.PMonitorSupport.

35.5.46 System.PointerArray Type

Pascal

```
PointerArray = array [0..512*1024*1024 - 2] of Pointer;
```

C++

```
array [0..512*1024*1024 - 2] of Pointer PointerArray;
```

File

System

Description

This is type System.PointerArray.

35.5.47 System.POleVariant Type

POleVariant is a pointer to a System::OleVariant (see page 3274) variable.

Pascal

```
POleVariant = ^OleVariant;
```

C++

```
^OleVariant POleVariant;
```

File

System

Description

POleVariant is a pointer to a System::OleVariant (see page 3274) variable.

See Also

System::OleVariant (see page 3274)

POleVariant1 (see page 807)

35.5.48 System.PPAnsiChar Type

Pascal

```
PPAnsiChar = ^PAnsiChar;
```

C++

```
^PAnsiChar PPAnsiChar;
```

File

System

Description

This is type System.PPAnsiChar.

35.5.49 System.PPChar Type

Pascal

```
PPChar = PPWideChar;
```

C++

```
PPWideChar PPChar;
```

File

System

Description

This is type System.PPChar.

35.5.50 System.PPCharArray Type

Pascal

```
PPCharArray = ^TPCharArray;
```

C++

```
^TPCharArray PPCharArray;
```

File

System

Description

This is type System.PPCharArray.

35.5.51 System.PPDispatch Type

Pascal

```
PPDispatch = ^PDispatch;
```

C++

```
^PDispatch PPDispatch;
```

File

System

Description

This is type System.PPDispatch.

35.5.52 System.PPMonitor Type

Pascal

```
PPMonitor = ^PMonitor;
```

C++

```
^PMonitor PPMonitor;
```

File

System

Description

This is type System.PPMonitor.

35.5.53 System.PPointer Type

PPointer is a pointer to a `Pointer` variable.

Pascal

```
PPointer = ^Pointer;
```

C++

```
^Pointer PPointer;
```

File

System

Description

PPointer is a pointer to a `Pointer` variable.

35.5.54 System.PPointerArray Type

PPointerArray is a pointer to a PointerArray (see page 3770) variable.

Pascal

```
PPointerArray = ^PointerArray;
```

C++

```
^PointerArray PPointerArray;
```

File

System

Description

PPointerArray is a pointer to a PointerArray (see page 3770) variable.

See Also

PointerArray (see page 3770)

35.5.55 System.PPUnknown Type

Pascal

```
PPUnknown = ^PUnknown;
```

C++

```
^PUnknown PPUnknown;
```

File

System

Description

This is type System.PPUnknown.

35.5.56 System.PPWideChar Type

Pascal

```
PPWideChar = ^PWideChar;
```

C++

```
^PWideChar PPWideChar;
```

File

System

Description

This is type System.PPWideChar.

35.5.57 System.PRawByteString Type

Pascal

```
PRawByteString = ^RawByteString;
```

C++

```
^RawByteString PRawByteString;
```

File

System

Description

This is type System.PRawByteString.

35.5.58 System::PResStringRec Type

Pascal

```
PResStringRec = ^TResStringRec;
```

C++

```
^TResStringRec PResStringRec;
```

File

System.pas

Description

This is type System::PResStringRec.

35.5.59 System.PShortInt Type

PShortInt is a pointer to a `ShortInt` variable.

Pascal

```
PShortInt = ^ShortInt;
```

C++

```
^ShortInt PShortInt;
```

File

System

Description

PShortInt is a pointer to a `ShortInt` variable.

35.5.60 System.PShortString Type

PShortString is a pointer to a `ShortString` variable.

Pascal

```
PShortString = ^ShortString;
```

C++

```
^ShortString PShortString;
```

File

System

Description

PShortString is a pointer to a `ShortString` variable.

35.5.61 System.PSingle Type

PSingle is a pointer to a `Single` variable.

Pascal

```
PSingle = ^Single;
```

C++

```
^Single PSingle;
```

File

System

Description

PSingle is a pointer to a `Single` variable.

35.5.62 System::PSmallBlockTypeState Type

Pascal

```
PSmallBlockTypeState = TSmallBlockTypeState *;
```

C++

```
typedef TSmallBlockTypeState * PSmallBlockTypeState;
```

File

sysclass.h

Description

This is type System::PSmallBlockTypeState.

35.5.63 System.PSmallInt Type

PSmallInt is a pointer to a `SmallInt` variable.

Pascal

```
PSmallInt = ^SmallInt;
```

C++

```
^SmallInt PSmallInt;
```

File

System

Description

PSmallInt is a pointer to a `SmallInt` variable.

35.5.64 System.PString Type

PString is a pointer to a `String` variable.

Pascal

```
PString = PUnicodeString;
```

C++

```
PUnicodeString PString;
```

File

System

Description

PString is a pointer to a `String` variable.

35.5.65 System.PTextBuf Type

Pascal

```
PTextBuf = ^TTextBuf;
```

C++

```
^TTextBuf PTextBuf;
```

File

System

Description

This is type System.PTextBuf.

35.5.66 System.PUCS2Char Type

Pascal

```
PUCS2Char = PWideChar;
```

C++

```
PWideChar PUCS2Char;
```

File

System

Description

This is type System.PUCS2Char.

35.5.67 System.PUCS4Char Type

Pascal

```
PUCS4Char = ^UCS4Char;
```

C++

```
^UCS4Char PUCS4Char;
```

File

System

Description

This is type System.PUCS4Char.

35.5.68 System.PUCS4CharArray Type

Pascal

```
PUCS4CharArray = ^TUCS4CharArray;
```

C++

```
^TUCS4CharArray PUCS4CharArray;
```

File

System

Description

This is type System.PUCS4CharArray.

35.5.69 System.PUInt64 Type

Pascal

```
PUInt64 = ^UInt64;
```

C++

```
^UInt64 PUInt64;
```

File

System

Description

This is type System.PUInt64.

35.5.70 System.PUnicodeString Type

Pascal

```
PUnicodeString = ^UnicodeString;
```

C++

```
^UnicodeString PUnicodeString;
```

File

System

Description

This is type System.PUnicodeString.

35.5.71 System.PUnitEntryTable Type

PUnitEntryTable is a pointer to a UnitEntryTable (see page 3804) variable.

Pascal

```
PUnitEntryTable = ^UnitEntryTable;
```

C++

```
^UnitEntryTable PUnitEntryTable;
```

File

System

Description

PUnitEntryTable is a pointer to a UnitEntryTable (see page 3804) variable.

See Also

UnitEntryTable (see page 3804)

35.5.72 System.PUnknown Type

PUnknown is a pointer to an IUnknown (see page 3756) variable.

Pascal

```
PUnknown = ^IUnknown;
```

C++

```
^IUnknown PUnknown;
```

File

System

Description

PUnknown is a pointer to an IUnknown (see page 3756) variable.

See Also

IUnknown (see page 3756)

35.5.73 System.PUTF8String Type

Pascal

```
PUTF8String = ^UTF8String;
```

C++

```
^UTF8String PUTF8String;
```

File

System

Description

This is type System.PUTF8String.

35.5.74 System.PVarArray Type

Pointer type to a TVarArray (see page 3739).

Pascal

```
PVarArray = ^TVarArray;
```

C++

```
^TVarArray PVarArray;
```

File

System

Description

This is a pointer to a TVarArray (see page 3739) data type, giving information about a safe array.

See Also

TVarArray (see page 3739)

35.5.75 System.PVarArrayBoundArray Type

Pascal

```
PVarArrayBoundArray = ^TVarArrayBoundArray;
```

C++

```
^TVarArrayBoundArray PVarArrayBoundArray;
```

File

System

Description

This is type System.PVarArrayBoundArray.

35.5.76 System.PVarArrayCoorArray Type

Pointer type to a TVarArrayCoorArray (see page 3799).

Pascal

```
PVarArrayCoorArray = ^TVarArrayCoorArray;
```

C++

```
^TVarArrayCoorArray PVarArrayCoorArray;
```

File

System

Description

This is a pointer to a TVarArrayCoorArray (see page 3799) data type, giving information about the position of an element in a safe array.

See Also

TVarArrayCoorArray (see page 3799)

35.5.77 System.PVarData Type

Pascal

```
PVarData = ^TVarData;
```

C++

```
^TVarData PVarData;
```

File

System

Description

This is type System.PVarData.

35.5.78 System.PVariant Type

PVariant is a pointer to a System::Variant (see page 3421) variable.

Pascal

```
PVariant = ^Variant;
```

C++

```
^Variant PVariant;
```

File

System

Description

PVariant is a pointer to a System::Variant (see page 3421) variable.

See Also

System::Variant (see page 3421)

35.5.79 System::PVariantManager Type

Pascal

```
PVariantManager = ^TVariantManager;
```

C++

```
^TVariantManager PVariantManager;
```

File

System.pas

Description

This is type System::PVariantManager.

35.5.80 System::PVarRec Type

System::PVarRec is a pointer to a System::TVarRec (see page 3747) variable.

Pascal

```
PVarRec = ^TVarRec;
```

C++

```
^TVarRec PVarRec;
```

File

System.pas

Description

System::PVarRec is a pointer to a System::TVarRec (see page 3747) variable.

See Also

System::TVarRec (see page 3747)

35.5.81 System.PWideString Type

PWideString is a pointer to a `WideString (see page 3467)` variable.

Pascal

```
PWideString = ^WideString;
```

C++

```
^WideString PWideString;
```

File

System

Description

PWideString is a pointer to a `WideString (see page 3467)` variable.

35.5.82 System.PWord Type

PWord is a pointer to a `Word` variable.

Pascal

```
PWord = ^Word;
```

C++

```
^Word PWord;
```

File

System

Description

PWord is a pointer to a `Word` variable.

35.5.83 System.PWordBool Type

PWordBool is a pointer to a `WordBool` variable.

Pascal

```
PWordBool = ^WordBool;
```

C++

```
^WordBool PWordBool;
```

File

System

Description

PWordBool is a pointer to a `WordBool` variable.

35.5.84 System.RawByteString Type

RawByteString enables the passing of string data of any code page without doing any codepage conversions.

Pascal

```
RawByteString = type AnsiString($ffff);
```

C++

```
type AnsiString($ffff) RawByteString;
```

File

System

Description

RawByteString enables the passing of string data of any code page without doing any codepage conversions. The purpose of RawByteString is to reduce the need for multiple overloads of procedures that read string data. This means that parameters of routines that process strings without regard for the string's code page should typically be of type RawByteString.

RawByteString should only be used as a parameter type, and only in routines which otherwise would need multiple overloads for AnsiStrings with different codepages. Such routines need to be written with care for the actual codepage of the string at runtime.

In general it is recommended that string processing routines should simply use "string" as the string type. Declaring variables or fields of type RawByteString should rarely, if ever, be done, because this practice can lead to undefined behavior and potential data loss.

35.5.85 System::ResourceString Type

Pascal

```
ResourceString = TResStringRec;
```

C++

```
typedef TResStringRec ResourceString;
```

File

sysclass.h

Description

This is type System::ResourceString.

35.5.86 System.TAssertErrorProc Type

Pascal

```
TAssertErrorProc = procedure (const Message, Filename: string; LineNumber: Integer; ErrorAddr:
Pointer);
```

C++

```
(const Message, Filename: string; LineNumber: Integer; ErrorAddr: Pointer) (
```

```
  TAssertErrorProc)();
```

File

System

Description

This is type System.TAssertErrorProc.

35.5.87 System::TBooleanDynArray Type

Pascal

```
  TBooleanDynArray = DynamicArray<Boolean>;
```

C++

```
  typedef DynamicArray<Boolean> TBooleanDynArray;
```

File

sysdyn.h

Description

This is type System::TBooleanDynArray.

35.5.88 System.TBoundArray Type

Pascal

```
  TBoundArray = array of Integer;
```

C++

```
  array of Integer TBoundArray;
```

File

System

Description

This is type System.TBoundArray.

35.5.89 System::TByteDynArray Type

Pascal

```
  TByteDynArray = DynamicArray<Byte>;
```

C++

```
  typedef DynamicArray<Byte> TByteDynArray;
```

File

sysdyn.h

Description

This is type System::TByteDynArray.

35.5.90 System::TCardinalDynArray Type

Pascal

```
TCardinalDynArray = DynamicArray<Cardinal>;
```

C++

```
typedef DynamicArray<Cardinal> TCardinalDynArray;
```

File

sysdyn.h

Description

This is type System::TCardinalDynArray.

35.5.91 System.TClass Type

TClass defines the metaclass for System::TObject (see page 3354).

Pascal

```
TClass = class of TObject;
```

C++

```
TObject * TClass;
```

File

System

Description

TClass is the metaclass for System::TObject (see page 3354). Its value is the class reference for System::TObject (see page 3354) or for one of its descendants.

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
```

```
      ClassRef := ClassRef.ClassParent;
    end;
  end;
  {
  The list box contains the following strings after the user clicks the button:
      TButton
      TButtonControl
      TWinControl or TWinControl
      TControl
      TComponent
      TPersistent
      TObject
  }
```

See Also

System::TObject (see page 3354)

Class References

35.5.92 System.TClassHelperBaseClass Type

Pascal

```
TClassHelperBaseClass = class of TClassHelperBase;
```

C++

```
TClassHelperBase TClassHelperBaseClass;
```

File

System

Description

This is type System.TClassHelperBaseClass.

35.5.93 System.TDate Type

TDate is used to represent a date.

Pascal

```
TDate = type TDateTime;
```

C++

```
type TDateTime TDate;
```

File

System

Description

TDate represents a special type of TDateTime (see page 3323) value that has no decimal part. A TDate value represents the number of days that have elapsed since 12/30/1899.

See Also

TTimeStamp (see page 4334)

35.5.94 System.TDateTime Type

TDateTime represents a date-and-time value in the Delphi language.

Pascal

```
TDateTime = type Double;
```

C++

```
type Double TDateTime;
```

File

System

Description

In Delphi, TDateTime is a type that maps to a Double. In C++, the TDateTime class corresponds to the Delphi TDateTime type.

The integral part of a Delphi TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of the TDateTime value is fraction of a 24 hour day that has elapsed.

Following are some examples of TDateTime values and their corresponding dates and times:

0	12/30/1899 12:00 am
2.75	1/1/1900 6:00 pm
-1.25	12/29/1899 6:00 am
35065	1/1/1996 12:00 am

To find the fractional number of days between two dates, simply subtract the two values, unless one of the TDateTime values is negative. Similarly, to increment a date and time value by a certain fractional number of days, add the fractional number to the date and time value if the TDateTime value is positive.

When working with negative TDateTime values, computations must handle time portion separately. The fractional part reflects the fraction of a 24-hour day without regard to the sign of the TDateTime value. For example, 6:00 am on 12/29/1899 is –1.25, not –1 + 0.25, which would be –0.75. There are no TDateTime values between –1 and 0.

Note: Delphi 1.0 calculated the date from year 1 instead of from 1899. To convert a Delphi 1.0 date to a TDateTime value in later versions of the Delphi language, subtract 693594.0 from the Delphi 1.0 date.

CompareDateTime

FormatDateTime (see page 4195)

35.5.95 System.TDLLProc Type

Pascal

```
TDLLProc = procedure (Reason: Integer);
```

C++

```
(Reason: Integer) ( TDLLProc)();
```

File

System

Description

This is type System.TDLLProc.

35.5.96 System.TDLLProcEx Type

Pascal

```
TDLLProcEx = procedure (Reason: Integer; Reserved: Integer);
```

C++

```
(Reason: Integer; Reserved: Integer) ( TDLLProcEx)();
```

File

System

Description

This is type System.TDLLProcEx.

35.5.97 System::TDoubleDynArray Type

Pascal

```
TDoubleDynArray = DynamicArray<Double>;
```

C++

```
typedef DynamicArray<Double> TDoubleDynArray;
```

File

sysdyn.h

Description

This is type System::TDoubleDynArray.

35.5.98 System.TEnumModuleFunc Type

Pascal

```
TEnumModuleFunc = function (HInstance: Integer; Data: Pointer): Boolean;
```

C++

```
(HInstance: Integer; Data: Pointer): Boolean ( TEnumModuleFunc)();
```

File

System

Description

This is type System.TEnumModuleFunc.

35.5.99 System.TEnumModuleFuncLW Type

Pascal

```
TEnumModuleFuncLW = function (HInstance: LongWord; Data: Pointer): Boolean;
```

C++

```
(HInstance: LongWord; Data: Pointer): Boolean ( TEnumModuleFuncLW)();
```

File

System

Description

This is type System.TEnumModuleFuncLW.

35.5.100 System.TFileIOFunc Type

Pascal

```
TFileIOFunc = function (var F: TFileRec): Integer;
```

C++

```
(var F: TFileRec): Integer ( TFileIOFunc)();
```

File

System

Description

This is type System.TFileIOFunc.

35.5.101 System.THandle Type

THandle is a general purpose data reference (handle).

Pascal

```
THandle = LongWord;
```

C++

```
LongWord THandle;
```

File

System

Description

For example, the SaveToClipboardFormat uses a THandle variable to hold a handle to the data of a bit map. SetAsHandle can then be used to store the bit map data, via its handle, to the clipboard.

Handles are used extensively in communication with Windows APIs.

See Also

SaveToClipboardFormat

SetAsHandle

35.5.102 System::TInt64DynArray Type

Pascal

```
TInt64DynArray = DynamicArray<__int64>;
```

C++

```
typedef DynamicArray<__int64> TInt64DynArray;
```

File

sysdyn.h

Description

This is type System::TInt64DynArray.

35.5.103 System::TIntegerDynArray Type

Pascal

```
TIntegerDynArray = DynamicArray<Integer>;
```

C++

```
typedef DynamicArray<Integer> TIntegerDynArray;
```

File

sysdyn.h

Description

This is type System::TIntegerDynArray.

35.5.104 System.TInterfacedClass Type

TInterfacedClass defines the metaclass for System::TInterfacedObject (see page 3342).

Pascal

```
TInterfacedClass = class of TInterfacedObject;
```

C++

```
TInterfacedObject TInterfacedClass;
```

File

System

Description

TInterfacedClass is the metaclass for System::TInterfacedObject (see page 3342). Its value is the class reference for System::TInterfacedObject (see page 3342) or for one of its descendants.

See Also

System::TInterfacedObject (see page 3342)

Class References

35.5.105 System::TLongWordDynArray Type

Pascal

```
TLongWordDynArray = DynamicArray<unsigned>;
```

C++

```
typedef DynamicArray<unsigned> TLongWordDynArray;
```

File

sysdyn.h

Description

This is type System::TLongWordDynArray.

35.5.106 System.TMemoryMap Type

TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 3714) values.

Pascal

```
TMemoryMap = array[0..65535] of TChunkStatus;
```

C++

```
array[0..65535] of TChunkStatus TMemoryMap;
```

File

System

Description

GetMemoryMap (see page 3592) returns a map of the address space of the current process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. TMemoryMap obtains a status value for each of them in the TMemoryMap array. Each TMemoryMap array element may have the following value :

Status value	Meaning
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

See Also

GetMemoryMap (see page 3592)

35.5.107 System.TModuleUnloadProc Type

TModuleUnloadProc defines a procedure that can be called during package unload.

Pascal

```
TModuleUnloadProc = procedure (HInstance: Integer);
```

C++

```
(HInstance: Integer) ( TModuleUnloadProc)();
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your TModuleUnloadProc routine. In essence, AddModuleUnloadProc (see page 3514) adds your callback routine to the head of the list of internal routines that Delphi invokes to perform the unload.

Proc is the Handle to the DLL Package instance being unloaded.

See Also

AddModuleUnloadProc (see page 3514)

TModuleUnloadProcLW (see page 3793)

35.5.108 System.TModuleUnloadProcLW Type

TModuleUnloadProcLW dehines a procedure that can be called during package unload.

Pascal

```
TModuleUnloadProcLW = procedure (HInstance: LongWord);
```

C++

```
(HInstance: LongWord) ( TModuleUnloadProcLW)();
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your TModuleUnloadProcLW routine. In essence, AddModuleUnloadProc (see page 3514) adds your callback routine to the head of the list of internal routines that Delphi invokes to perform the unload.

Proc is the Handle to the DLL Package instance being unloaded.

The LW part of the name refers to the Long Word type of package handle. This is in line with Windows handles, and the THandle (see page 3790) type.

See Also

AddModuleUnloadProc (see page 3514)

TModuleUnloadProc (see page 3792)

35.5.109 System.TPCharArray Type

Pascal

```
TPCharArray = array[0..(MaxLongint div SizeOf(PChar))-1] of PChar;
```

C++

```
array[0..(MaxLongint div SizeOf(PChar))-1] of PChar TPCharArray;
```

File

System

Description

This is type System.TPCharArray.

35.5.110 System.TResourceHandle Type

Pascal

```
TResourceHandle = HRSRC;
```

C++

```
HRSRC TResourceHandle;
```

File

System

Description

This is type System.TResourceHandle.

35.5.111 System.TSafeCallErrorProc Type

Pascal

```
TSafeCallErrorProc = procedure (ErrorCode: HResult; ErrorAddr: Pointer);
```

C++

```
(ErrorCode: HResult; ErrorAddr: Pointer) ( TSafeCallErrorProc)();
```

File

System

Description

This is type System.TSafeCallErrorProc.

35.5.112 System::TShortIntDynArray Type

Pascal

```
TShortIntDynArray = DynamicArray<Shortint>;
```

C++

```
typedef DynamicArray<Shortint> TShortIntDynArray;
```

File

sysdyn.h

Description

This is type System::TShortIntDynArray.

35.5.113 System::TSingleDynArray Type

Pascal

```
TSingleDynArray = DynamicArray<Single>;
```

C++

```
typedef DynamicArray<Single> TSingleDynArray;
```

File

sysdyn.h

Description

This is type System::TSingleDynArray.

35.5.114 System::TSmallBlockTypeStates Type

System::TSmallBlockTypeStates is an array of small memory block information records.

Pascal

```
TSmallBlockTypeStates = array[0..NumSmallBlockTypes - 1] of TSmallBlockTypeState;
```

C++

```
array[0..NumSmallBlockTypes - 1] of TSmallBlockTypeState
TSmallBlockTypeStates[NumSmallBlockTypes];
```

File

System.pas

Description

GetMemoryManagerState (see page 3591) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a System::TMemoryManagerState (see page 3730) record. Within that record is held a System::TSmallBlockTypeStates field - an array of System::TSmallBlockTypeState (see page 3736) records. There are NumSmallBlockTypes (see page 3849) (55) different small memory block sizes, and therefore 55 System::TSmallBlockTypeState (see page 3736) records in this array.

See Also

GetMemoryManagerState (see page 3591)

NumSmallBlockTypes (see page 3849)

System::TSmallBlockTypeState (see page 3736)

35.5.115 System::TSmallIntDynArray Type

Pascal

```
TSmallIntDynArray = DynamicArray<Smallint>;
```

C++

```
typedef DynamicArray<Smallint> TSmallIntDynArray;
```

File

sysdyn.h

Description

This is type System::TSmallIntDynArray.

35.5.116 System::TStringDynArray Type

Pascal

```
TStringDynArray = DynamicArray<String>;
```

C++

```
typedef DynamicArray<String> TStringDynArray;
```

File

sysdyn.h

Description

This is type System::TStringDynArray.

35.5.117 System.TSystemThreadEndProc Type

Pascal

```
TSystemThreadEndProc = procedure (ExitCode: Integer);
```

C++

```
(ExitCode: Integer) ( TSystemThreadEndProc)();
```

File

System

Description

This is type System.TSystemThreadEndProc.

35.5.118 System.TSystemThreadFuncProc Type

Pascal

```
TSystemThreadFuncProc = function (ThreadFunc: TThreadFunc; Parameter: Pointer): Pointer;
```

C++

```
(ThreadFunc: TThreadFunc; Parameter: Pointer): Pointer ( TSystemThreadFuncProc)();
```

File

System

Description

This is type System.TSystemThreadFuncProc.

35.5.119 System.TTextBuf Type

Pascal

```
TTextBuf = array[0..127] of AnsiChar;
```

C++

```
array[0..127] of AnsiChar TTextBuf;
```

File

System

Description

This is type System.TTextBuf.

35.5.120 System.TTextIOFunc Type

Pascal

```
TTextIOFunc = function (var F: TTextRec): Integer;
```

C++

```
(var F: TTextRec): Integer ( TTextIOFunc)();
```

File

System

Description

This is type System.TTextIOFunc.

35.5.121 System::TThreadFunc Type

System::TThreadFunc defines a new thread of execution.

Pascal

```
TThreadFunc = function (Parameter: Pointer): Integer;
```

C++

```
(Parameter: Pointer): Integer (* TThreadFunc)(Pointer Parameter);
```

File

System.pas

Description

Use BeginThread (see page 3527) or a TThread object to spawn separate threads of execution. BeginThread (see page 3527) spawns a new thread of execution via the System::TThreadFunc defined function.

Parameter is a pointer to any data you want to pass to the new thread.

When the thread completes, it returns a status code.

See Also

BeginThread (see page 3527)

TThread

35.5.122 System.TTime Type

TTime is used to represent a time.

Pascal

```
TTime = type TDateTime;
```

C++

```
type TDateTime TTime;
```

File

System

Description

TTime is simply a TDateTime (see page 3323) type.

See Also

TDateTime (see page 3787)

35.5.123 System.TUCS4CharArray Type

Pascal

```
TUCS4CharArray = array [0..$ffffff] of UCS4Char;
```

C++

```
array [0..$ffffff] of UCS4Char TUCS4CharArray;
```

File

System

Description

This is type System.TUCS4CharArray.

35.5.124 System.TVarArrayBoundArray Type

Gives bound information for all the dimensions of a safe array.

Pascal

```
TVarArrayBoundArray = array [0..0] of TVarArrayBound;
```

C++

```
array [0..0] of TVarArrayBound TVarArrayBoundArray;
```

File

System

Description

Declare a variable of TVarArrayBoundArray type to store information about the array bounds, corresponding to all the dimensions of a safe array.

Each element in a TVarArrayBoundArray array is of TVarArrayBound (see page 3740) type. The following list describes each field in the TVarArrayBound (see page 3740) type.

Field	Meaning
ElementCount	The number of elements, in the corresponding dimension.
LowBound	The low bound of the index range, in the corresponding dimension.

See Also

TVarArrayBound (see page 3740)

35.5.125 System.TVarArrayCoorArray Type

Gives the position of an element in a safe array.

Pascal

```
TVarArrayCoorArray = array [0..0] of Integer;
```

C++

```
array [0..0] of Integer TVarArrayCoorArray;
```

File

System

Description

Declare a variable of TVarArrayCoorArray type to store information about an element's position in a safe array. Such a variable can then be used in function calls to SafeArrayGetElement or to SafeArrayPutElement.

Each element in an array of TVarArrayCoorArray type stores the coordinate of the element in the safe array, in the increasing order of dimensions.

See Also

SafeArrayGetElement (see page 5121)

SafeArrayPutElement (see page 5125)

35.5.126 System.TVarOp Type

TVarOp defines a Variant (see page 3421) operation.

Pascal

```
TVarOp = Integer;
```

C++

```
int TVarOp;
```

File

System

Description

TVarOp is used to define an Variant (see page 3421) operation. There are three operation categories :

Type	Meaning
Two operand processing	A logical operation of left and right operands. Such as BinaryOp.
Two operand comparison	A comparison of left and right operands. Such as CompareOp.
One operand processing	Processing of a single operand. Such as UnaryOp.

TVarOp may hold one of the following values :

Value	Meaning
opAdd (see page 3850)	Addition.
opAnd (see page 3850)	Bitwise and.
opCmpEQ (see page 3851)	Compare for equality.
opCmpGE (see page 3851)	Compare left greater than or equal to right.
opCmpGT (see page 3852)	Compare left greater than right.
opCmpLE (see page 3852)	Compare left less than or equal to right.
opCmpLT (see page 3853)	Compare left less than right.
opCmpNE (see page 3853)	Compare for inequality.
opCompare (see page 3854)	Generalised comparison.
opDivide (see page 3854)	Division of left by right.
opIntDivide (see page 3855)	Integer division of left by right.
opModulus (see page 3855)	Remainder of left divide by right.
opMultiply (see page 3855)	Left multiplied by right.
opNegate (see page 3856)	Negation of a single operand value.
opNot (see page 3856)	Bitwise negation of a single operand.
opOr (see page 3857)	Bitwise or.
opShiftLeft (see page 3857)	Bitwise shift left.
opShiftRight (see page 3858)	Bitwise shift right.
opSubtract (see page 3858)	Right subtracted from left.
opXor (see page 3859)	Bitwise exclusive or.

See Also

BinaryOp (see page 4994)

CompareOp (see page 4998)

UnaryOp (see page 5006)

35.5.127 System.TVarType Type

Pascal

```
TVarType = Word;
```

C++

```
Word TVarType;
```

File

System

Description

This is type System.TVarType.

35.5.128 System::TWideStringDynArray Type

Pascal

```
TWideStringDynArray = DynamicArray<WideString>;
```

C++

```
typedef DynamicArray<WideString> TWideStringDynArray;
```

File

sysdyn.h

Description

This is type System::TWideStringDynArray.

35.5.129 System::TWordDynArray Type

Pascal

```
TWordDynArray = DynamicArray<Word>;
```

C++

```
typedef DynamicArray<Word> TWordDynArray;
```

File

sysdyn.h

Description

This is type System::TWordDynArray.

35.5.130 System.UCS2Char Type

Pascal

```
UCS2Char = WideChar;
```

C++

```
WideChar UCS2Char;
```

File

System

Description

This is type System.UCS2Char.

35.5.131 System.UCS4Char Type

UCS4Char is used for working with 4–byte Unicode characters.

Pascal

```
UCS4Char = type LongWord;
```

C++

```
type LongWord UCS4Char;
```

File

System

Description

UCS4Char represents a 4–byte Unicode character. UCS4String (see page 3802) is a dynamic array of UCS4Char.

See Also

UCS4String (see page 3802)

UCS4StringToWideString (see page 3687)

35.5.132 System.UCS4String Type

UCS4String is used for working with 4–byte Unicode characters.

Pascal

```
UCS4String = array of UCS4Char;
```

C++

```
array of UCS4Char UCS4String;
```

File

System

Description

UCS4Char (see page 3802) represents a 4–byte Unicode character. UCS4String, which is a dynamic array of UCS4Char (see page 3802), represents a string encoded using UCS4 (4–byte Unicode).

See Also

UCS4Char (see page 3802)

UCS4StringToWideString (see page 3687)

35.5.133 System.UInt16 Type

Alias for `Word`.

Pascal

```
UInt16 = Word;
```

C++

```
Word UInt16;
```

File

System

Description

UInt16 is an alias for a `Word` variable.

See Also

Simple Types

35.5.134 System.UInt32 Type

Alias for `Cardinal`.

Pascal

```
UInt32 = Cardinal;
```

C++

```
unsigned UInt32;
```

File

System

Description

UInt32 is an alias for a `Cardinal` variable.

See Also

Simple Types

35.5.135 System.UInt8 Type

Alias for `Byte`.

Pascal

```
UInt8 = Byte;
```

C++

```
Byte UInt8;
```

File

System

Description

UInt8 is an alias for a `Byte` variable.

See Also

Simple Types

35.5.136 System.UnitEntryTable Type

UnitEntryTable is an array type with entries of type PackageUnitEntry (see page 3713).

Pascal

```
UnitEntryTable = array [0..9999999] of PackageUnitEntry;
```

C++

```
array [0..9999999] of PackageUnitEntry UnitEntryTable;
```

File

System

Description

UnitEntryTable is an array type with entries of type PackageUnitEntry (see page 3713).

A variable of type UnitEntryTable contains a compiler generated table to be processed sequentially, in order to initialize and finalize all package units.

See Also

PackageUnitEntry (see page 3713)

35.5.137 System.UTF8String Type

UTF8String represents UTF-8 encoded Unicode strings.

Pascal

```
UTF8String = type AnsiString(65001);
```

C++

```
type AnsiString(65001) UTF8String;
```

File

System

Description

UTF8String represents a string encoded using UTF-8 (variable number of bytes Unicode). It is a System::AnsiStringBase (see page 3174) type with a UTF-8 code page.

In Delphi, UTF8String is a true compiler type. The compiler does conversions between System::UnicodeString (see page 3381) and UTF8String as necessary.

See Also

System::AnsiStringBase (see page 3174)

System::UnicodeString (see page 3381)

35.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AbstractErrorProc (see page 3807)	AbstractErrorProc defines a callback routine for abstract method call errors.
AllocMemCount (see page 3807)	Represents the total number of allocated memory blocks in a Delphi application.
AllocMemSize (see page 3809)	Represents the total size of allocated memory blocks.
AssertErrorProc (see page 3810)	Points to the assertion error-handler.
CmdLine (see page 3812)	Points to the command-line arguments specified when the application is invoked.
CmdShow (see page 3812)	Specifies the flags for displaying the application's main window.
CPUCount (see page 3813)	This is variable System.CPUCount.
DebugHook (see page 3813)	DebugHook is set if an application is running under the IDE debugger.
Default8087CW (see page 3813)	Specifies the Default 8087 control word.
DefaultSystemCodePage (see page 3815)	This is variable System.DefaultSystemCodePage.
DefaultTextLineBreakStyle (see page 3815)	Specifies the characters that are used by default to separate lines in text.
DefaultUnicodeCodePage (see page 3816)	This is variable System.DefaultUnicodeCodePage.
DispCallByIDProc (see page 3816)	This is variable System.DispCallByIDProc.
DLLProc (see page 3816)	Points to a procedure invoked by a DLL entry point.
envp (see page 3817)	This is variable System.envp.
ErrorAddr (see page 3817)	Contains the address of a statement causing a runtime error.
ErrorProc (see page 3818)	Points to the RTL runtime error handler.
ErrOutput (see page 3820)	ErrOutput specifies a write-only Text file associated with the process's error output file.
ExceptClsProc (see page 3820)	ExceptClsProc defines a pointer to a function called during exception handling.
ExceptionAcquired (see page 3821)	This is variable System.ExceptionAcquired.
ExceptionClass (see page 3821)	This is variable System.ExceptionClass.
ExceptObjProc (see page 3821)	ExceptObjProc defines a pointer to a function called during exception handling.
ExceptProc (see page 3822)	Points to the lowest-level exception handler.
ExitCode (see page 3823)	Contains the application's exit code.
ExitProc (see page 3823)	Points to a program's exit procedure (provided for backward compatibility).
ExitProcessProc (see page 3824)	Specifies the last procedure to execute before the application shuts down.
FileMode (see page 3824)	Indicates the access mode on typed and untyped files opened by the Reset (see page 3643) procedure.
HeapAllocFlags (see page 3825)	Indicates how the memory manager obtains memory from the operating system.
HPrevInst (see page 3826)	This is variable System.HPrevInst.
InitProc (see page 3826)	InitProc is the last installed initialization procedure.
Input (see page 3827)	Specifies a read-only Text file associated with the processes standard Input file.
IsConsole (see page 3828)	Indicates whether the module was compiled as a console application.
IsLibrary (see page 3828)	Indicates whether the module is a shared library.
IsMultiThread (see page 3829)	Indicates whether the application spawned additional threads using BeginThread (see page 3527) or TThread objects.
JITEnable (see page 3829)	Controls when the just-in-time debugger is called.
LibModuleList (see page 3830)	Lists module records for enumeration procedures.
MainInstance (see page 3830)	Indicates the instance handle for the main executable.
MainThreadID (see page 3831)	Indicates the instance handle for the current module's main thread of execution.
ModuleUnloadList (see page 3831)	This is variable System.ModuleUnloadList.
MonitorSupport (see page 3831)	This is variable System.MonitorSupport.
NeverSleepOnMMThreadContention (see page 3832)	Dictates memory manager behavior during a thread contention.
NoErrMsg (see page 3832)	Controls whether the application displays an error message when a runtime error occurs.

Output (see page 3833)	Specifies a write-only Text file associated with the process's standard output file.
RaiseExceptionProc (see page 3833)	Points to RaiseException Windows function.
RaiseExceptObjProc (see page 3834)	This is variable System.RaiseExceptObjProc.
RandSeed (see page 3834)	RandSeed stores the built-in random number generator's seed.
ReportMemoryLeaksOnShutdown (see page 3835)	Report memory leaks on shutdown.
RTLUnwindProc (see page 3835)	This is variable System.RTLUnwindProc.
SafeCallErrorProc (see page 3836)	SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.
SystemThreadEndProc (see page 3836)	This is variable System.SystemThreadEndProc.
SystemThreadFuncProc (see page 3837)	This is variable System.SystemThreadFuncProc.
Test8086 (see page 3837)	This is variable System.Test8086.
Test8087 (see page 3837)	This is variable System.Test8087.
TestFDIV (see page 3838)	This is variable System.TestFDIV.
UTF8CompareLocale (see page 3838)	This is variable System.UTF8CompareLocale.
VarAddRefProc (see page 3838)	The VarAddRefProc variable is used internally.
VarClearProc (see page 3839)	The VarClearProc variable is used internally.
VarCopyProc (see page 3839)	The VarCopyProc variable is used internally.
VarToLStrProc (see page 3840)	The VarToLStrProc variable is used internally.
VarToWStrProc (see page 3840)	The VarToWStrProc variable is used internally.

35.6.1 System.AbstractErrorProc Variable

AbstractErrorProc defines a callback routine for abstract method call errors.

Pascal

```
AbstractErrorProc: procedure;
```

C++

```
procedure AbstractErrorProc;
```

File

System

Description

An abstract method is a virtual or dynamic method that has no implementation in the class where it is declared. Its implementation is deferred to a descendant class. An EAbstractError exception will be thrown if a call is attempted to an abstact method.

You can define an AbstractErrorProc routine that will be called prior to the exception throw.

See Also

EAbstractError (see page 3916)

35.6.2 System.AllocMemCount Variable

Represents the total number of allocated memory blocks in a Delphi application.

Pascal

```
AllocMemCount: Integer deprecated;
```

C++

```
Integer deprecated AllocMemCount;
```

File

System

Description

Note: On Windows, AllocMemCount is the number of currently allocated blocks of memory that were requested by the user. AllocMemCount is incremented each time a block of memory is allocated and is decremented each time a block of memory is freed. Use AllocMemCount to find out how many unfreed blocks of memory remain.

Note: On Linux, the AllocMemCount variable is not maintained by default. Unless it is updated by a third-party memory manager, this variable always has a value of zero.

Warning: Caution:Because AllocMemCount is a global variable declared in the System (see page 3159) unit, it is not always safe to access it directly. In situations where modules are statically linked to the RTL, each module will have a different instance of AllocMemCount. The following table is a summary. Note that applications that use runtime packages are dynamically linked to the RTL, whereas applications that do not are statically linked.

Application type	Accessibility of AllocMemCount
EXE	Applications that do not use packages or Delphi DLLs can safely access this global variable directly because there is only one instance of it.
EXE with packages and no Delphi DLLs	Applications that use runtime packages and do not use any statically linked libraries can safely access AllocMemCount directly. In this situation all modules are dynamically linked to the RTL and there is only one instance of the variable. Unlike standard DLLs, packages allow access to global variables.
EXE with statically linked DLLs	If an application is statically linked to the RTL and also uses libraries that are statically linked to the RTL, then the AllocMemCount variable should never be accessed directly, since the EXE and each library will have its own instance of it. Instead, use the GetAllocMemCount function, implemented in BorlandMM, which returns the instance of the AllocMemCount global variable in the BorlandMM DLL. This DLL manages the memory allocation for all modules that include the ShareMem unit as the first unit in the application or library's uses clause. It is, therefore, this instance of the variable that contains the correct value. A function is used to access AllocMemCount in this situation because global variables in a DLL are private to the DLL.
EXE with packages and statically linked DLLs	It is not advisable to create applications that mix runtime packages with statically linked libraries. In this circumstance, use caution when allocating, freeing, and accessing memory. Be aware that each version of the RTL contains an instance of AllocMemCount that references memory that is allocated and freed only by that particular module.

See Also

AllocMemSize (see page 3809)

AllocMem (see page 3515)

35.6.3 System.AllocMemSize Variable

Represents the total size of allocated memory blocks.

Pascal

```
AllocMemSize: Integer deprecated;
```

C++

```
Integer deprecated AllocMemSize;
```

File

System

Description

Note: On Windows, AllocMemSize is the total size, in bytes, of all currently allocated blocks of memory in use by an application. Use AllocMemSize to find out how many bytes of memory an application is currently using.

Note: On Linux, the AllocMemSize variable is not maintained by default. Unless it is updated by a third-party memory manager, this variable always has a value of zero.

Warning: Caution:Because AllocMemSize is a global variable declared in the System (see page 3159) unit, it is not always safe to access it directly. In situations where modules are statically linked to the RTL, each module will have a different instance of AllocMemSize. The following table is a summary. Note that applications that use runtime packages are dynamically linked to the RTL, whereas applications that do not are statically linked.

Application type	Accessibility of AllocMemSize
EXE	Applications that do not use packages or Delphi DLLs can safely access this global variable directly because there is only one instance of it.
EXE with packages and no Delphi DLLs	Applications that use runtime packages and do not use any statically linked DLLs can safely access AllocMemSize directly. In this situation all modules are dynamically linked to the RTL and there is only one instance of the variable. Unlike standard DLLs, packages allow access to global variables.
EXE with statically linked DLLs	If an application is statically linked to the RTL and if that application is also using DLLs that are statically linked to the RTL then the AllocMemSize variable should never be accessed directly, since the EXE and each DLL will have its own instance of it. Instead use the GetAllocMemSize function, implemented in BorlandMM, which returns the instance of the AllocMemSize global variable in the BorlandMM DLL. This DLL manages the memory allocation for all modules that include the ShareMem unit as the first unit in the application or library's uses clause. It is, therefore, this instance of the variable that contains the correct value. A function is used to access AllocMemSize in this situation because global variables in a DLL are private to the DLL.
EXE with packages and statically linked DLLS	It is not advisable to create applications that mix runtime packages with statically linked DLLs. In this circumstance use caution when allocating, freeing, and accessing memory. Be aware that each version of the RTL contains an instance of AllocMemSize that references memory that is allocated and freed only by that particular module.

AllocMem (see page 3515)

AllocMemCount (see page 3807)

35.6.4 System.AssertErrorProc Variable

Points to the assertion error-handler.

Pascal

```
AssertErrorProc: TAssertErrorProc;
```

C++

```
TAssertErrorProc AssertErrorProc;
```

File

System

Description

AssertErrorProc points to a routine that produces runtime error 227 in Delphi code. The SysUtils (see page 3901) unit replaces it to cause an EAssertionFailed exception. If you do not use assertions, you can replace this with a method that that does something else, such as call OutputDebugString to add messages to the event log (see the example).

The value of AssertErrorProc must be a procedure with the following signature

procedure AssertErrorHandler(const Message, Filename: string; LineNumber: Integer; ErrorAddr (see page 3817): Pointer);

Delphi Examples:

```
{
The following code is a self-contained unit that you can add to a project
that logs failed assertions to the event log rather than raising an
exception. If /Debug is passed to the application as a command-line
parameter, all failed Assert calls cause a call to OutputDebugString,
which sends a messages to the Event Log window if run from Delphi, or
does nothing if run outside the IDE (OutputDebugString is a no-op if not
run from within a debugger). A nice side benefit is that all the line
numbers and unit names can be stripped from the EXE by turning off
assertions and rebuilding the project. Build the executable in the IDE
by hitting "Run".  Then go to the debug directory for the project and
execute the command line "AssertErrorProc_proj /Debug".
Note: AssertErrorHandler should do as little as possible.  This routine
does no cleanup, so no variables, no compiler generated variables.
Procedure calls are OK.
Note:   This example was originally provided by Brian Long.
}
type
  TForm1 = class(TForm)
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TStorage = class(TObject)
    FData: string;
    property Data: string read FData write FData;
```

```
    private
      { Private declarations }
    public
      { Public declarations }
    end;

    var
    Form1: TForm1;

procedure AssertErrorHandler(const Message, Filename: string;  LineNumber: Integer; ErrorAddr:
Pointer);

ErrorProc (see page 3818)

35.6.5 System.CmdLine Variable

Points to the command-line arguments specified when the application is invoked.

Pascal

```
CmdLine: PChar platform;
```

C++

```
PChar platform CmdLine;
```

File

System

Description

Note: On Windows, the CmdLine variable points to a null-terminated string that contains the command-line arguments specified when the application was started. Use ParamStr (see page 3625) to access individual arguments. In a library (DLL), CmdLine is nil (Delphi) or NULL (C++).

Note: On Linux, CmdLine is always nil (Delphi) or NULL (C++).

See Also

ParamStr (see page 3625)

FindCmdLineSwitch (see page 4174)

35.6.6 System.CmdShow Variable

Specifies the flags for displaying the application's main window.

Pascal

```
CmdShow: Integer platform;
```

C++

```
Integer platform CmdShow;
```

File

System

Description

Note: On Windows, CmdShow specifies the parameter that should be passed to the Windows API ShowWindow when displaying the main window of the application. In a library (DLL), CmdShow is always 0.

Note: On Linux, CmdShow is always 0. It exists only for compatibility with Windows code in cross-platform applications.

35.6.7 System.CPUCount Variable

Pascal

```
CPUCount: Integer;
```

C++

```
int CPUCount;
```

File

System

Description

This is variable System.CPUCount.

35.6.8 System.DebugHook Variable

DebugHook is set if an application is running under the IDE debugger.

Pascal

```
DebugHook: Byte platform = 0;
```

C++

```
Byte platform DebugHook = 0;
```

File

System

Description

DebugHook is 0 when an application operates outside the IDE debugger. DebugHook is 1 when an application operates inside the IDE debugger.

35.6.9 System.Default8087CW Variable

Specifies the Default 8087 control word.

Pascal

```
Default8087CW: Word = $1332;
```

C++

```
Word Default8087CW = 0x1332;
```

File

System

Description

Default8087CW is the value to which the Floating Point Unit (FPU) control register is set. The FPU control word includes bits that control the FPU's precision, rounding mode, and whether exceptions generate signals if they occur. See Intel's processor documentation for details.

The Set8087CW (see page 3653) procedure allows the programmer to have direct access to the Default8087CW. Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used. However, be aware that using this procedure to change the value of the 8087CW will change the behavior of the program's FP calculations. It is the programmer's responsibility to reset it.

C++ Examples:

```
/*
This example accesses the Floating Point Unit (FPU) control
register.  Try turning floating point exceptions off and on
and dividing a number by zero to test it.
*/
Word Saved8087CW;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit3->Text = FloatToStr(StrToFloat(Edit1->Text) / StrToFloat(Edit2->Text));
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "FPU Exceptions")
    System::Set8087CW(Saved8087CW);
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "No FPU Exceptions")
    System::Set8087CW(0x133f); // Disable all fpu exceptions
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("No FPU Exceptions");
  RadioGroup1->Items->Add("FPU Exceptions");
  RadioGroup1->ItemIndex = 2;
  Saved8087CW = Default8087CW;  // Save this because Set8087CW changes it!
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  System::Set8087CW(Saved8087CW); // Default value (with exceptions) is 0x1372
}
```

Delphi Examples:

```
{
This example accesses the Floating Point Unit (FPU) control
register.  Try turning floating point exceptions off and on
and dividing a number by zero to test it.
}
var
  Form1: TForm1;
  Saved8087CW: Word;

implementation

{$R *.dfm}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit3.Text := FloatToStr(StrToFloat(Edit1.Text) / StrToFloat(Edit2.Text));
end;
```

```
procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'FPU Exceptions' then
    System.Set8087CW(Saved8087CW);
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'No FPU Exceptions' then
    System.Set8087CW($133f); { Disable all fpu exceptions }
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('No FPU Exceptions');
  RadioGroup1.Items.Add('FPU Exceptions');
  RadioGroup1.ItemIndex := 2;
  Saved8087CW := Default8087CW;  // Save this because Set8087CW changes it!
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  System.Set8087CW(Saved8087CW); // Default value (with exceptions) is $1372
end;
```

See Also

Set8087CW (see page 3653)

35.6.10 System.DefaultSystemCodePage Variable

Pascal

```
DefaultSystemCodePage: Integer;
```

C++

```
int DefaultSystemCodePage;
```

File

System

Description

This is variable System.DefaultSystemCodePage.

35.6.11 System.DefaultTextLineBreakStyle Variable

Specifies the characters that are used by default to separate lines in text.

Pascal

```
DefaultTextLineBreakStyle: TTextLineBreakStyle = tlbsCRLF;
```

C++

```
TTextLineBreakStyle DefaultTextLineBreakStyle = tlbsCRLF;
```

File

System

Description

DefaultTextLineBreakStyle controls how the code editor represents the separation between lines of text in new files. For existing files, it maintains the line break style that the file currently uses.

See Also

SetLineBreakStyle (see page 3659)

35.6.12 System.DefaultUnicodeCodePage Variable

Pascal

```
DefaultUnicodeCodePage: Integer;
```

C++

```
int DefaultUnicodeCodePage;
```

File

System

Description

This is variable System.DefaultUnicodeCodePage.

35.6.13 System.DispCallByIDProc Variable

Pascal

```
DispCallByIDProc: Pointer;
```

C++

```
void * DispCallByIDProc;
```

File

System

Description

This is variable System.DispCallByIDProc.

35.6.14 System.DLLProc Variable

Points to a procedure invoked by a DLL entry point.

Pascal

```
DLLProc: Pointer;
```

C++

```
void * DLLProc;
```

File

System

Description

DLLProc is used to specify a procedure that is invoked every time a DLL's entry point is called. A procedure assigned to DLLProc must take one parameter of type Integer or int. For example,

- procedure LibraryProc(Reason: Integer); { Delphi }
- void LibraryProc(int Reason); // C++
- When the procedure is invoked, this single parameter contains a value between 0 and 3 as defined by the following group of constants (from the Windows unit):
- const
- DLL_PROCESS_DETACH = 0;
- DLL_PROCESS_ATTACH = 1;
- DLL_THREAD_ATTACH = 2;
- DLL_THREAD_DETACH = 3;
- For further details on the meaning of these constants, refer to the description of the DllEntryPoint function in the Win32 API online help.

Note: DLL_PROCESS_ATTACH is passed to the procedure only if the DLL's initialization code calls the procedure and specifies DLL_PROCESS_ATTACH as a parameter.

Note: When the Reason parameter is DLL_PROCESS_ATTACH, setting ExitCode (see page 3823) to a nonzero value causes the entry point to return false.

35.6.15 System.envp Variable

Pascal

```
envp: PPChar platform;
```

C++

```
PPChar platform envp;
```

File

System

Description

This is variable System.envp.

35.6.16 System.ErrorAddr Variable

Contains the address of a statement causing a runtime error.

Pascal

```
ErrorAddr: Pointer = nil;
```

C++

```
void * ErrorAddr = nil;
```

File

System

Description

If a program terminates normally or stops due to a call to Halt (see page 3594), ErrorAddr is nil (Delphi) or NULL (C++). If a program ends because of a runtime error, ErrorAddr contains the address of the statement in error.

See Also

ErrorProc (see page 3818)

ExceptProc (see page 3822)

AcquireExceptionObject (see page 3512)

ExceptAddr (see page 3562)

ExceptionErrorMessage (see page 4107)

ExceptObject (see page 3562)

GetLastError (see page 3582)

35.6.17 System.ErrorProc Variable

Points to the RTL runtime error handler.

Pascal

```
ErrorProc: procedure (ErrorCode: Byte; ErrorAddr: Pointer);
```

C++

```
procedure (ErrorCode: Byte; ErrorAddr: Pointer) ErrorProc;
```

File

System

Description

In Delphi, ErrorProc is a procedure variable pointing to the runtime error handler. The standard ErrorProc procedure reports the runtime error and terminates the program.

The ErrorProc variable is retained primarily for compatibility with older code. Newer applications should not specify an alternate runtime error procedure using ErrorProc as SysUtils (see page 3901) uses this variable to convert runtime errors into exceptions.

If you use SysUtils (see page 3901) in your program, it will force ErrorProc to its own routine and convert the runtime error into an exception. When a runtime library error occurs, the ErrorProc is called. The ErrorCode parameter contains the runtime error number and the ErrorAddr (see page 3817) parameter contains the machine code address that caused the runtime error.

Delphi Examples:

```
{
This example demostrates the use of ErrorProc and how to catch runtime
errors.
}
```

```
procedure MyErrorProc(ErrorCode : Byte; ErrorPtr : Pointer);
var
  ErrorName : String;
begin
  { Get the "name" of the enum value using RTTI }
  ErrorName := GetEnumName(TypeInfo(TRuntimeError), ErrorCode);

  { Show an error box }
  MessageDlg(Format('Error with code %d (%s) risen at $%X.',
      [ErrorCode, ErrorName, Integer(ErrorPtr)]), mtError, [mbOK], 0);
end;

procedure TForm2.btIOErrorClick(Sender: TObject);
begin
  {
  Try to write something onto the console - will raise an
  exception.
  }
  WriteLn('This will generate an error because there is no' +
          ' console attached!');
end;

{$OVERFLOWCHECKS ON}
{$OPTIMIZATION OFF}
{$HINTS OFF}
procedure TForm2.btOverflowErrClick(Sender: TObject);
var
  b : Cardinal;
begin
  {
  Simulate an overflow: Note, enabled the overflow
  checking and disabled optimizations because Delphi's
  compiler will not compile this code otherwise.
  }
  b := $FFFFFFFF;
  b := b * b;
end;
{$HINTS ON}
{$OPTIMIZATION ON}
{$OVERFLOWCHECKS OFF}

procedure TForm2.btRuntimeErrorClick(Sender: TObject);
begin
  { Simulate an access violation }
  System.Error(reAccessViolation);
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Register my System error proc }
  ErrorProc := MyErrorProc;
end;
```

See Also

ErrorAddr (see page 3817)

ExceptAddr (see page 3562)

ExceptionErrorMessage (see page 4107)

ExceptObject (see page 3562)

GetLastError (see page 3582)

ExceptProc (see page 3822)

AcquireExceptionObject (see page 3512)

35.6.18 System.ErrOutput Variable

ErrOutput specifies a write-only Text file associated with the process's error output file.

Pascal

```
ErrOutput: Text;
```

C++

```
Text ErrOutput;
```

File

System

Description

In Delphi, the ErrOutput variable is a write-only Text file associated with the process's error output file.

Note: On Windows, most processes don't have an error output file, and writing to ErrOutput raises an error. Delphi programs have a standard output file if they are linked as console applications.

Note: On Linux, all processes have an error output file. There are various ways to view the error output. One simple method is to run the program from a shell window.

See Also

Input (see page 3827)

Output (see page 3833)

35.6.19 System.ExceptClsProc Variable

ExceptClsProc defines a pointer to a function called during exception handling.

Pascal

```
ExceptClsProc: Pointer;
```

C++

```
void * ExceptClsProc;
```

File

System

Description

By default, ExceptClsProc is defined internally to point to a function that handles exceptions on your behalf. It returns the exception class. If you override ExceptClsProc to point to your function, that function will be called when an exception occurs in a try-except block. It will be passed an updateable TExceptionRecord value that describes the exception.

Internally, the class returned is used to determine which exception handler to use before ExceptObjProc (see page 3821) is called to create the exception instance.

See Also

ExceptObjProc (see page 3821)

TExceptionRecord (see page 4322)

35.6.20 System.ExceptionAcquired Variable

Pascal

```
ExceptionAcquired: Pointer;
```

C++

```
void * ExceptionAcquired;
```

File

System

Description

This is variable System.ExceptionAcquired.

35.6.21 System.ExceptionClass Variable

Pascal

```
ExceptionClass: TClass;
```

C++

```
TClass ExceptionClass;
```

File

System

Description

This is variable System.ExceptionClass.

35.6.22 System.ExceptObjProc Variable

ExceptObjProc defines a pointer to a function called during exception handling.

Pascal

```
ExceptObjProc: Pointer;
```

C++

```
void * ExceptObjProc;
```

File

System

Description

ExceptClsProc (see page 3820) defines the function that returns a class that is used to determine which exception handler to use before an exception object is created.

You can override the default exception object creation by defining your own function that returns a TObject (see page 3354). You point ExceptObjProc to that function. It is passed the an updateable version of the TExceptionRecord.

See Also

ExceptClsProc (see page 3820)

TExceptionRecord (see page 4322)

35.6.23 System.ExceptProc Variable

Points to the lowest-level exception handler.

Pascal

```
ExceptProc: Pointer;
```

C++

```
void * ExceptProc;
```

File

System

Description

In Delphi code, ExceptProc handles unhandled exceptions (exceptions that have not been caught in the except portion of a try..except statement.) If your application has a TApplication object, it automatically catches exceptions and generates an OnException event (to which you can respond using either the application's or a TApplicationEvents object's OnException event handler). Thus, because the TApplication object catches the exceptions, they never reach the ExceptProc handler. However, even if you have a TApplication object, it does not catch exceptions generated during initialization and finalization. These are handled by ExceptProc.

You can hook into ExceptProc to change how unhandled exceptions are reported. To do so, save the contexts of ExceptProc before changing it to the address of your own exception handler. The first statement of your new exception handler must then reinstall the saved value of ExceptProc. In this way, the ExceptProc procedure becomes part of a chain of exception procedures, each of which is executed in reverse order of installation.

The procedure assigned to ExceptProc must have a signature such as the following:

procedure ExceptHandler(ExceptObject (see page 3562): System::TObject (see page 3354); ExceptAddr (see page 3562): Pointer);

Note: :On Linux, ExceptProc may be called when most of the runtime has already shut down. This happens if an application terminates with an unhandled exception.

See Also

ErrorAddr (see page 3817)

ErrorProc (see page 3818)

TApplication

ExceptObject (see page 3562)

35.6.24 System.ExitCode Variable

Contains the application's exit code.

Pascal

```
ExitCode: Integer = 0;
```

C++

```
int ExitCode = 0;
```

File

System

Description

In Delphi code, the ExitCode variable contains the application's exit code. An exit procedure can learn the cause of termination by examining ExitCode. If the program terminates normally, ExitCode is zero. If the program terminates due to a call to Halt (see page 3594), ExitCode contains the value passed to Halt (see page 3594). If the program terminates due to a runtime error, ExitCode contains the error code.

Note: On Windows, setting the ExitCode variable to a value other than 0 in the initialization section of a unit will make loading of a DLL fail (DllMain will return false). You can also set ExitCode in code called from DLLProc (see page 3816) or DllProcEx to signal failure of loading.

Note: On Linux, although the ExitCode variable is accessible from shared object code, its value does not affect the loader of the shared object. Thus, using ExitCode in a shared object has no effect.

See Also

AddExitProc (see page 4048)

AddTerminateProc (see page 4048)

CallTerminateProcs (see page 4071)

ExitProc (see page 3823)

35.6.25 System.ExitProc Variable

Points to a program's exit procedure (provided for backward compatibility).

Pascal

```
ExitProc: Pointer;
```

C++

```
void * ExitProc;
```

File

System

Description

In Delphi code, ExitProc points to an exit procedure in an application. The exit procedure always gets called as part of a program's termination. ExitProc is only used when generating executable files.

An exit procedure takes no parameters and must be compiled with a far procedure directive to force it to use the far call model.

Do not use ExitProc in a dynamically loaded package. This procedure is called when the process halts, not when a package or DLL is unloaded. If you set ExitProc from a package or DLL, it may interfere with the ExitProc of the host executable. Because ExitProc is not compatible with packages, it is recommended that you add code to the finalization section of a unit instead. Inside a DLL, you can use the DLLProc (see page 3816) variable instead.

See Also

AddExitProc (see page 4048)

ExitCode (see page 3823)

AddTerminateProc (see page 4048)

CallTerminateProcs (see page 4071)

DLLProc (see page 3816)

35.6.26 System.ExitProcessProc Variable

Specifies the last procedure to execute before the application shuts down.

Pascal

```
ExitProcessProc: procedure;
```

C++

```
procedure ExitProcessProc;
```

File

System

Description

Assign a value to ExitProcessProc to specify a procedure that you want to execute when the application shuts down. The value of ExitProcessProc is a procedure with no parameters.

See Also

InitProc (see page 3826)

35.6.27 System.FileMode Variable

Indicates the access mode on typed and untyped files opened by the Reset (see page 3643) procedure.

Pascal

```
FileMode: Byte = 2;
```

C++

```
Byte FileMode = 2;
```

File

System

Description

In Delphi code, FileMode determines the access mode to use when typed and untyped files (not text files) are opened using the Reset (see page 3643) procedure.

The default FileMode is 2 (Read (see page 3634)/Write (see page 3707) access). Assigning another value to FileMode causes all subsequent Resets to use that mode. The SysUtils (see page 3901) unit declares a number of file open mode constants that can be assigned to the FileMode variable.

Note: Be sure to reset FileMode before calling Reset (see page 3643) with a read-only file. Even if you are only reading from the file, the default FileMode value (Read (see page 3634)/Write (see page 3707) access) will cause an attempt to open a read-only file to fail.

Warning: FileMode is declared as a variable, not as a threadvar. Therefore this variable is not thread-safe.

See Also

Reset (see page 3643)

Rewrite (see page 3645)

TFileStream

35.6.28 System.HeapAllocFlags Variable

Indicates how the memory manager obtains memory from the operating system.

Pascal

```
HeapAllocFlags: Word platform = 2;
```

C++

```
Word platform HeapAllocFlags = 2;
```

File

System

Description

On Windows, use HeapAllocFlags to customize the flags that the system memory manager uses when requesting blocks of memory from the operating system. By default, the value is GMEM_MOVEABLE.

HeapAllocFlags can be a combination of the following values:

GMEM_FIXED	Allocates fixed memory. The operating system can't move blocks, so there is no need to lock memory when obtaining a pointer. (can't be combined with GMEM_MOVEABLE).
GMEM_MOVEABLE	Allocates movable memory. In Win32, memory blocks are never moved in physical memory, but they can be moved within the default heap.
GMEM_ZEROINIT	Initializes memory contents to zero.
GMEM_MODIFY	Used to modify the attributes of an already-allocated block of memory.

GMEM_DDESHARE GMEM_SHARE	This flag is primarily for compatibility with 16-bit Window, but. can be used to enhance the performance of DDE operations. It should only be specified if the memory is to be used for DDE.
GPTR	Combines the GMEM_FIXED and GMEM_ZEROINIT flags.
GHND	Combines the GMEM_MOVEABLE and GMEM_ZEROINIT flags.

See Also

SetMemoryManager (see page 3660)

35.6.29 System.HPrevInst Variable

Pascal

```
HPrevInst: LongWord deprecated;
```

C++

```
LongWord deprecated HPrevInst;
```

File

System

Description

This is variable System.HPrevInst.

35.6.30 System.InitProc Variable

InitProc is the last installed initialization procedure.

Pascal

```
InitProc: Pointer;
```

C++

```
void * InitProc;
```

File

System

Description

Assign a value to InitProc to specify a procedure that you want to execute when the application starts up. The value of InitProc is a procedure with no parameters. For example:

In Delphi, the assignment can be made in the initialization section of a unit:

```
procedure MyInitProcedure;
...
initialization
  InitProc = @MyInitProcedure;
begin
end;
```

In C++, the assignment is most easily made in the project source file. This example is for Windows. On Linux applications, the code is similar.

```
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
  {
    // Note that call must precede call to Application->Initialize();
    System.InitProc = MyInitProcedure;
    Application->Initialize();
    Application->CreateForm(__classid(TForm1), &Form1);
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  catch (...)
  {
    try
    {
      throw Exception("");
    }
    catch (Exception &exception)
    {
      Application->ShowException(&exception);
    }
  }
  return 0;
}
```

Only one initialization procedure can be assigned to the InitProc variable. If your application defines more than one initialization procedure, only the last assignment to InitProc executes. To allow other initialization procedures to execute, you must "chain" the procedures together, calling the previously assigned value of InitProc from the new value.

See Also

TApplication

ExitProcessProc (see page 3824)

35.6.31 System.Input Variable

Specifies a read-only Text file associated with the processes standard Input file.

Pascal

```
Input: Text;
```

C++

```
Text Input;
```

File

System

Description

In Delphi, the Input variable is a read-only Text file associated with the process's standard Input file.

Note: On Windows, most processes don't have a standard Input file, and reading from Input raises an error. Delphi programs have a standard Input file if they are linked as console applications.

Note: On Linux, all processes have a standard Input file. There are various ways to use the standard Input. One simple method

is to run the program from a shell window.

See Also

Output (see page 3833)

35.6.32 System.IsConsole Variable

Indicates whether the module was compiled as a console application.

Pascal

```
IsConsole: Boolean;
```

C++

```
Boolean IsConsole;
```

File

System

Description

The IsConsole variable is true if the module was linked as a console application. This applies both to an executable and a shared library.

Note: On Linux, IsConsole is always true.

See Also

IsLibrary (see page 3828)

IsMultiThread (see page 3829)

Input (see page 3827)

Output (see page 3833)

ErrOutput (see page 3820)

35.6.33 System.IsLibrary Variable

Indicates whether the module is a shared library.

Pascal

```
IsLibrary: Boolean;
```

C++

```
Boolean IsLibrary;
```

File

System

Description

The IsLibrary variable is true if the module is a dynamic link library (Windows) or shared object (Linux).

See Also

IsConsole (see page 3828)

IsMultiThread (see page 3829)

35.6.34 System.IsMultiThread Variable

Indicates whether the application spawned additional threads using BeginThread (see page 3527) or TThread objects.

Pascal

```
IsMultiThread: Boolean;
```

C++

```
Boolean IsMultiThread;
```

File

System

Description

IsMultiThread is set to true to indicate that the memory manager should support multiple threads. IsMultiThread is set to true by BeginThread (see page 3527) and class factories.

See Also

BeginThread (see page 3527)

IsConsole (see page 3828)

IsLibrary (see page 3828)

CoInitFlags

TComObjectFactory

35.6.35 System.JITEnable Variable

Controls when the just-in-time debugger is called.

Pascal

```
JITEnable: Byte platform = 0;
```

C++

```
Byte platform JITEnable = 0;
```

File

System

Description

Use JITEnable to indicate what types of exceptions trigger the just-in-time debugger. JITEnable only has an effect on applications that run under Windows.

When JITEnable is 0 (the default), all exceptions are handled using the application's exception handling mechanism. The

just-in-time debugger is only called if the application provides no mechanism to catch exceptions. Note that any application that includes the Forms unit provides exception handling (via the Application object) for all but the initialization and finalization sections in Delphi units and does not trigger the just-in-time debugger.

When JITEnable is 1, any non-native exceptions (Exceptions raised by code that was compiled using other products) trigger the just-in-time debugger. Native exceptions are handled by the application's exception handling mechanism.

When JITEnable is greater than 1, all exceptions trigger the just-in-time debugger.

Note: When you install the IDE, it is registered as the just-in-time debugger. If you install other tools with debuggers, they may register themselves, overriding the registration of the IDE.

35.6.36 System.LibModuleList Variable

Lists module records for enumeration procedures.

Pascal

```
LibModuleList: PLibModule = nil;
```

C++

```
PLibModule LibModuleList = nil;
```

File

System

Description

LibModuleList implements a linked list of records for executables and packages in an application. LibModuleList is used by the EnumModules (see page 3556) and the EnumResourceModules (see page 3557) procedures.

See Also

EnumModules (see page 3556)

EnumResourceModules (see page 3557)

35.6.37 System.MainInstance Variable

Indicates the instance handle for the main executable.

Pascal

```
MainInstance: LongWord;
```

C++

```
LongWord MainInstance;
```

File

System

Description

Use MainInstance to obtain the instance handle for the main executable of an application. This is useful in applications that use runtime libraries or packages, when you need the handle for the executable rather than for the library.

Note:

See Also

FindHInstance (see page 3574)

35.6.38 System.MainThreadID Variable

Indicates the instance handle for the current module's main thread of execution.

Pascal

```
MainThreadID: LongWord;
```

C++

```
LongWord MainThreadID;
```

File

System

Description

Use MainThreadID to obtain the thread ID for the main execution thread (the current thread when the module was initialized).

During debugging, this ID appears in the thread status box for the main thread.

Note: On Windows, the value of MainThreadID is compatible with the thread ID required by some Win32 API calls.

See Also

TThread

35.6.39 System.ModuleUnloadList Variable

Pascal

```
ModuleUnloadList: PModuleUnloadRec = nil;
```

C++

```
PModuleUnloadRec ModuleUnloadList = nil;
```

File

System

Description

This is variable System.ModuleUnloadList.

35.6.40 System.MonitorSupport Variable

Pascal

```
MonitorSupport: PMonitorSupport;
```

C++

```
PMonitorSupport MonitorSupport;
```

File

System

Description

This is variable System.MonitorSupport.

35.6.41 System.NeverSleepOnMMThreadContention Variable

Dictates memory manager behavior during a thread contention.

Pascal

```
NeverSleepOnMMThreadContention: Boolean;
```

C++

```
Boolean NeverSleepOnMMThreadContention;
```

File

System

Description

The Memory Manager is a shared resource, and when many threads in the application attempt to perform a memory operation at the same time, one or more threads may have to wait for a pending operation in another thread to complete before it can continue. This situation is called a thread contention. When a thread contention occurs inside the Memory Manager the default behavior is to first relinquish the remaining time in the thread's time slice. If the resource is still not available when the thread enters its next time slice, the Memory Manager calls the OS procedure Sleep before trying again.

This behavior works well on machines with single or dual core CPUs, and also when the ratio of the number of running threads to number of CPU cores is relatively high (greater than 2:1). In other situations, better performance can be obtained by entering a busy waiting loop until the resource becomes available. If NeverSleepOnMMThreadContention is **True**, the Memory Manager will use this alternate strategy when a thread contention occurs. The default value for NeverSleepOnMMThreadContention is **False**.

See Also

Memory Management

Configuring the Memory Manager

35.6.42 System.NoErrMsg Variable

Controls whether the application displays an error message when a runtime error occurs.

Pascal

```
NoErrMsg: Boolean platform = False;
```

C++

```
Boolean platform NoErrMsg = False;
```

File

System

Description

Note: On Windows, set NoErrMsg to control whether a message appears to indicate that a runtime error has occurred. When NoErrMsg is false (the default), runtime errors cause the application to display a message box indicating the type of error that occurred. When NoErrMsg is true, these messages are suppressed.

On Linux, NoErrMsg only no effect.

Note: The SysUtils (see page 3901) unit turns most runtime errors into exceptions. If your application includes SysUtils (see page 3901), the runtime error message box is unlikely to appear, even if NoErrMsg is false.

35.6.43 System.Output Variable

Specifies a write-only Text file associated with the process's standard output file.

Pascal

```
Output: Text;
```

C++

```
Text Output;
```

File

System

Description

In Delphi, the Output variable is a write-only Text file associated with the process's standard output file.

Note: On Windows, most processes don't have a standard output file, and writing to Output raises an error. Delphi programs have a standard output file if they are linked as console applications.

Note: On Linux, all processes have a standard output file. There are various ways to view the standard error output. One simple method is to run the program from a shell window.

See Also

Input (see page 3827)

35.6.44 System.RaiseExceptionProc Variable

Points to RaiseException Windows function.

Pascal

```
RaiseExceptionProc: Pointer;
```

C++

```
void * RaiseExceptionProc;
```

File

System

Description

RaiseExceptionProc points to the RaiseException Windows API function. This can be used to invoke the function from assembly language.

35.6.45 System.RaiseExceptObjProc Variable

Pascal

```
RaiseExceptObjProc: Pointer;
```

C++

```
void * RaiseExceptObjProc;
```

File

System

Description

This is variable System.RaiseExceptObjProc.

35.6.46 System.RandSeed Variable

RandSeed stores the built-in random number generator's seed.

Pascal

```
RandSeed: Longint = 0;
```

C++

```
Longint RandSeed = 0;
```

File

System

Description

By assigning a specific value to RandSeed, you can use the Random (see page 3632) function to repetitively generate a specific sequence of random numbers. This is useful for applications that deal with data statistics and simulations. For applications that deal with encryption see the note under the Random (see page 3632) function.

See Also

Random (see page 3632)

Randomize (see page 3633)

35.6.47 System.ReportMemoryLeaksOnShutdown Variable

Report memory leaks on shutdown.

Pascal

```
ReportMemoryLeaksOnShutdown: Boolean;
```

C++

```
Boolean ReportMemoryLeaksOnShutdown;
```

File

System

Description

Set ReportMemoryLeaksOnShutdown to report memory leaks on shutdown.

The memory manager can report memory that was allocated but not freed by the time the memory manager shuts down. Such memory blocks are called memory leaks and are often the result of programming errors. When this global variable is set to **True**, the Memory Manager will scan the memory pool when it shuts down and report all unregistered memory leaks in a message dialog. The default value for ReportMemoryLeaksOnShutdown is **False**.

Expected memory leaks can be registered so the Memory Manager will ignore them during its checks for memory leaks. Use the procedures RegisterExpectedMemoryLeak (see page 3640) and UnregisterExpectedMemoryLeak (see page 3694) to control the memory areas that the Memory Manager checks for leaks.

See Also

Memory Management

Configuring the Memory Manager

Registering Memory Leaks

RegisterExpectedMemoryLeak (see page 3640)

UnregisterExpectedMemoryLeak (see page 3694)

35.6.48 System.RTLUnwindProc Variable

Pascal

```
RTLUnwindProc: Pointer;
```

C++

```
void * RTLUnwindProc;
```

File

System

Description

This is variable System.RTLUnwindProc.

35.6.49 System.SafeCallErrorProc Variable

SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.

Pascal

```
SafeCallErrorProc: TSafeCallErrorProc;
```

C++

```
TSafeCallErrorProc SafeCallErrorProc;
```

File

System

Description

A function or procedure defined with the safecall directive is invoked using a safe calling convention. When such a routine incurs an error, the System::TObject::SafeCallException (see page 3380) is invoked. However, you can override this call by defining your own handling routine, and setting SafeCallErrorProc to point to it.

SafeCallErrorProc should point to a procedure that takes two parameters :

ErrorCode is an integer holding the error code.

ErrorAddr (see page 3817) is the code address at the time of error.

If SafeCallErrorProc returns normally, or is set to nil, then the ESafecallException is raised.

See Also

ESafecallException (see page 3946)

System::TObject::SafeCallException (see page 3380)

35.6.50 System.SystemThreadEndProc Variable

Pascal

```
SystemThreadEndProc: TSystemThreadEndProc = nil;
```

C++

```
TSystemThreadEndProc SystemThreadEndProc = nil;
```

File

System

Description

This is variable System.SystemThreadEndProc.

35.6.51 System.SystemThreadFuncProc Variable

Pascal

```
SystemThreadFuncProc: TSystemThreadFuncProc = nil;
```

C++

```
TSystemThreadFuncProc SystemThreadFuncProc = nil;
```

File

System

Description

This is variable System.SystemThreadFuncProc.

35.6.52 System.Test8086 Variable

Pascal

```
Test8086: Byte;
```

C++

```
Byte Test8086;
```

File

System

Description

This is variable System.Test8086.

35.6.53 System.Test8087 Variable

Pascal

```
Test8087: Byte = 3;
```

C++

```
Byte Test8087 = 3;
```

File

System

Description

This is variable System.Test8087.

35.6.54 System.TestFDIV Variable

Pascal

```
TestFDIV: Shortint;
```

C++

```
Shortint TestFDIV;
```

File

System

Description

This is variable System.TestFDIV.

35.6.55 System.UTF8CompareLocale Variable

Pascal

```
UTF8CompareLocale: Cardinal;
```

C++

```
unsigned UTF8CompareLocale;
```

File

System

Description

This is variable System.UTF8CompareLocale.

35.6.56 System.VarAddRefProc Variable

The VarAddRefProc variable is used internally.

Pascal

```
VarAddRefProc: procedure (var v: TVarData) = nil;
```

C++

```
procedure (var v: TVarData) VarAddRefProc = nil;
```

File

System

Description

Do not modify or use the VarAddRefProc variable manually. VarAddRefProc is used internally by the Variant (see page 3421) manager.

Note: Applications should not modify or rely on the value of the VarAddRefProc variable. Changes made to VarAddRefProc may lead to unexpected errors.

See Also

VarClearProc (see page 3839)

VarCopyProc (see page 3839)

VarToLStrProc (see page 3840)

VarToWStrProc (see page 3840)

35.6.57 System.VarClearProc Variable

The VarClearProc variable is used internally.

Pascal

```
VarClearProc: procedure (var v: TVarData) = nil;
```

C++

```
procedure (var v: TVarData) VarClearProc = nil;
```

File

System

Description

Do not modify or use the VarClearProc variable manually. VarClearProc is used internally by the Variant (see page 3421) manager.

Note: Applications should not modify or rely on the value of the VarClearProc variable. Changes made to VarClearProc may lead to unexpected errors.

See Also

VarAddRefProc (see page 3838)

VarCopyProc (see page 3839)

VarToLStrProc (see page 3840)

VarToWStrProc (see page 3840)

35.6.58 System.VarCopyProc Variable

The VarCopyProc variable is used internally.

Pascal

```
VarCopyProc: procedure (var Dest: TVarData; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: TVarData; const Source: TVarData) VarCopyProc = nil;
```

File

System

Description

Do not modify or use the VarCopyProc variable manually. VarCopyProc is used internally by the Variant (see page 3421) manager.

Note: Applications should not modify or rely on the value of the VarCopyProc variable. Changes made to VarCopyProc may lead to unexpected errors.

See Also

VarClearProc (see page 3839)

VarAddRefProc (see page 3838)

VarToLStrProc (see page 3840)

VarToWStrProc (see page 3840)

35.6.59 System.VarToLStrProc Variable

The VarToLStrProc variable is used internally.

Pascal

```
VarToLStrProc: procedure (var Dest: AnsiString; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: AnsiString; const Source: TVarData) VarToLStrProc = nil;
```

File

System

Description

Do not modify or use the VarToLStrProc variable manually. VarToLStrProc is used internally by the Variant (see page 3421) manager.

Note: Applications should not modify or rely on the value of the VarToLStrProc variable. Changes made to VarToLStrProc may lead to unexpected errors.

See Also

VarClearProc (see page 3839)

VarAddRefProc (see page 3838)

VarCopyProc (see page 3839)

VarToWStrProc (see page 3840)

35.6.60 System.VarToWStrProc Variable

The VarToWStrProc variable is used internally.

Pascal

```
VarToWStrProc: procedure (var Dest: WideString; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: WideString; const Source: TVarData) VarToWStrProc = nil;
```

File

System

Description

Do not modify or use the VarToWStrProc variable manually. VarToWStrProc is used internally by the Variant (see page 3421) manager.

Note: Applications should not modify or rely on the value of VarToWStrProc variable. Changes made to VarToWStrProc may lead to unexpected errors.

See Also

VarClearProc (see page 3839)

VarAddRefProc (see page 3838)

VarCopyProc (see page 3839)

VarToLStrProc (see page 3840)

35.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CompilerVersion (see page 3844)	Designates the version number of the Delphi compiler.
CPUi386 (see page 3844)	This is constant System.CPUi386.
CPUi486 (see page 3845)	This is constant System.CPUi486.
CPUPentium (see page 3845)	This is constant System.CPUPentium.
E_NOINTERFACE (see page 3845)	This is constant System.E_NOINTERFACE.
E_NOTIMPL (see page 3846)	This is constant System.E_NOTIMPL.
E_UNEXPECTED (see page 3846)	This is constant System.E_UNEXPECTED.
fmClosed (see page 3846)	This is constant System.fmClosed.
fmInOut (see page 3847)	This is constant System.fmInOut.
fmInput (see page 3847)	This is constant System.fmInput.
fmOutput (see page 3847)	This is constant System.fmOutput.
hfFieldSize (see page 3848)	This is constant System.hfFieldSize.
hfMonitorOffset (see page 3848)	This is constant System.hfMonitorOffset.
INFINITE (see page 3848)	This is constant System.INFINITE.
MaxInt (see page 3849)	The maximum value of the Integer data type.
MaxLongint (see page 3849)	The maximum value of the Longint data type.
NumSmallBlockTypes (see page 3849)	NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.
opAdd (see page 3850)	opAdd defines an addition operation.
opAnd (see page 3850)	opAnd defines a logical and operation.
opCmpEQ (see page 3851)	opCmpEQ defines an equality comparison operator.
opCmpGE (see page 3851)	opCmpGE defines a greater than or equal comparison operator.
opCmpGT (see page 3852)	opCmpGT defines a greater than comparison operator.
opCmpLE (see page 3852)	opCmpLE defines a less than or equal comparison operator.
opCmpLT (see page 3853)	opCmpLT defines a less than comparison operator.
opCmpNE (see page 3853)	opCmpNE defines an inequality comparison operator.
opCompare (see page 3854)	opCompare defines a comparison operation.
opDivide (see page 3854)	opDivide defines a divide operation.
opIntDivide (see page 3855)	opIntDivide defines an integer divide operation.
opModulus (see page 3855)	opModulus defines a modulus operation.
opMultiply (see page 3855)	opMultiply defines a multiply operation.
opNegate (see page 3856)	opNegate defines a negate operation.
opNot (see page 3856)	opNot defines a binary negation operation.
opOr (see page 3857)	opOr defines a logical or operation.
opShiftLeft (see page 3857)	opShiftLeft defines a bitwise shift left operation.
opShiftRight (see page 3858)	opShiftRight defines a bitwise shift right operation.
opSubtract (see page 3858)	opSubtract defines a subtraction operation.
opXor (see page 3859)	opXor defines a logical exclusive or operation.
RTLVersion (see page 3859)	Designates the version number of the Delphi runtime library.
S_FALSE (see page 3859)	This is constant System.S_FALSE.
S_OK (see page 3860)	This is constant System.S_OK.
sLineBreak (see page 3860)	Represents the character(s) used to generate a line feed.
tfCRLF (see page 3861)	This is constant System.tfCRLF.
varAny (see page 3861)	Represents a Variant (see page 3421) that can hold any value.
varArray (see page 3861)	Represents a Variant (see page 3421) that holds dynamic array data.

varBoolean (see page 3862)	Represents a Variant (see page 3421) that holds WordBool data.
varByRef (see page 3862)	Represents a Variant (see page 3421) that points to another variable.
varByte (see page 3863)	Represents a Variant (see page 3421) that holds byte data.
varCurrency (see page 3863)	Represents a Variant (see page 3421) that holds a monetary floating point value.
varDate (see page 3864)	Represents a Variant (see page 3421) that holds a TDateTime (see page 3323) value.
varDispatch (see page 3864)	Represents a Variant (see page 3421) that has been assigned an IDispatch (see page 3494) value.
varDouble (see page 3865)	Represents a Variant (see page 3421) that holds a floating point value.
varEmpty (see page 3865)	Represents a Variant (see page 3421) that has not yet been assigned a value.
varError (see page 3866)	Represents a Variant (see page 3421) that holds a 32 bit error code.
varInt64 (see page 3867)	Represents a Variant (see page 3421) that holds Int64 data.
varInteger (see page 3867)	Represents a Variant (see page 3421) that holds Integer data.
varLongWord (see page 3868)	Represents a Variant (see page 3421) that holds LongWord data.
varNull (see page 3868)	Represents a Variant (see page 3421) that holds a null value.
varOleStr (see page 3869)	Represents a Variant (see page 3421) that has been assigned a COM interface type string value.
varShortInt (see page 3869)	Represents a Variant (see page 3421) that holds ShortInt data.
varSingle (see page 3870)	Represents a Variant (see page 3421) that holds byte data.
varSmallint (see page 3870)	Represents a Variant (see page 3421) that holds Smallint data.
varStrArg (see page 3871)	Represents a Variant (see page 3421) that has holds a COM compatible string value.
varString (see page 3871)	Represents a Variant (see page 3421) that holds string data.
varTypeMask (see page 3872)	Defines a mask for filtering out the meta data part of a Variant (see page 3421) data type.
varUInt64 (see page 3872)	This is constant System.varUInt64.
varUnknown (see page 3873)	Represents a Variant (see page 3421) that holds an unknown value.
varUString (see page 3873)	This is constant System.varUString.
varVariant (see page 3873)	Represents a Variant (see page 3421) data type.
varWord (see page 3874)	Represents a Variant (see page 3421) that holds Word data.
vmtAddRef (see page 3874)	This is constant System.vmtAddRef.
vmtAfterConstruction (see page 3875)	This is constant System.vmtAfterConstruction.
vmtAutoTable (see page 3875)	This is constant System.vmtAutoTable.
vmtBeforeDestruction (see page 3875)	This is constant System.vmtBeforeDestruction.
vmtClassName (see page 3876)	This is constant System.vmtClassName.
vmtCreateObject (see page 3876)	This is constant System.vmtCreateObject.
vmtDefaultHandler (see page 3876)	This is constant System.vmtDefaultHandler.
vmtDestroy (see page 3877)	This is constant System.vmtDestroy.
vmtDispatch (see page 3877)	This is constant System.vmtDispatch.
vmtDynamicTable (see page 3877)	This is constant System.vmtDynamicTable.
vmtEquals (see page 3878)	This is constant System.vmtEquals.
vmtFieldTable (see page 3878)	This is constant System.vmtFieldTable.
vmtFreeInstance (see page 3878)	This is constant System.vmtFreeInstance.
vmtGetHashCode (see page 3879)	This is constant System.vmtGetHashCode.
vmtInitTable (see page 3879)	This is constant System.vmtInitTable.
vmtInstanceSize (see page 3879)	This is constant System.vmtInstanceSize.
vmtIntfTable (see page 3880)	This is constant System.vmtIntfTable.
vmtMethodTable (see page 3880)	This is constant System.vmtMethodTable.
vmtNewInstance (see page 3880)	This is constant System.vmtNewInstance.
vmtParent (see page 3881)	This is constant System.vmtParent.
vmtQueryInterface (see page 3881)	This is constant System.vmtQueryInterface.
vmtRelease (see page 3881)	This is constant System.vmtRelease.
vmtSafeCallException (see page 3882)	This is constant System.vmtSafeCallException.
vmtSelfPtr (see page 3882)	This is constant System.vmtSelfPtr.
vmtToString (see page 3882)	This is constant System.vmtToString.

vmtTypeInfo (see page 3883)	This is constant System.vmtTypeInfo.
vtAnsiString (see page 3883)	vtAnsiString defines an AnsiString TVarData (see page 3740) VType value.
vtBoolean (see page 3883)	vtBoolean defines a Boolean TVarData (see page 3740) VType value.
vtChar (see page 3884)	vtChar defines a Char TVarData (see page 3740) VType value.
vtClass (see page 3884)	vtClass defines a TClass (see page 3785) TVarData (see page 3740) VType value.
vtCurrency (see page 3885)	vtCurrency defines a Currency (see page 3235) TVarData (see page 3740) VType value.
vtExtended (see page 3885)	vtExtended defines an Extended TVarData (see page 3740) VType value.
vtInt64 (see page 3886)	vtInt64 defines an Int64 TVarData (see page 3740) VType value.
vtInteger (see page 3886)	vtInteger defines an Integer TVarData (see page 3740) VType value.
vtInterface (see page 3887)	vtInterface defines an Interface pointer TVarData (see page 3740) VType value.
vtObject (see page 3887)	vtObject defines a TObject (see page 3354) TVarData (see page 3740) VType value.
vtPChar (see page 3888)	vtPChar defines a PChar TVarData (see page 3740) VType value.
vtPointer (see page 3888)	vtPointer defines a Pointer TVarData (see page 3740) VType value.
vtPWideChar (see page 3889)	vtPWideChar defines a PWideChar TVarData (see page 3740) VType value.
vtString (see page 3889)	vtString defines a String TVarData (see page 3740) VType value.
vtUnicodeString (see page 3890)	This is constant System.vtUnicodeString.
vtVariant (see page 3890)	vtString (see page 3889) defines a Variant (see page 3421) TVarData (see page 3740) VType value.
vtWideChar (see page 3890)	vtWideChar defines a WideChar TVarData (see page 3740) VType value.
vtWideString (see page 3891)	vtWideString defines a WideString (see page 3467) TVarData (see page 3740) VType value.

35.7.1 System.CompilerVersion Constant

Designates the version number of the Delphi compiler.

Pascal

```
CompilerVersion = 18.0;
```

C++

```
CompilerVersion = 18.0;
```

File

System

Description

Use CompilerVersion to test the version level of the Delphi compiler. This is useful if you want to conditionalize code that takes advantage of newer features in the Delphi language.

See Also

RTLVersion (see page 3859)

35.7.2 System.CPUi386 Constant

Pascal

```
CPUi386 = 2;
```

C++

```
CPUi386 = 2;
```

File

System

Description

This is constant System.CPUi386.

35.7.3 System.CPUi486 Constant

Pascal

```
CPUi486 = 3;
```

C++

```
CPUi486 = 3;
```

File

System

Description

This is constant System.CPUi486.

35.7.4 System.CPUPentium Constant

Pascal

```
CPUPentium = 4;
```

C++

```
CPUPentium = 4;
```

File

System

Description

This is constant System.CPUPentium.

35.7.5 System.E_NOINTERFACE Constant

Pascal

```
E_NOINTERFACE = HRESULT($80004002);
```

C++

```
E_NOINTERFACE = HRESULT($80004002);
```

File

System

Description

This is constant System.E_NOINTERFACE.

35.7.6 System.E_NOTIMPL Constant

Pascal

```
E_NOTIMPL = HRESULT($80004001);
```

C++

```
E_NOTIMPL = HRESULT($80004001);
```

File

System

Description

This is constant System.E_NOTIMPL.

35.7.7 System.E_UNEXPECTED Constant

Pascal

```
E_UNEXPECTED = HRESULT($8000FFFF);
```

C++

```
E_UNEXPECTED = HRESULT($8000FFFF);
```

File

System

Description

This is constant System.E_UNEXPECTED.

35.7.8 System.fmClosed Constant

Pascal

```
fmClosed = $D7B0;
```

C++

```
fmClosed = 0xD7B0;
```

File

System

Description

This is constant System.fmClosed.

35.7.9 System.fmInOut Constant

Pascal

```
fmInOut = $D7B3;
```

C++

```
fmInOut = 0xD7B3;
```

File

System

Description

This is constant System.fmInOut.

35.7.10 System.fmInput Constant

Pascal

```
fmInput = $D7B1;
```

C++

```
fmInput = 0xD7B1;
```

File

System

Description

This is constant System.fmInput.

35.7.11 System.fmOutput Constant

Pascal

```
fmOutput = $D7B2;
```

C++

```
fmOutput = 0xD7B2;
```

File

System

Description

This is constant System.fmOutput.

35.7.12 System.hfFieldSize Constant

Pascal

```
hfFieldSize = 4;
```

C++

```
hfFieldSize = 4;
```

File

System

Description

This is constant System.hfFieldSize.

35.7.13 System.hfMonitorOffset Constant

Pascal

```
hfMonitorOffset = 0;
```

C++

```
hfMonitorOffset = 0;
```

File

System

Description

This is constant System.hfMonitorOffset.

35.7.14 System.INFINITE Constant

Pascal

```
INFINITE = Cardinal($FFFFFFFF);
```

C++

```
INFINITE = Cardinal($FFFFFFFF);
```

File

System

Description

This is constant System.INFINITE.

35.7.15 System.MaxInt Constant

The maximum value of the Integer data type.

Pascal

```
MaxInt = 2147483647;
```

C++

```
MaxInt = 2147483647;
```

File

System

Description

MaxInt represents the highest value in the range of the integer data type (2147483647).

See Also

High (see page 3596)

35.7.16 System.MaxLongint Constant

The maximum value of the Longint data type.

Pascal

```
MaxLongint = 2147483647;
```

C++

```
MaxLongint = 2147483647;
```

File

System

Description

MaxLongint represents the highest value in the range of the Longint (Delphi) or int (C++) data type (2147483647).

See Also

High (see page 3596)

35.7.17 System.NumSmallBlockTypes Constant

NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.

Pascal

```
NumSmallBlockTypes = 55;
```

C++

```
NumSmallBlockTypes = 55;
```

File

System

Description

GetMemoryManagerState (see page 3591) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a System::TMemoryManagerState (see page 3730) record. Within that record is held a System::TSmallBlockTypeStates (see page 3795) field - an array of System::TSmallBlockTypeState (see page 3736) records. There are NumSmallBlockTypes (55) different small memory block sizes, and therefore 55 System::TSmallBlockTypeState (see page 3736) records in this array.

See Also

GetMemoryManagerState (see page 3591)

System::TMemoryManagerState (see page 3730)

System::TSmallBlockTypeState (see page 3736)

System::TSmallBlockTypeStates (see page 3795)

35.7.18 System.opAdd Constant

opAdd defines an addition operation.

Pascal

```
opAdd = 0;
```

C++

```
opAdd = 0;
```

File

System

Description

opAdd is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opAdd represents an addition of two operands.

See Also

TVarOp (see page 3799)

35.7.19 System.opAnd Constant

opAnd defines a logical and operation.

Pascal

```
opAnd = 8;
```

C++

```
opAnd = 8;
```

File

System

Description

opAnd is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opAnd represents a logical and of two operands.

See Also

TVarOp (see page 3799)

35.7.20 System.opCmpEQ Constant

opCmpEQ defines an equality comparison operator.

Pascal

```
opCmpEQ = 14;
```

C++

```
opCmpEQ = 14;
```

File

System

Description

opCmpEQ is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpEQ represents a comparison that two operands are equal in value.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.21 System.opCmpGE Constant

opCmpGE defines a greater than or equal comparison operator.

Pascal

```
opCmpGE = 19;
```

C++

```
opCmpGE = 19;
```

File

System

Description

opCmpGE is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpGE represents the comparison : left operand greater than or equal to the right operand.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.22 System.opCmpGT Constant

opCmpGT defines a greater than comparison operator.

Pascal

```
opCmpGT = 18;
```

C++

```
opCmpGT = 18;
```

File

System

Description

opCmpGT is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpGT represents the comparison : left operand greater than the right operand.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.23 System.opCmpLE Constant

opCmpLE defines a less than or equal comparison operator.

Pascal

```
opCmpLE = 17;
```

C++

```
opCmpLE = 17;
```

File

System

Description

opCmpLE is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right

operand comparisons, such as CompareOp.

opCmpLE represents the comparison : left operand less than or equal to the right operand.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.24 System.opCmpLT Constant

opCmpLT defines a less than comparison operator.

Pascal

```
opCmpLT = 16;
```

C++

```
opCmpLT = 16;
```

File

System

Description

opCmpLT is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpLT represents the comparison : left operand less than the right operand.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.25 System.opCmpNE Constant

opCmpNE defines an inequality comparison operator.

Pascal

```
opCmpNE = 15;
```

C++

```
opCmpNE = 15;
```

File

System

Description

opCmpNE is one of the opCmp* comparison values that TVarOp (see page 3799) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpNE represents a comparison that two operands are not equal in value.

See Also

CompareOp (see page 4998)

TVarOp (see page 3799)

35.7.26 System.opCompare Constant

opCompare defines a comparison operation.

Pascal

```
opCompare = 11;
```

C++

```
opCompare = 11;
```

File

System

Description

opCompare defines a comparison operation.

See Also

TVarOp (see page 3799)

35.7.27 System.opDivide Constant

opDivide defines a divide operation.

Pascal

```
opDivide = 3;
```

C++

```
opDivide = 3;
```

File

System

Description

opDivide is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opDivide represents the division of the left operand by the right operation.

See Also

TVarOp (see page 3799)

35.7.28 System.opIntDivide Constant

opIntDivide defines an integer divide operation.

Pascal

```
opIntDivide = 4;
```

C++

```
opIntDivide = 4;
```

File

System

Description

opIntDivide is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opIntDivide represents the integer division of the left operand by the right operation.

See Also

TVarOp (see page 3799)

35.7.29 System.opModulus Constant

opModulus defines a modulus operation.

Pascal

```
opModulus = 5;
```

C++

```
opModulus = 5;
```

File

System

Description

opModulus is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opModulus represents the remainder of the division of the left operand by the right operand.

See Also

TVarOp (see page 3799)

35.7.30 System.opMultiply Constant

opMultiply defines a multiply operation.

Pascal

```
opMultiply = 2;
```

C++

```
opMultiply = 2;
```

File

System

Description

opMultiply is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opMultiply represents the multiplication of the left operand by the right operation.

See Also

TVarOp (see page 3799)

35.7.31 System.opNegate Constant

opNegate defines a negate operation.

Pascal

```
opNegate = 12;
```

C++

```
opNegate = 12;
```

File

System

Description

opNegate is one of the operation types that TVarOp (see page 3799) may be set to when performing unary operations such as UnaryOp.

opNegate represents the inversion of an operand value.

See Also

TVarOp (see page 3799)

35.7.32 System.opNot Constant

opNot defines a binary negation operation.

Pascal

```
opNot = 13;
```

C++

```
opNot = 13;
```

File

System

Description

opNegate (see page 3856) represents the binary (bitwise) inversion of an operand value.

See Also

TVarOp (see page 3799)

35.7.33 System.opOr Constant

opOr defines a logical or operation.

Pascal

```
opOr = 9;
```

C++

```
opOr = 9;
```

File

System

Description

opOr is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opOr represents a logical or of two operands.

See Also

TVarOp (see page 3799)

35.7.34 System.opShiftLeft Constant

opShiftLeft defines a bitwise shift left operation.

Pascal

```
opShiftLeft = 6;
```

C++

```
opShiftLeft = 6;
```

File

System

Description

opShiftLeft is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opShiftLeft represents the left operand shifted left N times, where N is the numeric value of the right operand.

See Also

TVarOp (see page 3799)

35.7.35 System.opShiftRight Constant

opShiftRight defines a bitwise shift right operation.

Pascal

```
opShiftRight = 7;
```

C++

```
opShiftRight = 7;
```

File

System

Description

opShiftRight is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opShiftRight represents the left operand shifted right N times, where N is the numeric value of the right operand.

See Also

TVarOp (see page 3799)

35.7.36 System.opSubtract Constant

opSubtract defines a subtraction operation.

Pascal

```
opSubtract = 1;
```

C++

```
opSubtract = 1;
```

File

System

Description

opSubtract is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opSubtract represents the right operand subtracted from the left operand.

See Also

TVarOp (see page 3799)

35.7.37 System.opXor Constant

opXor defines a logical exclusive or operation.

Pascal

```
opXor = 10;
```

C++

```
opXor = 10;
```

File

System

Description

opXor is one of the operation types that TVarOp (see page 3799) may be set to when performing binary operations such as BinaryOp.

opXor represents a logical exclusive or of two operands.

See Also

TVarOp (see page 3799)

35.7.38 System.RTLVersion Constant

Designates the version number of the Delphi runtime library.

Pascal

```
RTLVersion = 20.00;
```

C++

```
RTLVersion = 20.00;
```

File

System

Description

Use RTLVersion to test the Delphi runtime library version level independently of the compiler version level.

See Also

CompilerVersion (see page 3844)

35.7.39 System.S_FALSE Constant

Pascal

```
S_FALSE = $00000001;
```

C++

```
S_FALSE = 0x00000001;
```

File

System

Description

This is constant System.S_FALSE.

35.7.40 System.S_OK Constant

Pascal

```
S_OK = 0;
```

C++

```
S_OK = 0;
```

File

System

Description

This is constant System.S_OK.

35.7.41 System.sLineBreak Constant

Represents the character(s) used to generate a line feed.

Pascal

```
sLineBreak = AnsiString(#13#10);
```

C++

```
sLineBreak = AnsiString(#13#10);
```

File

System

Description

Windows systems define sLineBreak as a combination of carriage return (#13) and line feed (#10).

Linux systems define sLineBreak as simply a line feed (#10).

It is preferable to use this constabnt rather than hard code #13#10 or #10 (as appropriate) to move to a new line in a text output.

35.7.42 System.tfCRLF Constant

Pascal

```
tfCRLF = $1;
```

C++

```
tfCRLF = 0x1;
```

File

System

Description

This is constant System.tfCRLF.

35.7.43 System.varAny Constant

Represents a Variant (see page 3421) that can hold any value.

Pascal

```
varAny = $0101;
```

C++

```
varAny = 0x0101;
```

File

System

Description

A variant with a varAny type is used as a placeholder for any variant value, such as when passed as a paremeter to a routine. A varAny variant cannot be directly processed - use ChangeAnyProc to convert it to a variant type that can be processed.

See Also

TVarType (see page 3801)

ChangeAnyProc (see page 5101)

VarType (see page 5090)

35.7.44 System.varArray Constant

Represents a Variant (see page 3421) that holds dynamic array data.

Pascal

```
varArray = $2000;
```

C++

```
varArray = 0x2000;
```

File

System

Description

The VarType routine returns a TVarType (see page 3801) value that describes the current data type used to hold the contents of a Variant (see page 3421) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The low order bits determine the basic data type, such as varDouble (see page 3865), varSmallInt.

The high order bits represent meta data types varArray and varByRef (see page 3862).

Logically And varArray with a Variant (see page 3421) to determine if a Variant (see page 3421) holds array data.

Use VarArrayCreate to generate an array Variant (see page 3421);

See Also

TVarType (see page 3801)

VarArrayCreate (see page 5059)

VarType (see page 5090)

35.7.45 System.varBoolean Constant

Represents a Variant (see page 3421) that holds WordBool data.

Pascal

```
varBoolean = $000B;
```

C++

```
varBoolean = 0x000B;
```

File

System

Description

varBoolean represents a Variant (see page 3421) variable that currently holds a 16-bit boolean (type WordBool) value.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.46 System.varByRef Constant

Represents a Variant (see page 3421) that points to another variable.

Pascal

```
varByRef = $4000;
```

C++

```
varByRef = 0x4000;
```

File

System

Description

The VarType routine returns a TVarType (see page 3801) value that describes the current data type used to hold the contents of a Variant (see page 3421) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The low order bits determine the basic data type, such as varDouble (see page 3865), varSmallInt.

The high order bits represent meta data types varArray (see page 3861) and varByRef.

In essence, a varByRef variant is a pointer. The data type of the variable it points to is determined in the low order bits.

Logically And varByRef with a Variant (see page 3421) to determine if a Variant (see page 3421) is a pointer.

See Also

TVarType (see page 3801)

VarType (see page 5090)

35.7.47 System.varByte Constant

Represents a Variant (see page 3421) that holds byte data.

Pascal

```
varByte = $0011;
```

C++

```
varByte = 0x0011;
```

File

System

Description

When a Variant (see page 3421) is assigned an integer value less than 256, it will be set to a varByte Variant (see page 3421) type. varByte represents a Variant (see page 3421) variable that currently holds a byte data value.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.48 System.varCurrency Constant

Represents a Variant (see page 3421) that holds a monetary floating point value.

Pascal

```
varCurrency = $0006;
```

C++

```
varCurrency = 0x0006;
```

File

System

Description

When a Variant (see page 3421) is assigned a floating point value with less than 5 decimal places, it is set to the varCurrency type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.49 System.varDate Constant

Represents a Variant (see page 3421) that holds a TDateTime (see page 3323) value.

Pascal

```
varDate = $0007;
```

C++

```
varDate = 0x0007;
```

File

System

Description

When a Variant (see page 3421) is assignned a TDateTime (see page 3323) value, it is set to the varDate type.

Use VarType to determine the variant type.

See Also

TDateTime (see page 3787)

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.50 System.varDispatch Constant

Represents a Variant (see page 3421) that has been assigned an IDispatch (see page 3494) value.

Pascal

```
varDispatch = $0009;
```

C++

```
varDispatch = 0x0009;
```

File

System

Description

When a Variant (see page 3421) is assigned an IDispatch (see page 3494) value, it is set to the varDispatch type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.51 System.varDouble Constant

Represents a Variant (see page 3421) that holds a floating point value.

Pascal

```
varDouble = $0005;
```

C++

```
varDouble = 0x0005;
```

File

System

Description

When a Variant (see page 3421) is assigned a floating point value with more than 4 decimal places, it is set to the varDouble type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.52 System.varEmpty Constant

Represents a Variant (see page 3421) that has not yet been assigned a value.

Pascal

```
varEmpty = $0000;
```

C++

```
varEmpty = 0x0000;
```

File

System

Description

When a Variant (see page 3421) is first created, it is set to the varEmpty type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarIsEmpty (see page 5080)

VarType (see page 5090)

35.7.53 System.varError Constant

Represents a Variant (see page 3421) that holds a 32 bit error code.

Pascal

```
varError = $000A;
```

C++

```
varError = 0x000A;
```

File

System

Description

When a Variant (see page 3421) is assigned a 32 bit error code, it is set to the varError type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarIsEmpty (see page 5080)

VarType (see page 5090)

35.7.54 System.varInt64 Constant

Represents a Variant (see page 3421) that holds Int64 data.

Pascal

```
varInt64 = $0014;
```

C++

```
varInt64 = 0x0014;
```

File

System

Description

When a Variant (see page 3421) is assigned an integer value greater in value than an LongWord type can hold, it will be set to a varInt64 Variant (see page 3421) type. varInt64 represents a Variant (see page 3421) variable that currently holds an Int64 data value.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.55 System.varInteger Constant

Represents a Variant (see page 3421) that holds Integer data.

Pascal

```
varInteger = $0003;
```

C++

```
varInteger = 0x0003;
```

File

System

Description

To define a Variant (see page 3421) to be a varInteger type, you should use VarAsType to create one. By default, a Variant (see page 3421) with an integer value greater than the Word type capacity, but less than the Int64 type capacity will normally be assigned a varLongWord (see page 3868) type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.56 System.varLongWord Constant

Represents a Variant (see page 3421) that holds LongWord data.

Pascal

```
varLongWord = $0013;
```

C++

```
varLongWord = 0x0013;
```

File

System

Description

When a Variant (see page 3421) is assigned an integer value greater in value than a Word type can hold, but less than an Int64 type can hold, it will be set to a varLongWord Variant (see page 3421) type. varLongWord represents a Variant (see page 3421) variable that currently holds a LongWord data value.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.57 System.varNull Constant

Represents a Variant (see page 3421) that holds a null value.

Pascal

```
varNull = $0001;
```

C++

```
varNull = 0x0001;
```

File

System

Description

When a Variant (see page 3421) is assigned a null value, it is set to the varNull type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarIsNull (see page 5083)

VarType (see page 5090)

35.7.58 System.varOleStr Constant

Represents a Variant (see page 3421) that has been assigned a COM interface type string value.

Pascal

```
varOleStr = $0008;
```

C++

```
varOleStr = 0x0008;
```

File

System

Description

When a Variant (see page 3421) is assigned a string value via a COM interface, it is set to the varOleStr type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.59 System.varShortInt Constant

Represents a Variant (see page 3421) that holds ShortInt data.

Pascal

```
varShortInt = $0010;
```

C++

```
varShortInt = 0x0010;
```

File

System

Description

To define a Variant (see page 3421) to be a varShortInt type, you should use VarAsType to create one. By default, a Variant (see page 3421) with an integer value less than the Word type capacity will normally be assigned a varByte (see page 3863) type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.60 System.varSingle Constant

Represents a Variant (see page 3421) that holds byte data.

Pascal

```
varSingle = $0004;
```

C++

```
varSingle = 0x0004;
```

File

System

Description

To define a Variant (see page 3421) to be a varSingle type, you should use VarAsType to create one. By default, a Variant (see page 3421) with a floating point value with less than 4 decimal places will be assigned the varCurrency (see page 3863) type. With greater than 4 decimal places, it will be assigned by default the varDouble (see page 3865) type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.61 System.varSmallint Constant

Represents a Variant (see page 3421) that holds Smallint data.

Pascal

```
varSmallint = $0002;
```

C++

```
varSmallint = 0x0002;
```

File

System

Description

To define a Variant (see page 3421) to be a varSmallint type, you should use VarAsType to create one. By default, a Variant (see page 3421) with an integer value less than the Byte type capacity, but less than the LongWord type capacity will normally be assigned a varWord (see page 3874) type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.62 System.varStrArg Constant

Represents a Variant (see page 3421) that has holds a COM compatible string value.

Pascal

```
varStrArg = $0048;
```

C++

```
varStrArg = 0x0048;
```

File

System

Description

In order to use a Variant (see page 3421) with a COM interface, you should create a varStrArg type using VarAsType.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.63 System.varString Constant

Represents a Variant (see page 3421) that holds string data.

Pascal

```
varString = $0100;
```

C++

```
varString = 0x0100;
```

File

System

Description

When a Variant (see page 3421) is assigned a string value, it will be set to a varString Variant (see page 3421) type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.64 System.varTypeMask Constant

Defines a mask for filtering out the meta data part of a Variant (see page 3421) data type.

Pascal

```
varTypeMask = $0FFF;
```

C++

```
varTypeMask = 0x0FFF;
```

File

System

Description

The VarType routine returns a TVarType (see page 3801) value that describes the current data type used to hold the contents of a Variant (see page 3421) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The high order bits give a meta data type (varArray (see page 3861) and varByRef (see page 3862)). The low order bits determine the basic data type, such as varDouble (see page 3865), varSmallInt. Use varTypeMask to mask out the meta data so as to be able to determine the basic data type of a Variant (see page 3421).

See Also

TVarType (see page 3801)

varArray (see page 3861)

VarAsType (see page 5073)

varByRef (see page 3862)

VarType (see page 5090)

35.7.65 System.varUInt64 Constant

Pascal

```
varUInt64 = $0015;
```

C++

```
varUInt64 = 0x0015;
```

File

System

Description

This is constant System.varUInt64.

35.7.66 System.varUnknown Constant

Represents a Variant (see page 3421) that holds an unknown value.

Pascal

```
varUnknown = $000D;
```

C++

```
varUnknown = 0x000D;
```

File

System

Description

When a Variant (see page 3421) is assignned a value that is not recognised, it is set to the varUnknown type.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.67 System.varUString Constant

Pascal

```
varUString = $0102;
```

C++

```
varUString = 0x0102;
```

File

System

Description

This is constant System.varUString.

35.7.68 System.varVariant Constant

Represents a Variant (see page 3421) data type.

Pascal

```
varVariant = $000C;
```

C++

```
varVariant = 0x000C;
```

File

System

Description

varVariant is principally used when using VarArrayCreate to create an array of Variants (see page 4973). It determines that such an arrray has unspecified Variant (see page 3421) types. Use such an array when element contents may differ.

See Also

TVarType (see page 3801)

VarArrayCreate (see page 5059)

VarType (see page 5090)

35.7.69 System.varWord Constant

Represents a Variant (see page 3421) that holds Word data.

Pascal

```
varWord = $0012;
```

C++

```
varWord = 0x0012;
```

File

System

Description

When a Variant (see page 3421) is assigned an integer value greater in value than a Byte type can hold, but less than an LongWord type can hold, it will be set to a varWord Variant (see page 3421) type. varWord represents a Variant (see page 3421) variable that currently holds a Word data value.

Use VarType to determine the variant type.

See Also

TVarType (see page 3801)

VarAsType (see page 5073)

VarType (see page 5090)

35.7.70 System.vmtAddRef Constant

Pascal

```
vmtAddRef = 4 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtAddRef = 4 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtAddRef.

35.7.71 System.vmtAfterConstruction Constant

Pascal

```
vmtAfterConstruction = -28 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtAfterConstruction = -28 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtAfterConstruction.

35.7.72 System.vmtAutoTable Constant

Pascal

```
vmtAutoTable = -80;
```

C++

```
vmtAutoTable = -80;
```

File

System

Description

This is constant System.vmtAutoTable.

35.7.73 System.vmtBeforeDestruction Constant

Pascal

```
vmtBeforeDestruction = -24 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtBeforeDestruction = -24 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtBeforeDestruction.

35.7.74 System.vmtClassName Constant

Pascal

```
vmtClassName = -56;
```

C++

```
vmtClassName = -56;
```

File

System

Description

This is constant System.vmtClassName.

35.7.75 System.vmtCreateObject Constant

Pascal

```
vmtCreateObject = 12 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtCreateObject = 12 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtCreateObject.

35.7.76 System.vmtDefaultHandler Constant

Pascal

```
vmtDefaultHandler = -16 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtDefaultHandler = -16 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtDefaultHandler.

35.7.77 System.vmtDestroy Constant

Pascal

```
vmtDestroy = -4 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtDestroy = -4 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtDestroy.

35.7.78 System.vmtDispatch Constant

Pascal

```
vmtDispatch = -20 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtDispatch = -20 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtDispatch.

35.7.79 System.vmtDynamicTable Constant

Pascal

```
vmtDynamicTable = -60;
```

C++

```
vmtDynamicTable = -60;
```

File

System

Description

This is constant System.vmtDynamicTable.

35.7.80 System.vmtEquals Constant

Pascal

```
vmtEquals = -44 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtEquals = -44 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtEquals.

35.7.81 System.vmtFieldTable Constant

Pascal

```
vmtFieldTable = -68;
```

C++

```
vmtFieldTable = -68;
```

File

System

Description

This is constant System.vmtFieldTable.

35.7.82 System.vmtFreeInstance Constant

Pascal

```
vmtFreeInstance = -8 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtFreeInstance = -8 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtFreeInstance.

35.7.83 System.vmtGetHashCode Constant

Pascal

```
vmtGetHashCode = -40 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtGetHashCode = -40 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtGetHashCode.

35.7.84 System.vmtInitTable Constant

Pascal

```
vmtInitTable = -76;
```

C++

```
vmtInitTable = -76;
```

File

System

Description

This is constant System.vmtInitTable.

35.7.85 System.vmtInstanceSize Constant

Pascal

```
vmtInstanceSize = -52;
```

C++

```
vmtInstanceSize = -52;
```

File

System

Description

This is constant System.vmtInstanceSize.

35.7.86 System.vmtIntfTable Constant

Pascal

```
vmtIntfTable = -84;
```

C++

```
vmtIntfTable = -84;
```

File

System

Description

This is constant System.vmtIntfTable.

35.7.87 System.vmtMethodTable Constant

Pascal

```
vmtMethodTable = -64;
```

C++

```
vmtMethodTable = -64;
```

File

System

Description

This is constant System.vmtMethodTable.

35.7.88 System.vmtNewInstance Constant

Pascal

```
vmtNewInstance = -12 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtNewInstance = -12 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtNewInstance.

35.7.89 System.vmtParent Constant

Pascal

```
vmtParent = -48;
```

C++

```
vmtParent = -48;
```

File

System

Description

This is constant System.vmtParent.

35.7.90 System.vmtQueryInterface Constant

Pascal

```
vmtQueryInterface = 0 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtQueryInterface = 0 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtQueryInterface.

35.7.91 System.vmtRelease Constant

Pascal

```
vmtRelease = 8 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtRelease = 8 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtRelease.

35.7.92 System.vmtSafeCallException Constant

Pascal

```
vmtSafeCallException = -32 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtSafeCallException = -32 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtSafeCallException.

35.7.93 System.vmtSelfPtr Constant

Pascal

```
vmtSelfPtr = -88;
```

C++

```
vmtSelfPtr = -88;
```

File

System

Description

This is constant System.vmtSelfPtr.

35.7.94 System.vmtToString Constant

Pascal

```
vmtToString = -36 deprecated 'Use VMTOFFSET in asm code';
```

C++

```
vmtToString = -36 deprecated 'Use VMTOFFSET in asm code';
```

File

System

Description

This is constant System.vmtToString.

35.7.95 System.vmtTypeInfo Constant

Pascal

```
vmtTypeInfo = -72;
```

C++

```
vmtTypeInfo = -72;
```

File

System

Description

This is constant System.vmtTypeInfo.

35.7.96 System.vtAnsiString Constant

vtAnsiString defines an AnsiString TVarData (see page 3740) VType value.

Pascal

```
vtAnsiString = 11;
```

C++

```
vtAnsiString = 11;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.97 System.vtBoolean Constant

vtBoolean defines a Boolean TVarData (see page 3740) VType value.

Pascal

```
vtBoolean = 1;
```

C++

```
vtBoolean = 1;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.98 System.vtChar Constant

vtChar defines a Char TVarData (see page 3740) VType value.

Pascal

```
vtChar = 2;
```

C++

```
vtChar = 2;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.99 System.vtClass Constant

vtClass defines a TClass (see page 3785) TVarData (see page 3740) VType value.

Pascal

```
vtClass = 8;
```

C++

```
vtClass = 8;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.100 System.vtCurrency Constant

vtCurrency defines a Currency (see page 3235) TVarData (see page 3740) VType value.

Pascal

```
vtCurrency = 12;
```

C++

```
vtCurrency = 12;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.101 System.vtExtended Constant

vtExtended defines an Extended TVarData (see page 3740) VType value.

Pascal

```
vtExtended = 3;
```

C++

```
vtExtended = 3;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows,

this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.102 System.vtInt64 Constant

vtInt64 defines an Int64 TVarData (see page 3740) VType value.

Pascal

```
vtInt64 = 16;
```

C++

```
vtInt64 = 16;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.103 System.vtInteger Constant

vtInteger defines an Integer TVarData (see page 3740) VType value.

Pascal

```
vtInteger = 0;
```

C++

```
vtInteger = 0;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.104 System.vtInterface Constant

vtInterface defines an Interface pointer TVarData (see page 3740) VType value.

Pascal

```
vtInterface = 14;
```

C++

```
vtInterface = 14;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.105 System.vtObject Constant

vtObject defines a TObject (see page 3354) TVarData (see page 3740) VType value.

Pascal

```
vtObject = 7;
```

C++

```
vtObject = 7;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.106 System.vtPChar Constant

vtPChar defines a PChar TVarData (see page 3740) VType value.

Pascal

```
vtPChar = 6;
```

C++

```
vtPChar = 6;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.107 System.vtPointer Constant

vtPointer defines a Pointer TVarData (see page 3740) VType value.

Pascal

```
vtPointer = 5;
```

C++

```
vtPointer = 5;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.108 System.vtPWideChar Constant

vtPWideChar defines a PWideChar TVarData (see page 3740) VType value.

Pascal

```
vtPWideChar = 10;
```

C++

```
vtPWideChar = 10;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.109 System.vtString Constant

vtString defines a String TVarData (see page 3740) VType value.

Pascal

```
vtString = 4;
```

C++

```
vtString = 4;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.110 System.vtUnicodeString Constant

Pascal

```
vtUnicodeString = 17;
```

C++

```
vtUnicodeString = 17;
```

File

System

Description

This is constant System.vtUnicodeString.

35.7.111 System.vtVariant Constant

vtString (see page 3889) defines a Variant (see page 3421) TVarData (see page 3740) VType value.

Pascal

```
vtVariant = 13;
```

C++

```
vtVariant = 13;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.112 System.vtWideChar Constant

vtWideChar defines a WideChar TVarData (see page 3740) VType value.

Pascal

```
vtWideChar = 9;
```

C++

```
vtWideChar = 9;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.7.113 System.vtWideString Constant

vtWideString defines a WideString (see page 3467) TVarData (see page 3740) VType value.

Pascal

```
vtWideString = 15;
```

C++

```
vtWideString = 15;
```

File

System

Description

The TVarData (see page 3740) type represents the internal structure of a Variant (see page 3421) variable (on Windows, this is identical to the Variant (see page 3421) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 3421) it holds.

See Also

TVarData (see page 3740)

System::TVarRec (see page 3747)

35.8 Macros

The following table lists macros in this documentation.

Macros

Name	Description
USE (see page 3892)	This is macro System::USE.
USEADDITIONALFILES (see page 3892)	This is macro System::USEADDITIONALFILES.
USEASM (see page 3893)	This is macro System::USEASM.
USEDATAMODULE (see page 3893)	This is macro System::USEDATAMODULE.
USEDATAMODULENS (see page 3893)	This is macro System::USEDATAMODULENS.
USEDEF (see page 3894)	This is macro System::USEDEF.
USEFILE (see page 3894)	This is macro System::USEFILE.
USEFORM (see page 3895)	This is macro System::USEFORM.
USEFORMNS (see page 3895)	This is macro System::USEFORMNS.
USEFORMRES (see page 3895)	This is macro System::USEFORMRES.
USEIDL (see page 3896)	This is macro System::USEIDL.
USELIB (see page 3896)	This is macro System::USELIB.
USEOBJ (see page 3896)	This is macro System::USEOBJ.
USEPACKAGE (see page 3897)	This is macro System::USEPACKAGE.
USERC (see page 3897)	This is macro System::USERC.
USERES (see page 3897)	This is macro System::USERES.
USETLB (see page 3898)	This is macro System::USETLB.
USEUNIT (see page 3898)	This is macro System::USEUNIT.

35.8.1 System::USE Macro

Pascal

USE

C++

```
#define USE(FileName, ContainerId) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USE.

35.8.2 System::USEADDITIONALFILES Macro

Pascal

USEADDITIONALFILES

C++

```
#define USEADDITIONALFILES(Exts) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEADDITIONALFILES.

35.8.3 System::USEASM Macro

Pascal

USEASM

C++

```
#define USEASM(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEASM.

35.8.4 System::USEDATAMODULE Macro

Pascal

USEDATAMODULE

C++

```
#define USEDATAMODULE(FileName, DataModuleName) \
    class DELPHICLASS T##DataModuleName;       \
    extern PACKAGE T##DataModuleName *DataModuleName;
```

File

sysclass.h

Description

This is macro System::USEDATAMODULE.

35.8.5 System::USEDATAMODULENS Macro

Pascal

USEDATAMODULENS

C++

```
#define USEDATAMODULENS(FileName, UnitName, DataModuleName) \
    namespace UnitName {          \
    class DELPHICLASS T##DataModuleName;       \
    extern PACKAGE T##DataModuleName *DataModuleName;              \
    };                \
    using namespace UnitName
```

File

sysclass.h

Description

This is macro System::USEDATAMODULENS.

35.8.6 System::USEDEF Macro

Pascal

```
USEDEF
```

C++

```
#define USEDEF(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEDEF.

35.8.7 System::USEFILE Macro

Pascal

```
USEFILE
```

C++

```
#define USEFILE(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEFILE.

35.8.8 System::USEFORM Macro

Pascal

```
USEFORM
```

C++

```
#define USEFORM(FileName, FormName) \
    class DELPHICLASS T##FormName;       \
    extern PACKAGE T##FormName *FormName;
```

File

sysclass.h

Description

This is macro System::USEFORM.

35.8.9 System::USEFORMNS Macro

Pascal

```
USEFORMNS
```

C++

```
#define USEFORMNS(FileName, UnitName, FormName) \
    namespace UnitName {         \
    class DELPHICLASS T##FormName;       \
    extern PACKAGE T##FormName *FormName;          \
    };               \
    using namespace UnitName
```

File

sysclass.h

Description

This is macro System::USEFORMNS.

35.8.10 System::USEFORMRES Macro

Pascal

```
USEFORMRES
```

C++

```
#define USEFORMRES(FileName, FormName, AncestorName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEFORMRES.

35.8.11 System::USEIDL Macro

Pascal

```
USEIDL
```

C++

```
#define USEIDL(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEIDL.

35.8.12 System::USELIB Macro

Pascal

```
USELIB
```

C++

```
#define USELIB(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USELIB.

35.8.13 System::USEOBJ Macro

Pascal

```
USEOBJ
```

C++

```
#define USEOBJ(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEOBJ.

35.8.14 System::USEPACKAGE Macro

Pascal

USEPACKAGE

C++

```
#define USEPACKAGE(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEPACKAGE.

35.8.15 System::USERC Macro

Pascal

USERC

C++

```
#define USERC(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USERC.

35.8.16 System::USERES Macro

Pascal

USERES

C++

```
#define USERES(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USERES.

35.8.17 System::USETLB Macro

Pascal

```
USETLB
```

C++

```
#define USETLB(FileName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USETLB.

35.8.18 System::USEUNIT Macro

Pascal

```
USEUNIT
```

C++

```
#define USEUNIT(ModName) \
   extern PACKAGE DummyThatIsNeverReferenced
```

File

sysclass.h

Description

This is macro System::USEUNIT.

36 Sysutils Namespace

This is namespace Sysutils.

Topics

Name	Description
Functions (see page 3900)	The following table lists functions in this documentation.

Functions

	Name	Description
	IntToStr (see page 3900)	This is function Sysutils::IntToStr.
	IntToStr (see page 3900)	This is function Sysutils::IntToStr.

36.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	IntToStr (see page 3900)	This is function Sysutils::IntToStr.
	IntToStr (see page 3900)	This is function Sysutils::IntToStr.

36.1.1 Sysutils::IntToStr Function

Pascal

```
function IntToStr(Value: __int64): PACKAGE String;
```

C++

```
__fastcall PACKAGE String IntToStr(__int64 Value);
```

File

dstring.h

Description

This is function Sysutils::IntToStr.

36.1.2 Sysutils::IntToStr Function

Pascal

```
function IntToStr(Value: Integer): PACKAGE String;
```

C++

```
__fastcall PACKAGE String IntToStr(int Value);
```

File

dstring.h

Description

This is function Sysutils::IntToStr.

37 SysUtils Namespace

This is namespace SysUtils.

Topics

Name	Description
Classes (see page 3915)	The following table lists classes in this documentation.
Interfaces (see page 4037)	The following table lists interfaces in this documentation.
Functions (see page 4039)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 4320)	The following table lists structs, records, enums in this documentation.
Types (see page 4336)	The following table lists types in this documentation.
Variables (see page 4347)	The following table lists variables in this documentation.
Constants (see page 4368)	The following table lists constants in this documentation.

Classes

	Name	Description
	EAbort (see page 3916)	EAbort is the exception class for errors that should not display an error message dialog box.
	EAbstractError (see page 3916)	EAbstractError is the exception class for attempts to call an abstract method.
	EAccessViolation (see page 3917)	EAccessViolation is the exception class for invalid memory access errors.
	EArgumentException (see page 3918)	This is class SysUtils.EArgumentException.
	EArgumentOutOfRangeException (see page 3918)	This is class SysUtils.EArgumentOutOfRangeException.
	EAssertionFailed (see page 3918)	EAssertionFailed is the exception class for Delphi assertion failure.
	EControlC (see page 3919)	EControlC is the exception class for user interrupts.
	EConvertError (see page 3919)	EConvertError is the exception class for string and object conversion errors.
	EDivByZero (see page 3921)	EDivByZero is the exception class for integer divide-by-zero errors.
	EEncodingError (see page 3922)	This is class SysUtils.EEncodingError.
	EExternal (see page 3922)	EExternal is the exception class that captures external error information.
	EExternalException (see page 3925)	EExternalException is the exception class for invalid exception codes.
	EHeapException (see page 3926)	EHeapException is the exception class for errors related to heap-allocated memory.
	EInOutError (see page 3929)	EInOutError is the exception class for file input/output errors.
	EIntError (see page 3933)	EIntError is the base class for integer math error exceptions.
	EIntfCastError (see page 3934)	EIntfCastError is the exception class for interface casting errors.
	EIntOverflow (see page 3934)	EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.
	EInvalidCast (see page 3935)	EInvalidCast is an exception class for typecasting errors.
	EInvalidContainer (see page 3935)	This is class SysUtils.EInvalidContainer.

	EInvalidInsert (see page 3936)	This is class SysUtils.EInvalidInsert.
	EInvalidOp (see page 3936)	EInvalidOp is the exception class for undefined floating-point operations.
	EInvalidPointer (see page 3937)	EInvalidPointer is the exception class for invalid pointer operations.
	EMathError (see page 3937)	EMathError is the base exception class for floating-point math errors.
	EMonitor (see page 3938)	This is class SysUtils.EMonitor.
	EMonitorLockException (see page 3938)	This is class SysUtils.EMonitorLockException.
	ENoConstructException (see page 3939)	This is class SysUtils.ENoConstructException.
	ENoMonitorSupportException (see page 3939)	This is class SysUtils.ENoMonitorSupportException.
	EOSError (see page 3939)	EOSError is the exception class for operating system errors.
	EOutOfMemory (see page 3942)	EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.
	EOverflow (see page 3942)	EOverflow is the exception class for floating-point register overflows.
	EPackageError (see page 3943)	EPackageError is the exception class for package-related errors.
	EPrivilege (see page 3943)	EPrivilege is the exception class for processor privilege violations.
	EProgrammerNotFound (see page 3944)	This is class SysUtils.EProgrammerNotFound.
	EPropReadOnly (see page 3944)	EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.
	EPropWriteOnly (see page 3945)	EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.
	ERangeError (see page 3945)	ERangeError is the exception for Delphi range errors.
	ESafecallException (see page 3946)	ESafecallException is the exception for problems with the safecall calling convention.
	EStackOverflow (see page 3947)	EStackOverflow is the exception class for stack overflows.
	EUnderflow (see page 3947)	EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.
	EVariantError (see page 3948)	EVariantError is the exception class for errors involving Variant (see page 3421) data types.
	EWin32Error (see page 3949)	EWin32Error is the exception class for Windows errors.
	Exception (see page 3949)	Exception is the base class for all runtime exceptions.
	EZeroDivide (see page 3966)	EZeroDivide is the exception class for floating-point divide-by-zero errors.
	TBigEndianUnicodeEncoding (see page 3967)	This is class SysUtils.TBigEndianUnicodeEncoding.
	TEncoding (see page 3969)	TEncoding is a class that defines a specific encoding for a character or string.
	TLanguages (see page 3987)	TLanguages lists all available Windows locales.
	TMBCSEncoding (see page 3992)	This is class SysUtils.TMBCSEncoding.
	TMultiReadExclusiveWriteSynchronizer (see page 3997)	TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.
	TSimpleRWSync (see page 4002)	This is class SysUtils.TSimpleRWSync.
	TStringBuilder (see page 4006)	An editable array of characters whose contents has all the functionality of a string object.
	TThreadLocalCounter (see page 4023)	This is class SysUtils.TThreadLocalCounter.
	TUnicodeEncoding (see page 4024)	This is class SysUtils.TUnicodeEncoding.
	TUTF7Encoding (see page 4029)	This is class SysUtils.TUTF7Encoding.
	TUTF8Encoding (see page 4034)	This is class SysUtils.TUTF8Encoding.

Constants

Name	Description
DateDelta (see page 4369)	Specifies the difference between TDateTime (see page 3323) and TTimeStamp (see page 4334) starting values.
DefaultFalseBoolStr (see page 4370)	Specifies the default string representation of the boolean false value.
DefaultTrueBoolStr (see page 4370)	Specifies the default string representation of the boolean true value.
DriveDelim (see page 4371)	Specifies the character used to separate the Windows drive from the path in a file name.
faAnyFile (see page 4371)	Specifies any file type.
faArchive (see page 4372)	Specifies only Windows archived file types.
faDirectory (see page 4372)	Specifies only directory 'file' types.
faHidden (see page 4373)	Specifies only hidden file types.
faNormal (see page 4374)	This is constant SysUtils.faNormal.

faReadOnly (see page 4374)	Specifies only read only file types.
faSymLink (see page 4375)	Specifies only symbolic link file types.
faSysFile (see page 4375)	Specifies only system file types.
faTemporary (see page 4376)	This is constant SysUtils.faTemporary.
faVolumeID (see page 4376)	Specifies Volume ID file types.
fmOpenRead (see page 4377)	Specifies a file should be opened for reading only.
fmOpenReadWrite (see page 4378)	Specifies a file should be opened for reading and writing.
fmOpenWrite (see page 4378)	Specifies a file should be opened for writing only.
fmShareCompat (see page 4379)	Specifies file sharing that is FCB compatible.
fmShareDenyNone (see page 4380)	Specifies file sharing that does not prevent file access by other applications.
fmShareDenyRead (see page 4380)	Specifies file sharing that prevents read file access by other applications.
fmShareDenyWrite (see page 4381)	Specifies file sharing that prevents write file access by other applications.
fmShareExclusive (see page 4382)	Specifies file sharing that prevents any file access by other applications.
HoursPerDay (see page 4382)	Specifies the number of hours in a day.
MaxCurrency (see page 4383)	Defines the largest value supported for Currency (see page 3235) data types.
MaxDateTime (see page 4383)	Specifies the highest supported TDateTime (see page 3323) value.
MaxEraCount (see page 4384)	This is constant SysUtils.MaxEraCount.
MinCurrency (see page 4384)	Defines the largest negative value supported for Currency (see page 3235) data types.
MinDateTime (see page 4384)	Specifies the earliest supported TDateTime (see page 3323) value.
MinsPerDay (see page 4385)	Specifies the number of minutes in a day.
MinsPerHour (see page 4386)	Specifies the number of minutes in an hour.
MonthDays (see page 4386)	Defines the number of days in each month for normal and leap years.
MSecsPerDay (see page 4387)	Specifies the number of milliseconds in a day.
MSecsPerSec (see page 4387)	Specifies the number of milliseconds in a second.
PathDelim (see page 4388)	Specifies the character used to separate each directory name in a file path.
PathSep (see page 4388)	Specifies the character used to separate a sequence of file or directory names.
pfBCB4Produced (see page 4389)	Indicates that a package was produced by via C++.
pfConsumerBCB (see page 4389)	Indicates that C++ can be a consumer of a package.
pfConsumerCompat (see page 4390)	This is constant SysUtils.pfConsumerCompat.
pfConsumerDelphi (see page 4390)	Indicates that Delphi can be a consumer of a package.
pfConsumerMask (see page 4391)	Indicates the comsumer of a package.
pfDelphi4Produced (see page 4391)	Indicates that a package was produced by Delphi 4 or later.
pfDesignOnly (see page 4392)	Indicates that a package was compiled with {$DESIGNONLY ON}.
pfExeModule (see page 4392)	Indicates that a module is an executable.
pfIgnoreDupUnits (see page 4392)	Indicates that a package was compiled with {$DUPLICATEENABLE ON}.
pfLibraryModule (see page 4393)	Indicates that a module is a library.
pfModuleTypeMask (see page 4393)	Indicates that a package is a module.
pfNeverBuild (see page 4394)	Indicates that a package was compiled with the -z flag.
pfPackageModule (see page 4394)	Indicates that a module is a package.
pfProducerMask (see page 4395)	Indicates the producer of a package.
pfProducerUndefined (see page 4395)	Indicates that a package was produced by an unknown developmemt environment.
pfRunOnly (see page 4396)	Indicates that a package was compiled with {$RUNONLY ON}.
pfV3Produced (see page 4396)	Indicates that a package was produced by Delphi 3 or later.
SecsPerDay (see page 4397)	Specifies the number of seconds in a day.
SecsPerHour (see page 4397)	This is constant SysUtils.SecsPerHour.
SecsPerMin (see page 4398)	Specifies the number of seconds in a minute.
SwitchChars (see page 4398)	Specifies the prefix character(s) for program command line arguments.
ufImplicitUnit (see page 4399)	Indicates that a unit was implicitly imported into a package.
ufMainUnit (see page 4399)	Indicates that a unit is the main one in a project.
ufOrgWeakUnit (see page 4400)	This is constant SysUtils.ufOrgWeakUnit.
ufPackageUnit (see page 4400)	Indicates that a unit is a package.
ufWeakPackageUnit (see page 4400)	Indicates that a unit is a either a weak unit or a package unit.
ufWeakUnit (see page 4401)	Indicates that a unit is a weak unit.

UnixDateDelta (see page 4401)	Specifies the difference between TDateTime (see page 3323) and Lunix date/time origins.

Functions

	Name	Description
	Abort (see page 4047)	Raises a silent exception.
	AddExitProc (see page 4048)	Adds a procedure to the exit list.
	AddTerminateProc (see page 4048)	Adds a terminate procedure to the system list of termination procedures.
	AdjustLineBreaks (see page 4049)	Adjusts line break characters to reflect Windows or Linux style.
	AnsiCompareFileName (see page 4049)	Compares file names based on the current locale.
	AnsiCompareStr (see page 4050)	Compares strings based on the current locale with case sensitivity.
	AnsiCompareText (see page 4051)	Compares strings based on the current locale without case sensitivity.
	AnsiDequotedStr (see page 4051)	Converts a quoted string into an unquoted string
	AnsiExtractQuotedStr (see page 4052)	Converts a quoted string into an unquoted string.
	AnsiExtractQuotedStr (see page 4052)	Converts a quoted string into an unquoted string.
	AnsiLastChar (see page 4052)	Returns a pointer to the last character in a string.
	AnsiLastChar (see page 4052)	Returns a pointer to the last character in a string.
	AnsiLowerCase (see page 4053)	Returns a string that is a copy of the given string converted to lower case.
	AnsiLowerCaseFileName (see page 4053)	Converts a file name to lower case.
	AnsiPos (see page 4054)	Locates the position of a substring.
	AnsiQuotedStr (see page 4054)	Returns the quoted version of a string.
	AnsiSameStr (see page 4055)	Compares strings based on the current locale with case sensitivity.
	AnsiSameText (see page 4055)	Compares strings based on the current locale without case sensitivity.
	AnsiStrAlloc (see page 4056)	This is function SysUtils.AnsiStrAlloc.
	AnsiStrComp (see page 4056)	Compares null-terminated character strings.
	AnsiStrComp (see page 4056)	Compares null-terminated character strings.
	AnsiStrIComp (see page 4057)	Compares null terminated character strings case insensitively.
	AnsiStrIComp (see page 4057)	Compares null terminated character strings case insensitively.
	AnsiStrLastChar (see page 4057)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLastChar (see page 4057)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLComp (see page 4058)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLComp (see page 4058)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLIComp (see page 4058)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLIComp (see page 4058)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLower (see page 4059)	Converts all characters in a null-terminated string to lower case.
	AnsiStrLower (see page 4059)	Converts all characters in a null-terminated string to lower case.
	AnsiStrPos (see page 4060)	Returns a pointer to the first occurrence of a substring.
	AnsiStrPos (see page 4060)	Returns a pointer to the first occurrence of a substring.
	AnsiStrRScan (see page 4060)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrRScan (see page 4060)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrScan (see page 4061)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrScan (see page 4061)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrUpper (see page 4061)	Converts all characters in a null-terminated string to upper case.
	AnsiStrUpper (see page 4061)	Converts all characters in a null-terminated string to upper case.
	AnsiUpperCase (see page 4062)	Converts a string to upper case.
	AnsiUpperCaseFileName (see page 4062)	Converts a file name to upper case.
	AppendStr (see page 4063)	Appends a dynamically allocated string to an existing string.
	AssignStr (see page 4063)	Assigns a new dynamically allocated string to a specified pointer.
	Beep (see page 4063)	Emits a message beep.
	BoolToStr (see page 4066)	Converts a Boolean value to a string.
	ByteLength (see page 4068)	This is function SysUtils.ByteLength.
	BytesOf (see page 4068)	Converts a string into a byte array.
	BytesOf (see page 4068)	Converts a string into a byte array.

	BytesOf (see page 4068)	Converts a string into a byte array.
	BytesOf (see page 4068)	Converts a string into a byte array.
	ByteToCharIndex (see page 4069)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharIndex (see page 4069)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharLen (see page 4070)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteToCharLen (see page 4070)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteType (see page 4070)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	ByteType (see page 4070)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	CallTerminateProcs (see page 4071)	Calls all of the functions in the termination procedure list.
	ChangeFileExt (see page 4071)	Changes the extension of a file name.
	ChangeFilePath (see page 4073)	Changes the path of a file name.
	CharInSet (see page 4073)	CharInSet checks whether a given character is contained within a set.
	CharInSet (see page 4073)	CharInSet checks whether a given character is contained within a set.
	CharLength (see page 4074)	Returns number of bytes used by character.
	CharLength (see page 4074)	Returns number of bytes used by character.
	CharToByteIndex (see page 4075)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteIndex (see page 4075)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteLen (see page 4076)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CharToByteLen (see page 4076)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CharToElementIndex (see page 4076)	This is function SysUtils.CharToElementIndex.
	CharToElementIndex (see page 4076)	This is function SysUtils.CharToElementIndex.
	CharToElementLen (see page 4077)	This is function SysUtils.CharToElementLen.
	CharToElementLen (see page 4077)	This is function SysUtils.CharToElementLen.
	CheckWin32Version (see page 4077)	Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 3159).
	CompareMem (see page 4078)	Performs a binary comparison of two memory images.
	CompareStr (see page 4078)	Compares two strings case sensitively.
	CompareStr (see page 4078)	Compares two strings case sensitively.
	CompareText (see page 4079)	Compares two strings by ordinal value without case sensitivity.
	CompareText (see page 4079)	Compares two strings by ordinal value without case sensitivity.
	CreateDir (see page 4083)	Creates a new directory.
	CreateGUID (see page 4084)	Creates a globally unique identifier.
	CurrentYear (see page 4086)	Returns the current year.
	CurrToStr (see page 4086)	Formats a Currency (see page 3235) value as a string.
	CurrToStr (see page 4086)	Formats a Currency (see page 3235) value as a string.
	CurrToStrF (see page 4086)	Converts a Currency (see page 3235) value to a string, using a specified format.
	CurrToStrF (see page 4086)	Converts a Currency (see page 3235) value to a string, using a specified format.
	Date (see page 4087)	Returns the current date.
	DateTimeToFileDate (see page 4088)	Converts a TDateTime (see page 3323) value to an OS timestamp value.
	DateTimeToStr (see page 4089)	Converts a TDateTime (see page 3323) value to a string.
	DateTimeToStr (see page 4089)	Converts a TDateTime (see page 3323) value to a string.
	DateTimeToString (see page 4089)	Converts a TDateTime (see page 3323) value to a string using a specified Format (see page 4188).
	DateTimeToString (see page 4089)	Converts a TDateTime (see page 3323) value to a string using a specified Format (see page 4188).
	DateTimeToSystemTime (see page 4091)	Converts a TDateTime (see page 3323) value into the Win32 API's system time type.
	DateTimeToTimeStamp (see page 4092)	Converts a TDateTime (see page 3323) value into the corresponding TTimeStamp (see page 4334) value.
	DateToStr (see page 4092)	Converts a TDateTime (see page 3323) value to a string.
	DateToStr (see page 4092)	Converts a TDateTime (see page 3323) value to a string.
	DayOfWeek (see page 4094)	Returns the day of the week for a specified date.

	DecodeDate (see page 4095)	Returns Year, Month, and Day values for a TDateTime (see page 3323) value.
	DecodeDateFully (see page 4096)	Returns Year, Month, and Day, and Day-of-Week values for a TDateTime (see page 3323) value.
	DecodeTime (see page 4097)	Breaks a TDateTime (see page 3323) value into hours, minutes, seconds, and milliseconds.
	DelegatesEqual (see page 4098)	This is function SysUtils.DelegatesEqual.
	DeleteFile (see page 4098)	Deletes a file from disk.
	DirectoryExists (see page 4100)	Determines whether a specified directory exists.
	DiskFree (see page 4101)	Returns the number of free bytes on a specified drive.
	DiskSize (see page 4102)	Returns the size, in bytes, of a specified drive.
	DisposeStr (see page 4103)	Disposes of a string pointer that was allocated using NewStr (see page 4227).
	ElementToCharIndex (see page 4104)	This is function SysUtils.ElementToCharIndex.
	ElementToCharIndex (see page 4104)	This is function SysUtils.ElementToCharIndex.
	ElementToCharLen (see page 4104)	This is function SysUtils.ElementToCharLen.
	ElementToCharLen (see page 4105)	This is function SysUtils.ElementToCharLen.
	EncodeDate (see page 4105)	Returns a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.
	EncodeTime (see page 4106)	Returns a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.
	ExceptionErrorMessage (see page 4107)	Formats a standard error message.
	ExcludeTrailingBackslash (see page 4108)	Returns a path name without a trailing delimiter.
	ExcludeTrailingPathDelimiter (see page 4109)	Returns a path name without a trailing delimiter.
	ExpandFileName (see page 4109)	Returns the full path name for a relative file name.
	ExpandFileNameCase (see page 4110)	Returns the full path name for a relative file name on a case-sensitive file system.
	ExpandUNCFileName (see page 4111)	Returns the full path of a file name in UNC format, if appropriate.
	ExtractFileDir (see page 4112)	Extracts the drive and directory parts from FileName.
	ExtractFileDrive (see page 4112)	Returns the drive portion of a file name.
	ExtractFileExt (see page 4113)	Returns the extension portions of a file name.
	ExtractFileName (see page 4113)	Extracts the name and extension parts of a file name.
	ExtractFilePath (see page 4115)	Returns the drive and directory portions of a file name.
	ExtractRelativePath (see page 4117)	Returns a relative path name, relative to a specific base directory.
	ExtractShortPathName (see page 4118)	Converts a file name to the short 8.3 form.
	FileAge (see page 4119)	Returns the OS timestamp of a file.
	FileAge (see page 4119)	Returns the OS timestamp of a file.
	FileClose (see page 4121)	Closes a specified file.
	FileCreate (see page 4128)	Creates a new file.
	FileCreate (see page 4128)	Creates a new file.
	FileDateToDateTime (see page 4130)	Converts an OS timestamp value to TDateTime (see page 3323) value.
	FileExists (see page 4133)	Tests if a specified file exists.
	FileGetAttr (see page 4139)	Returns the file attributes of FileName.
	FileGetDate (see page 4142)	Returns an OS timestamp for a specified file.
	FileIsReadOnly (see page 4142)	Reports whether a file is read-only.
	FileOpen (see page 4143)	Opens a specified file using a specified access mode.
	FileRead (see page 4150)	Reads a specified number of bytes from a file.
	FileSearch (see page 4156)	Searches a specified directory path for a file.
	FileSeek (see page 4157)	Repositions read/write point.
	FileSeek (see page 4157)	Repositions read/write point.
	FileSetAttr (see page 4162)	Sets the file attributes of a specified file.
	FileSetDate (see page 4164)	Sets the OS time stamp for a specified file.
	FileSetDate (see page 4164)	Sets the OS time stamp for a specified file.
	FileSetReadOnly (see page 4165)	Sets the file permissions to read-only.
	FileWrite (see page 4166)	Writes the contents of a buffer to the current position in a file.
	FinalizePackage (see page 4172)	Finalizes the specified package (.bpl file).
	FindClose (see page 4172)	Releases memory allocated by FindFirst (see page 4175).
	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.

	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.
	FindFirst (see page 4175)	Searches for the first instance of a file name with a given set of attributes in a specified directory.
	FindNext (see page 4177)	Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 4175).
	FloatToCurr (see page 4179)	Converts a floating-point value to a System::Currency (see page 3235) value.
	FloatToDateTime (see page 4179)	Converts a floating-point value to a TDateTime (see page 3323) value.
	FloatToDecimal (see page 4180)	Converts a floating-point value to a decimal representation.
	FloatToStr (see page 4180)	Converts a floating point value to a string.
	FloatToStr (see page 4180)	Converts a floating point value to a string.
	FloatToStrF (see page 4182)	Converts a floating point value to a string, using a specified Format (see page 4188), Precision, and Digits.
	FloatToStrF (see page 4182)	Converts a floating point value to a string, using a specified Format (see page 4188), Precision, and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FmtLoadStr (see page 4185)	Returns formatted output using a resourced format string.
	FmtStr (see page 4185)	Assembles a formatted string using a format string and an array of arguments.
	FmtStr (see page 4185)	Assembles a formatted string using a format string and an array of arguments.
	ForceDirectories (see page 4186)	Creates a new directory, including the creation of parent directories as needed.
	Format (see page 4188)	Returns a formatted string assembled from a format string and an array of arguments.
	Format (see page 4188)	Returns a formatted string assembled from a format string and an array of arguments.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatCurr (see page 4194)	Formats a System::Currency (see page 3235) object.
	FormatCurr (see page 4194)	Formats a System::Currency (see page 3235) object.
	FormatDateTime (see page 4195)	Formats a TDateTime (see page 3323) value.
	FormatDateTime (see page 4195)	Formats a TDateTime (see page 3323) value.
	FormatFloat (see page 4197)	Formats a floating point value.
	FormatFloat (see page 4197)	Formats a floating point value.
	FreeAndNil (see page 4201)	Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).
	GDAL (see page 4202)	Get Delphi Access Licence.
	GetCurrentDir (see page 4202)	Returns the name of the current directory.
	GetEnvironmentVariable (see page 4204)	Retrieves an environment variable value.
	GetFileVersion (see page 4205)	Returns file version.

	GetFormatSettings (see page 4206)	Resets the date and number format parameters to initial values.
	GetLocaleChar (see page 4206)	Retrieves the first character of a localisation value.
	GetLocaleFormatSettings (see page 4206)	Populates a TFormatSettings (see page 4326) data structure.
	GetLocaleStr (see page 4207)	Retrieves a localisation value.
	GetModuleName (see page 4207)	Returns the fully qualified name for a module, given its handle.
	GetPackageDescription (see page 4208)	Returns the description resource from a package.
	GetPackageInfo (see page 4209)	Enumerates all the units and required packages for a package.
	GetTime (see page 4209)	Returns the current time.
	GUIDToString (see page 4210)	Converts a class identifier GUID to a string.
	HashName (see page 4212)	This is function SysUtils.HashName.
	IncAMonth (see page 4212)	Increments date data by one month.
	IncludeTrailingBackslash (see page 4213)	Ensures path name ends with delimiter
	IncludeTrailingPathDelimiter (see page 4213)	Ensures path name ends with delimiter.
	IncMonth (see page 4214)	Returns a date shifted by a specified number of months.
	InitializePackage (see page 4215)	Validates and initializes a given package.
	InitializePackage (see page 4215)	Validates and initializes a given package.
	IntToHex (see page 4215)	Returns the hex representation of an integer.
	IntToHex (see page 4215)	Returns the hex representation of an integer.
	IntToStr (see page 4216)	Converts an integer to a string.
	IntToStr (see page 4216)	Converts an integer to a string.
	IsAssembly (see page 4217)	Determines whether a dll is an Assembly.
	IsDelimiter (see page 4218)	Indicates whether a specified character in a string matches one of a set of delimiters.
	IsEqualGUID (see page 4218)	Indicates whether two TGUID (see page 3718) values are the same.
	IsLeadChar (see page 4220)	This is function SysUtils.IsLeadChar.
	IsLeadChar (see page 4220)	This is function SysUtils.IsLeadChar.
	IsLeapYear (see page 4220)	Indicates whether a specified year is a leap year.
	IsPathDelimiter (see page 4222)	Indicates whether the byte at a specified position in a string is the path delimiter.
	IsValidIdent (see page 4222)	Determines whether a string conforms to Delphi identifier rules.
	Languages (see page 4223)	Lists the locales for which support is available.
	LastDelimiter (see page 4223)	Returns the byte index of the last character that matches any character in a specified set of delimiters.
	LoadPackage (see page 4224)	Loads a specified package.
	LoadPackage (see page 4224)	Loads a specified package.
	LoadStr (see page 4224)	Loads a string resource from the application's executable file.
	LowerCase (see page 4225)	Converts an ASCII string to lowercase.
	LowerCase (see page 4225)	Converts an ASCII string to lowercase.
	MSecsToTimeStamp (see page 4226)	Converts a specified number of milliseconds into a TTimeStamp (see page 4334) value.
	NewStr (see page 4227)	Allocates a string on the heap.
	NextCharIndex (see page 4227)	Returns the byte index of the next character.
	NextCharIndex (see page 4227)	Returns the byte index of the next character.
	Now (see page 4227)	Returns the current date and time.
	OutOfMemoryError (see page 4228)	Raises an EOutOfMemory (see page 3942) exception.
	PlatformBytesOf (see page 4229)	This is function SysUtils.PlatformBytesOf.
	PlatformStringOf (see page 4229)	This is function SysUtils.PlatformStringOf.
	QuotedStr (see page 4229)	Returns the quoted version of a string.
	RaiseLastOSError (see page 4230)	Raises an exception for the last occurring OS or system library error.
	RaiseLastOSError (see page 4230)	Raises an exception for the last occurring OS or system library error.
	RaiseLastWin32Error (see page 4231)	Raises an exception for the last occurring Win32 error.
	RCS (see page 4232)	Check for Delphi Client/Server Licence.
	RemoveDir (see page 4232)	Deletes an existing empty directory.
	RenameFile (see page 4233)	Changes a file name.
	ReplaceDate (see page 4236)	Replaces the date portion of a TDateTime (see page 3323) value with a specified date.

	ReplaceTime (see page 4236)	Replaces the time portion of a TDateTime (see page 3323) value with a specified time.
	RPR (see page 4237)	Check for Delphi Professional Licence.
	SafeLoadLibrary (see page 4238)	Safe and simple library loading.
	SameFileName (see page 4238)	Compares file names based on the current locale.
	SameStr (see page 4239)	Compares two strings by ordinal value with case sensitivity.
	SameStr (see page 4239)	Compares two strings by ordinal value with case sensitivity.
	SameText (see page 4239)	Compares two strings by ordinal value without case sensitivity.
	SameText (see page 4239)	Compares two strings by ordinal value without case sensitivity.
	SetCurrentDir (see page 4240)	Sets the current directory.
	ShowException (see page 4240)	Displays an exception message with its physical address
	Sleep (see page 4241)	Delay program execution for a specified number of milliseconds.
	StrAlloc (see page 4241)	Allocates a buffer for a null-terminated string and returns a pointer to its first character.
	StrBufSize (see page 4242)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 4241).
	StrBufSize (see page 4242)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 4241).
	StrByteType (see page 4242)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrByteType (see page 4242)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrCat (see page 4243)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCat (see page 4243)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCharLength (see page 4244)	Returns the length, in bytes, of a character.
	StrCharLength (see page 4244)	Returns the length, in bytes, of a character.
	StrComp (see page 4244)	Compares two strings with case sensitivity.
	StrComp (see page 4244)	Compares two strings with case sensitivity.
	StrCopy (see page 4246)	Copies a null-terminated string.
	StrCopy (see page 4246)	Copies a null-terminated string.
	StrDispose (see page 4247)	Disposes of a string.
	StrDispose (see page 4247)	Disposes of a string.
	StrECopy (see page 4248)	Copies null-terminated string.
	StrECopy (see page 4248)	Copies null-terminated string.
	StrEnd (see page 4249)	Returns a pointer to the end of a null terminated string.
	StrEnd (see page 4249)	Returns a pointer to the end of a null terminated string.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrIComp (see page 4251)	Compares two strings without case sensitivity.
	StrIComp (see page 4251)	Compares two strings without case sensitivity.
	StringOf (see page 4253)	This is function SysUtils.StringOf.
	StringReplace (see page 4253)	Replaces occurrences of a substring within a string.
	StringToGUID (see page 4254)	Converts a string to a GUID.
	StrLCat (see page 4255)	Appends up to a specified maximum number of characters to string.
	StrLCat (see page 4255)	Appends up to a specified maximum number of characters to string.
	StrLComp (see page 4257)	Compares up to a specified maximum number of characters in two strings.
	StrLComp (see page 4257)	Compares up to a specified maximum number of characters in two strings.
	StrLCopy (see page 4258)	Copies up to a specified maximum number of characters from Source to Dest.
	StrLCopy (see page 4258)	Copies up to a specified maximum number of characters from Source to Dest.
	StrLen (see page 4260)	Returns number of characters in a string excluding the null terminator.
	StrLen (see page 4260)	Returns number of characters in a string excluding the null terminator.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.

	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLIComp (see page 4262)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLIComp (see page 4262)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLower (see page 4264)	Converts a string to lowercase.
	StrLower (see page 4264)	Converts a string to lowercase.
	StrMove (see page 4265)	Copies specified number of characters to string.
	StrMove (see page 4265)	Copies specified number of characters to string.
	StrNew (see page 4266)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNew (see page 4266)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNextChar (see page 4268)	Returns pointer to following character.
	StrNextChar (see page 4268)	Returns pointer to following character.
	StrPas (see page 4268)	Converts null-terminated string to an AnsiString (long string).
	StrPas (see page 4269)	Converts null-terminated string to an AnsiString (long string).
	StrPCopy (see page 4271)	Copies an AnsiString (long string) to a null-terminated string.
	StrPCopy (see page 4271)	Copies an AnsiString (long string) to a null-terminated string.
	StrPLCopy (see page 4272)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPLCopy (see page 4272)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPos (see page 4272)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrPos (see page 4273)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrRScan (see page 4274)	Returns a pointer to the last occurrence of a specified character in a string.
	StrRScan (see page 4274)	Returns a pointer to the last occurrence of a specified character in a string.
	StrScan (see page 4275)	Returns a pointer to first occurrence of a specified character in a string.
	StrScan (see page 4275)	Returns a pointer to first occurrence of a specified character in a string.
	StrToBool (see page 4276)	Converts a string to a Boolean value.
	StrToBoolDef (see page 4277)	Converts a string to a Boolean value, with error default.
	StrToCurr (see page 4278)	Converts a string to a System::Currency (see page 3235) value.
	StrToCurr (see page 4278)	Converts a string to a System::Currency (see page 3235) value.
	StrToCurrDef (see page 4278)	Converts a string to a System::Currency (see page 3235) value, with error default.
	StrToCurrDef (see page 4278)	Converts a string to a System::Currency (see page 3235) value, with error default.
	StrToDate (see page 4279)	Converts a string to a TDateTime (see page 3323) value.
	StrToDate (see page 4279)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateDef (see page 4280)	Converts a string to a TDateTime (see page 3323) value, with error default.
	StrToDateDef (see page 4280)	Converts a string to a TDateTime (see page 3323) value, with error default.
	StrToDateTime (see page 4281)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateTime (see page 4281)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateTimeDef (see page 4282)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToDateTimeDef (see page 4282)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToFloat (see page 4282)	Converts a given string to a floating-point value.
	StrToFloat (see page 4282)	Converts a given string to a floating-point value.
	StrToFloatDef (see page 4286)	Converts a given string to a floating-point value with error default.
	StrToFloatDef (see page 4286)	Converts a given string to a floating-point value with error default.
	StrToInt (see page 4286)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64 (see page 4287)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64Def (see page 4288)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToIntDef (see page 4288)	Converts a string that represents an integer (decimal or hex notation) to a number with error default.
	StrToTime (see page 4291)	Converts a string to a TDateTime (see page 3323) value.
	StrToTime (see page 4291)	Converts a string to a TDateTime (see page 3323) value.

	StrToTimeDef (see page 4292)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToTimeDef (see page 4292)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrUpper (see page 4292)	Returns a string in upper case.
	StrUpper (see page 4292)	Returns a string in upper case.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	SysErrorMessage (see page 4294)	Converts OS error codes into strings.
	SystemTimeToDateTime (see page 4295)	Converts a system time value into a TDateTime (see page 3323) value.
	TextPos (see page 4296)	This is function SysUtils.TextPos.
	TextPos (see page 4296)	This is function SysUtils.TextPos.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	Time (see page 4297)	Returns the current time.
	TimeStampToDateTime (see page 4298)	Converts a TTimeStamp (see page 4334) value into the corresponding TDateTime (see page 3323) value.
	TimeStampToMSecs (see page 4299)	Converts a TTimeStamp (see page 4334) value into an absolute number of milliseconds.
	TimeToStr (see page 4299)	Returns a string that represents a TDateTime (see page 3323) value.
	TimeToStr (see page 4299)	Returns a string that represents a TDateTime (see page 3323) value.
	Trim (see page 4301)	Trims leading and trailing spaces and control characters from a string.
	TrimLeft (see page 4301)	Trims leading spaces and control characters from a string.
	TrimRight (see page 4302)	Trims trailing spaces and control characters from a string.
	TryEncodeDate (see page 4302)	Creates a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.
	TryEncodeTime (see page 4303)	Creates a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.
	TryFloatToCurr (see page 4304)	Converts a floating-point value to a System::Currency (see page 3235) value.
	TryFloatToDateTime (see page 4304)	Converts a floating-point value to a TDateTime (see page 3323) value.
	TryStrToBool (see page 4305)	Converts a string to a Boolean value, with a Boolean success code.
	TryStrToCurr (see page 4305)	Converts a string to a System::Currency (see page 3235) value, with a Boolean success code.
	TryStrToCurr (see page 4305)	Converts a string to a System::Currency (see page 3235) value, with a Boolean success code.
	TryStrToDate (see page 4306)	Converts a string to a TDateTime (see page 3323) value, with a Boolean success code.
	TryStrToDate (see page 4306)	Converts a string to a TDateTime (see page 3323) value, with a Boolean success code.
	TryStrToDateTime (see page 4307)	Converts a string to a TDateTime (see page 3323) value with a Boolean success code.
	TryStrToDateTime (see page 4307)	Converts a string to a TDateTime (see page 3323) value with a Boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToInt (see page 4308)	Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.
	TryStrToInt64 (see page 4309)	Converts a string that represents an integer (decimal or hex notation) to a number.
	TryStrToTime (see page 4309)	Converts a string to a TDateTime (see page 3323) value with an error default.
	TryStrToTime (see page 4309)	Converts a string to a TDateTime (see page 3323) value with an error default.

	UIntToStr (see page 4310)	This is function SysUtils.UIntToStr.
	UIntToStr (see page 4310)	This is function SysUtils.UIntToStr.
	UnloadPackage (see page 4310)	Unloads a package.
	UpperCase (see page 4311)	Returns a copy of a string in uppercase.
	UpperCase (see page 4311)	Returns a copy of a string in uppercase.
	WideBytesOf (see page 4312)	Converts an Unicode string to an array of bytes.
	WideCompareStr (see page 4313)	Compares Unicode strings based on the current locale with case sensitivity.
	WideCompareText (see page 4313)	Compares Unicode strings based on the current locale without case sensitivity.
	WideFmtStr (see page 4314)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFmtStr (see page 4314)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFormat (see page 4314)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormat (see page 4314)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormatBuf (see page 4315)	Formats the arguments from an array, placing the result in a buffer.
	WideFormatBuf (see page 4315)	Formats the arguments from an array, placing the result in a buffer.
	WideLowerCase (see page 4316)	Returns Unicode string converted to lower case.
	WideSameStr (see page 4316)	Compares Unicode strings based on the current locale with case sensitivity.
	WideSameText (see page 4316)	Compares Unicode strings based on the current locale without case sensitivity.
	WideStrAlloc (see page 4317)	This is function SysUtils.WideStrAlloc.
	WideStringOf (see page 4317)	This is function SysUtils.WideStringOf.
	WideUpperCase (see page 4318)	Returns Unicode string converted to upper case.
	Win32Check (see page 4318)	Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.
	WrapText (see page 4318)	Splits a string into multiple lines as its length approaches a specified size.
	WrapText (see page 4318)	Splits a string into multiple lines as its length approaches a specified size.

Interfaces

	Name	Description
	IReadWriteSync (see page 4037)	This is class SysUtils.IReadWriteSync.

Structs, Records, Enums

	Name	Description
	Int64Rec (see page 4320)	Int64Rec declares a utility record to provide access to the bytes of an Int64 value.
	LongRec (see page 4321)	LongRec declares a utility record to provide access to the bytes of a LongWord value.
	TCharSearch (see page 4321)	This is record SysUtils.TCharSearch.
	TExceptionRecord (see page 4322)	TExceptionRecord holds information about an exception in an application.
	TFilenameCaseMatch (see page 4323)	TFilenameCaseMatch indicates how close a match was found to a specified file name.
	TFloatFormat (see page 4323)	TFloatFormat is an enumerated list of formatting codes for float functions.
	TFloatRec (see page 4325)	TFloatRec declares a utility record that provides access to the attributes of a floating point number.
	TFloatValue (see page 4325)	TFloatValue is an enumeration of two basic floating point types.
	TFormatSettings (see page 4326)	TFormatSettings defines a thread-safe string formatting context.
	TLangRec (see page 4327)	TLangRec declares a record used to describe a Windows locale.
	TLocaleOptions (see page 4328)	TLocaleOptions defines a choice of dependent and independent locale options.
	TMbcsByteType (see page 4329)	TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).
	TNameType (see page 4329)	This is record SysUtils.TNameType.
	TSearchRec (see page 4330)	TSearchRec defines file information searched for by FindFirst (see page 4175) or FindNext (see page 4177).
	TSysLocale (see page 4333)	TSysLocale represents locale information.
	TThreadInfo (see page 4334)	This is record SysUtils.TThreadInfo.
	TTimeStamp (see page 4334)	TTimeStamp represents time and date values.

	WordRec (see page 4335)	WordRec declares a utility record to store high and low order bytes of a variable.

Types

Name	Description
ExceptClass (see page 4336)	ExceptClass declares an Exception (see page 3949) class.
PByteArray (see page 4337)	PByteArray declares a pointer to an array of Bytes.
PDayTable (see page 4337)	PDayTable is a pointer to a TDayTable (see page 4340) type.
PExceptionRecord (see page 4338)	PExceptionRecord is a pointer to a TExceptionRecord (see page 4322) type.
PThreadInfo (see page 4338)	This is type SysUtils.PThreadInfo.
PWordArray (see page 4338)	PWordArray is a pointer to a TWordArray (see page 4345) type.
TByteArray (see page 4339)	TByteArray declares an array of Bytes.
TBytes (see page 4339)	TBytes declares an array of Bytes.
TCharArray (see page 4340)	This is type SysUtils.TCharArray.
TDayTable (see page 4340)	TDayTable is used to hold the number of days of each month of a year.
TFileName (see page 4340)	TFileName is a string that represents a file name.
TFunc (see page 4341)	This is type SysUtils.TFunc.
TIntegerSet (see page 4341)	TIntegerSet is used to treat an integer as a set of bits.
TMREWSync (see page 4341)	TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 3997).
TPackageInfoProc (see page 4342)	TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 4209).
TPredicate (see page 4342)	This is type SysUtils.TPredicate.
TProc (see page 4343)	This is type SysUtils.TProc.
TProcedure (see page 4343)	TProcedure declares a procedure.
TReplaceFlags (see page 4343)	TReplaceFlags indicates how to perform a search-and-replace operation
TSysCharSet (see page 4344)	TSysCharSet is a set or characters.
TTerminateProc (see page 4344)	TTerminateProc is a call-back function invoked by CallTerminateProcs (see page 4071).
TValidatePackageProc (see page 4345)	TValidatePackageProc is a call-back function invoked by LoadPackage (see page 4224).
TWordArray (see page 4345)	TWordArray declares an array of Words.

Variables

Name	Description
CurrencyDecimals (see page 4348)	CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.
CurrencyFormat (see page 4348)	CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 \| 1 = 1$ | 2 = $ 1 | 3 = 1 $
CurrencyString (see page 4349)	CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.
DateSeparator (see page 4349)	DateSeparator is the character used to separate the year, month, and day parts of a date value.
DecimalSeparator (see page 4350)	DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.
EmptyAnsiStr (see page 4351)	This is variable SysUtils.EmptyAnsiStr.
EmptyStr (see page 4351)	An empty string constant.
EmptyWideStr (see page 4351)	An empty string version of the WideString (see page 3467) constant.
EraNames (see page 4352)	Defines the names of calendar eras for East Asian locales.
EraYearOffsets (see page 4352)	Controls the DateTimeToStr (see page 4089) function (for East Asian locales).
FalseBoolStrs (see page 4352)	Lists strings that can represent the boolean value false.
GetDiskFreeSpaceEx (see page 4353)	This is variable SysUtils.GetDiskFreeSpaceEx.
HexDisplayPrefix (see page 4353)	HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.
LeadBytes (see page 4354)	Lists all values that can be the first byte of a double byte character on the local system.
ListSeparator (see page 4354)	The character used to separate items in a list.

LongDateFormat (see page 4354)	LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.
LongDayNames (see page 4355)	LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a long day name to be substituted.
LongMonthNames (see page 4355)	LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a long month name to be substituted.
LongTimeFormat (see page 4356)	LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.
NegCurrFormat (see page 4356)	NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.
NullAnsiStr (see page 4357)	This is variable SysUtils.NullAnsiStr.
NullStr (see page 4357)	A pointer to an empty string.
NullWideStr (see page 4358)	A pointer to an empty wide string.
ShortDateFormat (see page 4358)	ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.
ShortDayNames (see page 4359)	ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a short day name to be substituted.
ShortMonthNames (see page 4359)	ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a short month name to be substituted.
ShortTimeFormat (see page 4360)	ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.
SysLocale (see page 4360)	SysLocale holds locale information.
ThousandSeparator (see page 4362)	ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.
TimeAMString (see page 4362)	TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.
TimePMString (see page 4362)	TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.
TimeSeparator (see page 4363)	TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.
TrueBoolStrs (see page 4363)	Lists strings that can represent the boolean value false.
TwoDigitYearCenturyWindow (see page 4364)	Determines what century is added to two-digit years when string dates are converted to numeric dates.
Win32BuildNumber (see page 4364)	Specifies which the build level of the Windows Operating System (see page 3159) operating.
Win32CSDVersion (see page 4365)	Specifies the Win32 latest installed service pack.
Win32MajorVersion (see page 4365)	Specifies which major Windows Operating System (see page 3159) version is operating.
Win32MinorVersion (see page 4366)	Specifies which minor Windows Operating System (see page 3159) version is operating.
Win32Platform (see page 4366)	Specifies the Windows Operating System (see page 3159) platform identifier.

37.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EAbort (see page 3916)	EAbort is the exception class for errors that should not display an error message dialog box.
	EAbstractError (see page 3916)	EAbstractError is the exception class for attempts to call an abstract method.
	EAccessViolation (see page 3917)	EAccessViolation is the exception class for invalid memory access errors.
	EArgumentException (see page 3918)	This is class SysUtils.EArgumentException.
	EArgumentOutOfRangeException (see page 3918)	This is class SysUtils.EArgumentOutOfRangeException.
	EAssertionFailed (see page 3918)	EAssertionFailed is the exception class for Delphi assertion failure.
	EControlC (see page 3919)	EControlC is the exception class for user interrupts.
	EConvertError (see page 3919)	EConvertError is the exception class for string and object conversion errors.
	EDivByZero (see page 3921)	EDivByZero is the exception class for integer divide-by-zero errors.
	EEncodingError (see page 3922)	This is class SysUtils.EEncodingError.
	EExternal (see page 3922)	EExternal is the exception class that captures external error information.
	EExternalException (see page 3925)	EExternalException is the exception class for invalid exception codes.
	EHeapException (see page 3926)	EHeapException is the exception class for errors related to heap-allocated memory.
	EInOutError (see page 3929)	EInOutError is the exception class for file input/output errors.
	EIntError (see page 3933)	EIntError is the base class for integer math error exceptions.
	EIntfCastError (see page 3934)	EIntfCastError is the exception class for interface casting errors.
	EIntOverflow (see page 3934)	EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.
	EInvalidCast (see page 3935)	EInvalidCast is an exception class for typecasting errors.
	EInvalidContainer (see page 3935)	This is class SysUtils.EInvalidContainer.
	EInvalidInsert (see page 3936)	This is class SysUtils.EInvalidInsert.
	EInvalidOp (see page 3936)	EInvalidOp is the exception class for undefined floating-point operations.
	EInvalidPointer (see page 3937)	EInvalidPointer is the exception class for invalid pointer operations.
	EMathError (see page 3937)	EMathError is the base exception class for floating-point math errors.
	EMonitor (see page 3938)	This is class SysUtils.EMonitor.
	EMonitorLockException (see page 3938)	This is class SysUtils.EMonitorLockException.
	ENoConstructException (see page 3939)	This is class SysUtils.ENoConstructException.
	ENoMonitorSupportException (see page 3939)	This is class SysUtils.ENoMonitorSupportException.
	EOSError (see page 3939)	EOSError is the exception class for operating system errors.
	EOutOfMemory (see page 3942)	EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.
	EOverflow (see page 3942)	EOverflow is the exception class for floating-point register overflows.
	EPackageError (see page 3943)	EPackageError is the exception class for package-related errors.
	EPrivilege (see page 3943)	EPrivilege is the exception class for processor privilege violations.
	EProgrammerNotFound (see page 3944)	This is class SysUtils.EProgrammerNotFound.
	EPropReadOnly (see page 3944)	EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.
	EPropWriteOnly (see page 3945)	EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.
	ERangeError (see page 3945)	ERangeError is the exception for Delphi range errors.
	ESafecallException (see page 3946)	ESafecallException is the exception for problems with the safecall calling convention.
	EStackOverflow (see page 3947)	EStackOverflow is the exception class for stack overflows.
	EUnderflow (see page 3947)	EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.

	EVariantError (see page 3948)	EVariantError is the exception class for errors involving Variant (see page 3421) data types.
	EWin32Error (see page 3949)	EWin32Error is the exception class for Windows errors.
	Exception (see page 3949)	Exception is the base class for all runtime exceptions.
	EZeroDivide (see page 3966)	EZeroDivide is the exception class for floating-point divide-by-zero errors.
	TBigEndianUnicodeEncoding (see page 3967)	This is class SysUtils.TBigEndianUnicodeEncoding.
	TEncoding (see page 3969)	TEncoding is a class that defines a specific encoding for a character or string.
	TLanguages (see page 3987)	TLanguages lists all available Windows locales.
	TMBCSEncoding (see page 3992)	This is class SysUtils.TMBCSEncoding.
	TMultiReadExclusiveWriteSynchronizer (see page 3997)	TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.
	TSimpleRWSync (see page 4002)	This is class SysUtils.TSimpleRWSync.
	TStringBuilder (see page 4006)	An editable array of characters whose contents has all the functionality of a string object.
	TThreadLocalCounter (see page 4023)	This is class SysUtils.TThreadLocalCounter.
	TUnicodeEncoding (see page 4024)	This is class SysUtils.TUnicodeEncoding.
	TUTF7Encoding (see page 4029)	This is class SysUtils.TUTF7Encoding.
	TUTF8Encoding (see page 4034)	This is class SysUtils.TUTF8Encoding.

37.1.1 EAbort Class

EAbort is the exception class for errors that should not display an error message dialog box.

Class Hierarchy

Pascal

```
EAbort = class(Exception);
```

C++

```
class EAbort : public Exception;
```

File

SysUtils

Description

Use EAbort to raise an exception without displaying an error message in a dialog box. If applications do not trap such "silent" exceptions, the EAbort exception is passed to the HandleException method of the Application object.

The Abort (see page 4047) procedure provides a simple, standard way to raise EAbort.

See Also

Abort (see page 4047)

TApplication

Application

37.1.2 EAbstractError Class

EAbstractError is the exception class for attempts to call an abstract method.

Class Hierarchy

Pascal

```
EAbstractError = class(Exception);
```

C++

```
class EAbstractError : public Exception;
```

File

SysUtils

Description

EAbstractError is raised when an application tries to call a Delphi abstract method. It is also raised at design time when a component with Delphi abstract method is placed on a form.

Delphi abstract methods are declared with the abstract directive and must be overridden in descendant classes before an instance object can be created.

C++ code can catch this error, but never throws it.

37.1.3 EAccessViolation Class

EAccessViolation is the exception class for invalid memory access errors.

Class Hierarchy

Pascal

```
EAccessViolation = class(EExternal);
```

C++

```
class EAccessViolation : public EExternal;
```

File

SysUtils

Description

EAccessViolation is raised when an application

Dereferences a nil (Delphi) or NULL (C++) pointer.

Writes to memory reserved for executable code.

Attempts to access a memory address for which there is no virtual memory allocated to the application.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Applications should not raise EAccessViolation directly, but should instead rely on the runtime to raise this exception.

See Also

EExternal (see page 3922)

EOutOfMemory (see page 3942)

EOutOfResources

37.1.4 EArgumentException Class

Class Hierarchy

Pascal

```
EArgumentException = class(Exception);
```

C++

```
class EArgumentException : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EArgumentException.

37.1.5 EArgumentOutOfRangeException Class

Class Hierarchy

Pascal

```
EArgumentOutOfRangeException = class(EArgumentException);
```

C++

```
class EArgumentOutOfRangeException : public EArgumentException;
```

File

SysUtils

Description

This is class SysUtils.EArgumentOutOfRangeException.

37.1.6 EAssertionFailed Class

EAssertionFailed is the exception class for Delphi assertion failure.

Class Hierarchy

Pascal

```
EAssertionFailed = class(Exception);
```

C++

```
class EAssertionFailed : public Exception;
```

File

SysUtils

Description

EAssertionFailed is raised when an assertion fails in Delphi code.

Note: To raise this exception, use the Assert (see page 3522) procedure. The exception is raised only in code compiled with the $ASSERTIONS ON directive.

See Also

Assert (see page 3522)

37.1.7 EControlC Class

EControlC is the exception class for user interrupts.

Class Hierarchy

Pascal

```
EControlC = class(EExternal);
```

C++

```
class EControlC : public EExternal;
```

File

SysUtils

Description

EControlC is raised when the application is interrupted by the user.

Note: On Windows, a user interrupt can only occur in console applications, when the user presses Ctrl+C.

Note: On Linux, EControlC is raised when the program receives a TERM (15) signal. The TERM signal can be generated by the user typing the interrupt character (normally Ctrl+C) or by another program using the signal system call.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EExternal (see page 3922)

37.1.8 EConvertError Class

EConvertError is the exception class for string and object conversion errors.

Class Hierarchy

Pascal

```
EConvertError = class(Exception);
```

C++

```
class EConvertError : public Exception;
```

File

SysUtils

Description

EConvertError is raised when

An application makes an unsuccessful attempt to convert an integer, float, date, or time to a string, or to convert a string to one of these other types.

An application passes an invalid argument to a formatting routine.

An application attempts to assign one type of component derived from TPersistent to another component derived from TPersistent when such an assignment is not possible. For example, EConvertError is raised by the attempted assignment of a TButton control to a TEdit control.

In the examples below, an EConvertError exception is raised on the attempt to convert a String to a TDateTime (see page 3323) and the date in the String is invalid. The type of exception and the error message are displayed.

//Delphi example

```
const
  LF = #10;
var
  TempDate: TDateTime;
begin
try
    TempDate := StrToDateTime('99/99/1998');
except
on E: EConvertError do
      ShowMessage(E.ClassName + LF + E.Message);
```

end;

//C++ example

```
  TDateTime TempDate;
try
  {
    TempDate = StrToDateTime("99/99/1998");
  }
catch (EConvertError &E)
  {
    ShowMessage(AnsiString(E.ClassName()) + "\n" + AnsiString(E.Message));
  }
```

37.1.9 EDivByZero Class

EDivByZero is the exception class for integer divide-by-zero errors.

Class Hierarchy

Pascal

```
EDivByZero = class(EIntError);
```

C++

```
class EDivByZero : public EIntError;
```

File

SysUtils

Description

EDivByZero is raised when an application tries to divide an integer by zero.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Floating-point divide-by-zero errors raise the EZeroDivide (see page 3966) exception.

See Also

EExternal (see page 3922)

EIntOverflow (see page 3934)

ERangeError (see page 3945)

EZeroDivide (see page 3966)

37.1.10 EEncodingError Class

Class Hierarchy

Pascal

```
EEncodingError = class(Exception);
```

C++

```
class EEncodingError : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EEncodingError.

37.1.11 EExternal Class

EExternal is the exception class that captures external error information.

Class Hierarchy

Pascal

```
EExternal = class(Exception);
```

C++

```
class EExternal : public Exception;
```

File

SysUtils

Description

EExternal is the ancestor of all exception classes that represent external run time errors.

Note: Under Windows, EExternal classes represent Win32 exception codes. The ExceptionRecord (see page 3925) member points to a Win32 exception record:

//Delphi syntax

```
type
PExceptionRecord = ^TExceptionRecord;
TExceptionRecord = record
  ExceptionCode: Cardinal;
  ExceptionFlags: Cardinal;
  ExceptionRecord: PExceptionRecord;
  ExceptionAddress: Pointer;
  NumberParameters: Cardinal;
  ExceptionInformation: array[0..14] of Cardinal;
end;
```

ExceptionRecord (see page 3925): PExceptionRecord (see page 4338);

//C++ syntax

```
struct TExceptionRecord;
typedef TExceptionRecord *PExceptionRecord;
struct TExceptionRecord
{
unsigned ExceptionCode;
unsigned ExceptionFlags;
  TExceptionRecord *ExceptionRecord;
void *ExceptionAddress;
unsigned NumberParameters;
unsigned ExceptionInformation[15];
} ;
```

Note: Under Linux, EExternal classes represent various runtime errors. EExternal has three fields with exception information:

ExceptionAddress, which contains the address of the instruction that caused the error;

AccessAddress, the address that was being accessed when the error occurred;

SignalNumber, for exceptions raised by Linux signals.

See Also

EAccessViolation (see page 3917)

EIntError (see page 3933)

EMathError (see page 3937)

EPrivilege (see page 3943)

EStackOverflow (see page 3947)

37.1.11.1 EExternal Members

The following tables list the members exposed by EExternal.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	ExceptionRecord (see page 3925)	ExceptionRecord stores the external error information.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.

	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3380)	Returns a string containing the class name.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.11.2 EExternal Fields

The fields of the EExternal class are listed here.

Public Fields

	Name	Description
	ExceptionRecord (see page 3925)	ExceptionRecord stores the external error information.

37.1.11.2.1 EExternal.ExceptionRecord Field

ExceptionRecord stores the external error information.

Pascal

```
ExceptionRecord: PExceptionRecord platform;
```

C++

```
PExceptionRecord platform ExceptionRecord;
```

Description

ExceptionRecord is a member of Exception (see page 3949), containing information associated with the error that is being thrown.

External exceptions are thrown when the application uses external tools (such as databases, 3rd party libraries, GDI API functions). When an exception needs to be thrown, the 3rd party populates the record with the error information.

See Also

Exception (see page 3949)

TExceptionRecord (see page 4322)

37.1.12 EExternalException Class

EExternalException is the exception class for invalid exception codes.

Class Hierarchy

Pascal

```
EExternalException = class(EExternal);
```

C++

```
class EExternalException : public EExternal;
```

File

SysUtils

Description

EExternalException is raised when the run time library detects an unrecognized exception code. The run time library recognizes the following exception codes:

STATUS_INTEGER_DIVIDE_BY_ZERO

STATUS_ARRAY_BOUNDS_EXCEEDED

STATUS_FLOAT_OVERFLOW

STATUS_FLOAT_INEXACT_RESULT

STATUS_FLOAT_INVALID_OPERATION

STATUS_FLOAT_STACK_CHECK

STATUS_FLOAT_DIVIDE_BY_ZERO

STATUS_INTEGER_OVERFLOW

STATUS_FLOAT_UNDERFLOW

STATUS_FLOAT_DENORMAL_OPERAND

STATUS_ACCESS_VIOLATION

STATUS_PRIVILEGED_INSTRUCTION

STATUS_CONTROL_C_EXIT

STATUS_STACK_OVERFLOW

Any exception code that is not on the list above raises an EExternalException.

Note: As a descendant of EExternal (see page 3922), EExternalException saves the exception record in its ExceptionRecord (see page 3925) data structure. An exception record is only generated under Windows.

See Also

EExternal (see page 3922)

37.1.13 EHeapException Class

EHeapException is the exception class for errors related to heap-allocated memory.

Class Hierarchy

Pascal

```
EHeapException = class(Exception);
```

C++

```
class EHeapException : public Exception;
```

File

SysUtils

Description

EHeapException's descendants—EOutOfMemory (see page 3942) and EInvalidPointer (see page 3937)—are used to handle failed allocations of dynamic memory and invalid pointer operations.

Note: Memory for these exceptions is pre-allocated whenever an application starts and remains allocated as long as the application is running. Never raise EHeapException or its descendants directly.

See Also

EOutOfMemory (see page 3942)

EInvalidPointer (see page 3937)

37.1.13.1 EHeapException Members

The following tables list the members exposed by EHeapException.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
V	RaisingException (see page 3929)	This is RaisingException, a member of class EHeapException.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.

	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3929)	Deallocates the memory occupied by an EHeapException (see page 3926) instance.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3380)	Returns a string containing the class name.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.13.2 EHeapException Methods

The methods of the EHeapException class are listed here.

Protected Methods

	Name	Description
	RaisingException (see page 3929)	This is RaisingException, a member of class EHeapException.

Public Methods

	Name	Description
	FreeInstance (see page 3929)	Deallocates the memory occupied by an EHeapException (see page 3926) instance.

37.1.13.2.1 EHeapException.FreeInstance Method

Deallocates the memory occupied by an EHeapException (see page 3926) instance.

Pascal

```
procedure FreeInstance; override;
```

C++

```
virtual __fastcall FreeInstance();
```

Description

FreeInstance is called internally when an application shuts down. Do not call this method directly or attempt to create or destroy instances of EHeapException (see page 3926).

37.1.13.2.2 EHeapException.RaisingException Method

Pascal

```
procedure RaisingException(P: PExceptionRecord); override;
```

C++

```
virtual __fastcall RaisingException(PExceptionRecord P);
```

Description

This is RaisingException, a member of class EHeapException.

37.1.14 EInOutError Class

EInOutError is the exception class for file input/output errors.

Class Hierarchy

Pascal

```
EInOutError = class(Exception);
```

C++

```
class EInOutError : public Exception;
```

File

SysUtils

Description

EInOutError is raised when an file input/output error occurs, provided I/O checking is enabled.

Note: In Delphi code, use the $I+ directive to enable I/O checking. If an I/O error occurs while this directive is disabled, the application must call IOResult (see page 3602) to clear the error.

Note: In C++ programs, I/O checking is a project option.

The error code is available in the ErrorCode (see page 3933) class member. Error (see page 3560) codes are come in

ranges: 0-99 (native OS errors)

Error (see page 3560) codes in the range 0-99 represent OS error conditions, which are different for Windows and Linux. Refer to the OS documentation for complete error summaries. The SysErrorMessage (see page 4294) function returns descriptive text for OS errors.

Here are some common OS I/O errors, arranged by rough equivalents in Linux and Windows:

LinuxWindows

Linux		**Windows**	
Error (see page 3560) Code	Description	Error (see page 3560) Code	Description
2	No such file or directory	2	File not found
3	Path not found		
5	I/O Error (see page 3560)		
13	Permission denied	5	Access denied
20	Not a directory		
21	Is a directory		
32	Sharing violation		
Error (see page 3560) codes in the range 100 to 149 represent error conditions raised by CLX. Here are the CLX I/O error codes:			

Error (see page 3560) code	**Meaning**
100	End of `File`
101	Disk Full
102	File variable not assigned
103	File not open
104	File not open for input
105	File not open for output
106	Error (see page 3560) in formatted input
107	File already open

Delphi Examples:

```
{
Click the button to open a TOpenDialog, then select a file
to delete.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  F: Textfile;
begin
  OpenDialog1.Title := 'Delete File';
  if OpenDialog1.Execute then
  begin
```

```
      AssignFile(F, OpenDialog1.FileName);
      try
        Reset(F);
        if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
          mtConfirmation, [mbYes, mbNo], 0) = mrYes then
        begin
          CloseFile(F);
          Erase(F);
        end;
      except
        on EInOutError do
          MessageDlg('File I/O error.', mtError, [mbOk], 0);
      end;
    end;
  end;
```

SysErrorMessage (see page 4294)

37.1.14.1 EInOutError Members

The following tables list the members exposed by EInOutError.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	ErrorCode (see page 3933)	This is ErrorCode, a member of class EInOutError.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.

	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Destroy (see page 3960)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
V	ToString (see page 3380)	Returns a string containing the class name.
V	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
R	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
R	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.14.2 EInOutError Fields

The fields of the EInOutError class are listed here.

Public Fields

	Name	Description
	ErrorCode (see page 3933)	This is ErrorCode, a member of class EInOutError.

37.1.14.2.1 EInOutError.ErrorCode Field

Pascal

```
ErrorCode: Integer;
```

C++

```
int ErrorCode;
```

Description

This is ErrorCode, a member of class EInOutError.

37.1.15 EIntError Class

EIntError is the base class for integer math error exceptions.

Class Hierarchy

Pascal

```
EIntError = class(EExternal);
```

C++

```
class EIntError : public EExternal;
```

File

SysUtils

Description

EIntError is a generic integer math exception. Although it is never raised in the runtime library, it is the base from which other integer math exceptions descend. These are the integer math exceptions:

Exception (see page 3949)	Meaning
EDivByZero (see page 3921)	An attempt was made to divide by zero
ERangeError (see page 3945)	Number or expression out of range
EIntOverflow (see page 3934)	Integer operation overflowed

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EDivByZero (see page 3921)

EExternal (see page 3922)

ERangeError (see page 3945)

EIntOverflow (see page 3934)

37.1.16 EIntfCastError Class

EIntfCastError is the exception class for interface casting errors.

Class Hierarchy

Pascal

```
EIntfCastError = class(Exception);
```

C++

```
class EIntfCastError : public Exception;
```

File

SysUtils

Description

EIntfCastError is raised when an illegal cast is attempted on an interface.

See Also

EInvalidCast (see page 3935)

37.1.17 EIntOverflow Class

EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.

Class Hierarchy

Pascal

```
EIntOverflow = class(EIntError);
```

C++

```
class EIntOverflow : public EIntError;
```

File

SysUtils

Description

EIntOverflow is a occurs when data is lost because an integer result is too large to retain.

Note: In Delphi Code, EIntOverflow is raised only if overflow checking is turned on. To turn on overflow checking, include the $Q+ directive in project source code, or select Project|Options, choose the Compiler tab, and check the Overflow-checking option in the dialog box.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Floating-point overflows raise the EOverflow (see page 3942) exception.

See Also

EExternal (see page 3922)

ERangeError (see page 3945)

EDivByZero (see page 3921)

EOverflow (see page 3942)

37.1.18 EInvalidCast Class

EInvalidCast is an exception class for typecasting errors.

Class Hierarchy

Pascal

```
EInvalidCast = class(Exception);
```

C++

```
class EInvalidCast : public Exception;
```

File

SysUtils

Description

EInvalidCast is raised when an illegal typecast is attempted.

See Also

EIntfCastError (see page 3934)

37.1.19 EInvalidContainer Class

Class Hierarchy

Pascal

```
EInvalidContainer = class(Exception);
```

C++

```
class EInvalidContainer : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EInvalidContainer.

37.1.20 EInvalidInsert Class

Class Hierarchy

Pascal

```
EInvalidInsert = class(Exception);
```

C++

```
class EInvalidInsert : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EInvalidInsert.

37.1.21 EInvalidOp Class

EInvalidOp is the exception class for undefined floating-point operations.

Class Hierarchy

Pascal

```
EInvalidOp = class(EMathError);
```

C++

```
class EInvalidOp : public EMathError;
```

File

SysUtils

Description

EInvalidOp is raised when the CPU encounters an undefined instruction, invalid operation, or floating-point stack overflow.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Do not confuse EInvalidOp with EInvalidOperation, the exception class for invalid component operations.

See Also

EExternal (see page 3922)

EInvalidOperation

EInvalidArgument

EOverflow (see page 3942)

EUnderflow (see page 3947)

EZeroDivide (see page 3966)

37.1.22 EInvalidPointer Class

EInvalidPointer is the exception class for invalid pointer operations.

Class Hierarchy

Pascal

```
EInvalidPointer = class(EHeapException);
```

C++

```
class EInvalidPointer : public EHeapException;
```

File

SysUtils

Description

EInvalidPointer is raised when an application attempts an invalid pointer operation. For example, it can occur if an application tries to dispose of the same pointer twice, or refers to a pointer which has already been disposed of.

Note: Never raise an EInvalidPointer exception directly. EInvalidPointer is raised internally by the memory manager.

37.1.23 EMathError Class

EMathError is the base exception class for floating-point math errors.

Class Hierarchy

Pascal

```
EMathError = class(EExternal);
```

C++

```
class EMathError : public EExternal;
```

File

SysUtils

Description

EMathError is the base class for floating-point math exception classes. EMathError itself is never raised.

The following exceptions descend from EMathError:

Exception (see page 3949)	Meaning
EInvalidArgument	Parameter out of range
EInvalidOp (see page 3936)	Processor encountered an undefined instruction
EOverflow (see page 3942)	Floating-point operation produced result too large to store

EUnderflow (see page 3947)	Floating-point operation produced result with no precision
EZeroDivide (see page 3966)	Attempt to divide by zero

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EExternal (see page 3922)

EInvalidArgument

EInvalidOp (see page 3936)

EOverflow (see page 3942)

EUnderflow (see page 3947)

EZeroDivide (see page 3966)

37.1.24 EMonitor Class

Class Hierarchy

Pascal

```
EMonitor = class(Exception);
```

C++

```
class EMonitor : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EMonitor.

37.1.25 EMonitorLockException Class

Class Hierarchy

Pascal

```
EMonitorLockException = class(EMonitor);
```

C++

```
class EMonitorLockException : public EMonitor;
```

File

SysUtils

Description

This is class SysUtils.EMonitorLockException.

37.1.26 ENoConstructException Class

Class Hierarchy

Pascal

```
ENoConstructException = class(Exception);
```

C++

```
class ENoConstructException : public Exception;
```

File

SysUtils

Description

This is class SysUtils.ENoConstructException.

37.1.27 ENoMonitorSupportException Class

Class Hierarchy

Pascal

```
ENoMonitorSupportException = class(EMonitor);
```

C++

```
class ENoMonitorSupportException : public EMonitor;
```

File

SysUtils

Description

This is class SysUtils.ENoMonitorSupportException.

37.1.28 EOSError Class

EOSError is the exception class for operating system errors.

Class Hierarchy

Pascal

```
EOSError = class(Exception);
```

C++

```
class EOSError : public Exception;
```

File

SysUtils

Description

EOSError is raised by the RaiseLastOSError (see page 4230) procedure if the operating system returns an error code. The exception dialog contains the error number and the message associated with the error.

Note: EOSError replaces EWin32Error (see page 3949), which is now deprecated.

See Also

RaiseLastOSError (see page 4230)

37.1.28.1 EOSError Members

The following tables list the members exposed by EOSError.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	ErrorCode (see page 3942)	This is ErrorCode, a member of class EOSError.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.

	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Destroy (see page 3960)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
V	ToString (see page 3380)	Returns a string containing the class name.
V	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
R	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
R	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.28.2 EOSError Fields

The fields of the EOSError class are listed here.

Public Fields

	Name	Description
	ErrorCode (see page 3942)	This is ErrorCode, a member of class EOSError.

37.1.28.2.1 EOSError.ErrorCode Field

Pascal

```
ErrorCode: DWORD;
```

C++

```
DWORD ErrorCode;
```

Description

This is ErrorCode, a member of class EOSError.

37.1.29 EOutOfMemory Class

EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.

Class Hierarchy

Pascal

```
EOutOfMemory = class(EHeapException);
```

C++

```
class EOutOfMemory : public EHeapException;
```

File

SysUtils

Description

EOutOfMemory occurs when an application attempts to allocate dynamic memory, but there is not enough free memory in the system to meet the request.

Memory for the EOutOfMemory exception is pre-allocated whenever an application starts and remains allocated as long as the application is running.

Note: Never raise EOutOfMemory directly. Instead, call the global OutOfMemoryError (see page 4228) procedure.

See Also

EOutOfResources

OutOfMemoryError (see page 4228)

EHeapException (see page 3926)

37.1.30 EOverflow Class

EOverflow is the exception class for floating-point register overflows.

Class Hierarchy

Pascal

```
EOverflow = class(EMathError);
```

C++

```
class EOverflow : public EMathError;
```

File

SysUtils

Description

EOverflow is raised when a calculated result is too large to fit in the floating-point register allocated for it and data is therefore lost.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Integer register overflows raise the EIntOverflow (see page 3934) exception.

See Also

EExternal (see page 3922)

EInvalidArgument

EInvalidOp (see page 3936)

EUnderflow (see page 3947)

EZeroDivide (see page 3966)

EIntOverflow (see page 3934)

37.1.31 EPackageError Class

EPackageError is the exception class for package-related errors.

Class Hierarchy

Pascal

```
EPackageError = class(Exception);
```

C++

```
class EPackageError : public Exception;
```

File

SysUtils

Description

EPackageError is raised at design time only, when an error occurs loading or utilizing a package.

37.1.32 EPrivilege Class

EPrivilege is the exception class for processor privilege violations.

Class Hierarchy

Pascal

```
EPrivilege = class(EExternal);
```

C++

```
class EPrivilege : public EExternal;
```

File

SysUtils

Description

EPrivilege is raised when an application tries to execute a processor instruction that is invalid for the current processor privilege level.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EExternal (see page 3922)

37.1.33 EProgrammerNotFound Class

Class Hierarchy

Pascal

```
EProgrammerNotFound = class(Exception);
```

C++

```
class EProgrammerNotFound : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EProgrammerNotFound.

37.1.34 EPropReadOnly Class

EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.

Class Hierarchy

Pascal

```
EPropReadOnly = class(Exception);
```

C++

```
class EPropReadOnly : public Exception;
```

File

SysUtils

Description

EPropReadOnly is raised when an application tries to write to a read-only property using OLE automation.

37.1.35 EPropWriteOnly Class

EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.

Class Hierarchy

Pascal

```
EPropWriteOnly = class(Exception);
```

C++

```
class EPropWriteOnly : public Exception;
```

File

SysUtils

Description

EPropWriteOnly is raised when an application tries to read a write-only property using OLE automation.

37.1.36 ERangeError Class

ERangeError is the exception for Delphi range errors.

Class Hierarchy

Pascal

```
ERangeError = class(EIntError);
```

C++

```
class ERangeError : public EIntError;
```

File

SysUtils

Description

ERangeError occurs in Delphi code when range checking is enabled and an ordinal values goes outside its declared range.

Note: Range checking is not a C++ feature. However, ERangeError can occur when C++ code calls Delphi code.

Note: By default, the Delphi compiler disables range checking. The compiler can always detect obvious range errors, which prevents the following code from compiling.

//Delphi subrange example

```
var
  SmallValue: 1..3;
  SevenBits: byte;
begin;
  SmallValue := 4;  //Won't compile: constant expression out of bounds
  SevenBits := 256; //Won't compile: constant expression out of bounds
end;
```

Note: However, the compiler can't anticipate out-of-range values provided at run time:

//Delphi subrange example

```
var
  SmallValue: 1..3;
  SevenBits: byte;
  ThirtyTwoBits: Integer
begin;
  ThirtyTwoBits := 4;
  SmallValue := ThirtyTwoBits; //Assigns 4 to SmallValue (SmallValue is stored as a Byte)
  ThirtyTwoBits := 256;
  SevenBits := ThirtyTwoBits;  //Assigns 0 to ThirtyTwoBits (high-order bits discarded)
end;
```

Note: If range checking is enabled, both out-of-bounds assignments throw ERangeError exceptions. To enable range checking, use the Project option in the IDE or the $R+ directive.

Note: Range checking is considered a debugging feature. It produces bigger and slower executables.

Note: Do not confuse ERangeError with ERangeException, which relates to errors using graduated controls in VisualCLX.

See Also

EExternal (see page 3922)

EIntOverflow (see page 3934)

EDivByZero (see page 3921)

37.1.37 ESafecallException Class

ESafecallException is the exception for problems with the safecall calling convention.

Class Hierarchy

Pascal

```
ESafecallException = class(Exception);
```

C++

```
class ESafecallException : public Exception;
```

File

SysUtils

Description

ESafecallException is raised when the safecall error handler has not been set up and a safecall routine returns a non-0 HResult, or if the safecall error handler does not raise an exception.

If this exception occurs, the Comobj unit is probably missing from the application's uses list (Delphi) or not included in the project source file (C++). You may want to consider removing the safecall calling convention from the routine that gave rise to the exception.

See Also

TComponent

37.1.38 EStackOverflow Class

EStackOverflow is the exception class for stack overflows.

Class Hierarchy

Pascal

```
EStackOverflow = class(EExternal);
```

C++

```
class EStackOverflow : public EExternal;
```

File

SysUtils

Description

EStackOverflow is raised when the system is unable to allocate necessary stack space. This can happen because of extremely large local variables, deeply recursive routines, or invalid machine-language code.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EExternal (see page 3922)

37.1.39 EUnderflow Class

EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.

Class Hierarchy

Pascal

```
EUnderflow = class(EMathError);
```

C++

```
class EUnderflow : public EMathError;
```

File

SysUtils

Description

When a floating-point math operation produces a value that is too small to be represented in a floating-point variable, the result ordinarily becomes zero. However, an application can change the numeric coprocessor's control word to unmask underflow hardware exceptions. In this case, EUnderflow is raised when the processor reports an underflow hardware exception. The control word is reset after the exception.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

See Also

EExternal (see page 3922)

EInvalidArgument

EInvalidOp (see page 3936)

EOverflow (see page 3942)

EZeroDivide (see page 3966)

37.1.40 EVariantError Class

EVariantError is the exception class for errors involving Variant (see page 3421) data types.

Class Hierarchy

Pascal

```
EVariantError = class(Exception);
```

C++

```
class EVariantError : public Exception;
```

File

SysUtils

Description

EVariantError is raised when a variant operation fails. EVariantError has a number of descendant classes which provide more specific information about the error.

See Also

EVariantArrayCreateError (see page 4978)

EVariantArrayLockedError (see page 4979)

EVariantBadIndexError (see page 4980)

EVariantBadVarTypeError (see page 4980)

EVariantDispatchError (see page 4981)

EVariantInvalidArgError (see page 4981)

EVariantInvalidOpError (see page 4983)

EVariantNotImplError (see page 4984)

EVariantOutOfMemoryError (see page 4984)

EVariantOverflowError (see page 4985)

EVariantTypeCastError (see page 4986)

EVariantUnexpectedError (see page 4987)

37.1.41 EWin32Error Class

EWin32Error is the exception class for Windows errors.

Class Hierarchy

Pascal

```
EWin32Error = class(EOSError);
```

C++

```
class EWin32Error : public EOSError;
```

File

SysUtils

Description

EWin32Error is now deprecated in favor of EOSError (see page 3939).

See Also

RaiseLastWin32Error (see page 4231)

EOSError (see page 3939)

37.1.42 Exception Class

Exception is the base class for all runtime exceptions.

Class Hierarchy

Pascal

```
Exception = class(TObject);
```

C++

```
class Exception : public TObject;
```

File

SysUtils

Description

Exception encapsulates the fundamental properties and methods for all exceptions. Use Exception as the base class for creating custom exceptions.

All methods introduced for the Exception object are constructors that provide alternative ways to create exception messages. Some constructors also create help context IDs. Typically, an application calls these constructors dynamically when an exception occurs.

Exception messages can be hard-coded strings, formatted strings, or strings (including formatted strings) loaded from an application resource.

Exceptions are raised when a runtime error occurs in an application, such as attempting to divide by zero. When an exception is raised, typically an exception instance displays a dialog box describing the error condition. If an application does not handle the exception condition, then the default exception handler is called. This handler also displays a dialog box with an OK button that usually permits an application to continue processing when the user clicks OK.

Note: Standard practice is to derive all exception classes from Exception, and specify a name beginning with "E", followed by an abbreviated, descriptive name.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

37.1.42.1 Exception Members

The following tables list the members exposed by Exception.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.

	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.42.2 Exception.Create Constructor

Instantiates an instance of an exception with a simple message string.

Pascal

```
constructor Create(const Msg: string);
```

C++

```
__fastcall Exception(const UnicodeString Msg);
```

Description

Call Create to construct an exception object with a simple message string.

Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("Cannot create C:\\temp again!");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
```

```
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
          FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
          GetMem(Buffer, StringLen); { allocate the buffer }
          cellString := StringGrid1.Cells[X,Y];
          for I := 1 to StringLen do
             Buffer[I - 1] := cellString[I];
          FileWrite(FileHandle, Buffer^, StringLen);
        finally
          FreeMem(Buffer, StringLen);
        end;
      end;
    end;
    FileClose(FileHandle);
  end;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;

procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

37.1.42.3 Exception.CreateFmt Constructor

Instantiates an instance of an exception with a formatted message string.

Pascal

```
constructor CreateFmt(const Msg: string; const Args: array of const);
```

C++

```
__fastcall Exception(const UnicodeString Msg, const array of const Args);
```

Description

Call CreateFmt to construct an exception with a formatted message string. Msg is a string constant containing format specifiers

to be replaced with values from Args. Args is an array of constants containing values to format according to format specifiers in Msg, and insert into Msg. CreateFmt calls the Format (see page 4188) function to transform Msg with the values in Arg.

CreateResFmt (see page 3957)

CreateResFmtHelp (see page 3958)

Format (see page 4188)

Message (see page 3965)

37.1.42.4 Exception.CreateFmtHelp Constructor

Instantiates an instance of an exception with a formatted message string and a help-context ID.

Pascal

```
constructor CreateFmtHelp(const Msg: string; const Args: array of const; AHelpContext:
Integer);
```

C++

```
__fastcall Exception(const UnicodeString Msg, const array of const Args, int AHelpContext);
```

Description

Call CreateFmtHelp to construct an exception with a formatted message string and a help context ID. Msg is a string constant containing format specifiers to be replaced with values from Args. Args is an array of constants containing values to format according to format specifiers in Msg, and insert into Msg. CreateFmt (see page 3954) calls the Format (see page 4188) function to transform Msg with the values in Arg.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

See Also

Message (see page 3965)

37.1.42.5 Exception.CreateHelp Constructor

Creates an instance of an exception with a simple message string and a help- context ID.

Pascal

```
constructor CreateHelp(const Msg: string; AHelpContext: Integer);
```

C++

```
__fastcall Exception(const UnicodeString Msg, int AHelpContext);
```

Description

Call CreateHelp to construct an exception with a simple message string and a help-context ID. Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

CreateResFmtHelp (see page 3958)

Format (see page 4188)

37.1.42.6 CreateRes Constructor

This is the overview for the CreateRes constructor overload.

Overload List

	Name	Description
	Exception.CreateRes (Integer) (see page 3956)	Creates an instance of an exception with a simple message string that is loaded from the application's resources.
	Exception.CreateRes (PResStringRec) (see page 3956)	Creates an instance of an exception with a simple message string that is loaded from the application's resources.

37.1.42.6.1 Exception.CreateRes Constructor (Integer)

Creates an instance of an exception with a simple message string that is loaded from the application's resources.

Pascal

```
constructor CreateRes(Ident: Integer); overload;
constructor CreateRes(ResStringRec: PResStringRec); overload;
```

C++

```
__fastcall Exception(int Ident);
__fastcall Exception(PResStringRec ResStringRec);
```

Description

Call CreateRes to construct an exception with a simple message string loaded from an application's resources. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateRes creates an empty message string for the exception.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'You shouldn''t have done that';
...
Exception.Create(@sMyNewErrorMessage);
```

See Also

Message (see page 3965)

CreateResFmtHelp (see page 3958)

37.1.42.7 CreateResFmt Constructor

This is the overview for the CreateResFmt constructor overload.

Overload List

	Name	Description
	Exception.CreateResFmt (Integer, array of const) (see page 3957)	Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.
	Exception.CreateResFmt (PResStringRec, array of const) (see page 3957)	Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.

37.1.42.7.1 Exception.CreateResFmt Constructor (Integer, array of const)

Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.

Pascal

```
constructor CreateResFmt(Ident: Integer; const Args: array of const); overload;
constructor CreateResFmt(ResStringRec: PResStringRec; const Args: array of const); overload;
```

C++

```
__fastcall Exception(int Ident, const array of const Args);
__fastcall Exception(PResStringRec ResStringRec, const array of const Args);
```

Description

Call CreateResFmt to construct an exception with a message string loaded from an application's resources and then formatted with additional information. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResFmt creates an empty message string for the exception.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'Illegal value: %s';
...
Exception.CreateResFmt(@sMyNewErrorMessage, [-1]);
```

Args is an array of constants containing values to:

1Format (see page 4188) according to format specifiers embedded in the string, and

2Insert (see page 3601) into the message string.

CreateResFmt calls the Format (see page 4188) function to transform the message string with the values in Arg.

See Also

Message (see page 3965)

CreateRes (see page 3956)

CreateResFmtHelp (see page 3958)

Format (see page 4188)

37.1.42.8 CreateResFmtHelp Constructor

This is the overview for the CreateResFmtHelp constructor overload.

Overload List

	Name	Description
	Exception.CreateResFmtHelp (Integer, array of const, Integer) (see page 3958)	Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources
	Exception.CreateResFmtHelp (PResStringRec, array of const, Integer) (see page 3958)	Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources

37.1.42.8.1 Exception.CreateResFmtHelp Constructor (Integer, array of const, Integer)

Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources

Pascal

```
constructor CreateResFmtHelp(ResStringRec: PResStringRec; const Args: array of const;
AHelpContext: Integer); overload;
constructor CreateResFmtHelp(Ident: Integer; const Args: array of const; AHelpContext:
Integer); overload;
```

C++

```
__fastcall Exception(PResStringRec ResStringRec, const array of const Args, int AHelpContext);
__fastcall Exception(int Ident, const array of const Args, int AHelpContext);
```

Description

Call CreateResFmtHelp to construct an exception with a:

1Message (see page 3965) string loaded from an application's resources and formatted with additional information.

2Help-context ID.

Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file. Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResFmt (see page 3957) creates an empty message string.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'Illegal value: %s';
const IDH_MYNEWERROR: Integer = 30000;
...
Exception.CreateResFmt(@sMyNewErrorMessage, [-1], IDH_MYNEWERROR);
```

Args is an array of constants containing values to:

1Format (see page 4188) according to format specifiers embedded in the string, and

2Insert (see page 3601) into the message string.

CreateResFmtHelp calls the Format (see page 4188) function to transform the message string with the values in Arg.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

See Also

HelpContext (see page 3964)

Message (see page 3965)

CreateHelp (see page 3955)

CreateRes (see page 3956)

CreateResHelp (see page 3959)

Format (see page 4188)

37.1.42.9 CreateResHelp Constructor

This is the overview for the CreateResHelp constructor overload.

Overload List

	Name	Description
	Exception.CreateResHelp (Integer, Integer) (see page 3959)	Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.
	Exception.CreateResHelp (PResStringRec, Integer) (see page 3959)	Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.

37.1.42.9.1 Exception.CreateResHelp Constructor (Integer, Integer)

Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.

Pascal

```
constructor CreateResHelp(Ident: Integer; AHelpContext: Integer); overload;
constructor CreateResHelp(ResStringRec: PResStringRec; AHelpContext: Integer); overload;
```

C++

```
__fastcall Exception(int Ident, int AHelpContext);
__fastcall Exception(PResStringRec ResStringRec, int AHelpContext);
```

Description

Call CreateResHelp to construct an exception with a help-context ID and a simple message string loaded from an application's resources. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResHelp creates an empty message string for the exception.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

ResStringRec is a pointer to a resource string. Its syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'You shouldn''t have done that';
const IDH_MYNEWERROR: Integer = 30000;
...
Exception.Create(@sMyNewErrorMessage, IDH_MYNEWERROR);
```

See Also

HelpContext (see page 3964)

Message (see page 3965)

CreateRes (see page 3956)

CreateResFmtHelp (see page 3958)

Format (see page 4188)

37.1.42.10 Exception.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~Exception();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

37.1.42.11 Exception Fields

The fields of the Exception class are listed here.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

37.1.42.11.1 Exception.CleanUpStackInfoProc Field

Pascal

```
class var CleanUpStackInfoProc: procedure (Info: Pointer);
```

C++

```
procedure (Info: Pointer) CleanUpStackInfoProc;
```

Description

This is CleanUpStackInfoProc, a member of class Exception.

37.1.42.11.2 Exception.GetExceptionStackInfoProc Field

Pascal

```
class var GetExceptionStackInfoProc: function (P: PExceptionRecord): Pointer;
```

C++

```
function (P: PExceptionRecord): Pointer GetExceptionStackInfoProc;
```

Description

This is GetExceptionStackInfoProc, a member of class Exception.

37.1.42.11.3 Exception.GetStackInfoStringProc Field

Pascal

```
class var GetStackInfoStringProc: function (Info: Pointer): string;
```

C++

```
function (Info: Pointer): string GetStackInfoStringProc;
```

Description

This is GetStackInfoStringProc, a member of class Exception.

37.1.42.12 Exception Methods

The methods of the Exception class are listed here.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
V	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Methods

	Name	Description
V	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
V	ToString (see page 3963)	Returns a string containing the class name.

37.1.42.12.1 Exception.GetBaseException Method

Pascal

```
function GetBaseException: Exception; virtual;
```

C++

```
virtual __fastcall Exception GetBaseException();
```

Description

This is GetBaseException, a member of class Exception.

37.1.42.12.2 Exception.GetStackTrace Method

Pascal

```
function GetStackTrace: string;
```

C++

```
__fastcall UnicodeString GetStackTrace();
```

Description

This is GetStackTrace, a member of class Exception.

37.1.42.12.3 Exception.RaiseOuterException Method

Pascal

```
class procedure RaiseOuterException(E: Exception); static;
```

C++

```
static __fastcall RaiseOuterException(Exception E);
```

Description

This is RaiseOuterException, a member of class Exception.

37.1.42.12.4 Exception.RaisingException Method

Pascal

```
procedure RaisingException(P: PExceptionRecord); virtual;
```

C++

```
virtual __fastcall RaisingException(PExceptionRecord P);
```

Description

This is RaisingException, a member of class Exception.

37.1.42.12.5 Exception.SetInnerException Method

Pascal

```
procedure SetInnerException;
```

C++

```
__fastcall SetInnerException();
```

Description

This is SetInnerException, a member of class Exception.

37.1.42.12.6 Exception.SetStackInfo Method

Pascal

```
procedure SetStackInfo(AStackInfo: Pointer);
```

C++

```
__fastcall SetStackInfo(void * AStackInfo);
```

Description

This is SetStackInfo, a member of class Exception.

37.1.42.12.7 Exception.ThrowOuterException Method

Pascal

```
class procedure ThrowOuterException(E: Exception); static;
```

C++

```
static __fastcall ThrowOuterException(Exception E);
```

Description

This is ThrowOuterException, a member of class Exception.

37.1.42.12.8 Exception.ToString Method

Returns a string containing the class name.

Pascal

```
function ToString: string; override;
```

C++

```
virtual __fastcall UnicodeString ToString();
```

Description

By default, the System::TObject::ToString returns a string containing the class name of the instance that is being called.

Example

Calling System::TObject::ToString on a TButton instance returns a string containing "TButton".

Note: System::TObject::ToString is intended to be overridden in user derived classes, in order to provide consumer objects with a string representation.

See Also

System::TObject::ClassType (see page 3364)

System::TObject::ClassName (see page 3359)

System::TObject::ClassParent (see page 3361)

System::TObject::FieldAddress (see page 3372)

System::TObject::MethodAddress (see page 3378)

System::TObject::InstanceSize (see page 3377)

System::TObject::MethodName (see page 3379)

System::TObject::InheritsFrom (see page 3376)

37.1.42.13 Exception Properties

The properties of the Exception class are listed here.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

37.1.42.13.1 Exception.BaseException Property

Pascal

```
property BaseException: Exception;
```

C++

```
__property Exception BaseException;
```

Description

This is BaseException, a member of class Exception.

37.1.42.13.2 Exception.HelpContext Property

Indicates the context ID number for context-sensitive online help associated with the exception.

Pascal

```
property HelpContext: Integer;
```

C++

```
__property int HelpContext;
```

Description

HelpContext provides storage for the help context ID number associated with the exception object. The context ID number determines the contents of the help screen that appears when a user presses F1 in response to an exception error message.

Note: To initialize HelpContext when the Exception (see page 3949) object is instantiated, use the appropriate constructor.

Note: In Delphi code, instantiate the Exception (see page 3949) object with CreateFmtHelp (see page 3955), CreateHelp (see page 3955), CreateResFmtHelp (see page 3958), or CreateResHelp (see page 3959).

Note: In C++ code, use a form of the constructor that takes a help context parameter.

See Also

Create (see page 3952)

CreateFmtHelp (see page 3955)

CreateHelp (see page 3955)

CreateResFmtHelp (see page 3958)

CreateResHelp (see page 3959)

37.1.42.13.3 Exception.InnerException Property

Pascal

```
property InnerException: Exception;
```

C++

```
__property Exception InnerException;
```

Description

This is InnerException, a member of class Exception.

37.1.42.13.4 Exception.Message Property

Message contains the text string to display in the exception dialog box when the exception is raised.

Pascal

```
property Message: string;
```

C++

```
__property UnicodeString Message;
```

Description

Message stores the error-message string to display when the exception is raised. All Exception (see page 3949) constructors expect a string parameter to store in Message. Message text can be hard-coded as a parameter to an Exception (see page 3949) constructor, created as dynamic parameter, or loaded from a resource file as a static or dynamically formatted parameter.

37.1.42.13.5 Exception.StackInfo Property

Pascal

```
property StackInfo: Pointer;
```

C++

```
__property void * StackInfo;
```

Description

This is StackInfo, a member of class Exception.

37.1.42.13.6 Exception.StackTrace Property

Pascal

```
property StackTrace: string;
```

C++

```
__property UnicodeString StackTrace;
```

Description

This is StackTrace, a member of class Exception.

37.1.43 EZeroDivide Class

EZeroDivide is the exception class for floating-point divide-by-zero errors.

Class Hierarchy

Pascal

```
EZeroDivide = class(EMathError);
```

C++

```
class EZeroDivide : public EMathError;
```

File

SysUtils

Description

EZeroDivide exception is raised when an application attempts to divide a floating-point value by zero.

Run-time exception information is saved in fields provided by EExternal (see page 3922).

Note: Integer divide-by-zero errors raise the EDivByZero (see page 3921) exception.

See Also

EExternal (see page 3922)

EInvalidOp (see page 3936)

EOverflow (see page 3942)

EUnderflow (see page 3947)

EDivByZero (see page 3921)

37.1.44 TBigEndianUnicodeEncoding Class

Class Hierarchy

Pascal

```
TBigEndianUnicodeEncoding = class(TUnicodeEncoding);
```

C++

```
class TBigEndianUnicodeEncoding : public TUnicodeEncoding;
```

File

SysUtils

Description

This is class SysUtils.TBigEndianUnicodeEncoding.

37.1.44.1 TBigEndianUnicodeEncoding Members

The following tables list the members exposed by TBigEndianUnicodeEncoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
V	Create (see page 4026)	This is Create, a member of class TUnicodeEncoding.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
A	GetMaxByteCount (see page 3980)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxByteCount (see page 4028)	Calculates the maximum bytes generated to encode the specified number of characters.
A	GetMaxCharCount (see page 3980)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetMaxCharCount (see page 4028)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetPreamble (see page 3969)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.

	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
	GetByteCount (see page 4026)	Returns the number of bytes generated by encoding Chars.
	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
	GetBytes (see page 3968)	Encodes a set of characters into a sequence of bytes.
	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
	GetCharCount (see page 4027)	Calcuates a number of characters generated by decoding a sequence of bytes.
	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
	GetChars (see page 3969)	Decodes a set of bytes into a set of characters.
	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.44.2 TBigEndianUnicodeEncoding Methods

The methods of the TBigEndianUnicodeEncoding class are listed here.

Public Methods

	Name	Description
	GetPreamble (see page 3969)	Returns a preamble in a byte array that specifies the encoding used.

Strict protected Methods

	Name	Description
	GetBytes (see page 3968)	Encodes a set of characters into a sequence of bytes.
	GetChars (see page 3969)	Decodes a set of bytes into a set of characters.

37.1.44.2.1 TBigEndianUnicodeEncoding.GetBytes Method

Encodes a set of characters into a sequence of bytes.

Pascal

```
function GetBytes(Chars: PChar; CharCount: Integer; Bytes: PByte; ByteCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetBytes(const char * Chars, int CharCount, PByte Bytes, int ByteCount);
```

Description

TEncoding.GetBytes encodes Chars parameter into a sequence of bytes.

Chars can be a character array or a character pointer which will be encoded into a sequence of bytes.

S is a string of type UnicodeString to be encoded into a sequence of bytes.

The **CharCount** parameter specifies the number of characters to encode.

Bytes specifies the location to write the sequence of bytes.

ByteCount is the maximum number of bytes that can be written to the given location.

The **Return Value** is the number of bytes actually encoded or the actual TBytes sequence of bytes.

See Also

Encoding.GetBytes (MSDN)

37.1.44.2.2 TBigEndianUnicodeEncoding.GetChars Method

Decodes a set of bytes into a set of characters.

Pascal

```
function GetChars(Bytes: PByte; ByteCount: Integer; Chars: PChar; CharCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetChars(PByte Bytes, int ByteCount, const char * Chars, int CharCount);
```

Description

TEncoding.GetChars generates a number of characters by decoding Bytes.

Bytes can be a byte pointer or a byte array.

ByteIndex specifies the first byte to decode. If not present, the index is 0.

ByteCount specifies the number of bytes to decode. If not present, all bytes will be decoded.

Chars is a pointer to the destination of the decoded characters.

CharIndex specifies the maximum number of characters to store.

The **Return Value** is either a character array of the decoded characters, or the number of characters decoded.

See Also

Encoding.GetChars (MSDN)

37.1.44.2.3 TBigEndianUnicodeEncoding.GetPreamble Method

Returns a preamble in a byte array that specifies the encoding used.

Pascal

```
function GetPreamble: TBytes; override;
```

C++

```
virtual __fastcall TBytes GetPreamble();
```

Description

TEncoding.GetPreamble returns an array of bytes of type TBytes that contains the preamble required for the encoding used. If no preamble is required a zero length array is returned.

See Also

Encoding.GetPreamble (MSDN)

37.1.45 TEncoding Class

TEncoding is a class that defines a specific encoding for a character or string.

Class Hierarchy

Pascal

```
TEncoding = class;
```

C++

```
class TEncoding;
```

File

SysUtils

Description

Use the TEncoding class to define a specific encoding desired for a given string. For instance, the TStringStream class now includes an overloaded constructor that enables the developer to define encoding for strings that will be added to an instance of TStringStream.

To simplify cross platform developement, there are similarities between this interface and System.Text.Encoding. For that reason, links are provided to MSDN counterparts in Encoding (MSDN) class.

C++ Examples:

```
/*
This example reads any file and converts the encoding to UTF8.
This example uses the TBytesStream to read the files into a TBytes'
and also uses the auto_ptr construction to clean up created class
instances.

*/
#include <tchar.h>
#include <memory>       //for STL auto_ptr class
//---------------------------------------------------------------------------

#pragma argsused
int _tmain(int argc, _TCHAR* argv[])
{
  // Sample to convert a file of any encoding to UTF8.
  TEncoding *LEncoding = NULL;
  std::auto_ptr<TFileStream> LFileStream(new TFileStream("..\\Sample.txt", fmOpenRead));

  // Read file into buffer
  TBytes myBytes;
  std::auto_ptr<TBytesStream> myBytesStream(new TBytesStream(myBytes));
  myBytesStream->CopyFrom(LFileStream.get(), LFileStream->Size);

  // Identify encoding and convert buffer to UTF8
  int LOffset = TEncoding::GetBufferEncoding(myBytesStream->Bytes, LEncoding);
  if (LOffset == 0)
    return 1; // Unknown encoding, don't convert.
  myBytes = TEncoding::Convert(LEncoding, TEncoding::UTF8,
                               myBytesStream->Bytes,
                               LOffset, myBytesStream->Size-LOffset);
  // Create output file
  std::auto_ptr<TFileStream> DestFileStream(new TFileStream("..\\SampleUTF8.txt", fmCreate));

  // Write UTF8 byte order mark and buffer to output file
  TBytes LByteOrderMark;
  LByteOrderMark = TEncoding::UTF8->GetPreamble();

  // Grab preamble and write to destination
  DestFileStream->Write(&LByteOrderMark[0], LByteOrderMark.Length);
```

```
  // Write converted buffer
  DestFileStream->Write(&myBytes[0], myBytes.Length);
  return 0;
}
```

Delphi Examples:

```
{
This example determines the encoding of a source file and then
writes the file in any encoding chosen.  Use this project to
create files of any encoding.  This example requires two text edits
and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
  LOffset: Integer;
  LEncoding, DestEncoding: TEncoding;
  LFileStream: TFileStream;
  EncodingArray: array[0..5] of TEncoding;
begin
  LEncoding:= nil;
  EncodingArray[0]:= TEncoding.UTF8;
  EncodingArray[1]:= TEncoding.UTF7;
  EncodingArray[2]:= TEncoding.Unicode;
  EncodingArray[3]:= TEncoding.Default;
  EncodingArray[4]:= TEncoding.BigEndianUnicode;
  EncodingArray[5]:= TEncoding.ASCII;
  DestEncoding := EncodingArray[ComboBox1.ItemIndex];
  LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
  try
    // Read file into buffer
    SetLength(LBuffer, LFileStream.Size);
//    LFileStream.Read(LBuffer[0], Length(LBuffer));
    LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));

    // Identify encoding and convert buffer to UTF8
    LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
//    for I := 0 to Length(LBuffer) - 1 do
//      Memo1.Lines.Add((LBuffer[I]));
    LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
      LOffset, Length(LBuffer) - LOffset);
  finally
    LFileStream.Free;
  end;

  LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
  try
    // Write an encoding byte order mark and buffer to output file
    LByteOrderMark := DestEncoding.GetPreamble;
    LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
    LFileStream.Write(LBuffer[0], Length(LBuffer));
  finally
    LFileStream.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  StringList: TStrings;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
      Add('TEncoding.UTF8');
      Add('TEncoding.UTF7');
```

```
        Add('TEncoding.Unicode');
        Add('TEncoding.Default');
        Add('TEncoding.BigEndianUnicode');
        Add('TEncoding.ASCII');
      end;
      with ComboBox1 do begin
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

37.1.45.1 TEncoding Members

The following tables list the members exposed by TEncoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
A	GetMaxByteCount (see page 3980)	Calculates the maximum bytes generated to encode the specified number of characters.
A	GetMaxCharCount (see page 3980)	Calculates the maximum number of characters generated to decode a specified number of bytes.
A	GetPreamble (see page 3981)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
A	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.45.2 TEncoding Fields

The fields of the TEncoding class are listed here.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

37.1.45.2.1 TEncoding.FIsSingleByte Field

Pascal

```
FIsSingleByte: Boolean;
```

C++

```
Boolean FIsSingleByte;
```

Description

This is FIsSingleByte, a member of class TEncoding.

37.1.45.2.2 TEncoding.FMaxCharSize Field

Pascal

```
FMaxCharSize: Integer;
```

C++

```
int FMaxCharSize;
```

Description

This is FMaxCharSize, a member of class TEncoding.

37.1.45.3 TEncoding Methods

The methods of the TEncoding class are listed here.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
A	GetMaxByteCount (see page 3980)	Calculates the maximum bytes generated to encode the specified number of characters.
A	GetMaxCharCount (see page 3980)	Calculates the maximum number of characters generated to decode a specified number of bytes.
A	GetPreamble (see page 3981)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Strict protected Methods

	Name	Description
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
A	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.45.3.1 Convert Method

This is the overview for the Convert method overload.

Overload List

	Name	Description
	TEncoding.Convert (TEncoding, TEncoding, TBytes) (see page 3975)	Convert an array of bytes from one encoding to another.
	TEncoding.Convert (TEncoding, TEncoding, TBytes, Integer, Integer) (see page 3975)	Convert an array of bytes from one encoding to another.

37.1.45.3.1.1 TEncoding.Convert Method (TEncoding, TEncoding, TBytes)

Convert an array of bytes from one encoding to another.

Pascal

```
class function Convert(Source: TEncoding; Destination: TEncoding; Bytes: TBytes): TBytes;
overload;
class function Convert(Source: TEncoding; Destination: TEncoding; Bytes: TBytes; StartIndex:
Integer; Count: Integer): TBytes; overload;
```

C++

```
__fastcall TBytes Convert(TEncoding Source, TEncoding Destination, TBytes Bytes);
__fastcall TBytes Convert(TEncoding Source, TEncoding Destination, TBytes Bytes, int
StartIndex, int Count);
```

Description

TEncoding.Convert converts an array of bytes from one encoding to another.

Source refers to the encoding type of the encoding of the original bytes.

Destination refers to the encoding type that the bytes are to be converted to.

StartIndex specifies the index of the array to begin converting.

Count specifies the number of bytes to convert.

The **Return Value** is the converted array of bytes.

See Also

Encoding.Convert (MSDN)

37.1.45.3.2 TEncoding.FreeEncodings Method

Frees the internal standard encoding instances.

Pascal

```
class procedure FreeEncodings;
```

C++

```
__fastcall FreeEncodings();
```

Description

TEncoding.FreeEncodings clears and frees the internal standard encodings returned by the properties ASCII (see page 3985), Default (see page 3985), UTF8 (see page 3987), Unicode (see page 3986) and BigEndianUnicode (see page 3985). This method is for internal use only, do not call directly.

See Also

ASCII (see page 3985)

Default (see page 3985)

UTF8 (see page 3987)

Unicode (see page 3986)

BigEndianUnicode (see page 3985)

37.1.45.3.3 TEncoding.GetBufferEncoding Method

Determines the encoding for a given buffer.

Pascal

```
class function GetBufferEncoding(const Buffer: TBytes; var AEncoding: TEncoding): Integer;
static;
```

C++

```
static __fastcall int GetBufferEncoding(const TBytes Buffer, TEncoding AEncoding);
```

Description

GetBufferEncoding examines the Buffer parameter and determines its encoding by looking for known byte order marks (BOM). If the buffer doesn't contain a byte order mark for one of the standard encodings, the Default (see page 3985) standard encoding is returned.

Buffer refers to a TBytes (see page 4339) instance that will be examined.

AEncoding refers to an instance of TEncoding (see page 3969) that will be filled out with the encoding type of the buffer.

The **Return Value** of GetBufferEncoding is the length of the preamble in the Buffer of bytes.

Note: The `AEncoding` parameter should have the value NIL, otherwise its value is used to detect the encoding.

37.1.45.3.4 GetByteCount Method

This is the overview for the GetByteCount method overload.

Overload List

	Name	Description
	TEncoding.GetByteCount (PChar, Integer) (see page 3976)	Returns the number of bytes generated by encoding Chars.
	TEncoding.GetByteCount (string) (see page 3976)	Returns the number of bytes generated by encoding Chars.
	TEncoding.GetByteCount (string, Integer, Integer) (see page 3976)	Returns the number of bytes generated by encoding Chars.
	TEncoding.GetByteCount (TCharArray) (see page 3976)	Returns the number of bytes generated by encoding Chars.
	TEncoding.GetByteCount (TCharArray, Integer, Integer) (see page 3976)	Returns the number of bytes generated by encoding Chars.

37.1.45.3.4.1 TEncoding.GetByteCount Method (PChar, Integer)

Returns the number of bytes generated by encoding Chars.

Pascal

```
function GetByteCount(Chars: PChar; CharCount: Integer): Integer; virtual; abstract; overload;
function GetByteCount(const Chars: TCharArray): Integer; overload;
function GetByteCount(const Chars: TCharArray; CharIndex: Integer; CharCount: Integer):
Integer; overload;
function GetByteCount(const S: string): Integer; overload;
function GetByteCount(const S: string; CharIndex: Integer; CharCount: Integer): Integer;
overload;
```

C++

```
virtual __fastcall int GetByteCount(const char * Chars, int CharCount) = 0;
__fastcall int GetByteCount(const TCharArray Chars);
__fastcall int GetByteCount(const TCharArray Chars, int CharIndex, int CharCount);
__fastcall int GetByteCount(const UnicodeString S);
__fastcall int GetByteCount(const UnicodeString S, int CharIndex, int CharCount);
```

Description

Returns the number of bytes generated by encoding Chars. Note that the number of bytes in a string is not necessarily exactly proportional to the number of characters in a given character array or string.

The **Chars** parameter can be a character array or a character pointer containing the bytes to be counted.

The **S** parameter refers to a UnicodeString (see page 3381) from which the Byte count will be extracted.

The **CharCount** parameter specifies the number of characters to encode.

The **CharIndex** parameter indicates the index within the Chars array where counting should begin.

The **CharCount** parameter indicates the number of characters that should be included when counting the bytes.

The Return Value is the number of bytes in the passed Chars or S parameter.

See Also

Encoding.GetByteCount (MSDN)

37.1.45.3.5 GetBytes Method

This is the overview for the GetBytes method overload.

Overload List

	Name	Description
	TEncoding.GetBytes (PChar, Integer, PByte, Integer) (see page 3977)	Encodes a set of characters into a sequence of bytes.
	TEncoding.GetBytes (string) (see page 3977)	Encodes a set of characters into a sequence of bytes.
	TEncoding.GetBytes (string, Integer, Integer, TBytes, Integer) (see page 3977)	Encodes a set of characters into a sequence of bytes.
	TEncoding.GetBytes (TCharArray) (see page 3977)	Encodes a set of characters into a sequence of bytes.
	TEncoding.GetBytes (TCharArray, Integer, Integer, TBytes, Integer) (see page 3977)	Encodes a set of characters into a sequence of bytes.

37.1.45.3.5.1 TEncoding.GetBytes Method (PChar, Integer, PByte, Integer)

Encodes a set of characters into a sequence of bytes.

Pascal

```
function GetBytes(Chars: PChar; CharCount: Integer; Bytes: PByte; ByteCount: Integer):
Integer; virtual; abstract; overload;
function GetBytes(const Chars: TCharArray): TBytes; overload;
function GetBytes(const Chars: TCharArray; CharIndex: Integer; CharCount: Integer; var Bytes:
TBytes; ByteIndex: Integer): Integer; overload;
function GetBytes(const S: string): TBytes; overload;
function GetBytes(const S: string; CharIndex: Integer; CharCount: Integer; var Bytes: TBytes;
ByteIndex: Integer): Integer; overload;
```

C++

```
virtual __fastcall int GetBytes(const char * Chars, int CharCount, PByte Bytes, int ByteCount)
= 0;
__fastcall TBytes GetBytes(const TCharArray Chars);
__fastcall int GetBytes(const TCharArray Chars, int CharIndex, int CharCount, TBytes Bytes,
int ByteIndex);
__fastcall TBytes GetBytes(const UnicodeString S);
__fastcall int GetBytes(const UnicodeString S, int CharIndex, int CharCount, TBytes Bytes, int
ByteIndex);
```

Description

TEncoding.GetBytes encodes Chars parameter into a sequence of bytes.

Chars can be a character array or a character pointer which will be encoded into a sequence of bytes.

S is a string of type UnicodeString (see page 3381) to be encoded into a sequence of bytes.

The **CharCount** parameter specifies the number of characters to encode.

Bytes specifies the location to write the sequence of bytes.

ByteCount is the maximum number of bytes that can be written to the given location.

The **Return Value** is the number of bytes actually encoded or the actual TBytes (see page 4339) sequence of bytes.

37.1.45.3.6 GetCharCount Method

This is the overview for the GetCharCount method overload.

Overload List

	Name	Description
	TEncoding.GetCharCount (PByte, Integer) (see page 3978)	Calcuates a number of characters generated by decoding a sequence of bytes.
	TEncoding.GetCharCount (TBytes) (see page 3978)	Calcuates a number of characters generated by decoding a sequence of bytes.
	TEncoding.GetCharCount (TBytes, Integer, Integer) (see page 3978)	Calcuates a number of characters generated by decoding a sequence of bytes.

37.1.45.3.6.1 TEncoding.GetCharCount Method (PByte, Integer)

Calcuates a number of characters generated by decoding a sequence of bytes.

Pascal

```
function GetCharCount(Bytes: PByte; ByteCount: Integer): Integer; virtual; abstract; overload;
function GetCharCount(const Bytes: TBytes): Integer; overload;
function GetCharCount(const Bytes: TBytes; ByteIndex: Integer; ByteCount: Integer): Integer;
overload;
```

C++

```
virtual __fastcall int GetCharCount(PByte Bytes, int ByteCount) = 0;
__fastcall int GetCharCount(const TBytes Bytes);
__fastcall int GetCharCount(const TBytes Bytes, int ByteIndex, int ByteCount);
```

Description

TEncoding.GetCharCount generates a number of characters by decoding **Bytes**.

Bytes can be a byte array, or a byte pointer.

The **ByteCount** parameter specifies the number of bytes to decode.

The **Return Value** is the number of characters decoded.

Encoding.GetCharCount (MSDN)

37.1.45.3.7 GetChars Method

This is the overview for the GetChars method overload.

Overload List

	Name	Description
	TEncoding.GetChars (PByte, Integer, PChar, Integer) (see page 3979)	Decodes a set of bytes into a set of characters.
	TEncoding.GetChars (TBytes) (see page 3979)	Decodes a set of bytes into a set of characters.
	TEncoding.GetChars (TBytes, Integer, Integer) (see page 3979)	Decodes a set of bytes into a set of characters.
	TEncoding.GetChars (TBytes, Integer, Integer, TCharArray, Integer) (see page 3979)	Decodes a set of bytes into a set of characters.

37.1.45.3.7.1 TEncoding.GetChars Method (PByte, Integer, PChar, Integer)

Decodes a set of bytes into a set of characters.

Pascal

```
function GetChars(Bytes: PByte; ByteCount: Integer; Chars: PChar; CharCount: Integer):
Integer; virtual; abstract; overload;
function GetChars(const Bytes: TBytes): TCharArray; overload;
function GetChars(const Bytes: TBytes; ByteIndex: Integer; ByteCount: Integer): TCharArray;
overload;
function GetChars(const Bytes: TBytes; ByteIndex: Integer; ByteCount: Integer; var Chars:
TCharArray; CharIndex: Integer): Integer; overload;
```

C++

```
virtual __fastcall int GetChars(PByte Bytes, int ByteCount, const char * Chars, int CharCount)
= 0;
__fastcall TCharArray GetChars(const TBytes Bytes);
__fastcall TCharArray GetChars(const TBytes Bytes, int ByteIndex, int ByteCount);
__fastcall int GetChars(const TBytes Bytes, int ByteIndex, int ByteCount, TCharArray Chars,
int CharIndex);
```

Description

TEncoding.GetChars generates a number of characters by decoding Bytes.

Bytes can be a byte pointer or a byte array.

ByteIndex specifies the first byte to decode. If not present, the index is 0.

ByteCount specifies the number of bytes to decode. If not present, all bytes will be decoded.

Chars is a pointer to the destination of the decoded characters.

CharIndex specifies the maximum number of characters to store.

The **Return Value** is either a character array of the decoded characters, or the number of characters decoded.

See Also

Encoding.GetChars (MSDN)

37.1.45.3.8 TEncoding.GetEncoding Method

Returns the encoding used for the code page supplied.

Pascal

```
class function GetEncoding(CodePage: Integer): TEncoding; static;
```

C++

```
static __fastcall TEncoding GetEncoding(int CodePage);
```

Description

TEncoding.GetEncoding returns the preferred encoding for CodePage.

CodePage must be a valid codepage identifier or one of the CP_XXX constants defined by the Windows API.

See Also

Encoding.GetEncoding (MSDN)

CodePage Identifiers (MSDN)

37.1.45.3.9 TEncoding.GetMaxByteCount Method

Calculates the maximum bytes generated to encode the specified number of characters.

Pascal

```
function GetMaxByteCount(CharCount: Integer): Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetMaxByteCount(int CharCount) = 0;
```

Description

TEncoding.GetMaxByteCount calculates the maximum bytes generated to encode CharCount number of characters.

CharCount must be a positive integer.

The **Return Value** is the number of bytes calculated.

See Also

Encoding.GetMaxByteCount (MSDN)

37.1.45.3.10 TEncoding.GetMaxCharCount Method

Calculates the maximum number of characters generated to decode a specified number of bytes.

Pascal

```
function GetMaxCharCount(ByteCount: Integer): Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetMaxCharCount(int ByteCount) = 0;
```

Description

TEncoding.GetMaxCharCount calculates the maximum number of characters generated to decode **ByteCount** number of bytes.

The **Return Value** is the number of characters calculated.

See Also

Encoding.GetMaxCharCount (MSDN)

37.1.45.3.11 TEncoding.GetPreamble Method

Returns a preamble in a byte array that specifies the encoding used.

Pascal

```
function GetPreamble: TBytes; virtual; abstract;
```

C++

```
virtual __fastcall TBytes GetPreamble() = 0;
```

Description

TEncoding.GetPreamble returns an array of bytes of type TBytes (see page 4339) that contains the preamble required for the encoding used. If no preamble is required a zero length array is returned.

See Also

Encoding.GetPreamble (MSDN)

37.1.45.3.12 GetString Method

This is the overview for the GetString method overload.

Overload List

	Name	Description
	TEncoding.GetString (TBytes) (see page 3981)	Decodes the byte array into a string.
	TEncoding.GetString (TBytes, Integer, Integer) (see page 3981)	Decodes the byte array into a string.

37.1.45.3.12.1 TEncoding.GetString Method (TBytes)

Decodes the byte array into a string.

Pascal

```
function GetString(const Bytes: TBytes): string; overload;
function GetString(const Bytes: TBytes; ByteIndex: Integer; ByteCount: Integer): string;
overload;
```

C++

```
__fastcall UnicodeString GetString(const TBytes Bytes);
__fastcall UnicodeString GetString(const TBytes Bytes, int ByteIndex, int ByteCount);
```

Description

TEncoding.GetString decodes the Bytes byte array into a string.

ByteIndex specifies the first byte to decode.

ByteCount specifies the number of bytes to decode.

Delphi Examples:

```
{
This example converts various string formats to and from Unicode.
This example requires two text edits and a combobox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  LBuffer: TBytes;
  LByteOrderMark: TBytes;
  LFileStream: TFileStream;
  LOffset: Integer;
  LEncoding, DestEncoding: TEncoding;
  ComboIndex: Integer;
  ByteString: RawByteString;
  FileText: string;
  ucs4Text: UCS4String;
  wideStringText: WideString;
  utf8Text: UTF8String;
  L: Cardinal;

begin
  LEncoding:= nil;
  ComboIndex := ComboBox1.ItemIndex;
  LFileStream := TFileStream.Create(Edit1.Text, fmOpenRead);
  try
    // Read file into buffer
    SetLength(LBuffer, LFileStream.Size);
    LFileStream.ReadBuffer(Pointer(LBuffer)^, Length(LBuffer));
    // Get data encoding of data read
    LOffset := TEncoding.GetBufferEncoding(LBuffer, LEncoding);
  finally
    LFileStream.Free;
  end;

  // Process various types
  case ComboIndex of

    // AnsiToUtf8
    0:
    begin
      // Identify encoding and convert buffer to Ansi
      DestEncoding := TEncoding.ASCII;
      LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
        LOffset, Length(LBuffer) - LOffset);
      LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
      FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
      ByteString := AnsiToUtf8(FileText);
      ShowMessage(UTF8ToString(ByteString));

      // Write to file
      LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
      try
        // New destination encoding
        DestEncoding := TEncoding.UTF8;
        LByteOrderMark := DestEncoding.GetPreamble;
        LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
        LFileStream.Write(ByteString[1], Length(ByteString));
      finally
        LFileStream.Free;
      end;
    end;
```

```
      // UCS4StringToWideString
      1:
      begin
        // Identify encoding and convert buffer to UCS4
        DestEncoding := TEncoding.Unicode;
        LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
          LOffset, Length(LBuffer) - LOffset);
        LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
        FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
        ucs4Text := UnicodeStringToUCS4String(FileText);
        wideStringText := UCS4StringToWideString(ucs4Text);
        ShowMessage(wideStringText);

        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
//          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(wideStringText[1], Length(wideStringText) * SizeOf(Char));
        finally
          LFileStream.Free;
        end;
      end;

      // UnicodeToUtf8
      2:
      begin
        // Identify encoding and convert buffer to Unicode
        DestEncoding := TEncoding.Unicode;
        LBuffer := LEncoding.Convert(LEncoding, DestEncoding, LBuffer,
          LOffset, Length(LBuffer) - LOffset);
        LOffset := TEncoding.GetBufferEncoding(LBuffer, DestEncoding);
        FileText := DestEncoding.GetString(LBuffer, LOffset, Length(LBuffer) - LOffset);
        L := Length(FileText);
        SetLength(utf8Text, L * SizeOf(Char) + 1);
        L := UnicodeToUtf8(PAnsiChar(utf8Text), Length(utf8Text), PWideChar(FileText), L);
        ShowMessage(UTF8ToString(utf8Text));

        // Write to file
        LFileStream := TFileStream.Create(Edit2.Text, fmCreate);
        try
          // New destination encoding
          DestEncoding := TEncoding.UTF8;
          LByteOrderMark := DestEncoding.GetPreamble;
          LFileStream.Write(LByteOrderMark[0], Length(LByteOrderMark));
          LFileStream.Write(utf8Text[1], L);
        finally
          LFileStream.Free;
        end;
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    StringList: TStrings;
  begin
    Edit1.Text := 'Sample.txt';
    Edit2.Text := 'Dest.txt';
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('AnsiToUtf8');
```

```
        Add('UCS4StringToWideString');
        Add('UnicodeToUtf8');
      end;
      with ComboBox1 do begin
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

See Also

Encoding.GetString (MSDN)

37.1.45.3.13 TEncoding.IsStandardEncoding Method

Reports if this instance is a standard encoding instance.

Pascal

```
class function IsStandardEncoding(AEncoding: TEncoding): Boolean; static;
```

C++

```
static __fastcall Boolean IsStandardEncoding(TEncoding AEncoding);
```

Description

TEncoding.IsStandardEncoding compares AEncoding to the instances of TEncoding (see page 3969) provided in the TEncoding (see page 3969) class properties: Default (see page 3985), ASCII (see page 3985), BigEndianUnicode (see page 3985), Unicode (see page 3986), UTF7 (see page 3986) and UTF8 (see page 3987). The Return Value specifies if that search was successful.

See Also

ASCII (see page 3985)

BigEndianUnicode (see page 3985)

Default (see page 3985)

Unicode (see page 3986)

UTF7 (see page 3986)

UTF8 (see page 3987)

37.1.45.4 TEncoding Properties

The properties of the TEncoding class are listed here.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

37.1.45.4.1 TEncoding.ASCII Property

Returns an encoding for the ASCII character set.

Pascal

```
class property ASCII: TEncoding;
```

C++

```
__property TEncoding ASCII;
```

Description

TEncoding.ASCII returns an encoding for the ASCII character set.

The **Return Value** is an instance of type TMBCSEncoding (see page 3992).

See Also

Encoding.ASCII (MSDN)

37.1.45.4.2 TEncoding.BigEndianUnicode Property

Returns an encoding for the UTF-16 format with big-endian byte order.

Pascal

```
class property BigEndianUnicode: TEncoding;
```

C++

```
__property TEncoding BigEndianUnicode;
```

Description

TEncoding.BigEndianUnicode returns an encoding for the UTF-16 format with big-endian byte order.

The **Return Value** is an instance of type TBigEndianUnicodeEncoding (see page 3967). This encoding has a byte order mark of hexadecimal FEFF.

See Also

Encoding.BigEndianUnicode (MSDN)

37.1.45.4.3 TEncoding.Default Property

Returns an encoding for the operating system's default ANSI code page.

Pascal

```
class property Default: TEncoding;
```

C++

```
__property TEncoding Default;
```

Description

TEncoding.Default returns an encoding for the operating system's default ANSI code page.

The **Return Value** is an instance of type TMBCSEncoding (see page 3992).

See Also

Encoding.Default (MSDN)

37.1.45.4.4 TEncoding.IsSingleByte Property

This boolean specifies if the current encoding is of single-byte format.

Pascal

```
property IsSingleByte: Boolean;
```

C++

```
__property Boolean IsSingleByte;
```

Description

TEncoding.IsSingleByte specifies if the current encoding is of single-byte format.

See Also

Encoding.IsSingleByte (MSDN)

37.1.45.4.5 TEncoding.Unicode Property

Returns an encoding for the UTF-16 format with little-endian byte order.

Pascal

```
class property Unicode: TEncoding;
```

C++

```
__property TEncoding Unicode;
```

Description

TEncoding.Unicode returns an encoding for the UTF-16 format with little-endian byte order.

The **Return Value** is an instance of type TUnicodeEncoding (see page 4024). This encoding has a byte order mark of hexadecimal FFFE.

See Also

Encoding.Unicode (MSDN)

37.1.45.4.6 TEncoding.UTF7 Property

Returns an encoding for the UTF-7 format.

Pascal

```
class property UTF7: TEncoding;
```

C++

```
__property TEncoding UTF7;
```

Description

TEncoding.UTF7 returns an encoding for the UTF-7 format..

The **Return Value** is an instance of type TUTF7Encoding (see page 4029).

See Also

Encoding.UTF7 (MSDN)

37.1.45.4.7 TEncoding.UTF8 Property

Returns an encoding for the UTF-8 format.

Pascal

```
class property UTF8: TEncoding;
```

C++

```
__property TEncoding UTF8;
```

Description

TEncoding.UTF8 returns an encoding for the UTF-8 format.

The **Return Value** is an instance of type TUTF8Encoding (see page 4034). This encoding has a byte order mark of hexadecimal EFBBBF.

See Also

Encoding.UTF8 (MSDN)

37.1.46 TLanguages Class

TLanguages lists all available Windows locales.

Class Hierarchy

Pascal

```
TLanguages = class;
```

C++

```
class TLanguages;
```

File

SysUtils

Description

The Languages (see page 4223) function returns a TLanguages instance that lists the Windows locales supported by the current system. For each locale, TLanguages indicates the locale ID (see page 3990) (LCID), standard name, and recommended file-name extension. This information is obtained from the operating system; all TLanguages properties are read-only.

See Also

Languages (see page 4223)

37.1.46.1 TLanguages Members

The following tables list the members exposed by TLanguages.

Public Methods

	Name	Description
	Create (see page 3988)	Creates a new TLanguages (see page 3987) object.
	IndexOf (see page 3988)	Returns the index of the first locale in the array with the specified LCID.

Public Properties

	Name	Description
R	Count (see page 3989)	Contains the number of locales listed in the TLanguages (see page 3987) object.
R	Ext (see page 3989)	Contains the standard file-name extension at the specified position in the array.
R	ID (see page 3990)	Contains a locale ID as a string.
R	LocaleID (see page 3990)	Contains a locale ID (see page 3990) as an integer.
R	Name (see page 3991)	Contains the locale name at the specified position in the array.
R	NameFromLCID (see page 3991)	Contains the locale name specified by a string representation of a locale ID (see page 3990).
R	NameFromLocaleID (see page 3991)	Contains the locale name specified by an integer locale ID (see page 3990).

37.1.46.2 TLanguages.Create Constructor

Creates a new TLanguages (see page 3987) object.

Pascal

```
constructor Create;
```

C++

```
__fastcall TLanguages();
```

Description

Do not construct a TLanguages (see page 3987) object directly. Instead, call the Languages (see page 4223) function, which returns an instance of TLanguages (see page 3987) with locale information obtained from Windows.

See Also

Languages (see page 4223)

37.1.46.3 TLanguages Methods

The methods of the TLanguages class are listed here.

Public Methods

	Name	Description
	IndexOf (see page 3988)	Returns the index of the first locale in the array with the specified LCID.

37.1.46.3.1 TLanguages.IndexOf Method

Returns the index of the first locale in the array with the specified LCID.

Pascal

```
function IndexOf(ID: LCID): Integer;
```

C++

```
__fastcall int IndexOf(LCID ID);
```

Description

Call IndexOf to get the position in the array of a specified locale ID (see page 3990). For example, if U.S. English is the first locale listed in TLanguages (see page 3987), then IndexOf($0409) returns 0.

If the specified LCID is not found, IndexOf returns -1.

See Also

Ext (see page 3989)

ID (see page 3990)

LocaleID (see page 3990)

Name (see page 3991)

37.1.46.4 TLanguages Properties

The properties of the TLanguages class are listed here.

Public Properties

	Name	Description
	Count (see page 3989)	Contains the number of locales listed in the TLanguages (see page 3987) object.
	Ext (see page 3989)	Contains the standard file-name extension at the specified position in the array.
	ID (see page 3990)	Contains a locale ID as a string.
	LocaleID (see page 3990)	Contains a locale ID (see page 3990) as an integer.
	Name (see page 3991)	Contains the locale name at the specified position in the array.
	NameFromLCID (see page 3991)	Contains the locale name specified by a string representation of a locale ID (see page 3990).
	NameFromLocaleID (see page 3991)	Contains the locale name specified by an integer locale ID (see page 3990).

37.1.46.4.1 TLanguages.Count Property

Contains the number of locales listed in the TLanguages (see page 3987) object.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read (see page 3634) Count to determine the number of locales supported by the current system.

See Also

ID (see page 3990)

LocaleID (see page 3990)

IndexOf (see page 3988)

37.1.46.4.2 TLanguages.Ext Property

Contains the standard file-name extension at the specified position in the array.

Pascal

```
property Ext [Index: Integer]: string;
```

C++

```
__property UnicodeString Ext[int Index];
```

Description

Read (see page 3634) Ext to get the standard three-letter file-name extension for a locale. For example, Ext[IndexOf (see page 3988)($0409)] returns the string ENU.

Ext is a zero-based array.

See Also

IndexOf (see page 3988)

37.1.46.4.3 TLanguages.ID Property

Contains a locale ID as a string.

Pascal

```
property ID [Index: Integer]: string;
```

C++

```
__property UnicodeString ID[int Index];
```

Description

Read (see page 3634) ID to get the locale ID at a specified position in the array as a string. (To get the same ID as an integer, use the LocaleID (see page 3990) property.) For example, if U.S. English is the first locale listed in TLanguages (see page 3987), then ID[0] returns the string $00000409. You can iterate through the ID array (from 0 to Count (see page 3989) - 1) to determine whether a specific locale is in the array.

See Also

Count (see page 3989)

LocaleID (see page 3990)

37.1.46.4.4 TLanguages.LocaleID Property

Contains a locale ID (see page 3990) as an integer.

Pascal

```
property LocaleID [Index: Integer]: LCID;
```

C++

```
__property LCID LocaleID[int Index];
```

Description

Read (see page 3634) LocaleID to get the locale ID (see page 3990) at a specified position in the array as an integer. (To get the same ID (see page 3990) as a string, use the ID (see page 3990) property.) For example, if U.S. English is the first locale listed in TLanguages (see page 3987), then LocaleID[0] returns the integer $409. You can iterate through the LocaleID array (from 0 to Count (see page 3989) - 1) to determine whether a specific locale is in the array.

See Also

Count (see page 3989)

ID (see page 3990)

37.1.46.4.5 TLanguages.Name Property

Contains the locale name at the specified position in the array.

Pascal

```
property Name [Index: Integer]: string;
```

C++

```
__property UnicodeString Name[int Index];
```

Description

Read (see page 3634) Name to get the standard Windows name for a locale. For example, Name[IndexOf (see page 3988)($0409)] returns the string English (United States).

Name is a zero-based array.

See Also

IndexOf (see page 3988)

NameFromLCID (see page 3991)

NameFromLocaleID (see page 3991)

37.1.46.4.6 TLanguages.NameFromLCID Property

Contains the locale name specified by a string representation of a locale ID (see page 3990).

Pascal

```
property NameFromLCID [const ID: string]: string;
```

C++

```
__property UnicodeString NameFromLCID[UnicodeString const ID];
```

Description

Read (see page 3634) NameFromLCID to get the standard Windows name for a locale using a locale ID (see page 3990) represented by a string.

See Also

Name (see page 3991)

NameFromLocaleID (see page 3991)

37.1.46.4.7 TLanguages.NameFromLocaleID Property

Contains the locale name specified by an integer locale ID (see page 3990).

Pascal

```
property NameFromLocaleID [ID: LCID]: string;
```

C++

```
__property UnicodeString NameFromLocaleID[LCID ID];
```

Description

Read (see page 3634) NameFromLocaleID to get the standard Windows name for a locale using an integer locale ID (see page 3990). For example, NameFromLCID (see page 3991)[$0409] returns the string English (United States).

See Also

NameFromLCID (see page 3991)

Name (see page 3991)

37.1.47 TMBCSEncoding Class

Class Hierarchy

Pascal

```
TMBCSEncoding = class(TEncoding);
```

C++

```
class TMBCSEncoding : public TEncoding;
```

File

SysUtils

Description

This is class SysUtils.TMBCSEncoding.

37.1.47.1 TMBCSEncoding Members

The following tables list the members exposed by TMBCSEncoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
V	Create (see page 3993)	This is the overview for the Create constructor overload.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
V	GetMaxByteCount (see page 3996)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxCharCount (see page 3996)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetPreamble (see page 3997)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.

R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
V	GetByteCount (see page 3994)	Returns the number of bytes generated by encoding Chars.
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
V	GetBytes (see page 3995)	Encodes a set of characters into a sequence of bytes.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
V	GetCharCount (see page 3995)	Calcuates a number of characters generated by decoding a sequence of bytes.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
V	GetChars (see page 3996)	Decodes a set of bytes into a set of characters.
A	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.47.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
V	TMBCSEncoding.Create () (see page 3993)	This is Create, a member of class TMBCSEncoding.
V	TMBCSEncoding.Create (Integer) (see page 3993)	This is Create, a member of class TMBCSEncoding.
V	TMBCSEncoding.Create (Integer, Integer, Integer) (see page 3994)	This is Create, a member of class TMBCSEncoding.

37.1.47.2.1 TMBCSEncoding.Create Constructor ()

Pascal

```
constructor Create; virtual; overload;
```

C++

```
virtual __fastcall TMBCSEncoding();
```

Description

This is Create, a member of class TMBCSEncoding.

37.1.47.2.2 TMBCSEncoding.Create Constructor (Integer)

Pascal

```
constructor Create(CodePage: Integer); virtual; overload;
```

C++

```
virtual __fastcall TMBCSEncoding(int CodePage);
```

Description

This is Create, a member of class TMBCSEncoding.

37.1.47.2.3 TMBCSEncoding.Create Constructor (Integer, Integer, Integer)

Pascal

```
constructor Create(CodePage: Integer; MBToWCharFlags: Integer; WCharToMBFlags: Integer);
virtual; overload;
```

C++

```
virtual __fastcall TMBCSEncoding(int CodePage, int MBToWCharFlags, int WCharToMBFlags);
```

Description

This is Create, a member of class TMBCSEncoding.

37.1.47.3 TMBCSEncoding Methods

The methods of the TMBCSEncoding class are listed here.

Public Methods

	Name	Description
	GetMaxByteCount (see page 3996)	Calculates the maximum bytes generated to encode the specified number of characters.
	GetMaxCharCount (see page 3996)	Calculates the maximum number of characters generated to decode a specified number of bytes.
	GetPreamble (see page 3997)	Returns a preamble in a byte array that specifies the encoding used.

Strict protected Methods

	Name	Description
	GetByteCount (see page 3994)	Returns the number of bytes generated by encoding Chars.
	GetBytes (see page 3995)	Encodes a set of characters into a sequence of bytes.
	GetCharCount (see page 3995)	Calcuates a number of characters generated by decoding a sequence of bytes.
	GetChars (see page 3996)	Decodes a set of bytes into a set of characters.

37.1.47.3.1 TMBCSEncoding.GetByteCount Method

Returns the number of bytes generated by encoding Chars.

Pascal

```
function GetByteCount(Chars: PChar; CharCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetByteCount(const char * Chars, int CharCount);
```

Description

Returns the number of bytes generated by encoding Chars. Note that the number of bytes in a string is not necessarily exactly proportional to the number of characters in a given character array or string.

The **Chars** parameter can be a character array or a character pointer containing the bytes to be counted.

The **S** parameter refers to a UnicodeString from which the Byte count will be extracted.

The **CharCount** parameter specifies the number of characters to encode.

The **CharIndex** parameter indicates the index within the Chars array where counting should begin.

The **CharCount** parameter indicates the number of characters that should be included when counting the bytes.

The Return Value is the number of bytes in the passed Chars or S parameter.

See Also

Encoding.GetByteCount (MSDN)

37.1.47.3.2 TMBCSEncoding.GetBytes Method

Encodes a set of characters into a sequence of bytes.

Pascal

```
function GetBytes(Chars: PChar; CharCount: Integer; Bytes: PByte; ByteCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetBytes(const char * Chars, int CharCount, PByte Bytes, int ByteCount);
```

Description

TEncoding.GetBytes encodes Chars parameter into a sequence of bytes.

Chars can be a character array or a character pointer which will be encoded into a sequence of bytes.

S is a string of type UnicodeString to be encoded into a sequence of bytes.

The **CharCount** parameter specifies the number of characters to encode.

Bytes specifies the location to write the sequence of bytes.

ByteCount is the maximum number of bytes that can be written to the given location.

The **Return Value** is the number of bytes actually encoded or the actual TBytes sequence of bytes.

See Also

Encoding.GetBytes (MSDN)

37.1.47.3.3 TMBCSEncoding.GetCharCount Method

Calcuates a number of characters generated by decoding a sequence of bytes.

Pascal

```
function GetCharCount(Bytes: PByte; ByteCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetCharCount(PByte Bytes, int ByteCount);
```

Description

TEncoding.GetCharCount generates a number of characters by decoding **Bytes**.

Bytes can be a byte array, or a byte pointer.

The **ByteCount** parameter specifies the number of bytes to decode.

The **Return Value** is the number of characters decoded.

See Also

Encoding.GetCharCount (MSDN)

37.1.47.3.4 TMBCSEncoding.GetChars Method

Decodes a set of bytes into a set of characters.

Pascal

```
function GetChars(Bytes: PByte; ByteCount: Integer; Chars: PChar; CharCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetChars(PByte Bytes, int ByteCount, const char * Chars, int CharCount);
```

Description

TEncoding.GetChars generates a number of characters by decoding Bytes.

Bytes can be a byte pointer or a byte array.

ByteIndex specifies the first byte to decode. If not present, the index is 0.

ByteCount specifies the number of bytes to decode. If not present, all bytes will be decoded.

Chars is a pointer to the destination of the decoded characters.

CharIndex specifies the maximum number of characters to store.

The **Return Value** is either a character array of the decoded characters, or the number of characters decoded.

See Also

Encoding.GetChars (MSDN)

37.1.47.3.5 TMBCSEncoding.GetMaxByteCount Method

Calculates the maximum bytes generated to encode the specified number of characters.

Pascal

```
function GetMaxByteCount(CharCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxByteCount(int CharCount);
```

Description

TEncoding.GetMaxByteCount calculates the maximum bytes generated to encode CharCount number of characters.

CharCount must be a positive integer.

The **Return Value** is the number of bytes calculated.

See Also

Encoding.GetMaxByteCount (MSDN)

37.1.47.3.6 TMBCSEncoding.GetMaxCharCount Method

Calculates the maximum number of characters generated to decode a specified number of bytes.

Pascal

```
function GetMaxCharCount(ByteCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxCharCount(int ByteCount);
```

Description

TEncoding.GetMaxCharCount calculates the maximum number of characters generated to decode **ByteCount** number of bytes.

The **Return Value** is the number of characters calculated.

See Also

Encoding.GetMaxCharCount (MSDN)

37.1.47.3.7 TMBCSEncoding.GetPreamble Method

Returns a preamble in a byte array that specifies the encoding used.

Pascal

```
function GetPreamble: TBytes; override;
```

C++

```
virtual __fastcall TBytes GetPreamble();
```

Description

TEncoding.GetPreamble returns an array of bytes of type TBytes that contains the preamble required for the encoding used. If no preamble is required a zero length array is returned.

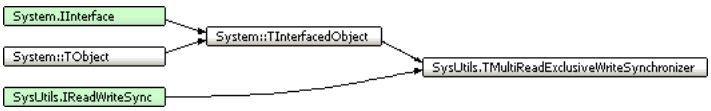
See Also

Encoding.GetPreamble (MSDN)

37.1.48 TMultiReadExclusiveWriteSynchronizer Class

TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.

Class Hierarchy



Pascal

```
TMultiReadExclusiveWriteSynchronizer = class(TInterfacedObject, IReadWriteSync);
```

C++

```
class TMultiReadExclusiveWriteSynchronizer : public TInterfacedObject, public IReadWriteSync;
```

File

SysUtils

Description

Use TMultiReadExclusiveWriteSynchronizer to guard access to memory in a multi-threaded application. Unlike a critical section,

which blocks all other threads from reading or writing its associated memory, TMultiReadExclusiveWriteSynchronizer allows multiple threads to read from the protected memory simultaneously, while ensuring that any thread writing to the memory has exclusive access.

In applications where threads read from an object or variable frequently and only write to it occasionally, using the multi-read exclusive-write synchronizer instead of a critical section can result in considerable performance improvement.

All access to the protected memory must be bracketed by calls to the BeginRead (see page 4000) and EndRead (see page 4001) or BeginWrite (see page 4000) and EndWrite (see page 4001) methods. Any thread that reads from or writes to this memory without using these calls can introduce thread conflicts.

TCriticalSection (see page 3125)

TThread

Using the Multi-read Exclusive-write Synchronizer

37.1.48.1 TMultiReadExclusiveWriteSynchronizer Members

The following tables list the members exposed by TMultiReadExclusiveWriteSynchronizer.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	BeginRead (see page 4000)	Allows a thread to read from the protected memory when it is safe to do so.
	BeginWrite (see page 4000)	Allows a thread to write to the protected memory when it is safe to do so.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3999)	Creates and initializes an instance of TMultiReadExclusiveWriteSynchronizer (see page 3997).
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.

	Destroy (see page 3999)	Destroys an instance of TMultiReadExclusiveWriteSynchronizer (see page 3997).
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndRead (see page 4001)	Removes a thread from the internal list of threads that are accessing the protected memory.
	EndWrite (see page 4001)	Allows other threads to access the associated memory.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.
	RevisionLevel (see page 4002)	Changes revision level of protected memory.

37.1.48.2 TMultiReadExclusiveWriteSynchronizer.Create Constructor

Creates and initializes an instance of TMultiReadExclusiveWriteSynchronizer (see page 3997).

Pascal

```
constructor Create;
```

C++

```
__fastcall TMultiReadExclusiveWriteSynchronizer();
```

Description

Call Create to instantiate TMultiReadExclusiveWriteSynchronizer (see page 3997). The synchronizer must be created in the same thread as the memory it protects, so that it is accessible to all threads that need to access that memory.

37.1.48.3 TMultiReadExclusiveWriteSynchronizer.Destroy Destructor

Destroys an instance of TMultiReadExclusiveWriteSynchronizer (see page 3997).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMultiReadExclusiveWriteSynchronizer();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TMultiReadExclusiveWriteSynchronizer (see page 3997) reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

37.1.48.4 TMultiReadExclusiveWriteSynchronizer Methods

The methods of the TMultiReadExclusiveWriteSynchronizer class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 4000)	Allows a thread to read from the protected memory when it is safe to do so.
	BeginWrite (see page 4000)	Allows a thread to write to the protected memory when it is safe to do so.
	EndRead (see page 4001)	Removes a thread from the internal list of threads that are accessing the protected memory.
	EndWrite (see page 4001)	Allows other threads to access the associated memory.

37.1.48.4.1 TMultiReadExclusiveWriteSynchronizer.BeginRead Method

Allows a thread to read from the protected memory when it is safe to do so.

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

Call BeginRead before reading from the memory protected by the multi-read exclusive-write synchronizer. BeginRead does not return until there are no other threads writing to the memory. After calling BeginRead, other threads can be granted read access to the protected memory by the BeginRead method. However, any thread asking for write permission by calling BeginWrite (see page 4000) must wait until all reading threads have called EndRead (see page 4001).

See Also

EndRead (see page 4001)

BeginWrite (see page 4000)

Using the Multi-read Exclusive-write Synchronizer

37.1.48.4.2 TMultiReadExclusiveWriteSynchronizer.BeginWrite Method

Allows a thread to write to the protected memory when it is safe to do so.

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

BeginWrite obtains an exclusive write lock on the memory protected by the synchronizer object. Call BeginWrite before writing to this memory. BeginWrite does not return until no other threads are reading from or writing to the memory. After a thread calls BeginWrite, any other thread asking to access that memory by calling BeginRead (see page 4000) or BeginWrite must wait until the writing thread calls EndWrite (see page 4001).

Note that a write lock operation is not atomic. Data in protected memory will always be in a consistent state when BeginWrite returns, but is not necessarily in the same state as when BeginWrite was called. As a rule, a thread should always discard previous samples from protected memory after promoting a read lock to a write lock. However, the calling thread can determine whether a state change has occurred by examining return value of BeginWrite: true if protected memory has not be written to by another thread, false if another thread may have modified protected memory.

See Also

EndWrite (see page 4001)

BeginRead (see page 4000)

Using the Multi-read Exclusive-write Synchronizer

37.1.48.4.3 TMultiReadExclusiveWriteSynchronizer.EndRead Method

Removes a thread from the internal list of threads that are accessing the protected memory.

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

Call EndRead after reading from the memory protected by the multi-read exclusive-write synchronizer. Each call to BeginRead (see page 4000) must be matched by a call to EndRead, or other threads can never return from the BeginWrite (see page 4000) method.

See Also

BeginRead (see page 4000)

BeginWrite (see page 4000)

Using the Multi-read Exclusive-write Synchronizer

37.1.48.4.4 TMultiReadExclusiveWriteSynchronizer.EndWrite Method

Allows other threads to access the associated memory.

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

Call EndWrite after writing to the memory that is protected by the multi-read exclusive-write synchronizer. Each call to BeginWrite (see page 4000) must be matched by a call to EndWrite, or other threads can never return from the BeginRead (see page 4000) or BeginWrite (see page 4000) methods.

See Also

BeginWrite (see page 4000)

BeginRead (see page 4000)

Using the Multi-read Exclusive-write Synchronizer

37.1.48.5 TMultiReadExclusiveWriteSynchronizer Properties

The properties of the TMultiReadExclusiveWriteSynchronizer class are listed here.

Public Properties

	Name	Description
	RevisionLevel (see page 4002)	Changes revision level of protected memory.

37.1.48.5.1 TMultiReadExclusiveWriteSynchronizer.RevisionLevel Property

Changes revision level of protected memory.

Pascal

```
property RevisionLevel: Cardinal;
```

C++

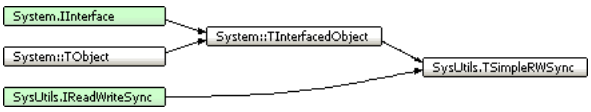
```
__property unsigned RevisionLevel;
```

Description

RevisionLevel changes each time a write lock is granted. This property should be used for identity comparisons only, not for determining revision sequence.

37.1.49 TSimpleRWSync Class

Class Hierarchy



Pascal

```
TSimpleRWSync = class(TInterfacedObject, IReadWriteSync);
```

C++

```
class TSimpleRWSync : public TInterfacedObject, public IReadWriteSync;
```

File

SysUtils

Description

This is class SysUtils.TSimpleRWSync.

37.1.49.1 TSimpleRWSync Members

The following tables list the members exposed by TSimpleRWSync.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	BeginRead (see page 4005)	This is BeginRead, a member of class TSimpleRWSync.
	BeginWrite (see page 4005)	This is BeginWrite, a member of class TSimpleRWSync.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 4004)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 4004)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndRead (see page 4006)	This is EndRead, a member of class TSimpleRWSync.
	EndWrite (see page 4006)	This is EndWrite, a member of class TSimpleRWSync.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.

	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

37.1.49.2 TSimpleRWSync.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
__fastcall TSimpleRWSync();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 3356)

System::TObject::Free (see page 3372)

37.1.49.3 TSimpleRWSync.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSimpleRWSync();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

37.1.49.4 TSimpleRWSync Methods

The methods of the TSimpleRWSync class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 4005)	This is BeginRead, a member of class TSimpleRWSync.
	BeginWrite (see page 4005)	This is BeginWrite, a member of class TSimpleRWSync.
	EndRead (see page 4006)	This is EndRead, a member of class TSimpleRWSync.
	EndWrite (see page 4006)	This is EndWrite, a member of class TSimpleRWSync.

37.1.49.4.1 TSimpleRWSync.BeginRead Method

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

This is BeginRead, a member of class TSimpleRWSync.

37.1.49.4.2 TSimpleRWSync.BeginWrite Method

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

This is BeginWrite, a member of class TSimpleRWSync.

37.1.49.4.3 TSimpleRWSync.EndRead Method

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

This is EndRead, a member of class TSimpleRWSync.

37.1.49.4.4 TSimpleRWSync.EndWrite Method

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

This is EndWrite, a member of class TSimpleRWSync.

37.1.50 TStringBuilder Class

An editable array of characters whose contents has all the functionality of a string object.

Class Hierarchy

Pascal

```
TStringBuilder = class;
```

C++

```
class TStringBuilder;
```

File

SysUtils

Description

Use a TStringBuilder as an editable string.

The TStringBuilder class is completely compatable with the .Net framework's StringBuilder (MSDN) class. Use a TStringBuilder instance to hold a character array. This array can be modified after creation. Substrings can be appended, searched and replaced, or inserted. The character array can be queried by index or converted to a string for comparison.

The character array can be referenced directly by using the Chars (see page 4022) property. The Length (see page 4022) property contains the current length of the character array.

builder.Length (see page 4022) = builder.ToString.Length (see page 4022);

The Capacity (see page 4021) property holds the current allocated storage space for this TStringBuilder instance. Capacity (see page 4021) can be increased up to the value of MaxCapacity (see page 4022) and down to the current value of Length (see page 4022). Capacity (see page 4021) is increased if Length (see page 4022) is increased, or the character array is altered by appending to increase it's length.

The Append (see page 4014) method converts a multitude of possible types to a string and appends that to the current character array. AppendFormat (see page 4015) allows you to append several objects to the character array, each object with it's own format.

The Equals (see page 4017) method compares a specified object or another TStringBuilder to this instance of TStringBuilder.

The Append (see page 4014), CopyTo (see page 4016), Insert (see page 4018), Remove (see page 4019) and Replace (see page 4020) methods access the character array by index or search the character as a string. The ToString (see page 4021) method converts the character array to a string to provide string functionality.

TStringBuilder is an implementation of the .NET StringBuilder (MSDN) class.

C++ Examples:

```
/*
This example exercises many of the members of the TStringBuilder class.
*/
template <class T>
void testAppend(T t)
{
    std::auto_ptr<TStringBuilder> builder(new TStringBuilder());
    builder->Append(t);
    UnicodeString s1 = builder->ToString();
    UnicodeString s2(t);
    assert(s1 == s2);
}

#if defined(_DELPHI_STRING_UNICODE)
const wchar_t* ext_chars =
    L"Ð• Ð‘ Ð’ Ð“ Ð„ Ð… Ð† Ð‡ Ðˆ Ð‰"
    L"Ðš Ð› Ðœ Ð• Ðž ÐŸ Ò€ Ð  Ð¡ Ð¢ Ñ„"
    L"Ð¤ Ð¥ Ñ  Ð¦ Ð§ Ð¨ Ð© Ðª Ð« Ð¬ Ñ¢"
    L"Ð® Ð†Ð• Ñ¦ Ñ¨ Ñª Ñ¬ Ñ® Ñ° Ñ² Ñ´ Ñ¤";
#else
const char* ext_chars =
    "Ã€ Ã• Ã‚ Ãƒ Ã„ Ã… Ã† Ã‡ Ãˆ Ã‰ Ãˆ Ã‹ Ãœ Ã• ÃŽ Ã•"
    "Ã• Ã‘ Ã’ Ã“ Ã” Ã• Ã– Ã— Ã˜ Ã™ Ãš Ã› Ãœ Ã• Ãž ÃŸ"
    "Ã  Ã¡ Ã¢ Ã£ Ã¤ Ã¥ Ã¦ Ã§ Ã¨ Ã© Ãª Ã« Ã¬ Ã- Ã® Ã¯"
    "Ã° Ã± Ã² Ã³ Ã´ Ãµ Ã¶ Ã· Ã¸ Ã¹ Ãº Ã» Ã¼ Ã½ Ã¾ Ã¿";
#endif

//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    {
        // Test starts out as empty
        std::auto_ptr<TStringBuilder> builder(new TStringBuilder());
        assert(builder->ToString() == System::String());
    }

    {
        // Append
        short s = 0xffe;
        testAppend(s);

        unsigned short us = 0xfffe;
        testAppend(us);
```

```
}

{
    const _DCHAR* p = ext_chars;

    std::auto_ptr<TStringBuilder> builder(new TStringBuilder());
    System::String str1(p);

    // Appending of wchar_t
    while (*p)
    {
        builder->Append(*p++);
    }

    // Length property
    assert(builder->Length == str1.Length());

    // Subscript operator
    for (int i=0; i<str1.Length(); i++)
    {
        // NOTE: strings are 1-based
        assert((*(builder.get()))[i] == str1[i+1]);
    }

    // ToString()
    System::String str2 = builder->ToString();
    Edit1->Text = str1;
    Edit2->Text = str2;
    assert(str2 == str1);

    // Replace
    builder->Replace(' ', '.');
    UnicodeString str3;
    str3 = builder->ToString();
    Edit3->Text = str3;
    assert(str3 != str2);

    // Replace back
    builder->Replace(L'.', L' ');
    System::String str4 = builder->ToString();
    Edit4->Text = str4;
    assert(str2 == str4);
}

{
    System::String str(ext_chars);

    std::auto_ptr<TStringBuilder> builder(new TStringBuilder());

    // Insert at start when empty, at start when not empty and at end
    builder->Insert(0, str);
    builder->Insert(0, str);
    builder->Insert(builder->Length, str);

    // Concatenate string 3 times
    System::String str2;
    str2 += str;
    str2 += str;
    str2 += str;

    str = builder->ToString();

    Edit5->Text = str;
    assert(builder->ToString() == str2);
}
MessageDlg("All assertions passed in the TStringBuilder Test test.",
```

```
        mtInformation, TMsgDlgButtons() << mbOK, 0);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button2Click(TObject *Sender)
{
    const _DCHAR* p = ext_chars;

    std::auto_ptr<TStringBuilder> builder(new TStringBuilder());

    // Appending of chars
    while (*p)
    {
        builder->Append(*p++);
    }

    System::String str1(ext_chars);
    System::String str2 = builder->ToString();
    assert(str1 == str2);

    builder->Replace(_D(" "), _D("."));
    System::String str3;
    str3 = builder->ToString();
    assert(str1 != str3);

    builder->Replace(_D("."), _D(" "));
    System::String str4(builder->ToString());
    assert(str1 == str4);
    MessageDlg("All assertions passed in the TStringBuilder Replace test.",
        mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

StringBuilder (MSDN)

37.1.50.1 TStringBuilder Members

The following tables list the members exposed by TStringBuilder.

Protected Fields

	Name	Description
	FData (see page 4012)	This is FData, a member of class TStringBuilder.
	FLength (see page 4012)	This is FLength, a member of class TStringBuilder.
	FMaxCapacity (see page 4012)	This is FMaxCapacity, a member of class TStringBuilder.

Public Methods

	Name	Description
	Append (see page 4013)	This is the overview for the Append method overload.
	AppendFormat (see page 4015)	Appends a number of objects to the current character array in this TStringBuilder (see page 4006) instance.
	AppendLine (see page 4015)	This is the overview for the AppendLine method overload.
	CopyTo (see page 4016)	Copys a part of the instance character array into a destination string.
	Create (see page 4010)	This is the overview for the Create constructor overload.
	EnsureCapacity (see page 4016)	Sets the Capacity (see page 4021) property to the supplied value, if the new capacity is larger than the old capacity.
	Equals (see page 4017)	Compares the character array in the Chars (see page 4022) property, the Capacity (see page 4021) property, and the MaxCapacity (see page 4022) property of this instance to that of a supplied TStringBuilder (see page 4006) instance.
	Insert (see page 4017)	This is the overview for the Insert method overload.
	Remove (see page 4019)	Removes a substring from the character array of this instance.
	Replace (see page 4019)	This is the overview for the Replace method overload.
V	ToString (see page 4020)	This is the overview for the ToString method overload.

Public Properties

	Name	Description
	Capacity (see page 4021)	Used to get or set the maximum number of characters that can be stored in this TStringBuilder (see page 4006) instance.
	Chars (see page 4022)	Used to get or set the characters stored in this TStringBuilder (see page 4006) instance.
	Length (see page 4022)	Used to get or set the size of the character array stored in this TStringBuilder (see page 4006) instance.
R	MaxCapacity (see page 4022)	Used to get the maximum size allowed of the character array stored in this TStringBuilder (see page 4006) instance.

37.1.50.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TStringBuilder.Create () (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).
	TStringBuilder.Create (Integer) (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).
	TStringBuilder.Create (Integer, Integer) (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).

	TStringBuilder.Create (string) (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).
	TStringBuilder.Create (string, Integer) (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).
	TStringBuilder.Create (string, Integer, Integer, Integer) (see page 4011)	Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).

37.1.50.2.1 TStringBuilder.Create Constructor ()

Allocates memory and constructs a safely initialized instance of a TStringBuilder (see page 4006).

Pascal

```
constructor Create; overload;
constructor Create(aCapacity: Integer); overload;
constructor Create(const Value: string); overload;
constructor Create(aCapacity: Integer; aMaxCapacity: Integer); overload;
constructor Create(const Value: string; aCapacity: Integer); overload;
constructor Create(const Value: string; StartIndex: Integer; Length: Integer; aCapacity:
Integer); overload;
```

C++

```
__fastcall TStringBuilder();
__fastcall TStringBuilder(int aCapacity);
__fastcall TStringBuilder(const UnicodeString Value);
__fastcall TStringBuilder(int aCapacity, int aMaxCapacity);
__fastcall TStringBuilder(const UnicodeString Value, int aCapacity);
__fastcall TStringBuilder(const UnicodeString Value, int StartIndex, int Length, int
aCapacity);
```

Description

Use Create to Create an instance of the TStringBuilder (see page 4006) class.

aCapacity specifies the initial value of the Capacity (see page 4021) property, the maximum number of characters this TStringBuilder (see page 4006) instance can hold. The value of the Capacity (see page 4021) property can be changed.

Value specifies the initial character array to be stored in this TStringBuilder (see page 4006) instance.

aMaxCapacity is the maximum value that the Capacity (see page 4021) property can be for this instance of the TStringBuilder (see page 4006) class.

StartIndex specifies the index of the first character in the Value string to be copied into the initial character array of this TStringBuilder (see page 4006) instance.

Length (see page 4022) is the number of characters to copy from the Value string into the initial character array of this TStringBuilder (see page 4006) instance.

37.1.50.3 TStringBuilder Fields

The fields of the TStringBuilder class are listed here.

Protected Fields

	Name	Description
	FData (see page 4012)	This is FData, a member of class TStringBuilder.
	FLength (see page 4012)	This is FLength, a member of class TStringBuilder.
	FMaxCapacity (see page 4012)	This is FMaxCapacity, a member of class TStringBuilder.

37.1.50.3.1 TStringBuilder.FData Field

Pascal

```
FData: TCharArray;
```

C++

```
TCharArray FData;
```

Description

This is FData, a member of class TStringBuilder.

37.1.50.3.2 TStringBuilder.FLength Field

Pascal

```
FLength: Integer;
```

C++

```
int FLength;
```

Description

This is FLength, a member of class TStringBuilder.

37.1.50.3.3 TStringBuilder.FMaxCapacity Field

Pascal

```
FMaxCapacity: Integer;
```

C++

```
int FMaxCapacity;
```

Description

This is FMaxCapacity, a member of class TStringBuilder.

37.1.50.4 TStringBuilder Methods

The methods of the TStringBuilder class are listed here.

Public Methods

	Name	Description
	Append (see page 4013)	This is the overview for the Append method overload.
	AppendFormat (see page 4015)	Appends a number of objects to the current character array in this TStringBuilder (see page 4006) instance.
	AppendLine (see page 4015)	This is the overview for the AppendLine method overload.
	CopyTo (see page 4016)	Copys a part of the instance character array into a destination string.

	EnsureCapacity (see page 4016)	Sets the Capacity (see page 4021) property to the supplied value, if the new capacity is larger than the old capacity.
	Equals (see page 4017)	Compares the character array in the Chars (see page 4022) property, the Capacity (see page 4021) property, and the MaxCapacity (see page 4022) property of this instance to that of a supplied TStringBuilder (see page 4006) instance.
	Insert (see page 4017)	This is the overview for the Insert method overload.
	Remove (see page 4019)	Removes a substring from the character array of this instance.
	Replace (see page 4019)	This is the overview for the Replace method overload.
	ToString (see page 4020)	This is the overview for the ToString method overload.

37.1.50.4.1 Append Method

This is the overview for the Append method overload.

Overload List

	Name	Description
	TStringBuilder.Append (Boolean) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Byte) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Cardinal) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Char) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Char, Integer) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Currency) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Double) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Int64) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Integer) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Shortint) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Single) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.

	TStringBuilder.Append (Smallint) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (string) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (string, Integer, Integer) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (TCharArray) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (TCharArray, Integer, Integer) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (TObject) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (UInt64) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.
	TStringBuilder.Append (Word) (see page 4014)	Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.

37.1.50.4.1.1 TStringBuilder.Append Method (Boolean)

Appends a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.

Pascal

```
function Append(const Value: Boolean): TStringBuilder; overload;
function Append(const Value: Byte): TStringBuilder; overload;
function Append(const Value: Char): TStringBuilder; overload;
function Append(const Value: Currency): TStringBuilder; overload;
function Append(const Value: Double): TStringBuilder; overload;
function Append(const Value: Smallint): TStringBuilder; overload;
function Append(const Value: Integer): TStringBuilder; overload;
function Append(const Value: Int64): TStringBuilder; overload;
function Append(const Value: TObject): TStringBuilder; overload;
function Append(const Value: Shortint): TStringBuilder; overload;
function Append(const Value: Single): TStringBuilder; overload;
function Append(const Value: string): TStringBuilder; overload;
function Append(const Value: UInt64): TStringBuilder; overload;
function Append(const Value: TCharArray): TStringBuilder; overload;
function Append(const Value: Word): TStringBuilder; overload;
function Append(const Value: Cardinal): TStringBuilder; overload;
function Append(const Value: Char; RepeatCount: Integer): TStringBuilder; overload;
function Append(const Value: TCharArray; StartIndex: Integer; CharCount: Integer):
TStringBuilder; overload;
function Append(const Value: string; StartIndex: Integer; Count: Integer): TStringBuilder;
overload;
```

C++

```
__fastcall TStringBuilder Append(const Boolean Value);
__fastcall TStringBuilder Append(const Byte Value);
```

```
__fastcall TStringBuilder Append(const Char Value);
__fastcall TStringBuilder Append(const Currency Value);
__fastcall TStringBuilder Append(const Double Value);
__fastcall TStringBuilder Append(const Smallint Value);
__fastcall TStringBuilder Append(const int Value);
__fastcall TStringBuilder Append(const Int64 Value);
__fastcall TStringBuilder Append(const TObject * Value);
__fastcall TStringBuilder Append(const Shortint Value);
__fastcall TStringBuilder Append(const Single Value);
__fastcall TStringBuilder Append(const UnicodeString Value);
__fastcall TStringBuilder Append(const UInt64 Value);
__fastcall TStringBuilder Append(const TCharArray Value);
__fastcall TStringBuilder Append(const Word Value);
__fastcall TStringBuilder Append(const unsigned Value);
__fastcall TStringBuilder Append(const Char Value, int RepeatCount);
__fastcall TStringBuilder Append(const TCharArray Value, int StartIndex, int CharCount);
__fastcall TStringBuilder Append(const UnicodeString Value, int StartIndex, int Count);
```

Description

Use Append to append a string representation of the supplied argument to the current character array in this TStringBuilder (see page 4006) instance.

In the case where **Value** is a Char, **Value** is a Unicode character and repeatedly appended to the end of theTStringBuilder string **Count** number of times.

The two overloads that use the parameters **CharCount** or **Count** append a substring. **StartIndex** indicates the first character is the string **Value** to append, and **CharCount** or **Count** specifies the number of characters to append.

See Also

StringBuilder.Append (MSDN)

37.1.50.4.2 TStringBuilder.AppendFormat Method

Appends a number of objects to the current character array in this TStringBuilder (see page 4006) instance.

Pascal

```
function AppendFormat(const Format: string; const Args: array of const): TStringBuilder;
overload;
```

C++

```
__fastcall TStringBuilder AppendFormat(const UnicodeString Format, const array of const Args);
```

Description

Use AppendFormat to append a number of objects to the current character array in this TStringBuilder (see page 4006) instance. The objects are represented by a string of format specifications and an array of objects to format. There is a one to one relationship between the format specifications and the objects in the objects array.

Format (see page 4188) is a string of format specifications.

Args is the corresponding array of objects to format.

See Also

StringBuilder.AppendFormat (MSDN)

37.1.50.4.3 AppendLine Method

This is the overview for the AppendLine method overload.

Overload List

	Name	Description
	TStringBuilder.AppendLine () (see page 4016)	Appends a line terminator or a string and a line terminator to the current character array in this instance.
	TStringBuilder.AppendLine (string) (see page 4016)	Appends a line terminator or a string and a line terminator to the current character array in this instance.

37.1.50.4.3.1 TStringBuilder.AppendLine Method ()

Appends a line terminator or a string and a line terminator to the current character array in this instance.

Pascal

```
function AppendLine: TStringBuilder; overload;
function AppendLine(const Value: string): TStringBuilder; overload;
```

C++

```
__fastcall TStringBuilder AppendLine();
__fastcall TStringBuilder AppendLine(const UnicodeString Value);
```

Description

Use AppendLine to append a line terminator or a string and a line terminator to the current character array in this instance.

See Also

StringBuilder.AppendLine (MSDN)

37.1.50.4.4 TStringBuilder.CopyTo Method

Copys a part of the instance character array into a destination string.

Pascal

```
procedure CopyTo(SourceIndex: Integer; const Destination: TCharArray; DestinationIndex:
Integer; Count: Integer);
```

C++

```
__fastcall CopyTo(int SourceIndex, const TCharArray Destination, int DestinationIndex, int
Count);
```

Description

Use CopyTo to copy a part of the instance character array into a destination string.

SourceIndex specifies the first character in the instance character array to copy.

Destination indicates the character array to copy to.

DestinationIndex specifies the position in the destination string to insert the substring.

Count is the number of characters to copy.

See Also

StringBuilder.CopyTo (MSDN)

37.1.50.4.5 TStringBuilder.EnsureCapacity Method

Sets the Capacity (see page 4021) property to the supplied value, if the new capacity is larger than the old capacity.

Pascal

```
function EnsureCapacity(aCapacity: Integer): Integer;
```

C++

```
__fastcall int EnsureCapacity(int aCapacity);
```

Description

Sets the Capacity (see page 4021) property to the supplied value, if the new capacity is larger than the old capacity. Also allocates more memory for the character array if needed. Returns the new capacity.

See Also

Capacity (see page 4021)

StringBuilder.EnsureCapacity (MSDN)

37.1.50.4.6 TStringBuilder.Equals Method

Compares the character array in the Chars (see page 4022) property, the Capacity (see page 4021) property, and the MaxCapacity (see page 4022) property of this instance to that of a supplied TStringBuilder (see page 4006) instance.

Pascal

```
function Equals(StringBuilder: TStringBuilder): Boolean; reintroduce;
```

C++

```
__fastcall Boolean Equals(TStringBuilder StringBuilder);
```

Description

Use Equals to compare the character array in the Chars (see page 4022) property, the Capacity (see page 4021) property, and the MaxCapacity (see page 4022) property of this instance to that of a supplied TStringBuilder (see page 4006) instance.

See Also

Capacity (see page 4021)

Chars (see page 4022)

MaxCapacity (see page 4022)

StringBuilder.Equals (MSDN)

37.1.50.4.7 Insert Method

This is the overview for the Insert method overload.

Overload List

	Name	Description
	TStringBuilder.Insert (Integer, Boolean) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Byte) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Cardinal) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.

	TStringBuilder.Insert (Integer, Char) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Currency) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Double) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Int64) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Integer) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Shortint) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Single) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Smallint) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, string) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, string, Integer) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, TCharArray) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, TCharArray, Integer, Integer) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, TObject) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, UInt64) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.
	TStringBuilder.Insert (Integer, Word) (see page 4018)	Inserts a string representation of the object parameter at the Index provided.

37.1.50.4.7.1 TStringBuilder.Insert Method (Integer, Boolean)

Inserts a string representation of the object parameter at the Index provided.

Pascal

```
function Insert(Index: Integer; const Value: Boolean): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Byte): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Char): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Currency): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Double): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Smallint): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Integer): TStringBuilder; overload;
function Insert(Index: Integer; const Value: TCharArray): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Int64): TStringBuilder; overload;
function Insert(Index: Integer; const Value: TObject): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Shortint): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Single): TStringBuilder; overload;
function Insert(Index: Integer; const Value: string): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Word): TStringBuilder; overload;
function Insert(Index: Integer; const Value: Cardinal): TStringBuilder; overload;
function Insert(Index: Integer; const Value: UInt64): TStringBuilder; overload;
```

```
function Insert(Index: Integer; const Value: string; count: Integer): TStringBuilder; overload;
function Insert(Index: Integer; const Value: TCharArray; startIndex: Integer; charCount:
Integer): TStringBuilder; overload;
```

C++

```
__fastcall TStringBuilder Insert(int Index, const Boolean Value);
__fastcall TStringBuilder Insert(int Index, const Byte Value);
__fastcall TStringBuilder Insert(int Index, const Char Value);
__fastcall TStringBuilder Insert(int Index, const Currency Value);
__fastcall TStringBuilder Insert(int Index, const Double Value);
__fastcall TStringBuilder Insert(int Index, const Smallint Value);
__fastcall TStringBuilder Insert(int Index, const int Value);
__fastcall TStringBuilder Insert(int Index, const TCharArray Value);
__fastcall TStringBuilder Insert(int Index, const Int64 Value);
__fastcall TStringBuilder Insert(int Index, const TObject * Value);
__fastcall TStringBuilder Insert(int Index, const Shortint Value);
__fastcall TStringBuilder Insert(int Index, const Single Value);
__fastcall TStringBuilder Insert(int Index, const UnicodeString Value);
__fastcall TStringBuilder Insert(int Index, const Word Value);
__fastcall TStringBuilder Insert(int Index, const unsigned Value);
__fastcall TStringBuilder Insert(int Index, const UInt64 Value);
__fastcall TStringBuilder Insert(int Index, const UnicodeString Value, int count);
__fastcall TStringBuilder Insert(int Index, const TCharArray Value, int startIndex, int
charCount);
```

Description

Use Insert to insert a string representation of the object parameter at the Index provided.

In the overload that uses the parameter **count**, **count** provides a way to insert the object **count** number of times.

startIndex and **charCount** provide a way to insert a substring of the **Value** TCharArray (see page 4340) into the character array of this instance.

See Also

StringBuilder.Insert (MSDN)

37.1.50.4.8 TStringBuilder.Remove Method

Removes a substring from the character array of this instance.

Pascal

```
function Remove(StartIndex: Integer; RemLength: Integer): TStringBuilder;
```

C++

```
__fastcall TStringBuilder Remove(int StartIndex, int RemLength);
```

Description

Use Remove to remove a substring from the character array of this instance.

StartIndex indicates the index of the first character to remove.

RemLength indicates the number of characters to remove.

See Also

StringBuilder.Remove (MSDN)

37.1.50.4.9 Replace Method

This is the overview for the Replace method overload.

Overload List

	Name	Description
	TStringBuilder.Replace (Char, Char) (see page 4020)	Replaces all occurences of a specified string with another.
	TStringBuilder.Replace (Char, Char, Integer, Integer) (see page 4020)	Replaces all occurences of a specified string with another.
	TStringBuilder.Replace (string, string) (see page 4020)	Replaces all occurences of a specified string with another.
	TStringBuilder.Replace (string, string, Integer, Integer) (see page 4020)	Replaces all occurences of a specified string with another.

37.1.50.4.9.1 TStringBuilder.Replace Method (Char, Char)

Replaces all occurences of a specified string with another.

Pascal

```
function Replace(const OldChar: Char; const NewChar: Char): TStringBuilder; overload;
function Replace(const OldValue: string; const NewValue: string): TStringBuilder; overload;
function Replace(const OldChar: Char; const NewChar: Char; StartIndex: Integer; Count:
Integer): TStringBuilder; overload;
function Replace(const OldValue: string; const NewValue: string; StartIndex: Integer; Count:
Integer): TStringBuilder; overload;
```

C++

```
__fastcall TStringBuilder Replace(const Char OldChar, const Char NewChar);
__fastcall TStringBuilder Replace(const UnicodeString OldValue, const UnicodeString NewValue);
__fastcall TStringBuilder Replace(const Char OldChar, const Char NewChar, int StartIndex, int
Count);
__fastcall TStringBuilder Replace(const UnicodeString OldValue, const UnicodeString NewValue,
int StartIndex, int Count);
```

Description

Use Replace to replace all occurences of a specified string with another. Replace can replace a single **OldChar** with a **NewChar** everywhere, an **OldValue string** with a **NewValue** string, an **OldChar** with a **NewChar** everywhere in a specified substring, or an **OldValue** string with a **NewValue** string everywhere in a specified substring.

StringBuilder.Replace (MSDN)

37.1.50.4.10 ToString Method

This is the overview for the ToString method overload.

Overload List

	Name	Description
	TStringBuilder.ToString () (see page 4021)	Returns a string representation of the character array contained in this TStringBuilder (see page 4006) instance.
	TStringBuilder.ToString (Integer, Integer) (see page 4021)	Returns a string representation of the character array contained in this TStringBuilder (see page 4006) instance.

37.1.50.4.10.1 TStringBuilder.ToString Method ()

Returns a string representation of the character array contained in this TStringBuilder (see page 4006) instance.

Pascal

```
function ToString: string; override; overload;
function ToString(StartIndex: Integer; StrLength: Integer): string; overload; reintroduce;
```

C++

```
virtual __fastcall UnicodeString ToString();
__fastcall UnicodeString ToString(int StartIndex, int StrLength);
```

Description

Use ToString to create a string representation of the character array contained in this TStringBuilder (see page 4006) instance.

StartIndex and **StrLength** specify a substing of the character array to convert.

See Also

StringBuilder.ToString (MSDN)

37.1.50.5 TStringBuilder Properties

The properties of the TStringBuilder class are listed here.

Public Properties

	Name	Description
	Capacity (see page 4021)	Used to get or set the maximum number of characters that can be stored in this TStringBuilder (see page 4006) instance.
	Chars (see page 4022)	Used to get or set the characters stored in this TStringBuilder (see page 4006) instance.
	Length (see page 4022)	Used to get or set the size of the character array stored in this TStringBuilder (see page 4006) instance.
R	MaxCapacity (see page 4022)	Used to get the maximum size allowed of the character array stored in this TStringBuilder (see page 4006) instance.

37.1.50.5.1 TStringBuilder.Capacity Property

Used to get or set the maximum number of characters that can be stored in this TStringBuilder (see page 4006) instance.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

Use Capacity to get or set the maximum number of characters that can be stored in this TStringBuilder (see page 4006) instance. Capacity cannot be set higher than the value of MaxCapacity (see page 4022) and cannot be set lower than the current value of Length (see page 4022).

See Also

MaxCapacity (see page 4022)

Length (see page 4022)

StringBuilder.Capacity (MSDN)

37.1.50.5.2 TStringBuilder.Chars Property

Used to get or set the characters stored in this TStringBuilder (see page 4006) instance.

Pascal

```
property Chars [index: Integer]: Char;
```

C++

```
__property Char Chars[int index];
```

Description

Use Chars to get or set the characters stored in this TStringBuilder (see page 4006) instance.

index specifies the position of the character to access.

The value of this property is the character stored at location index.

See Also

StringBuilder.Chars (MSDN)

37.1.50.5.3 TStringBuilder.Length Property

Used to get or set the size of the character array stored in this TStringBuilder (see page 4006) instance.

Pascal

```
property Length: Integer;
```

C++

```
__property int Length;
```

Description

Use Length to get or set the size of the character array stored in this TStringBuilder (see page 4006) instance. If the value of **Length** is lowered, the character array is truncated. If the value is raised, the character array is padded with spaces and the Capacity (see page 4021) property is increased. An error occurs if an attempt is made to increase **Length** larger than the MaxCapacity (see page 4022) property.

See Also

Capacity (see page 4021)

MaxCapacity (see page 4022)

StringBuilder.Length (MSDN)

37.1.50.5.4 TStringBuilder.MaxCapacity Property

Used to get the maximum size allowed of the character array stored in this TStringBuilder (see page 4006) instance.

Pascal

```
property MaxCapacity: Integer;
```

C++

```
__property int MaxCapacity;
```

Description

Use MaxCapacity to get the maximum size allowed of the character array stored in this TStringBuilder (see page 4006)

instance. **MaxCapacity** is set when the instance of TStringBuilder (see page 4006) is created and determines the maximum value to which the Capacity (see page 4021) property can be set.

See Also

Capacity (see page 4021)

StringBuilder.MaxCapacity (MSDN)

37.1.51 TThreadLocalCounter Class

Class Hierarchy

Pascal

```
TThreadLocalCounter = class;
```

C++

```
class TThreadLocalCounter;
```

File

SysUtils

Description

This is class SysUtils.TThreadLocalCounter.

37.1.51.1 TThreadLocalCounter Members

The following tables list the members exposed by TThreadLocalCounter.

Public Methods

	Name	Description
	Close (see page 4024)	This is Close, a member of class TThreadLocalCounter.
	Delete (see page 4024)	This is Delete, a member of class TThreadLocalCounter.
	Destroy (see page 4023)	This is Destroy, a member of class TThreadLocalCounter.
	Open (see page 4024)	This is Open, a member of class TThreadLocalCounter.

37.1.51.2 TThreadLocalCounter.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TThreadLocalCounter();
```

Description

This is Destroy, a member of class TThreadLocalCounter.

37.1.51.3 TThreadLocalCounter Methods

The methods of the TThreadLocalCounter class are listed here.

Public Methods

	Name	Description
	Close (see page 4024)	This is Close, a member of class TThreadLocalCounter.
	Delete (see page 4024)	This is Delete, a member of class TThreadLocalCounter.
	Open (see page 4024)	This is Open, a member of class TThreadLocalCounter.

37.1.51.3.1 TThreadLocalCounter.Close Method

Pascal

```
procedure Close(var Thread: PThreadInfo);
```

C++

```
__fastcall Close(PThreadInfo Thread);
```

Description

This is Close, a member of class TThreadLocalCounter.

37.1.51.3.2 TThreadLocalCounter.Delete Method

Pascal

```
procedure Delete(var Thread: PThreadInfo);
```

C++

```
__fastcall Delete(PThreadInfo Thread);
```

Description

This is Delete, a member of class TThreadLocalCounter.

37.1.51.3.3 TThreadLocalCounter.Open Method

Pascal

```
procedure Open(var Thread: PThreadInfo);
```

C++

```
__fastcall Open(PThreadInfo Thread);
```

Description

This is Open, a member of class TThreadLocalCounter.

37.1.52 TUnicodeEncoding Class

Class Hierarchy

Pascal

```
TUnicodeEncoding = class(TEncoding);
```

C++

```
class TUnicodeEncoding : public TEncoding;
```

File

SysUtils

Description

This is class SysUtils.TUnicodeEncoding.

37.1.52.1 TUnicodeEncoding Members

The following tables list the members exposed by TUnicodeEncoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
V	Create (see page 4026)	This is Create, a member of class TUnicodeEncoding.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
V	GetMaxByteCount (see page 4028)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxCharCount (see page 4028)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetPreamble (see page 4029)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
V	GetByteCount (see page 4026)	Returns the number of bytes generated by encoding Chars.
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
V	GetBytes (see page 4027)	Encodes a set of characters into a sequence of bytes.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
V	GetCharCount (see page 4027)	Calcuates a number of characters generated by decoding a sequence of bytes.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.

	GetChars (see page 4028)	Decodes a set of bytes into a set of characters.
	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.52.2 TUnicodeEncoding.Create Constructor

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TUnicodeEncoding();
```

Description

This is Create, a member of class TUnicodeEncoding.

37.1.52.3 TUnicodeEncoding Methods

The methods of the TUnicodeEncoding class are listed here.

Public Methods

	Name	Description
	GetMaxByteCount (see page 4028)	Calculates the maximum bytes generated to encode the specified number of characters.
	GetMaxCharCount (see page 4028)	Calculates the maximum number of characters generated to decode a specified number of bytes.
	GetPreamble (see page 4029)	Returns a preamble in a byte array that specifies the encoding used.

Strict protected Methods

	Name	Description
	GetByteCount (see page 4026)	Returns the number of bytes generated by encoding Chars.
	GetBytes (see page 4027)	Encodes a set of characters into a sequence of bytes.
	GetCharCount (see page 4027)	Calcuates a number of characters generated by decoding a sequence of bytes.
	GetChars (see page 4028)	Decodes a set of bytes into a set of characters.

37.1.52.3.1 TUnicodeEncoding.GetByteCount Method

Returns the number of bytes generated by encoding Chars.

Pascal

```
function GetByteCount(Chars: PChar; CharCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetByteCount(const char * Chars, int CharCount);
```

Description

Returns the number of bytes generated by encoding Chars. Note that the number of bytes in a string is not necessarily exactly proportional to the number of characters in a given character array or string.

The **Chars** parameter can be a character array or a character pointer containing the bytes to be counted.

The **S** parameter refers to a UnicodeString from which the Byte count will be extracted.

The **CharCount** parameter specifies the number of characters to encode.

The **CharIndex** parameter indicates the index within the Chars array where counting should begin.

The **CharCount** parameter indicates the number of characters that should be included when counting the bytes.

The Return Value is the number of bytes in the passed Chars or S parameter.

See Also

Encoding.GetByteCount (MSDN)

37.1.52.3.2 TUnicodeEncoding.GetBytes Method

Encodes a set of characters into a sequence of bytes.

Pascal

```
function GetBytes(Chars: PChar; CharCount: Integer; Bytes: PByte; ByteCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetBytes(const char * Chars, int CharCount, PByte Bytes, int ByteCount);
```

Description

TEncoding.GetBytes encodes Chars parameter into a sequence of bytes.

Chars can be a character array or a character pointer which will be encoded into a sequence of bytes.

S is a string of type UnicodeString to be encoded into a sequence of bytes.

The **CharCount** parameter specifies the number of characters to encode.

Bytes specifies the location to write the sequence of bytes.

ByteCount is the maximum number of bytes that can be written to the given location.

The **Return Value** is the number of bytes actually encoded or the actual TBytes sequence of bytes.

See Also

Encoding.GetBytes (MSDN)

37.1.52.3.3 TUnicodeEncoding.GetCharCount Method

Calcuates a number of characters generated by decoding a sequence of bytes.

Pascal

```
function GetCharCount(Bytes: PByte; ByteCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetCharCount(PByte Bytes, int ByteCount);
```

Description

TEncoding.GetCharCount generates a number of characters by decoding **Bytes**.

Bytes can be a byte array, or a byte pointer.

The **ByteCount** parameter specifies the number of bytes to decode.

The **Return Value** is the number of characters decoded.

See Also

Encoding.GetCharCount (MSDN)

37.1.52.3.4 TUnicodeEncoding.GetChars Method

Decodes a set of bytes into a set of characters.

Pascal

```
function GetChars(Bytes: PByte; ByteCount: Integer; Chars: PChar; CharCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetChars(PByte Bytes, int ByteCount, const char * Chars, int CharCount);
```

Description

TEncoding.GetChars generates a number of characters by decoding Bytes.

Bytes can be a byte pointer or a byte array.

ByteIndex specifies the first byte to decode. If not present, the index is 0.

ByteCount specifies the number of bytes to decode. If not present, all bytes will be decoded.

Chars is a pointer to the destination of the decoded characters.

CharIndex specifies the maximum number of characters to store.

The **Return Value** is either a character array of the decoded characters, or the number of characters decoded.

See Also

Encoding.GetChars (MSDN)

37.1.52.3.5 TUnicodeEncoding.GetMaxByteCount Method

Calculates the maximum bytes generated to encode the specified number of characters.

Pascal

```
function GetMaxByteCount(CharCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxByteCount(int CharCount);
```

Description

TEncoding.GetMaxByteCount calculates the maximum bytes generated to encode CharCount number of characters.

CharCount must be a positive integer.

The **Return Value** is the number of bytes calculated.

See Also

Encoding.GetMaxByteCount (MSDN)

37.1.52.3.6 TUnicodeEncoding.GetMaxCharCount Method

Calculates the maximum number of characters generated to decode a specified number of bytes.

Pascal

```
function GetMaxCharCount(ByteCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxCharCount(int ByteCount);
```

Description

TEncoding.GetMaxCharCount calculates the maximum number of characters generated to decode **ByteCount** number of bytes.

The **Return Value** is the number of characters calculated.

See Also

Encoding.GetMaxCharCount (MSDN)

37.1.52.3.7 TUnicodeEncoding.GetPreamble Method

Returns a preamble in a byte array that specifies the encoding used.

Pascal

```
function GetPreamble: TBytes; override;
```

C++

```
virtual __fastcall TBytes GetPreamble();
```

Description

TEncoding.GetPreamble returns an array of bytes of type TBytes that contains the preamble required for the encoding used. If no preamble is required a zero length array is returned.

See Also

Encoding.GetPreamble (MSDN)

37.1.53 TUTF7Encoding Class

Class Hierarchy

Pascal

```
TUTF7Encoding = class(TMBCSEncoding);
```

C++

```
class TUTF7Encoding : public TMBCSEncoding;
```

File

SysUtils

Description

This is class SysUtils.TUTF7Encoding.

37.1.53.1 TUTF7Encoding Members

The following tables list the members exposed by TUTF7Encoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
V	Create (see page 4030)	This is Create, a member of class TUTF7Encoding.
V	Create (see page 3993)	This is the overview for the Create constructor overload.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
V	GetMaxByteCount (see page 4033)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxCharCount (see page 4033)	Calculates the maximum number of characters generated to decode a specified number of bytes.
A	GetPreamble (see page 3981)	Returns a preamble in a byte array that specifies the encoding used.
V	GetPreamble (see page 3997)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.
	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
V	GetByteCount (see page 4031)	Returns the number of bytes generated by encoding Chars.
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
V	GetBytes (see page 4031)	Encodes a set of characters into a sequence of bytes.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
V	GetCharCount (see page 4032)	Calcuates a number of characters generated by decoding a sequence of bytes.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
V	GetChars (see page 4032)	Decodes a set of bytes into a set of characters.
A	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.53.2 TUTF7Encoding.Create Constructor

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TUTF7Encoding();
```

Description

This is Create, a member of class TUTF7Encoding.

37.1.53.3 TUTF7Encoding Methods

The methods of the TUTF7Encoding class are listed here.

Public Methods

	Name	Description
	GetMaxByteCount (see page 4033)	Calculates the maximum bytes generated to encode the specified number of characters.
	GetMaxCharCount (see page 4033)	Calculates the maximum number of characters generated to decode a specified number of bytes.

Strict protected Methods

	Name	Description
	GetByteCount (see page 4031)	Returns the number of bytes generated by encoding Chars.
	GetBytes (see page 4031)	Encodes a set of characters into a sequence of bytes.
	GetCharCount (see page 4032)	Calcuates a number of characters generated by decoding a sequence of bytes.
	GetChars (see page 4032)	Decodes a set of bytes into a set of characters.

37.1.53.3.1 TUTF7Encoding.GetByteCount Method

Returns the number of bytes generated by encoding Chars.

Pascal

```
function GetByteCount(Chars: PChar; CharCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetByteCount(const char * Chars, int CharCount);
```

Description

Returns the number of bytes generated by encoding Chars. Note that the number of bytes in a string is not necessarily exactly proportional to the number of characters in a given character array or string.

The **Chars** parameter can be a character array or a character pointer containing the bytes to be counted.

The **S** parameter refers to a UnicodeString from which the Byte count will be extracted.

The **CharCount** parameter specifies the number of characters to encode.

The **CharIndex** parameter indicates the index within the Chars array where counting should begin.

The **CharCount** parameter indicates the number of characters that should be included when counting the bytes.

The Return Value is the number of bytes in the passed Chars or S parameter.

See Also

Encoding.GetByteCount (MSDN)

37.1.53.3.2 TUTF7Encoding.GetBytes Method

Encodes a set of characters into a sequence of bytes.

Pascal

```
function GetBytes(Chars: PChar; CharCount: Integer; Bytes: PByte; ByteCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetBytes(const char * Chars, int CharCount, PByte Bytes, int ByteCount);
```

Description

TEncoding.GetBytes encodes Chars parameter into a sequence of bytes.

Chars can be a character array or a character pointer which will be encoded into a sequence of bytes.

S is a string of type UnicodeString to be encoded into a sequence of bytes.

The **CharCount** parameter specifies the number of characters to encode.

Bytes specifies the location to write the sequence of bytes.

ByteCount is the maximum number of bytes that can be written to the given location.

The **Return Value** is the number of bytes actually encoded or the actual TBytes sequence of bytes.

See Also

Encoding.GetBytes (MSDN)

37.1.53.3.3 TUTF7Encoding.GetCharCount Method

Calcuates a number of characters generated by decoding a sequence of bytes.

Pascal

```
function GetCharCount(Bytes: PByte; ByteCount: Integer): Integer; override; overload;
```

C++

```
virtual __fastcall int GetCharCount(PByte Bytes, int ByteCount);
```

Description

TEncoding.GetCharCount generates a number of characters by decoding **Bytes**.

Bytes can be a byte array, or a byte pointer.

The **ByteCount** parameter specifies the number of bytes to decode.

The **Return Value** is the number of characters decoded.

See Also

Encoding.GetCharCount (MSDN)

37.1.53.3.4 TUTF7Encoding.GetChars Method

Decodes a set of bytes into a set of characters.

Pascal

```
function GetChars(Bytes: PByte; ByteCount: Integer; Chars: PChar; CharCount: Integer):
Integer; override; overload;
```

C++

```
virtual __fastcall int GetChars(PByte Bytes, int ByteCount, const char * Chars, int CharCount);
```

Description

TEncoding.GetChars generates a number of characters by decoding Bytes.

Bytes can be a byte pointer or a byte array.

ByteIndex specifies the first byte to decode. If not present, the index is 0.

ByteCount specifies the number of bytes to decode. If not present, all bytes will be decoded.

Chars is a pointer to the destination of the decoded characters.

CharIndex specifies the maximum number of characters to store.

The **Return Value** is either a character array of the decoded characters, or the number of characters decoded.

See Also

Encoding.GetChars (MSDN)

37.1.53.3.5 TUTF7Encoding.GetMaxByteCount Method

Calculates the maximum bytes generated to encode the specified number of characters.

Pascal

```
function GetMaxByteCount(CharCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxByteCount(int CharCount);
```

Description

TEncoding.GetMaxByteCount calculates the maximum bytes generated to encode CharCount number of characters.

CharCount must be a positive integer.

The **Return Value** is the number of bytes calculated.

See Also

Encoding.GetMaxByteCount (MSDN)

37.1.53.3.6 TUTF7Encoding.GetMaxCharCount Method

Calculates the maximum number of characters generated to decode a specified number of bytes.

Pascal

```
function GetMaxCharCount(ByteCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxCharCount(int ByteCount);
```

Description

TEncoding.GetMaxCharCount calculates the maximum number of characters generated to decode **ByteCount** number of bytes.

The **Return Value** is the number of characters calculated.

Encoding.GetMaxCharCount (MSDN)

37.1.54 TUTF8Encoding Class

Class Hierarchy

Pascal

```
TUTF8Encoding = class(TUTF7Encoding);
```

C++

```
class TUTF8Encoding : public TUTF7Encoding;
```

File

SysUtils

Description

This is class SysUtils.TUTF8Encoding.

37.1.54.1 TUTF8Encoding Members

The following tables list the members exposed by TUTF8Encoding.

Public Methods

	Name	Description
	Convert (see page 3974)	This is the overview for the Convert method overload.
V	Create (see page 4035)	This is Create, a member of class TUTF8Encoding.
V	Create (see page 3993)	This is the overview for the Create constructor overload.
	FreeEncodings (see page 3975)	Frees the internal standard encoding instances.
	GetBufferEncoding (see page 3976)	Determines the encoding for a given buffer.
	GetEncoding (see page 3980)	Returns the encoding used for the code page supplied.
V	GetMaxByteCount (see page 4035)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxCharCount (see page 4036)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetPreamble (see page 4036)	Returns a preamble in a byte array that specifies the encoding used.
	GetString (see page 3981)	This is the overview for the GetString method overload.
	IsStandardEncoding (see page 3984)	Reports if this instance is a standard encoding instance.

Public Properties

	Name	Description
R	ASCII (see page 3985)	Returns an encoding for the ASCII character set.
R	BigEndianUnicode (see page 3985)	Returns an encoding for the UTF-16 format with big-endian byte order.
R	Default (see page 3985)	Returns an encoding for the operating system's default ANSI code page.
R	IsSingleByte (see page 3986)	This boolean specifies if the current encoding is of single-byte format.
R	Unicode (see page 3986)	Returns an encoding for the UTF-16 format with little-endian byte order.
R	UTF7 (see page 3986)	Returns an encoding for the UTF-7 format.
R	UTF8 (see page 3987)	Returns an encoding for the UTF-8 format.

Strict protected Fields

	Name	Description
	FIsSingleByte (see page 3973)	This is FIsSingleByte, a member of class TEncoding.

	FMaxCharSize (see page 3974)	This is FMaxCharSize, a member of class TEncoding.

Strict protected Methods

	Name	Description
V	GetByteCount (see page 3994)	Returns the number of bytes generated by encoding Chars.
V	GetByteCount (see page 4031)	Returns the number of bytes generated by encoding Chars.
A	GetByteCount (see page 3976)	This is the overview for the GetByteCount method overload.
V	GetBytes (see page 3995)	Encodes a set of characters into a sequence of bytes.
V	GetBytes (see page 4031)	Encodes a set of characters into a sequence of bytes.
A	GetBytes (see page 3977)	This is the overview for the GetBytes method overload.
V	GetCharCount (see page 3995)	Calcuates a number of characters generated by decoding a sequence of bytes.
V	GetCharCount (see page 4032)	Calcuates a number of characters generated by decoding a sequence of bytes.
A	GetCharCount (see page 3978)	This is the overview for the GetCharCount method overload.
V	GetChars (see page 3996)	Decodes a set of bytes into a set of characters.
V	GetChars (see page 4032)	Decodes a set of bytes into a set of characters.
A	GetChars (see page 3979)	This is the overview for the GetChars method overload.

37.1.54.2 TUTF8Encoding.Create Constructor

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TUTF8Encoding();
```

Description

This is Create, a member of class TUTF8Encoding.

37.1.54.3 TUTF8Encoding Methods

The methods of the TUTF8Encoding class are listed here.

Public Methods

	Name	Description
V	GetMaxByteCount (see page 4035)	Calculates the maximum bytes generated to encode the specified number of characters.
V	GetMaxCharCount (see page 4036)	Calculates the maximum number of characters generated to decode a specified number of bytes.
V	GetPreamble (see page 4036)	Returns a preamble in a byte array that specifies the encoding used.

37.1.54.3.1 TUTF8Encoding.GetMaxByteCount Method

Calculates the maximum bytes generated to encode the specified number of characters.

Pascal

```
function GetMaxByteCount(CharCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxByteCount(int CharCount);
```

Description

TEncoding.GetMaxByteCount calculates the maximum bytes generated to encode CharCount number of characters.

CharCount must be a positive integer.

The **Return Value** is the number of bytes calculated.

See Also

Encoding.GetMaxByteCount (MSDN)

37.1.54.3.2 TUTF8Encoding.GetMaxCharCount Method

Calculates the maximum number of characters generated to decode a specified number of bytes.

Pascal

```
function GetMaxCharCount(ByteCount: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetMaxCharCount(int ByteCount);
```

Description

TEncoding.GetMaxCharCount calculates the maximum number of characters generated to decode **ByteCount** number of bytes.

The **Return Value** is the number of characters calculated.

See Also

Encoding.GetMaxCharCount (MSDN)

37.1.54.3.3 TUTF8Encoding.GetPreamble Method

Returns a preamble in a byte array that specifies the encoding used.

Pascal

```
function GetPreamble: TBytes; override;
```

C++

```
virtual __fastcall TBytes GetPreamble();
```

Description

TEncoding.GetPreamble returns an array of bytes of type TBytes that contains the preamble required for the encoding used. If no preamble is required a zero length array is returned.

See Also

Encoding.GetPreamble (MSDN)

37.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IReadWriteSync (see page 4037)	This is class SysUtils.IReadWriteSync.

37.2.1 IReadWriteSync Interface

Class Hierarchy

SysUtils.IReadWriteSync

Pascal

```
IReadWriteSync = interface;
```

C++

```
__interface IReadWriteSync;
```

File

SysUtils

Description

This is class SysUtils.IReadWriteSync.

37.2.1.1 IReadWriteSync Members

The following tables list the members exposed by IReadWriteSync.

Public Methods

	Name	Description
	BeginRead (see page 4038)	This is BeginRead, a member of class IReadWriteSync.
	BeginWrite (see page 4038)	This is BeginWrite, a member of class IReadWriteSync.
	EndRead (see page 4038)	This is EndRead, a member of class IReadWriteSync.
	EndWrite (see page 4038)	This is EndWrite, a member of class IReadWriteSync.

37.2.1.2 IReadWriteSync Methods

The methods of the IReadWriteSync class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 4038)	This is BeginRead, a member of class IReadWriteSync.
	BeginWrite (see page 4038)	This is BeginWrite, a member of class IReadWriteSync.
	EndRead (see page 4038)	This is EndRead, a member of class IReadWriteSync.

	EndWrite (see page 4038)	This is EndWrite, a member of class IReadWriteSync.

37.2.1.2.1 IReadWriteSync.BeginRead Method

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

This is BeginRead, a member of class IReadWriteSync.

37.2.1.2.2 IReadWriteSync.BeginWrite Method

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

This is BeginWrite, a member of class IReadWriteSync.

37.2.1.2.3 IReadWriteSync.EndRead Method

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

This is EndRead, a member of class IReadWriteSync.

37.2.1.2.4 IReadWriteSync.EndWrite Method

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

This is EndWrite, a member of class IReadWriteSync.

37.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Abort (see page 4047)	Raises a silent exception.
	AddExitProc (see page 4048)	Adds a procedure to the exit list.
	AddTerminateProc (see page 4048)	Adds a terminate procedure to the system list of termination procedures.
	AdjustLineBreaks (see page 4049)	Adjusts line break characters to reflect Windows or Linux style.
	AnsiCompareFileName (see page 4049)	Compares file names based on the current locale.
	AnsiCompareStr (see page 4050)	Compares strings based on the current locale with case sensitivity.
	AnsiCompareText (see page 4051)	Compares strings based on the current locale without case sensitivity.
	AnsiDequotedStr (see page 4051)	Converts a quoted string into an unquoted string
	AnsiExtractQuotedStr (see page 4052)	Converts a quoted string into an unquoted string.
	AnsiExtractQuotedStr (see page 4052)	Converts a quoted string into an unquoted string.
	AnsiLastChar (see page 4052)	Returns a pointer to the last character in a string.
	AnsiLastChar (see page 4052)	Returns a pointer to the last character in a string.
	AnsiLowerCase (see page 4053)	Returns a string that is a copy of the given string converted to lower case.
	AnsiLowerCaseFileName (see page 4053)	Converts a file name to lower case.
	AnsiPos (see page 4054)	Locates the position of a substring.
	AnsiQuotedStr (see page 4054)	Returns the quoted version of a string.
	AnsiSameStr (see page 4055)	Compares strings based on the current locale with case sensitivity.
	AnsiSameText (see page 4055)	Compares strings based on the current locale without case sensitivity.
	AnsiStrAlloc (see page 4056)	This is function SysUtils.AnsiStrAlloc.
	AnsiStrComp (see page 4056)	Compares null-terminated character strings.
	AnsiStrComp (see page 4056)	Compares null-terminated character strings.
	AnsiStrIComp (see page 4057)	Compares null terminated character strings case insensitively.
	AnsiStrIComp (see page 4057)	Compares null terminated character strings case insensitively.
	AnsiStrLastChar (see page 4057)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLastChar (see page 4057)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLComp (see page 4058)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLComp (see page 4058)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLIComp (see page 4058)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLIComp (see page 4058)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLower (see page 4059)	Converts all characters in a null-terminated string to lower case.
	AnsiStrLower (see page 4059)	Converts all characters in a null-terminated string to lower case.
	AnsiStrPos (see page 4060)	Returns a pointer to the first occurrence of a substring.
	AnsiStrPos (see page 4060)	Returns a pointer to the first occurrence of a substring.
	AnsiStrRScan (see page 4060)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrRScan (see page 4060)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrScan (see page 4061)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrScan (see page 4061)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrUpper (see page 4061)	Converts all characters in a null-terminated string to upper case.
	AnsiStrUpper (see page 4061)	Converts all characters in a null-terminated string to upper case.
	AnsiUpperCase (see page 4062)	Converts a string to upper case.
	AnsiUpperCaseFileName (see page 4062)	Converts a file name to upper case.
	AppendStr (see page 4063)	Appends a dynamically allocated string to an existing string.
	AssignStr (see page 4063)	Assigns a new dynamically allocated string to a specified pointer.

	Beep (see page 4063)	Emits a message beep.
	BoolToStr (see page 4066)	Converts a Boolean value to a string.
	ByteLength (see page 4068)	This is function SysUtils.ByteLength.
	BytesOf (see page 4068)	Converts a string into a byte array.
	BytesOf (see page 4068)	Converts a string into a byte array.
	BytesOf (see page 4068)	Converts a string into a byte array.
	BytesOf (see page 4068)	Converts a string into a byte array.
	ByteToCharIndex (see page 4069)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharIndex (see page 4069)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharLen (see page 4070)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteToCharLen (see page 4070)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteType (see page 4070)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	ByteType (see page 4070)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	CallTerminateProcs (see page 4071)	Calls all of the functions in the termination procedure list.
	ChangeFileExt (see page 4071)	Changes the extension of a file name.
	ChangeFilePath (see page 4073)	Changes the path of a file name.
	CharInSet (see page 4073)	CharInSet checks whether a given character is contained within a set.
	CharInSet (see page 4073)	CharInSet checks whether a given character is contained within a set.
	CharLength (see page 4074)	Returns number of bytes used by character.
	CharLength (see page 4074)	Returns number of bytes used by character.
	CharToByteIndex (see page 4075)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteIndex (see page 4075)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteLen (see page 4076)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CharToByteLen (see page 4076)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CharToElementIndex (see page 4076)	This is function SysUtils.CharToElementIndex.
	CharToElementIndex (see page 4076)	This is function SysUtils.CharToElementIndex.
	CharToElementLen (see page 4077)	This is function SysUtils.CharToElementLen.
	CharToElementLen (see page 4077)	This is function SysUtils.CharToElementLen.
	CheckWin32Version (see page 4077)	Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 3159).
	CompareMem (see page 4078)	Performs a binary comparison of two memory images.
	CompareStr (see page 4078)	Compares two strings case sensitively.
	CompareStr (see page 4078)	Compares two strings case sensitively.
	CompareText (see page 4079)	Compares two strings by ordinal value without case sensitivity.
	CompareText (see page 4079)	Compares two strings by ordinal value without case sensitivity.
	CreateDir (see page 4083)	Creates a new directory.
	CreateGUID (see page 4084)	Creates a globally unique identifier.
	CurrentYear (see page 4086)	Returns the current year.
	CurrToStr (see page 4086)	Formats a Currency (see page 3235) value as a string.
	CurrToStr (see page 4086)	Formats a Currency (see page 3235) value as a string.
	CurrToStrF (see page 4086)	Converts a Currency (see page 3235) value to a string, using a specified format.
	CurrToStrF (see page 4086)	Converts a Currency (see page 3235) value to a string, using a specified format.
	Date (see page 4087)	Returns the current date.
	DateTimeToFileDate (see page 4088)	Converts a TDateTime (see page 3323) value to an OS timestamp value.
	DateTimeToStr (see page 4089)	Converts a TDateTime (see page 3323) value to a string.
	DateTimeToStr (see page 4089)	Converts a TDateTime (see page 3323) value to a string.
	DateTimeToString (see page 4089)	Converts a TDateTime (see page 3323) value to a string using a specified Format (see page 4188).
	DateTimeToString (see page 4089)	Converts a TDateTime (see page 3323) value to a string using a specified Format (see page 4188).

	DateTimeToSystemTime (see page 4091)	Converts a TDateTime (see page 3323) value into the Win32 API's system time type.
	DateTimeToTimeStamp (see page 4092)	Converts a TDateTime (see page 3323) value into the corresponding TTimeStamp (see page 4334) value.
	DateToStr (see page 4092)	Converts a TDateTime (see page 3323) value to a string.
	DateToStr (see page 4092)	Converts a TDateTime (see page 3323) value to a string.
	DayOfWeek (see page 4094)	Returns the day of the week for a specified date.
	DecodeDate (see page 4095)	Returns Year, Month, and Day values for a TDateTime (see page 3323) value.
	DecodeDateFully (see page 4096)	Returns Year, Month, and Day, and Day-of-Week values for a TDateTime (see page 3323) value.
	DecodeTime (see page 4097)	Breaks a TDateTime (see page 3323) value into hours, minutes, seconds, and milliseconds.
	DelegatesEqual (see page 4098)	This is function SysUtils.DelegatesEqual.
	DeleteFile (see page 4098)	Deletes a file from disk.
	DirectoryExists (see page 4100)	Determines whether a specified directory exists.
	DiskFree (see page 4101)	Returns the number of free bytes on a specified drive.
	DiskSize (see page 4102)	Returns the size, in bytes, of a specified drive.
	DisposeStr (see page 4103)	Disposes of a string pointer that was allocated using NewStr (see page 4227).
	ElementToCharIndex (see page 4104)	This is function SysUtils.ElementToCharIndex.
	ElementToCharIndex (see page 4104)	This is function SysUtils.ElementToCharIndex.
	ElementToCharLen (see page 4104)	This is function SysUtils.ElementToCharLen.
	ElementToCharLen (see page 4105)	This is function SysUtils.ElementToCharLen.
	EncodeDate (see page 4105)	Returns a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.
	EncodeTime (see page 4106)	Returns a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.
	ExceptionErrorMessage (see page 4107)	Formats a standard error message.
	ExcludeTrailingBackslash (see page 4108)	Returns a path name without a trailing delimiter.
	ExcludeTrailingPathDelimiter (see page 4109)	Returns a path name without a trailing delimiter.
	ExpandFileName (see page 4109)	Returns the full path name for a relative file name.
	ExpandFileNameCase (see page 4110)	Returns the full path name for a relative file name on a case-sensitive file system.
	ExpandUNCFileName (see page 4111)	Returns the full path of a file name in UNC format, if appropriate.
	ExtractFileDir (see page 4112)	Extracts the drive and directory parts from FileName.
	ExtractFileDrive (see page 4112)	Returns the drive portion of a file name.
	ExtractFileExt (see page 4113)	Returns the extension portions of a file name.
	ExtractFileName (see page 4113)	Extracts the name and extension parts of a file name.
	ExtractFilePath (see page 4115)	Returns the drive and directory portions of a file name.
	ExtractRelativePath (see page 4117)	Returns a relative path name, relative to a specific base directory.
	ExtractShortPathName (see page 4118)	Converts a file name to the short 8.3 form.
	FileAge (see page 4119)	Returns the OS timestamp of a file.
	FileAge (see page 4119)	Returns the OS timestamp of a file.
	FileClose (see page 4121)	Closes a specified file.
	FileCreate (see page 4128)	Creates a new file.
	FileCreate (see page 4128)	Creates a new file.
	FileDateToDateTime (see page 4130)	Converts an OS timestamp value to TDateTime (see page 3323) value.
	FileExists (see page 4133)	Tests if a specified file exists.
	FileGetAttr (see page 4139)	Returns the file attributes of FileName.
	FileGetDate (see page 4142)	Returns an OS timestamp for a specified file.
	FileIsReadOnly (see page 4142)	Reports whether a file is read-only.
	FileOpen (see page 4143)	Opens a specified file using a specified access mode.
	FileRead (see page 4150)	Reads a specified number of bytes from a file.
	FileSearch (see page 4156)	Searches a specified directory path for a file.
	FileSeek (see page 4157)	Repositions read/write point.
	FileSeek (see page 4157)	Repositions read/write point.
	FileSetAttr (see page 4162)	Sets the file attributes of a specified file.
	FileSetDate (see page 4164)	Sets the OS time stamp for a specified file.

	FileSetDate (see page 4164)	Sets the OS time stamp for a specified file.
	FileSetReadOnly (see page 4165)	Sets the file permissions to read-only.
	FileWrite (see page 4166)	Writes the contents of a buffer to the current position in a file.
	FinalizePackage (see page 4172)	Finalizes the specified package (.bpl file).
	FindClose (see page 4172)	Releases memory allocated by FindFirst (see page 4175).
	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 4174)	Determines whether a string was passed as a command line argument to the application.
	FindFirst (see page 4175)	Searches for the first instance of a file name with a given set of attributes in a specified directory.
	FindNext (see page 4177)	Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 4175).
	FloatToCurr (see page 4179)	Converts a floating-point value to a System::Currency (see page 3235) value.
	FloatToDateTime (see page 4179)	Converts a floating-point value to a TDateTime (see page 3323) value.
	FloatToDecimal (see page 4180)	Converts a floating-point value to a decimal representation.
	FloatToStr (see page 4180)	Converts a floating point value to a string.
	FloatToStr (see page 4180)	Converts a floating point value to a string.
	FloatToStrF (see page 4182)	Converts a floating point value to a string, using a specified Format (see page 4188), Precision, and Digits.
	FloatToStrF (see page 4182)	Converts a floating point value to a string, using a specified Format (see page 4188), Precision, and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToText (see page 4183)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 4184)	Converts a floating-point value to an unterminated character string, using a specified format.
	FmtLoadStr (see page 4185)	Returns formatted output using a resourced format string.
	FmtStr (see page 4185)	Assembles a formatted string using a format string and an array of arguments.
	FmtStr (see page 4185)	Assembles a formatted string using a format string and an array of arguments.
	ForceDirectories (see page 4186)	Creates a new directory, including the creation of parent directories as needed.
	Format (see page 4188)	Returns a formatted string assembled from a format string and an array of arguments.
	Format (see page 4188)	Returns a formatted string assembled from a format string and an array of arguments.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 4193)	Formats the arguments from an array, placing the result in a buffer.
	FormatCurr (see page 4194)	Formats a System::Currency (see page 3235) object.
	FormatCurr (see page 4194)	Formats a System::Currency (see page 3235) object.
	FormatDateTime (see page 4195)	Formats a TDateTime (see page 3323) value.
	FormatDateTime (see page 4195)	Formats a TDateTime (see page 3323) value.
	FormatFloat (see page 4197)	Formats a floating point value.

	FormatFloat (see page 4197)	Formats a floating point value.
	FreeAndNil (see page 4201)	Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).
	GDAL (see page 4202)	Get Delphi Access Licence.
	GetCurrentDir (see page 4202)	Returns the name of the current directory.
	GetEnvironmentVariable (see page 4204)	Retrieves an environment variable value.
	GetFileVersion (see page 4205)	Returns file version.
	GetFormatSettings (see page 4206)	Resets the date and number format parameters to initial values.
	GetLocaleChar (see page 4206)	Retrieves the first character of a localisation value.
	GetLocaleFormatSettings (see page 4206)	Populates a TFormatSettings (see page 4326) data structure.
	GetLocaleStr (see page 4207)	Retrieves a localisation value.
	GetModuleName (see page 4207)	Returns the fully qualified name for a module, given its handle.
	GetPackageDescription (see page 4208)	Returns the description resource from a package.
	GetPackageInfo (see page 4209)	Enumerates all the units and required packages for a package.
	GetTime (see page 4209)	Returns the current time.
	GUIDToString (see page 4210)	Converts a class identifier GUID to a string.
	HashName (see page 4212)	This is function SysUtils.HashName.
	IncAMonth (see page 4212)	Increments date data by one month.
	IncludeTrailingBackslash (see page 4213)	Ensures path name ends with delimiter
	IncludeTrailingPathDelimiter (see page 4213)	Ensures path name ends with delimiter.
	IncMonth (see page 4214)	Returns a date shifted by a specified number of months.
	InitializePackage (see page 4215)	Validates and initializes a given package.
	InitializePackage (see page 4215)	Validates and initializes a given package.
	IntToHex (see page 4215)	Returns the hex representation of an integer.
	IntToHex (see page 4215)	Returns the hex representation of an integer.
	IntToStr (see page 4216)	Converts an integer to a string.
	IntToStr (see page 4216)	Converts an integer to a string.
	IsAssembly (see page 4217)	Determines whether a dll is an Assembly.
	IsDelimiter (see page 4218)	Indicates whether a specified character in a string matches one of a set of delimiters.
	IsEqualGUID (see page 4218)	Indicates whether two TGUID (see page 3718) values are the same.
	IsLeadChar (see page 4220)	This is function SysUtils.IsLeadChar.
	IsLeadChar (see page 4220)	This is function SysUtils.IsLeadChar.
	IsLeapYear (see page 4220)	Indicates whether a specified year is a leap year.
	IsPathDelimiter (see page 4222)	Indicates whether the byte at a specified position in a string is the path delimiter.
	IsValidIdent (see page 4222)	Determines whether a string conforms to Delphi identifier rules.
	Languages (see page 4223)	Lists the locales for which support is available.
	LastDelimiter (see page 4223)	Returns the byte index of the last character that matches any character in a specified set of delimiters.
	LoadPackage (see page 4224)	Loads a specified package.
	LoadPackage (see page 4224)	Loads a specified package.
	LoadStr (see page 4224)	Loads a string resource from the application's executable file.
	LowerCase (see page 4225)	Converts an ASCII string to lowercase.
	LowerCase (see page 4225)	Converts an ASCII string to lowercase.
	MSecsToTimeStamp (see page 4226)	Converts a specified number of milliseconds into a TTimeStamp (see page 4334) value.
	NewStr (see page 4227)	Allocates a string on the heap.
	NextCharIndex (see page 4227)	Returns the byte index of the next character.
	NextCharIndex (see page 4227)	Returns the byte index of the next character.
	Now (see page 4227)	Returns the current date and time.
	OutOfMemoryError (see page 4228)	Raises an EOutOfMemory (see page 3942) exception.
	PlatformBytesOf (see page 4229)	This is function SysUtils.PlatformBytesOf.
	PlatformStringOf (see page 4229)	This is function SysUtils.PlatformStringOf.
	QuotedStr (see page 4229)	Returns the quoted version of a string.
	RaiseLastOSError (see page 4230)	Raises an exception for the last occurring OS or system library error.
	RaiseLastOSError (see page 4230)	Raises an exception for the last occurring OS or system library error.

	RaiseLastWin32Error (see page 4231)	Raises an exception for the last occurring Win32 error.
	RCS (see page 4232)	Check for Delphi Client/Server Licence.
	RemoveDir (see page 4232)	Deletes an existing empty directory.
	RenameFile (see page 4233)	Changes a file name.
	ReplaceDate (see page 4236)	Replaces the date portion of a TDateTime (see page 3323) value with a specified date.
	ReplaceTime (see page 4236)	Replaces the time portion of a TDateTime (see page 3323) value with a specified time.
	RPR (see page 4237)	Check for Delphi Professional Licence.
	SafeLoadLibrary (see page 4238)	Safe and simple library loading.
	SameFileName (see page 4238)	Compares file names based on the current locale.
	SameStr (see page 4239)	Compares two strings by ordinal value with case sensitivity.
	SameStr (see page 4239)	Compares two strings by ordinal value with case sensitivity.
	SameText (see page 4239)	Compares two strings by ordinal value without case sensitivity.
	SameText (see page 4239)	Compares two strings by ordinal value without case sensitivity.
	SetCurrentDir (see page 4240)	Sets the current directory.
	ShowException (see page 4240)	Displays an exception message with its physical address
	Sleep (see page 4241)	Delay program execution for a specified number of milliseconds.
	StrAlloc (see page 4241)	Allocates a buffer for a null-terminated string and returns a pointer to its first character.
	StrBufSize (see page 4242)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 4241).
	StrBufSize (see page 4242)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 4241).
	StrByteType (see page 4242)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrByteType (see page 4242)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrCat (see page 4243)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCat (see page 4243)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCharLength (see page 4244)	Returns the length, in bytes, of a character.
	StrCharLength (see page 4244)	Returns the length, in bytes, of a character.
	StrComp (see page 4244)	Compares two strings with case sensitivity.
	StrComp (see page 4244)	Compares two strings with case sensitivity.
	StrCopy (see page 4246)	Copies a null-terminated string.
	StrCopy (see page 4246)	Copies a null-terminated string.
	StrDispose (see page 4247)	Disposes of a string.
	StrDispose (see page 4247)	Disposes of a string.
	StrECopy (see page 4248)	Copies null-terminated string.
	StrECopy (see page 4248)	Copies null-terminated string.
	StrEnd (see page 4249)	Returns a pointer to the end of a null terminated string.
	StrEnd (see page 4249)	Returns a pointer to the end of a null terminated string.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrFmt (see page 4250)	Formats entries in an array.
	StrIComp (see page 4251)	Compares two strings without case sensitivity.
	StrIComp (see page 4251)	Compares two strings without case sensitivity.
	StringOf (see page 4253)	This is function SysUtils.StringOf.
	StringReplace (see page 4253)	Replaces occurrences of a substring within a string.
	StringToGUID (see page 4254)	Converts a string to a GUID.
	StrLCat (see page 4255)	Appends up to a specified maximum number of characters to string.
	StrLCat (see page 4255)	Appends up to a specified maximum number of characters to string.
	StrLComp (see page 4257)	Compares up to a specified maximum number of characters in two strings.
	StrLComp (see page 4257)	Compares up to a specified maximum number of characters in two strings.
	StrLCopy (see page 4258)	Copies up to a specified maximum number of characters from Source to Dest.

	StrLCopy (see page 4258)	Copies up to a specified maximum number of characters from Source to Dest.
	StrLen (see page 4260)	Returns number of characters in a string excluding the null terminator.
	StrLen (see page 4260)	Returns number of characters in a string excluding the null terminator.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 4261)	Formats a series of arguments from a specified open array into a buffer.
	StrLIComp (see page 4262)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLIComp (see page 4262)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLower (see page 4264)	Converts a string to lowercase.
	StrLower (see page 4264)	Converts a string to lowercase.
	StrMove (see page 4265)	Copies specified number of characters to string.
	StrMove (see page 4265)	Copies specified number of characters to string.
	StrNew (see page 4266)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNew (see page 4266)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNextChar (see page 4268)	Returns pointer to following character.
	StrNextChar (see page 4268)	Returns pointer to following character.
	StrPas (see page 4268)	Converts null-terminated string to an AnsiString (long string).
	StrPas (see page 4269)	Converts null-terminated string to an AnsiString (long string).
	StrPCopy (see page 4271)	Copies an AnsiString (long string) to a null-terminated string.
	StrPCopy (see page 4271)	Copies an AnsiString (long string) to a null-terminated string.
	StrPLCopy (see page 4272)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPLCopy (see page 4272)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPos (see page 4272)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrPos (see page 4273)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrRScan (see page 4274)	Returns a pointer to the last occurrence of a specified character in a string.
	StrRScan (see page 4274)	Returns a pointer to the last occurrence of a specified character in a string.
	StrScan (see page 4275)	Returns a pointer to first occurrence of a specified character in a string.
	StrScan (see page 4275)	Returns a pointer to first occurrence of a specified character in a string.
	StrToBool (see page 4276)	Converts a string to a Boolean value.
	StrToBoolDef (see page 4277)	Converts a string to a Boolean value, with error default.
	StrToCurr (see page 4278)	Converts a string to a System::Currency (see page 3235) value.
	StrToCurr (see page 4278)	Converts a string to a System::Currency (see page 3235) value.
	StrToCurrDef (see page 4278)	Converts a string to a System::Currency (see page 3235) value, with error default.
	StrToCurrDef (see page 4278)	Converts a string to a System::Currency (see page 3235) value, with error default.
	StrToDate (see page 4279)	Converts a string to a TDateTime (see page 3323) value.
	StrToDate (see page 4279)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateDef (see page 4280)	Converts a string to a TDateTime (see page 3323) value, with error default.
	StrToDateDef (see page 4280)	Converts a string to a TDateTime (see page 3323) value, with error default.
	StrToDateTime (see page 4281)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateTime (see page 4281)	Converts a string to a TDateTime (see page 3323) value.
	StrToDateTimeDef (see page 4282)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToDateTimeDef (see page 4282)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToFloat (see page 4282)	Converts a given string to a floating-point value.
	StrToFloat (see page 4282)	Converts a given string to a floating-point value.
	StrToFloatDef (see page 4286)	Converts a given string to a floating-point value with error default.
	StrToFloatDef (see page 4286)	Converts a given string to a floating-point value with error default.
	StrToInt (see page 4286)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64 (see page 4287)	Converts a string that represents an integer (decimal or hex notation) to a number.

	StrToInt64Def (see page 4288)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToIntDef (see page 4288)	Converts a string that represents an integer (decimal or hex notation) to a number with error default.
	StrToTime (see page 4291)	Converts a string to a TDateTime (see page 3323) value.
	StrToTime (see page 4291)	Converts a string to a TDateTime (see page 3323) value.
	StrToTimeDef (see page 4292)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrToTimeDef (see page 4292)	Converts a string to a TDateTime (see page 3323) value with error default.
	StrUpper (see page 4292)	Returns a string in upper case.
	StrUpper (see page 4292)	Returns a string in upper case.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 4294)	Indicates whether a given object or interface supports a specified interface.
	SysErrorMessage (see page 4294)	Converts OS error codes into strings.
	SystemTimeToDateTime (see page 4295)	Converts a system time value into a TDateTime (see page 3323) value.
	TextPos (see page 4296)	This is function SysUtils.TextPos.
	TextPos (see page 4296)	This is function SysUtils.TextPos.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 4296)	Converts a null-terminated string to a floating-point value.
	Time (see page 4297)	Returns the current time.
	TimeStampToDateTime (see page 4298)	Converts a TTimeStamp (see page 4334) value into the corresponding TDateTime (see page 3323) value.
	TimeStampToMSecs (see page 4299)	Converts a TTimeStamp (see page 4334) value into an absolute number of milliseconds.
	TimeToStr (see page 4299)	Returns a string that represents a TDateTime (see page 3323) value.
	TimeToStr (see page 4299)	Returns a string that represents a TDateTime (see page 3323) value.
	Trim (see page 4301)	Trims leading and trailing spaces and control characters from a string.
	TrimLeft (see page 4301)	Trims leading spaces and control characters from a string.
	TrimRight (see page 4302)	Trims trailing spaces and control characters from a string.
	TryEncodeDate (see page 4302)	Creates a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.
	TryEncodeTime (see page 4303)	Creates a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.
	TryFloatToCurr (see page 4304)	Converts a floating-point value to a System::Currency (see page 3235) value.
	TryFloatToDateTime (see page 4304)	Converts a floating-point value to a TDateTime (see page 3323) value.
	TryStrToBool (see page 4305)	Converts a string to a Boolean value, with a Boolean success code.
	TryStrToCurr (see page 4305)	Converts a string to a System::Currency (see page 3235) value, with a Boolean success code.
	TryStrToCurr (see page 4305)	Converts a string to a System::Currency (see page 3235) value, with a Boolean success code.
	TryStrToDate (see page 4306)	Converts a string to a TDateTime (see page 3323) value, with a Boolean success code.
	TryStrToDate (see page 4306)	Converts a string to a TDateTime (see page 3323) value, with a Boolean success code.
	TryStrToDateTime (see page 4307)	Converts a string to a TDateTime (see page 3323) value with a Boolean success code.
	TryStrToDateTime (see page 4307)	Converts a string to a TDateTime (see page 3323) value with a Boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 4307)	Converts a given string to a floating-point value with a boolean success code.

	TryStrToInt (see page 4308)	Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.
	TryStrToInt64 (see page 4309)	Converts a string that represents an integer (decimal or hex notation) to a number.
	TryStrToTime (see page 4309)	Converts a string to a TDateTime (see page 3323) value with an error default.
	TryStrToTime (see page 4309)	Converts a string to a TDateTime (see page 3323) value with an error default.
	UIntToStr (see page 4310)	This is function SysUtils.UIntToStr.
	UIntToStr (see page 4310)	This is function SysUtils.UIntToStr.
	UnloadPackage (see page 4310)	Unloads a package.
	UpperCase (see page 4311)	Returns a copy of a string in uppercase.
	UpperCase (see page 4311)	Returns a copy of a string in uppercase.
	WideBytesOf (see page 4312)	Converts an Unicode string to an array of bytes.
	WideCompareStr (see page 4313)	Compares Unicode strings based on the current locale with case sensitivity.
	WideCompareText (see page 4313)	Compares Unicode strings based on the current locale without case sensitivity.
	WideFmtStr (see page 4314)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFmtStr (see page 4314)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFormat (see page 4314)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormat (see page 4314)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormatBuf (see page 4315)	Formats the arguments from an array, placing the result in a buffer.
	WideFormatBuf (see page 4315)	Formats the arguments from an array, placing the result in a buffer.
	WideLowerCase (see page 4316)	Returns Unicode string converted to lower case.
	WideSameStr (see page 4316)	Compares Unicode strings based on the current locale with case sensitivity.
	WideSameText (see page 4316)	Compares Unicode strings based on the current locale without case sensitivity.
	WideStrAlloc (see page 4317)	This is function SysUtils.WideStrAlloc.
	WideStringOf (see page 4317)	This is function SysUtils.WideStringOf.
	WideUpperCase (see page 4318)	Returns Unicode string converted to upper case.
	Win32Check (see page 4318)	Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.
	WrapText (see page 4318)	Splits a string into multiple lines as its length approaches a specified size.
	WrapText (see page 4318)	Splits a string into multiple lines as its length approaches a specified size.

37.3.1 SysUtils.Abort Function

Raises a silent exception.

Pascal

```
procedure Abort;
```

C++

```
Abort();
```

File

SysUtils

Description

Use Abort to escape from an execution path without reporting an error.

Abort raises a special "silent exception" (EAbort (see page 3916)), which operates like any other exception, but does not display an error message to the end user. Abort redirects execution to the end of the last exception block.

Delphi Examples:

```
{
This example checks for a valid entry in a TDBEdit control
and calls the Abort procedure if the control is empty; Abort
cancels the post before it happens.
}
procedure TForm1.ClientDataSet1BeforePost(DataSet: TDataSet);
begin
  if DBEdit1.Text = '' then
    Abort;
  DataSet.Fields[2].AsString := DBEdit1.Text;
end;
```

See Also

EAbort (see page 3916)

37.3.2 SysUtils.AddExitProc Function

Adds a procedure to the exit list.

Pascal

```
procedure AddExitProc(Proc: TProcedure);
```

C++

```
AddExitProc(TProcedure Proc);
```

File

SysUtils

Description

AddExitProc adds Proc to the Delphi exit procedure list, so that Proc is automatically executed when the application terminates. AddExitProc is not compatible with CLX package support and is provided for backward compatibility only. Do not use AddExitProc in new applications.

37.3.3 SysUtils.AddTerminateProc Function

Adds a terminate procedure to the system list of termination procedures.

Pascal

```
procedure AddTerminateProc(TermProc: TTerminateProc);
```

C++

```
AddTerminateProc(TTerminateProc TermProc);
```

File

SysUtils

Description

Call AddTerminateProc in Delphi code to add a procedure that is called when the application is about to terminate. The run time library calls all termination procedures before the application terminates. The supplied termination procedure (TermProc) should return true if the application can safely terminate or false if the application cannot safely terminate. If any termination procedure returns false, the application does not terminate.

See Also

CallTerminateProcs (see page 4071)

37.3.4 SysUtils.AdjustLineBreaks Function

Adjusts line break characters to reflect Windows or Linux style.

Pascal

```
function AdjustLineBreaks(const S: string; Style: TTextLineBreakStyle = tlbsCRLF): string;
overload;
```

C++

```
UnicodeString AdjustLineBreaks(const UnicodeString S, TTextLineBreakStyle Style = tlbsCRLF);
```

File

SysUtils

Description

AdjustLineBreaks returns a text string with its line breaks adjusted to fit a specified style.

S is the string to convert.

Style indicates whether line breaks should all be Windows-style line breaks with a carriage return and linefeed (tlbsCRLF), or Linux-style breaks with a single linefeed character (tlbsLF). If Style is omitted, the style for the compile target is used.

See Also

TrimLeft (see page 4301)

TrimRight (see page 4302)

37.3.5 SysUtils.AnsiCompareFileName Function

Compares file names based on the current locale.

Pascal

```
function AnsiCompareFileName(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareFileName(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

AnsiCompareFileName compares two file names. The current locale controls the compare operation. Comparison is case-insensitive under Windows, case-sensitive under Linux.

The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

AnsiCompareFileName supports the idiosyncrasies of MS-DOS file names that use Zenkaku Moji, a character encoding used in some Asian locales. Under Windows locales that do not use MBCS, AnsiCompareFileName is identical to AnsiCompareText (see page 4051). Under Linux, AnsiCompareFileName is identical to AnsiCompareStr (see page 4050).

See Also

SameFileName (see page 4238)

AnsiCompareText (see page 4051)

37.3.6 SysUtils.AnsiCompareStr Function

Compares strings based on the current locale with case sensitivity.

Pascal

```
function AnsiCompareStr(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareStr(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

AnsiCompareStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters. Thus, setting S1 to 'a' and S2 to 'A' causees AnsiCompareStr to return a value less than zero, while CompareStr (see page 4078), with the same arguments, returns a value greater than zero.

See Also

AnsiCompareText (see page 4051)

AnsiStrComp (see page 4056)

AnsiSameStr (see page 4055)

37.3.7 SysUtils.AnsiCompareText Function

Compares strings based on the current locale without case sensitivity.

Pascal

```
function AnsiCompareText(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareText(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

AnsiCompareText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. AnsiCompareText returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

AnsiCompareStr (see page 4050)

AnsiStrIComp (see page 4057)

AnsiSameText (see page 4055)

37.3.8 SysUtils.AnsiDequotedStr Function

Converts a quoted string into an unquoted string

Pascal

```
function AnsiDequotedStr(const S: string; AQuote: Char): string; overload;
```

C++

```
UnicodeString AnsiDequotedStr(const UnicodeString S, Char AQuote);
```

File

SysUtils

Description

AnsiDequotedStr removes the quote characters from the beginning and end of a quoted string, and reduces pairs of quote characters within the string to a single quote character. The AQuote parameter defines what character to use as a quote character. If the S parameter does not begin and end with the quote character, AnsiDequotedStr returns S unchanged.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiQuotedStr (see page 4054)

AnsiExtractQuotedStr (see page 4052)

37.3.9 SysUtils.AnsiExtractQuotedStr Function

Converts a quoted string into an unquoted string.

Pascal

```
function AnsiExtractQuotedStr(var Src: PAnsiChar; Quote: AnsiChar): AnsiString; overload;
function AnsiExtractQuotedStr(var Src: PWidechar; Quote: WideChar): UnicodeString; overload;
```

C++

```
AnsiString AnsiExtractQuotedStr(PAnsiChar Src, AnsiChar Quote);
UnicodeString AnsiExtractQuotedStr(PWidechar Src, WideChar Quote);
```

File

SysUtils

Description

AnsiExtractQuotedStr removes the quote characters from the beginning and end of a quoted string, and reduces pairs of quote characters within the string to a single quote character. The Quote parameter defines what character to use as a quote character. If the first character in Src is not the value of the Quote parameter, AnsiExtractQuotedStr returns an empty string.

The function copies characters from Src to the result string until the second solitary quote character or the first null character in Src. The Src parameter is updated to point to the first character following the quoted string. If Src does not contain a matching end quote character, the Src parameter is updated to point to the terminating null character.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiQuotedStr (see page 4054)

37.3.10 SysUtils.AnsiLastChar Function

Returns a pointer to the last character in a string.

Pascal

```
function AnsiLastChar(const S: AnsiString): PAnsiChar; overload;
function AnsiLastChar(const S: UnicodeString): PWideChar; overload;
```

C++

```
PAnsiChar AnsiLastChar(const AnsiString S);
PWideChar AnsiLastChar(const UnicodeString S);
```

File

SysUtils

Description

Call AnsiLastChar to obtain the last character in a string. This function supports multi-byte character sets (MBCS).

See Also

AnsiStrLastChar (see page 4057)

AnsiStrRScan (see page 4060)

37.3.11 SysUtils.AnsiLowerCase Function

Returns a string that is a copy of the given string converted to lower case.

Pascal

```
function AnsiLowerCase(const S: string): string; overload;
```

C++

```
UnicodeString AnsiLowerCase(const UnicodeString S);
```

File

SysUtils

Description

AnsiLowerCase returns a string that is a copy of the given string converted to lower case. The conversion uses the current locale. This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCaseFileName (see page 4053)

AnsiUpperCase (see page 4062)

LowerCase (see page 4225)

37.3.12 SysUtils.AnsiLowerCaseFileName Function

Converts a file name to lower case.

Pascal

```
function AnsiLowerCaseFileName(const S: string): string; overload;
```

C++

```
UnicodeString AnsiLowerCaseFileName(const UnicodeString S);
```

File

SysUtils

Description

AnsiLowerCaseFileName returns a string that is a copy of S converted to lower case. The conversion uses the current locale.

Note: On Windows, AnsiLowerCaseFileName supports lowercase conversion idiosyncrasies of file names in Asian locales (Zenkaku).

On Linux, or in locales that do not use multi byte character systems (MBCS), AnsiLowerCaseFileName is identical to AnsiLowerCase (see page 4053).

See Also

AnsiLowerCase (see page 4053)

AnsiUpperCaseFileName (see page 4062)

37.3.13 SysUtils.AnsiPos Function

Locates the position of a substring.

Pascal

```
function AnsiPos(const Substr: string; const S: string): Integer; overload;
```

C++

```
int AnsiPos(const UnicodeString Substr, const UnicodeString S);
```

File

SysUtils

Description

Call AnsiPos to obtain the byte offset of the Substr parameter, as it appears in the string S. For example, if Substr is the string "AB", and S is the string "ABCDE", AnsiPos returns 1. If Substr does not appear in S, AnsiPos returns 0.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiStrPos (see page 4060)

37.3.14 SysUtils.AnsiQuotedStr Function

Returns the quoted version of a string.

Pascal

```
function AnsiQuotedStr(const S: string; Quote: Char): string; overload;
```

C++

```
UnicodeString AnsiQuotedStr(const UnicodeString S, Char Quote);
```

File

SysUtils

Description

Use AnsiQuotedStr to convert a string (S) to a quoted string, using the provided Quote character. A Quote character is inserted at the beginning and end of S, and each Quote character in the string is doubled. To remove the quotes from a quoted string, use AnsiDequotedStr (see page 4051) routine.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiExtractQuotedStr (see page 4052)

QuotedStr (see page 4229)

37.3.15 SysUtils.AnsiSameStr Function

Compares strings based on the current locale with case sensitivity.

Pascal

```
function AnsiSameStr(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean AnsiSameStr(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

AnsiSameStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

AnsiSameText (see page 4055)

AnsiCompareStr (see page 4050)

AnsiSameCaption

37.3.16 SysUtils.AnsiSameText Function

Compares strings based on the current locale without case sensitivity.

Pascal

```
function AnsiSameText(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean AnsiSameText(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

AnsiSameText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

AnsiSameStr (see page 4055)

AnsiCompareText (see page 4051)

AnsiSameCaption

37.3.17 SysUtils.AnsiStrAlloc Function

Pascal

```
function AnsiStrAlloc(Size: Cardinal): PAnsiChar;
```

C++

```
PAnsiChar AnsiStrAlloc(unsigned Size);
```

File

SysUtils

Description

This is function SysUtils.AnsiStrAlloc.

37.3.18 SysUtils.AnsiStrComp Function

Compares null-terminated character strings.

Pascal

```
function AnsiStrComp(S1: PAnsiChar; S2: PAnsiChar): Integer;
function AnsiStrComp(S1: PWideChar; S2: PWideChar): Integer;
```

C++

```
int AnsiStrComp(PAnsiChar S1, PAnsiChar S2);
int AnsiStrComp(PWideChar S1, PWideChar S2);
```

File

SysUtils

Description

AnsiStrComp compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiCompareStr (see page 4050)

AnsiStrIComp (see page 4057)

AnsiStrLComp (see page 4058)

37.3.19 SysUtils.AnsiStrIComp Function

Compares null terminated character strings case insensitively.

Pascal

```
function AnsiStrIComp(S1: PAnsiChar; S2: PAnsiChar): Integer;
function AnsiStrIComp(S1: PWideChar; S2: PWideChar): Integer;
```

C++

```
int AnsiStrIComp(PAnsiChar S1, PAnsiChar S2);
int AnsiStrIComp(PWideChar S1, PWideChar S2);
```

File

SysUtils

Description

AnsiStrIComp compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is the same as for CompareStr (see page 4078).

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiCompareText (see page 4051)

AnsiStrComp (see page 4056)

37.3.20 SysUtils.AnsiStrLastChar Function

Returns a pointer to the last character in a null-terminated string.

Pascal

```
function AnsiStrLastChar(P: PAnsiChar): PAnsiChar; overload;
function AnsiStrLastChar(P: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar AnsiStrLastChar(PAnsiChar P);
PWideChar AnsiStrLastChar(PWideChar P);
```

File

SysUtils

Description

Call AnsiStrLastChar to obtain a pointer to the last full character in a null-terminated sequence. When working with multi-byte character sets (MBCS), the last character will not be the same as the last char value if the last two bytes represent a single double byte character.

See Also

AnsiLastChar (see page 4052)

37.3.21 SysUtils.AnsiStrLComp Function

Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.

Pascal

```
function AnsiStrLComp(S1: PAnsiChar; S2: PAnsiChar; MaxLen: Cardinal): Integer; overload;
function AnsiStrLComp(S1: PWideChar; S2: PWideChar; MaxLen: Cardinal): Integer;
```

C++

```
int AnsiStrLComp(PAnsiChar S1, PAnsiChar S2, unsigned MaxLen);
int AnsiStrLComp(PWideChar S1, PWideChar S2, unsigned MaxLen);
```

File

SysUtils

Description

AnsiStrLComp compares S1 to S2, with case sensitivity. If S1 or S2 is longer than MaxLen bytes, AnsiStrLComp only compares the first MaxLen bytes. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2 (up to MaxLen characters)	= 0

Note: This function supports multi-byte character sets (MBCS).

Note: AnsiStrLComp can continue the comparison beyond a null terminating character if S1 and S2 are equal up to a null character and the null character occurs before MaxLen bytes.

Note: Most locales consider lowercase characters to come before corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters come after uppercase characters.

See Also

AnsiStrComp (see page 4056)

AnsiStrLIComp (see page 4058)

StrLComp (see page 4257)

37.3.22 SysUtils.AnsiStrLIComp Function

Compares two strings, case-insensitively, up to the first MaxLen bytes.

Pascal

```
function AnsiStrLIComp(S1: PAnsiChar; S2: PAnsiChar; MaxLen: Cardinal): Integer; overload;
function AnsiStrLIComp(S1: PWideChar; S2: PWideChar; MaxLen: Cardinal): Integer;
```

C++

```
int AnsiStrLIComp(PAnsiChar S1, PAnsiChar S2, unsigned MaxLen);
int AnsiStrLIComp(PWideChar S1, PWideChar S2, unsigned MaxLen);
```

File

SysUtils

Description

AnsiStrLIComp compares S1 to S2, without case sensitivity. If S1 or S2 is longer than MaxLen characters, AnsiStrLIComp only compares up to the first MaxLen characters. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2 (up to MaxLen characters)	= 0

Note: This function supports multi-byte character sets (MBCS).

Note: AnsiStrLIComp can continue the comparison beyond a null terminating character if S1 and S2 are equal up to a null character and the null character occurs before MaxLen bytes.

See Also

AnsiStrIComp (see page 4057)

AnsiStrLComp (see page 4058)

StrLIComp (see page 4262)

37.3.23 SysUtils.AnsiStrLower Function

Converts all characters in a null-terminated string to lower case.

Pascal

```
function AnsiStrLower(Str: PAnsiChar): PAnsiChar; overload;
function AnsiStrLower(Str: PWideChar): PWideChar;
```

C++

```
PAnsiChar AnsiStrLower(PAnsiChar Str);
PWideChar AnsiStrLower(PWideChar Str);
```

File

SysUtils

Description

AnsiStrLower returns a null-terminated character sequence where all characters are lower case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCase (see page 4053)

AnsiLowerCaseFileName (see page 4053)

AnsiStrUpper (see page 4061)

37.3.24 SysUtils.AnsiStrPos Function

Returns a pointer to the first occurrence of a substring.

Pascal

```
function AnsiStrPos(Str: PAnsiChar; SubStr: PAnsiChar): PAnsiChar; overload;
function AnsiStrPos(Str: PWideChar; SubStr: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar AnsiStrPos(PAnsiChar Str, PAnsiChar SubStr);
PWideChar AnsiStrPos(PWideChar Str, PWideChar SubStr);
```

File

SysUtils

Description

Call AnsiStrPos to locate the first occurrence of SubStr in Str (see page 3676). If SubStr does not occur in Str (see page 3676), AnsiStrPos returns nil (Delphi) or NULL (C++).

Unlike the StrPos (see page 4272) function, AnsiStrPos works with multi-byte characters sets (MBCS).

See Also

AnsiPos (see page 4054)

StrPos (see page 4272)

37.3.25 SysUtils.AnsiStrRScan Function

Returns a pointer to the last occurrence of a specified character in a specified string.

Pascal

```
function AnsiStrRScan(Str: PAnsiChar; Chr: AnsiChar): PAnsiChar; overload;
function AnsiStrRScan(Str: PWideChar; Chr: WideChar): PWideChar;
```

C++

```
PAnsiChar AnsiStrRScan(PAnsiChar Str, AnsiChar Chr);
PWideChar AnsiStrRScan(PWideChar Str, WideChar Chr);
```

File

SysUtils

Description

Call AnsiStrRScan to obtain a pointer to the last occurrence of Chr (see page 3536) in Str (see page 3676). If Chr (see page 3536) does not occur in Str (see page 3676), AnsiStrRScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Unlike the StrRScan (see page 4274) function, AnsiStrRScan works with multi-byte character systems (MBCS).

See Also

AnsiStrScan (see page 4061)

StrRScan (see page 4274)

37.3.26 SysUtils.AnsiStrScan Function

Returns a pointer to first occurrence of a character in a string.

Pascal

```
function AnsiStrScan(Str: PAnsiChar; Chr: AnsiChar): PAnsiChar; overload;
function AnsiStrScan(Str: PWideChar; Chr: WideChar): PWideChar; overload;
```

C++

```
PAnsiChar AnsiStrScan(PAnsiChar Str, AnsiChar Chr);
PWideChar AnsiStrScan(PWideChar Str, WideChar Chr);
```

File

SysUtils

Description

Call AnsiStrScan to obtain a pointer to the first occurrence of Chr (see page 3536) in Str (see page 3676). If Chr (see page 3536) does not occur in Str (see page 3676), AnsiStrScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Unlike the StrScan (see page 4275) function, AnsiStrScan works with multi-byte character systems (MBCS).

See Also

AnsiStrRScan (see page 4060)

StrScan (see page 4275)

37.3.27 SysUtils.AnsiStrUpper Function

Converts all characters in a null-terminated string to upper case.

Pascal

```
function AnsiStrUpper(Str: PAnsiChar): PAnsiChar; overload;
function AnsiStrUpper(Str: PWideChar): PWideChar;
```

C++

```
PAnsiChar AnsiStrUpper(PAnsiChar Str);
PWideChar AnsiStrUpper(PWideChar Str);
```

File

SysUtils

Description

AnsiStrUpper returns a null-terminated string where all characters are upper case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiUpperCase (see page 4062)

AnsiUpperCaseFileName (see page 4062)

AnsiStrLower (see page 4059)

37.3.28 SysUtils.AnsiUpperCase Function

Converts a string to upper case.

Pascal

```
function AnsiUpperCase(const S: string): string; overload;
```

C++

```
UnicodeString AnsiUpperCase(const UnicodeString S);
```

File

SysUtils

Description

AnsiUpperCase returns a string that is a copy of S, converted to upper case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCase (see page 4053)

UpperCase (see page 4311)

37.3.29 SysUtils.AnsiUpperCaseFileName Function

Converts a file name to upper case.

Pascal

```
function AnsiUpperCaseFileName(const S: string): string; overload;
```

C++

```
UnicodeString AnsiUpperCaseFileName(const UnicodeString S);
```

File

SysUtils

Description

AnsiUpperCaseFileName returns a string that is a copy of S converted to upper case. The conversion uses the current locale.

Note: On Windows, AnsiUpperCaseFileName supports uppercase conversion idiosyncrasies of file names in Asian locales (Zenkaku).

On Linux or in locales that do not use multi byte character systems (MBCS), AnsiUpperCaseFileName is identical to AnsiUpperCase (see page 4062).

See Also

AnsiLowerCaseFileName (see page 4053)

AnsiUpperCase (see page 4062)

37.3.30 SysUtils.AppendStr Function

Appends a dynamically allocated string to an existing string.

Pascal

```
procedure AppendStr(var Dest: AnsiString; const S: AnsiString); deprecated;
```

C++

```
AppendStr(AnsiString Dest, const AnsiString S);
```

File

SysUtils

Description

AppendStr appends S to the end of Dest. It is provided for backwards compatibility only. Use the + operator instead:

Dest := Dest + S;

Dest = Dest + S;

37.3.31 SysUtils.AssignStr Function

Assigns a new dynamically allocated string to a specified pointer.

Pascal

```
procedure AssignStr(var P: PAnsiString; const S: AnsiString); deprecated;
```

C++

```
AssignStr(PAnsiString P, const AnsiString S);
```

File

SysUtils

Description

Do not use AssignStr in new applications. It is provided for backward compatibility only.

See Also

DisposeStr (see page 4103)

37.3.32 SysUtils.Beep Function

Emits a message beep.

Pascal

```
procedure Beep;
```

C++

```
Beep();
```

File

SysUtils

Description

Beep generates a conventional message beep.

Note: On Windows, Beep calls the Windows API MessageBeep.

Note: On Linux, to minimize library dependencies in the run time library, the SysUtils (see page 3901) version of Beep has limited Linux functionality. For cross-platform GUI applications, use the QControls version of Beep instead.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection. Notice that the
"Match whole word only" and "Match case" work.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FindDialog1->Position = Point(RichEdit1->Left + RichEdit1->Width, RichEdit1->Top);
  FindDialog1->Execute();
}

void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  int FoundAt, StartPos, ToEnd;
  TSearchTypes mySearchTypes = TSearchTypes();
  // begin the search after the current selection
  // if there is one
  // otherwise, begin at the start of the text
  if (FindDialog1->Options.Contains(frMatchCase))
    mySearchTypes << stMatchCase;
  if (FindDialog1->Options.Contains(frWholeWord))
    mySearchTypes << stWholeWord;
  if (RichEdit1->SelLength)
    StartPos = RichEdit1->SelStart + RichEdit1->SelLength;
  else
    StartPos = 0;
  // ToEnd is the length from StartPos
  // to the end of the text in the rich edit control
  ToEnd = RichEdit1->Text.Length() - StartPos;
  FoundAt = RichEdit1->FindText(FindDialog1->FindText, StartPos, ToEnd, mySearchTypes);
  if (FoundAt != -1)
  {
    RichEdit1->SetFocus();
    RichEdit1->SelStart = FoundAt;
    RichEdit1->SelLength = FindDialog1->FindText.Length();
  }
  else Beep();
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("../Overview.RTF");  // starts in Debug
  RichEdit1->ScrollBars = ssVertical;
}
/*
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    "System ParamStr = " + AnsiString(System::ParamStr(i)),
//    mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  for (int i=1;i<=ParamCount();i++)
  {
    if (LowerCase(ParamStr(i)) == "beep")
      Beep();
    else if (LowerCase(ParamStr(i)) == "exit")
      Application->Terminate();
  }
}
```

Delphi Examples:

```
{
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button click will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FindDialog1.Position :=
    Point(RichEdit1.Left + RichEdit1.Width, RichEdit1.Top);
  FindDialog1.Execute;
end;

procedure TForm1.FindDialog1Find(Sender: TObject);
var
  FoundAt: LongInt;
  StartPos, ToEnd: Integer;
  mySearchTypes : TSearchTypes;
  myFindOptions : TFindOptions;
begin
  mySearchTypes := [];
  with RichEdit1 do
  begin
    if frMatchCase in FindDialog1.Options then
       mySearchTypes := mySearchTypes + [stMatchCase];
    if frWholeWord in FindDialog1.Options then
       mySearchTypes := mySearchTypes + [stWholeWord];
    { begin the search after the current selection if there is one }
    { otherwise, begin at the start of the text }
    if SelLength <> 0 then
      StartPos := SelStart + SelLength
    else
      StartPos := 0;
```

```
      { ToEnd is the length from StartPos to the end of the
        text in the rich edit control }
      ToEnd := Length(Text) - StartPos;
      FoundAt :=
        FindText(FindDialog1.FindText, StartPos, ToEnd, mySearchTypes);
      if FoundAt <> -1 then
      begin
        SetFocus;
        SelStart := FoundAt;
        SelLength := Length(FindDialog1.FindText);
      end
      else Beep;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
  {
  The following example beeps once for each "beep" passed in
  on the command line.  The example terminates the application
  if  "exit" is passed in on the command line.  Build the
  project to generate a .exe file and then execute that file
  from a command line: "ParamCount_proj beep beep exit".
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
  //  Use print statements since you can't use the debugger.
  //  MessageDlg(
  //    'System ParamCount = ' + IntToStr(System.ParamCount),
  //    mtConfirmation, [mbOK], 0);
    for i := 1 to System.ParamCount do
    begin
      if LowerCase(ParamStr(i)) = 'beep' then
        Beep
      else if LowerCase(ParamStr(i)) = 'exit' then
        Application.Terminate;
      Sleep(250);
    end;
  end;
```

37.3.33 SysUtils.BoolToStr Function

Converts a Boolean value to a string.

Pascal

```
function BoolToStr(B: Boolean; UseBoolStrs: Boolean = False): string;
```

C++

```
UnicodeString BoolToStr(Boolean B, Boolean UseBoolStrs = False);
```

File

SysUtils

Description

BoolToStr converts the given Boolean value to a string as follows:

Value of B	Value of UseBoolStrs	Value of returned string
true	false	'-1'
true	true	The first string in TrueBoolStrs (see page 4363) (default 'True');
false	false	'0'
false	true	The first string in FalseBoolStrs (see page 4352) (default 'False');

Note: The TrueBoolStrs (see page 4363) and FalseBoolStrs (see page 4352) variables are undefined when an application starts. Any use of StrToBool (see page 4276), BoolToStr or TryStrToBool (see page 4305) will cause these variables to be initialised with the default values above.

C++ Examples:

```
/*
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
Regional and Language Options in the Windows Control Panel.
*/
void __fastcall TForm1::ApplicationEvents1SettingChange(TObject *Sender, int Flag, const
AnsiString Section, int &Result)
{
  Memo1->Lines->BeginUpdate();
  try
  {
//    char buffer[64];
    AnsiString buffer;
    buffer.sprintf("Section = %s", Section.c_str());
    Memo1->Lines->Add(buffer);
    buffer.sprintf("Flag = %8x", Flag);
    Memo1->Lines->Add(buffer);
    if (strcmp(Section.c_str(), "intl") == 0)
    {
      buffer.sprintf("DefaultLCID = %8x", SysLocale.DefaultLCID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("PriLangID = %8x", SysLocale.PriLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("SubLangID = %8x", SysLocale.SubLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("FarEast = %s", BoolToStr(SysLocale.FarEast, true));
      Memo1->Lines->Add(buffer);
      buffer.sprintf("MiddleEast = %s", BoolToStr(SysLocale.MiddleEast, true));
      Memo1->Lines->Add(buffer);
      Memo1->Lines->Add("");
    }
  }
  __finally
  {
    Memo1->Lines->EndUpdate();
  }
}
```

Delphi Examples:

```
{
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
Regional and Language Options in the Windows Control Panel.
```

```
}
procedure TForm1.ApplicationEvents1SettingChange(Sender: TObject; Flag: Integer; const
Section: string; var Result: Integer);
begin
  Memo1.Lines.BeginUpdate;
  try
    Memo1.Lines.Add(Format('Section  = %s', [Section]));
    Memo1.Lines.Add(Format('Flags  = %.8x', [Flag]));
    if AnsiSameStr(Section, 'intl') then
    with SysLocale do
    begin
      Memo1.Lines.Add(Format('DefaultLCID  = %.8x', [DefaultLCID]));
      Memo1.Lines.Add(Format('PriLangID  = %.8x', [PriLangID]));
      Memo1.Lines.Add(Format('SubLangID  = %.8x', [SubLangID]));
      Memo1.Lines.Add(Format('FarEast  = %s', [BoolToStr(FarEast, True)]));
      Memo1.Lines.Add(Format('MiddleEast  = %s', [BoolToStr(MiddleEast, True)]));
    end;
    Memo1.Lines.Add('');
  finally
    Memo1.Lines.EndUpdate;
  end;
//  Result:= 0;
end;
```

37.3.34 SysUtils.ByteLength Function

Pascal

```
function ByteLength(const S: string): Integer;
```

C++

```
int ByteLength(const UnicodeString S);
```

File

SysUtils

Description

This is function SysUtils.ByteLength.

37.3.35 SysUtils.BytesOf Function

Converts a string into a byte array.

Pascal

```
function BytesOf(const Val: RawByteString): TBytes; overload;
function BytesOf(const Val: UnicodeString): TBytes; overload;
function BytesOf(const Val: WideChar): TBytes; overload;
```

```
function BytesOf(const Val: AnsiChar): TBytes; overload;
```

C++

```
TBytes BytesOf(const RawByteString Val);
TBytes BytesOf(const UnicodeString Val);
TBytes BytesOf(const WideChar Val);
TBytes BytesOf(const AnsiChar Val);
```

File

SysUtils

Description

Call BytesOf to convert a string or a character to an array of bytes. Unicode strings and WideStrings (see page 6807) are converted using the default system locale represented by the Default property of the TEncoding (see page 3969) class.

See Also

TEncoding (see page 3969)

GetBytes (see page 3977)

WideBytesOf (see page 4312)

StringCodePage (see page 3676)

37.3.36 SysUtils.ByteToCharIndex Function

Returns the position of the character that contains a specified byte in a string.

Pascal

```
function ByteToCharIndex(const S: AnsiString; Index: Integer): Integer; overload;
function ByteToCharIndex(const S: UnicodeString; Index: Integer): Integer; overload;
```

C++

```
int ByteToCharIndex(const AnsiString S, int Index);
int ByteToCharIndex(const UnicodeString S, int Index);
```

File

SysUtils

Description

Call ByteToCharIndex to determine which character contains a particular byte in a string, where 1 specifies the first byte, 2 specifies the second byte, and so on. If the Index parameter specifies a byte that is not in the AnsiString (Index < 0 or Index > Length (see page 3607)(S)), ByteToCharIndex returns 0.

If the system does not use a multi-byte character system (MBCS), ByteToCharIndex simply returns the value of Index, because there is a 1:1 correspondence between bytes and characters. Otherwise, ByteToCharIndex returns the position of the character, where 1 specifies the first character, 2 specifies the second character, and so on.

For example, if an AnsiString contains two characters, a single-byte character followed by a double byte character, then ByteToCharIndex returns 1 when Index is 1, it returns 2 when Index is 2 or 3, and it returns 0 for any other value of Index.

See Also

ByteToCharLen (see page 4070)

CharToByteIndex (see page 4075)

37.3.37 SysUtils.ByteToCharLen Function

Returns the number of characters fully contained in the first MaxLen bytes of a string.

Pascal

```
function ByteToCharLen(const S: AnsiString; MaxLen: Integer): Integer; overload;
function ByteToCharLen(const S: UnicodeString; MaxLen: Integer): Integer; overload;
```

C++

```
int ByteToCharLen(const AnsiString S, int MaxLen);
int ByteToCharLen(const UnicodeString S, int MaxLen);
```

File

SysUtils

Description

Call ByteToCharLen to determine the number of characters represented by a portion of a string. ByteToCharLen counts characters until it reaches MaxLen bytes or the end of the string, whichever comes first.

When working with multi-byte character systems (MBCS), the value returned by ByteToCharLen may be less than MaxLen or the length of the string.

Note: ByteToCharLen will count a partial character if it appears as the last of the first MaxLen bytes.

See Also

ByteToCharIndex (see page 4069)

CharToByteIndex (see page 4075)

CharToByteLen (see page 4076)

37.3.38 SysUtils.ByteType Function

Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.

Pascal

```
function ByteType(const S: AnsiString; Index: Integer): TMbcsByteType; overload;
function ByteType(const S: UnicodeString; Index: Integer): TMbcsByteType; overload;
```

C++

```
TMbcsByteType ByteType(const AnsiString S, int Index);
TMbcsByteType ByteType(const UnicodeString S, int Index);
```

File

SysUtils

Description

Call ByteType to determine whether a specified byte in a string is a single-byte character, the first byte of a multibyte character, or one of the trailing bytes.

AnsiString is the string that contains the byte in question.

Index identifies the byte for which you want to know the byte type. Bytes are numbered from 1.

If the system is not using a multi-byte character system (MBCS), ByteType always returns mbSingleByte. Otherwise, ByteType returns mbSingleByte if the indicated byte represents a complete character in S, mbLeadByte if it represents the first byte of a double byte character, and mbTrailByte if it represents a subsequent byte of a multibyte character.

Note: No checking is done to ensure that Index is less than the length of S. It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

LeadBytes (see page 4354)

StrByteType (see page 4242)

37.3.39 SysUtils.CallTerminateProcs Function

Calls all of the functions in the termination procedure list.

Pascal

```
function CallTerminateProcs: Boolean;
```

C++

```
Boolean CallTerminateProcs();
```

File

SysUtils

Description

CallTerminateProcs is called internally when an application is about to terminate. It returns true only if all of the functions in the application's terminate procedure list return true. Do not call this function directly. Its use is automatic in Delphi application.

See Also

AddTerminateProc (see page 4048)

37.3.40 SysUtils.ChangeFileExt Function

Changes the extension of a file name.

Pascal

```
function ChangeFileExt(const FileName: string; const Extension: string): string; overload;
```

C++

```
UnicodeString ChangeFileExt(const UnicodeString FileName, const UnicodeString Extension);
```

File

SysUtils

Description

ChangeFileExt takes the file name passed in FileName and changes the extension of the file name to the extension passed in Extension. Extension specifies the new extension, including the initial dot character.

ChangeFileExt does not rename the actual file, it just creates a new file name string.

Note: This function works with multi-byte character sets (MBCS).

C++ Examples:

```
/*
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::ConvertIcon2BitmapClick(TObject *Sender)
{
  OpenDialog1->DefaultExt = ".ICO";
  OpenDialog1->Filter = "icons (*.ico)|*.ICO";
  OpenDialog1->Options << ofOverwritePrompt << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    std::auto_ptr<TIcon> pi(new Graphics::TIcon);
    AnsiString as;
    pi->LoadFromFile(OpenDialog1->FileName);
    as = ChangeFileExt(OpenDialog1->FileName,".BMP");
    Image1->Width = pi->Width;
    Image1->Height = pi->Height;
    Image1->Canvas->Draw(0, 0, pi.get());
    Image1->Picture->SaveToFile(as);
    ShowMessage(OpenDialog1->FileName + " Saved to " + as);
  }
}
```

Delphi Examples:

```
{
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
}
procedure TForm1.ConvertIcon2BitmapClick(Sender: TObject);
var
  s : string;
  Icon: TIcon;
begin
  OpenDialog1.DefaultExt := '.ICO';
  OpenDialog1.Filter := 'icons (*.ico)|*.ICO';
  OpenDialog1.Options := [ofOverwritePrompt, ofFileMustExist, ofHideReadOnly ];
  if OpenDialog1.Execute then
  begin
    Icon := TIcon.Create;
    try
      Icon.Loadfromfile(OpenDialog1.FileName);
      s:= ChangeFileExt(OpenDialog1.FileName,'.BMP');
      Image1.Width := Icon.Width;
      Image1.Height := Icon.Height;
      Image1.Canvas.Draw(0,0,Icon);
      Image1.Picture.SaveToFile(s);
      ShowMessage(OpenDialog1.FileName + ' Saved to ' + s);
    finally
      Icon.Free;
    end;
  end;
```

```
end;
```

See Also

ExtractFileExt (see page 4113)

37.3.41 SysUtils.ChangeFilePath Function

Changes the path of a file name.

Pascal

```
function ChangeFilePath(const FileName: string; const Path: string): string; overload;
```

C++

```
UnicodeString ChangeFilePath(const UnicodeString FileName, const UnicodeString Path);
```

File

SysUtils

Description

ChangeFilePath replaces the drive and directory parts of the passed FileName with the passed Path value. If Path is not blank, it must specify a drive (terminated by a colon) and/or a directory (terminated by a backslash).

ChangeFilePath does not rename the actual file, it just creates a new file name string.

Note: This function works with multi-byte character sets (MBCS).

See Also

ExtractFilePath (see page 4115)

37.3.42 SysUtils.CharInSet Function

CharInSet checks whether a given character is contained within a set.

Pascal

```
function CharInSet(C: AnsiChar; const CharSet: TSysCharSet): Boolean; overload;
function CharInSet(C: WideChar; const CharSet: TSysCharSet): Boolean; overload;
```

C++

```
Boolean CharInSet(AnsiChar C, const TSysCharSet CharSet);
Boolean CharInSet(WideChar C, const TSysCharSet CharSet);
```

File

SysUtils

Description

Use CharInSet to check whether a given character is contained within a set of characters. CharInSet checks whether the `C` parameter is contained within the `CharSet` set. `C` can either be a Unicode or an ANSI character, while `CharSet` can only be a set of ANSI characters. The function returns **True** if the character is contained within the set and **False** if the character is not contained within the set or if the character is Unicode.

Note: We recommend that the TCharacter class (which is Unicode enabled) be used whenever possible to check whether a

character enters a certain category, such as digits or letters.

See Also

inOpArray (see page 6871)

inOpSet (see page 6871)

TCharacter

37.3.43 SysUtils.CharLength Function

Returns number of bytes used by character.

Pascal

```
function CharLength(const S: AnsiString; Index: Integer): Integer; overload;
function CharLength(const S: UnicodeString; Index: Integer): Integer; overload;
```

C++

```
int CharLength(const AnsiString S, int Index);
int CharLength(const UnicodeString S, int Index);
```

File

SysUtils

Description

Call CharLength to determine the size in bytes of the character starting at `Index` in `S`. If the character does not start at `Index`, this function returns the size of the *remainder* of the character, not the full character length.

Note: `Index` is an *element* index into S, not a byte or character index.

If `S` is an **AnsiString** and the system is not using a multi-byte character system (MBCS), CharLength always returns 1.

The following example illustrates CharLength's operation.

```
type
  SJISString = type AnsiString(932);
var
  A: SJISString;
  L: Integer;
begin
  A := 'A' +
       'B' +
       #$82#$A0 +  // Japanese Hiragana 'A'
       #$82#$A2 +  // Japanese Hiragana 'I'
       #$82#$A4 +  // Japanese Hiragana 'U'
       'C' +
       'D';

  L := CharLength(A, 1);     //returns 1 ('A')
  L := CharLength(A, 2);     //returns 1 ('B')
  L := CharLength(A, 3);     //returns 2
  L := CharLength(A, 4);     //returns 1
end;
```

In this example, when the index is 1 or 2, it points to the beginning of a single byte character, so the function returns 1. When the index is 3, it points to the beginning of a two byte character, and the function returns 2. When the index is 4, it points to the second half of a two byte character and returns 1. Note that for this example, the element size is 1. Some characters require two elements, and some only need one element.

In general, CharLength is only useful when you start indexing at the beginning of a string and note where multibyte characters start as the index increases.

This function also works for Unicode characters:

```
var
  U: UnicodeString;
  L: Integer;
begin
  U := 'abc';
  L := SysUtils.CharLength(U,1); //returns 2
  L := SysUtils.CharLength(U,2); //returns 2

  U := #$20BB7; //surrogate pair
  L := SysUtils.CharLength(U,1); //returns 4
  L := SysUtils.CharLength(U,2); //returns 2
  end;
```

Note that the element size is 2 in this example, and the surrogate pair character consists of two elements.

When the string is 'abc', each character is a single two byte element, so the function returns 2. String literals are Unicode by default.

For the surrogate pair, when the index is 1, it points to the first element in the character, so the function returns 4. When the index is 2, it points to the second element in the character and returns 2.

See Also

CharLength

37.3.44 SysUtils.CharToByteIndex Function

Returns the 1-based index of the first byte of a specified character in a string.

Pascal

```
function CharToByteIndex(const S: AnsiString; Index: Integer): Integer; overload;
function CharToByteIndex(const S: UnicodeString; Index: Integer): Integer; overload;
```

C++

```
int CharToByteIndex(const AnsiString S, int Index);
int CharToByteIndex(const UnicodeString S, int Index);
```

File

SysUtils

Description

Call CharToByteIndex to obtain the byte offset for the character at a specified position in the string S, where 1 specifies the first character, 2 specifies the second character, and so on. CharToByteIndex returns zero if Index is out of range (Index <= 0 or S contains fewer than Index characters). If the Index parameter indicates a double-byte character, CharToByteIndex returns the offset of the first byte.

If the system is not using a multi-byte character system (MBCS), CharToByteIndex returns the value of Index, because there is a 1:1 correspondence between bytes and characters.

See Also

ByteToCharIndex (see page 4069)

CharToByteLen (see page 4076)

37.3.45 SysUtils.CharToByteLen Function

Returns the length, in bytes, of the first MaxLen characters of a string.

Pascal

```
function CharToByteLen(const S: AnsiString; MaxLen: Integer): Integer; overload;
function CharToByteLen(const S: UnicodeString; MaxLen: Integer): Integer; overload;
```

C++

```
int CharToByteLen(const AnsiString S, int MaxLen);
int CharToByteLen(const UnicodeString S, int MaxLen);
```

File

SysUtils

Description

Call CharToByteLen to convert the length of a string in characters to the corresponding length in bytes. CharToByteLen returns the number of bytes required by the first MaxLen characters of S. If S contains fewer than MaxLen characters, CharToByteLen returns the byte length of S.

If the system is not using a multi-byte character system (MBCS), CharToByteLen returns the length of S or MaxLen, whichever is smaller.

See Also

ByteToCharLen (see page 4070)

CharToByteIndex (see page 4075)

37.3.46 SysUtils.CharToElementIndex Function

Pascal

```
function CharToElementIndex(const S: AnsiString; Index: Integer): Integer; overload;
```

C++

```
int CharToElementIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

This is function SysUtils.CharToElementIndex.

37.3.47 SysUtils.CharToElementIndex Function

Pascal

```
function CharToElementIndex(const S: UnicodeString; Index: Integer): Integer; overload;
```

C++

```
int CharToElementIndex(const UnicodeString S, int Index);
```

File

SysUtils

Description

This is function SysUtils.CharToElementIndex.

37.3.48 SysUtils.CharToElementLen Function

Pascal

```
function CharToElementLen(const S: AnsiString; MaxLen: Integer): Integer; overload;
```

C++

```
int CharToElementLen(const AnsiString S, int MaxLen);
```

File

SysUtils

Description

This is function SysUtils.CharToElementLen.

37.3.49 SysUtils.CharToElementLen Function

Pascal

```
function CharToElementLen(const S: UnicodeString; MaxLen: Integer): Integer; overload;
```

C++

```
int CharToElementLen(const UnicodeString S, int MaxLen);
```

File

SysUtils

Description

This is function SysUtils.CharToElementLen.

37.3.50 SysUtils.CheckWin32Version Function

Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 3159).

Pascal

```
function CheckWin32Version(AMajor: Integer; AMinor: Integer = 0): Boolean;
```

C++

```
Boolean CheckWin32Version(int AMajor, int AMinor = 0);
```

File

SysUtils

Description

The Windows Operating System (see page 3159) Major.Minor version number is compared with the passed AMajor and AMinor values. AMinor defaults to 0 if not supplied.

CheckWin32Version Returns true if the Windows OS Major.Minor version number is >= the passed AMajor.AMinor value.

Note: Prior to Delphi 7, this routine returned a different result.

See Also

Win32MajorVersion (see page 4365)Win32MinorVersion (see page 4366)

37.3.51 SysUtils.CompareMem Function

Performs a binary comparison of two memory images.

Pascal

```
function CompareMem(P1: Pointer; P2: Pointer; Length: Integer): Boolean;
```

C++

```
Boolean CompareMem(void * P1, void * P2, int Length);
```

File

SysUtils

Description

CompareMem performs a binary compare of Length (see page 3607) bytes of memory referenced by P1 to that of P2. CompareMem returns true if the memory referenced by P1 is identical to that of P2.

See Also

CompareStr (see page 4078)

CompareText (see page 4079)

CollectionsEqual

37.3.52 SysUtils.CompareStr Function

Compares two strings case sensitively.

Pascal

```
function CompareStr(const S1: string; const S2: string): Integer; overload;
function CompareStr(const S1: string; const S2: string; LocaleOptions: TLocaleOptions):
Integer; overload;
```

C++

```
int CompareStr(const UnicodeString S1, const UnicodeString S2);
int CompareStr(const UnicodeString S1, const UnicodeString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

CompareStr compares S1 to S2, with case-sensitivity. The return value is less than 0 if S1 is less than S2, 0 if S1 equals S2, or greater than 0 if S1 is greater than S2. The compare operation is based on the 8-bit ordinal value of each character and is not affected by the current locale.

C++ Examples:

```
/*
The following code compares String1, 'STEVE', to String2,
'STEVe'. Note that CompareStr returns a number less than 0
because the value of 'e' is greater than the value of 'E'.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString String1 = "STEVE";
  AnsiString String2 = "Steve";
  int I = CompareStr(String1, String2);  // the value of I is < 0
  Edit1->Text = IntToStr(I);
  if (I != 0)
    ShowMessage ("The strings are not equal");
}
```

Delphi Examples:

```
{
The following code compares String1, 'STEVE', to String2,
'STEVe'. Note that CompareStr returns a number less than 0
because the value of 'e' is greater than the value of 'E'.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  String1, String2 : string;
  I : Integer;
begin
  String1 := 'STEVE';
  String2 := 'STEVe';
  I := SysUtils.CompareStr(String1, String2);  { the value of I is < 0 }
  Edit1.Text := InttoStr(I);
  if I <> 0 then
    MessageDlg('The strings are not equal', mtWarning, [mbOK], 0)
end;
```

AnsiCompareStr (see page 4050)

37.3.53 SysUtils.CompareText Function

Compares two strings by ordinal value without case sensitivity.

Pascal

```
function CompareText(const S1: string; const S2: string): Integer; overload;
function CompareText(const S1: string; const S2: string; LocaleOptions: TLocaleOptions):
Integer; overload;
```

C++

```
int CompareText(const UnicodeString S1, const UnicodeString S2);
int CompareText(const UnicodeString S1, const UnicodeString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

CompareText compares S1 and S2 and returns 0 if they are equal. If S1 is greater than S2, CompareText returns an integer greater than 0. If S1 is less than S2, CompareText returns an integer less than 0. CompareText is not case sensitive and is not affected by the current locale.

C++ Examples:

```
/*
The following code orders a list view in reverse
alphabetical order on the click of a button. The callback
function CustomSortProc calls the global CompareText
function and negates its return value.
*/
int __stdcall CustomSortProc(long Item1, long Item2, long ParamSort)
{
  return -CompareText((reinterpret_cast<TListItem *>(Item1))->Caption,
                      (reinterpret_cast<TListItem *>(Item2))->Caption);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListView1->CustomSort(CustomSortProc, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *ListItem;
  ListView1->ViewStyle = vsList;
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Apples";
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Oranges";
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Pears";
}
/*
This example shows how to use the OnColumnClick and
OnCompare events of a list view to let users sort the
columns in a report-style list view by clicking on the
column headers. This requires a global variable to keep
track of the column that was clicked.  The OnColumnClick
event handler sets the global variable to indicate the
column to sort and calls AlphaSort:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {
    "C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {
    "Documentation for the C++ icon.",
    "Borland icon.", "Delphi icon."
    };
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
```

```
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  ListView1->ViewStyle = vsReport;
}

int ColumnToSort = 0;

/*
The OnColumnClick event handler sets the global variable to
indicate the column to sort and calls AlphaSort:
*/

void __fastcall TForm1::ListView1ColumnClick(TObject *Sender,
      TListColumn *Column)
{
  ColumnToSort = Column->Index;
  dynamic_cast<TCustomListView *>(Sender)->AlphaSort();
}

/*
The OnCompare event handler causes the list view to sort on
the selected column:
*/

void __fastcall TForm1::ListView1Compare(TObject *Sender, TListItem *Item1,
      TListItem *Item2, int Data, int &Compare)
{
  if (ColumnToSort == 0)
    Compare = CompareText(Item1->Caption,Item2->Caption);
  else
  {
    int ix = ColumnToSort - 1;
    Compare =
      CompareText(Item1->SubItems->Strings[ix], Item2->SubItems->Strings[ix]);
  }
}
```

Delphi Examples:

```
{
The following code orders a list view in reverse
alphabetical order on the click of a button. The callback
function CustomSortProc calls the global CompareText
function and negates its return value.
}
function CustomSortProc(Item1, Item2: TListItem; ParamSort: integer): integer; stdcall;
begin
  Result := -CompareText(Item1.Caption,Item2.Caption);
end;
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListView1.CustomSort(@CustomSortProc, 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
  var ListItem : TListItem;
  begin
    ListView1.ViewStyle := vsList;
    ListItem := ListView1.Items.Add;
    ListItem.Caption := 'Apples';
    ListItem := ListView1.Items.Add;
    ListItem.Caption := 'Oranges';
    ListItem := ListView1.Items.Add;
    ListItem.Caption := 'Pears';
  end;
  {
  This example shows how to use the OnColumnClick and
  OnCompare events of a list view to let users sort the
  columns in a report-style list view by clicking on the
  column headers. This requires a global variable to keep
  track of the column that was clicked.  The OnColumnClick
  event handler sets the global variable to indicate the
  column to sort and calls AlphaSort:
  }
  var ColumnToSort: Integer;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    I: Integer;
    ListItem: TListItem;
    NewColumn: TListColumn;
  const
    imagenames: Array[0..2] of string = ('C++ Image', 'Borland Image', 'Delphi Image');
  begin
    Col2Array[0]:= 'Documentation for the C++ icon.';
    Col2Array[1]:= 'Borland icon.';
    Col2Array[2]:= 'Delphi icon.';
    // Create a ListView item for each image in the ImageList
    with ListView1 do
    begin
      SmallImages := ImageList1;
      LargeImages := ImageList1;
      for I := 0 to ImageList1.Count - 1 do
      begin
        ListItem := Items.Add;
        Listitem.Caption := imagenames[I];
        ListItem.ImageIndex := I;
        Listitem.SubItems.Add(Col2Array[I]);
      end;
      // Create two columns to show during viewing as vsReport
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 1';
      NewColumn.Width := 200;
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 2';
      NewColumn.Width := 200;
      ListView1.ViewStyle := vsReport;
    end;
  end;

  procedure TForm1.ListView1ColumnClick(Sender: TObject; Column: TListColumn);
  begin
    ColumnToSort := Column.Index;
    (Sender as TCustomListView).AlphaSort;
  end;

  {
  The OnCompare event handler causes the list view to sort on
  the selected column:
  }
  procedure TForm1.ListView1Compare(Sender: TObject; Item1, Item2: TListItem; Data: Integer; var
```

```
  Compare: Integer);
  var
    ix: Integer;
  begin
    if ColumnToSort = 0 then
      Compare := CompareText(Item1.Caption,Item2.Caption)
    else begin
     ix := ColumnToSort - 1;
     Compare := CompareText(Item1.SubItems[ix],Item2.SubItems[ix]);
    end;
  end;
  {
  Note:   This OnCompare event handler uses the global
  CompareText function. An application may want to use
  AnsiCompareText, CompareStr, or AnsiCompareStr instead,
  depending on whether the comparison should be case-sensitive
  and whether the locale should be considered.
  }
```

AnsiCompareText (see page 4051)

CompareMem (see page 4078)

SameText (see page 4239)

37.3.54 SysUtils.CreateDir Function

Creates a new directory.

Pascal

```
function CreateDir(const Dir: string): Boolean;
```

C++

```
Boolean CreateDir(const UnicodeString Dir);
```

File

SysUtils

Description

CreateDir creates a new directory. The return value is true if a new directory was successfully created, or false if an error occurred.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
```

```
  if (!CreateDir("C:\\temp"))
    throw Exception("Cannot create C:\\temp again!");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
```

GetCurrentDir (see page 4202)

RemoveDir (see page 4232)

SetCurrentDir (see page 4240)

37.3.55 SysUtils.CreateGUID Function

Creates a globally unique identifier.

Pascal

```
function CreateGUID(out Guid: TGUID): HResult; stdcall;
```

C++

```
__stdcall HRESULT CreateGUID(TGUID Guid);
```

File

SysUtils

Description

CreateGUID sets Guid to a new-created Globally Unique Identifier.

Note: Under Windows, CreateGUID calls the Windows API CoCreateGUID.

Note: Under Linux, CreateGUID calls uuid_generate_time.

C++ Examples:

```
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
```

```
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
              "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
         ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
         myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
         myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7])));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));

    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));

  { Auto-generate a random GUID at runtime }
  if CreateGUID(MyGuid1) <> 0 then
     Memo1.Lines.Add('Creating GUID failed!')
  else
     Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

  { Generating second random GUID }
  CreateGUID(MyGuid0);
```

```
    { Testing if 2 guids are equal }
    if IsEqualGUID(MyGuid0, MyGuid1) then
       Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                       '2 randomly generated GUIDs cannot be equal!');
end;
```

37.3.56 SysUtils.CurrentYear Function

Returns the current year.

Pascal

```
function CurrentYear: Word;
```

C++

```
Word CurrentYear();
```

File

SysUtils

Description

CurrentYear returns the current year on the Gregorian calendar. The value returned is the complete four-digit year.

37.3.57 SysUtils.CurrToStr Function

Formats a Currency (see page 3235) value as a string.

Pascal

```
function CurrToStr(Value: Currency): string; overload;
function CurrToStr(Value: Currency; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
UnicodeString CurrToStr(Currency Value);
UnicodeString CurrToStr(Currency Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

CurrToStr converts the Currency (see page 3235) value given by Value to its string representation. The conversion uses the ffGeneral floating point conversion rules.

The first form of CurrToStr is not thread-safe, because it uses localization information contained in global variables. The second form of CurrToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of CurrToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.58 SysUtils.CurrToStrF Function

Converts a Currency (see page 3235) value to a string, using a specified format.

Pascal

```
function CurrToStrF(Value: Currency; Format: TFloatFormat; Digits: Integer): string; overload;
function CurrToStrF(Value: Currency; Format: TFloatFormat; Digits: Integer; const
FormatSettings: TFormatSettings): string; overload;
```

C++

```
UnicodeString CurrToStrF(Currency Value, TFloatFormat Format, int Digits);
UnicodeString CurrToStrF(Currency Value, TFloatFormat Format, int Digits, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

CurrToStrF converts the Currency (see page 3235) value given by Value to its string representation using the indicated float format convention. A call to CurrToStrF corresponds to a call to FloatToStrF (see page 4182) with an implied precision of 19 digits.

The first form of CurrToStrF is not thread-safe, because it uses localization information contained in global variables. The second form of CurrToStrF, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of CurrToStrF, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.59 SysUtils.Date Function

Returns the current date.

Pascal

```
function Date: TDateTime;
```

C++

```
TDateTime Date();
```

File

SysUtils

Description

Use Date to obtain the current local date as a TDateTime (see page 3323) value. The time portion of the value is 0 (midnight).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateToStr(Date());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := 'Today is  ' + SysUtils.DateToStr(Date);
end;
```

37.3.60 SysUtils.DateTimeToFileDate Function

Converts a TDateTime (see page 3323) value to an OS timestamp value.

Pascal

```
function DateTimeToFileDate(DateTime: TDateTime): Integer;
```

C++

```
int DateTimeToFileDate(TDateTime DateTime);
```

File

SysUtils

Description

A timestamp is a signed 32-bit integer, used by the Operating System (see page 3159) to record information such as the date and time a file was modified. The precise format of a timestamp depends on the OS. Use DateTimeToFileDate to convert a TDateTime (see page 3323) value to an OS timestamp value.

DateTimeToFileDate is particularly useful for converting the Time (see page 4297) field of the TSearchRec (see page 4330) type used by the FindFirst (see page 4175) and FindNext (see page 4177) functions.

See Also

FileDateToDateTime (see page 4130)

FindFirst (see page 4175)

FindNext (see page 4177)

TSearchRec (see page 4330)

37.3.61 SysUtils.DateTimeToStr Function

Converts a TDateTime (see page 3323) value to a string.

Pascal

```
function DateTimeToStr(const DateTime: TDateTime): string; overload;
function DateTimeToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings):
string; overload;
```

C++

```
UnicodeString DateTimeToStr(const TDateTime DateTime);
UnicodeString DateTimeToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

The first form of DateTimeToStr is not thread-safe, because it uses localization information contained in global variables. The second form of DateTimeToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateTimeToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateTimeToStr(Now());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.DateTimeToStr(Now);
end;
```

37.3.62 SysUtils.DateTimeToString Function

Converts a TDateTime (see page 3323) value to a string using a specified Format (see page 4188).

Pascal

```
procedure DateTimeToString(var Result: string; const Format: string; DateTime: TDateTime);
overload;
```

```
procedure DateTimeToString(var Result: string; const Format: string; DateTime: TDateTime;
const FormatSettings: TFormatSettings); overload;
```

C++

```
DateTimeToString(UnicodeString Result, const UnicodeString Format, TDateTime DateTime);
DateTimeToString(UnicodeString Result, const UnicodeString Format, TDateTime DateTime, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

DateTimeToString converts the TDateTime (see page 3323) value given by DateTime using the format string given by Format (see page 4188) into the string variable given by Result. See the table below for information about the supported format strings.

The first form of DateTimeToString is not thread-safe, because it uses localization information contained in global variables. The second form of DateTimeToString, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateTimeToString, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

Date (see page 4087) Time (see page 4297) Format (see page 4188) Strings are composed from specifiers that represent values to be inserted into the formatted string. Some specifiers (such as "d"), simply format numbers or strings. Other specifiers (such as "/") refer to locale-specific strings from global variables.

In the following table, specifiers are given in lower case. Case is ignored in formats, except for the "am/pm" and "a/p" specifiers.

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat (see page 4358) global variable, followed by the time using the format given by the LongTimeFormat (see page 4356) global variable. The time is not displayed if the date-time value indicates midnight precisely.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames (see page 4359) global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames (see page 4355) global variable.
ddddd	Displays the date using the format given by the ShortDateFormat (see page 4358) global variable.
dddddd	Displays the date using the format given by the LongDateFormat (see page 4354) global variable.
e	(Windows only) Displays the year in the current period/era as a number without a leading zero (Japanese, Korean and Taiwanese locales only).
ee	(Windows only) Displays the year in the current period/era as a number with a leading zero (Japanese, Korean and Taiwanese locales only).
g	(Windows only) Displays the period/era as an abbreviation (Japanese and Taiwanese locales only).
gg	(Windows only) Displays the period/era as a full name. (Japanese and Taiwanese locales only).
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec (see page 3550)) using the strings given by the ShortMonthNames (see page 4359) global variable.

mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames (see page 4355) global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
z	Displays the millisecond without a leading zero (0-999).
zzz	Displays the millisecond with a leading zero (000-999).
t	Displays the time using the format given by the ShortTimeFormat (see page 4360) global variable.
tt\	Displays the time using the format given by the LongTimeFormat (see page 4356) global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString (see page 4362) global variable for any hour before noon, and the contents of the TimePMString (see page 4362) global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator (see page 4349) global variable.
:	Displays the time separator character given by the TimeSeparator (see page 4363) global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, and do not affect formatting.

DateTimeToStr (see page 4089)

GetLocaleFormatSettings (see page 4206)

37.3.63 SysUtils.DateTimeToSystemTime Function

Converts a TDateTime (see page 3323) value into the Win32 API's system time type.

Pascal

```
procedure DateTimeToSystemTime(const DateTime: TDateTime; var SystemTime: TSystemTime);
```

C++

```
DateTimeToSystemTime(const TDateTime DateTime, TSystemTime SystemTime);
```

File

SysUtils

Description

Use DateTimeToSystemTime to convert a TDateTime (see page 3323) value into a TSystemTime (Delphi) or _SYSTEMTIME (C++) value. This procedure is primarily used to convert TDateTime (see page 3323) values for making a Windows API call.

See Also

SystemTimeToDateTime (see page 4295)

37.3.64 SysUtils.DateTimeToTimeStamp Function

Converts a TDateTime (see page 3323) value into the corresponding TTimeStamp (see page 4334) value.

Pascal

```
function DateTimeToTimeStamp(DateTime: TDateTime): TTimeStamp;
```

C++

```
TTimeStamp DateTimeToTimeStamp(TDateTime DateTime);
```

File

SysUtils

Description

Call DateTimeToTimeStamp to convert a TDateTime (see page 3323) value into a TTimeStamp (see page 4334) value.

See Also

TimeStampToDateTime (see page 4298)

37.3.65 SysUtils.DateToStr Function

Converts a TDateTime (see page 3323) value to a string.

Pascal

```
function DateToStr(const DateTime: TDateTime): string; overload;
function DateToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings): string;
overload;
```

C++

```
UnicodeString DateToStr(const TDateTime DateTime);
UnicodeString DateToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use DateToStr to obtain a string representation of a date value that can be used for display purposes.

The first form of DateToStr is not thread-safe, because it uses localization information contained in global variables. The second form of DateToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DateSeparator = '-';
  ShortDateFormat = "m/d/yyyy";
  Label1->Caption = DateToStr(Date());
}
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateToStr(Date());
}
/*
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeDate((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text));
    Label1->Caption = DateToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid day, month, or year.");
  }
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DateSeparator := '-';
  ShortDateFormat := 'm/d/yyyy';
  Label1.Caption := DateToStr(Date);
end;
{
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := 'Today is  ' + SysUtils.DateToStr(Date);
end;
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeDate(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text));
  Label1.Caption := DateToStr(MyDate);
end;
```

37.3.66 SysUtils.DayOfWeek Function

Returns the day of the week for a specified date.

Pascal

```
function DayOfWeek(const DateTime: TDateTime): Word;
```

C++

```
Word DayOfWeek(const TDateTime DateTime);
```

File

SysUtils

Description

DayOfWeek returns the day of the week of the specified date as an integer between 1 and 7, where Sunday is the first day of the week and Saturday is the seventh.

Note: DayOfWeek is not compliant with the ISO 8601 standard, which defines Monday as the first day of the week. For an ISO 8601 compliant version, use the DayOfTheWeek function instead.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char days[7][10] = {"Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday",
"Saturday" };
  TDateTime dtDate = StrToDate(Edit1->Text);
  ShowMessage(Edit1->Text + AnsiString(" is a ") + days[dtDate.DayOfWeek() - 1]);
}
```

Delphi Examples:

```
{
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ADate: TDateTime;
  days: array[1..7] of string;
begin
  days[1] := 'Sunday';
  days[2] := 'Monday';
  days[3] := 'Tuesday';
  days[4] := 'Wednesday';
  days[5] := 'Thursday';
  days[6] := 'Friday';
  days[7] := 'Saturday';
  ADate := StrToDate(Edit1.Text);
  ShowMessage(Edit1.Text + ' is a ' + days[SysUtils.DayOfWeek(ADate)]);
end;
```

DayOfTheWeek

37.3.67 SysUtils.DecodeDate Function

Returns Year, Month, and Day values for a TDateTime (see page 3323) value.

Pascal

```
procedure DecodeDate(const DateTime: TDateTime; var Year: Word; var Month: Word; var Day:
Word);
```

C++

```
DecodeDate(const TDateTime DateTime, Word Year, Word Month, Word Day);
```

File

SysUtils

Description

The DecodeDate procedure breaks the value specified as the Date (see page 4087) parameter into Year, Month, and Day values. If the given TDateTime (see page 3323) value has a negative (BC) year, the year, month, and day return parameters are all set to zero.

C++ Examples:

```
/*
This example uses a button and two labels on a form. When
```

```
  the user clicks the button, the current date and time are
  reported in the captions of the two labels.
  */
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    Word Year, Month, Day, Hour, Min, Sec, MSec;
    TDateTime dtPresent = Now();
    DecodeDate(dtPresent, Year, Month, Day);
    Label1->Caption = AnsiString("Today is Day ") + IntToStr(Day) + AnsiString(" of Month ") +
  IntToStr(Month) + AnsiString(" of Year ") + IntToStr(Year);
    DecodeTime(dtPresent, Hour, Min, Sec, MSec);
    Label2->Caption = AnsiString("The time is Minute ") + IntToStr(Min) + AnsiString(" of Hour
  ") + IntToStr(Hour);
  }
```

Delphi Examples:

```
  {
  This example uses a button and two labels on a form. When
  the user clicks the button, the current date and time are
  reported in the captions of the two labels.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    Present: TDateTime;
    Year, Month, Day, Hour, Min, Sec, MSec: Word;
   begin
    Present:= Now;
    SysUtils.DecodeDate(Present, Year, Month, Day);
    Label1.Caption := 'Today is Day ' + IntToStr(Day) + ' of Month '
      + IntToStr(Month) + ' of Year ' + IntToStr(Year);
    SysUtils.DecodeTime(Present, Hour, Min, Sec, MSec);
    Label2.Caption := 'The time is Minute ' + IntToStr(Min) + ' of Hour '
      + IntToStr(Hour);
  end;
```

MonthOf

DecodeDateTime

37.3.68 SysUtils.DecodeDateFully Function

Returns Year, Month, and Day, and Day-of-Week values for a TDateTime (see page 3323) value.

Pascal

```
  function DecodeDateFully(const DateTime: TDateTime; var Year: Word; var Month: Word; var Day:
  Word; var DOW: Word): Boolean;
```

C++

```
  Boolean DecodeDateFully(const TDateTime DateTime, Word Year, Word Month, Word Day, Word DOW);
```

File

SysUtils

Description

DecodeDateFully procedure breaks the value specified as the Date (see page 4087) parameter into Year, Month, Day, and DOW values. If Year is a leap year, the function return value is True; otherwise the function return value is false. If the given TDateTime (see page 3323) value has a negative (BC) year, the return parameters are all set to zero.

DayOf

YearOf

MonthOf

DecodeDateTime

37.3.69 SysUtils.DecodeTime Function

Breaks a TDateTime (see page 3323) value into hours, minutes, seconds, and milliseconds.

Pascal

```
procedure DecodeTime(const DateTime: TDateTime; var Hour: Word; var Min: Word; var Sec: Word;
var MSec: Word);
```

C++

```
DecodeTime(const TDateTime DateTime, Word Hour, Word Min, Word Sec, Word MSec);
```

File

SysUtils

Description

DecodeTime breaks the object specified as the Time (see page 4297) parameter into hours, minutes, seconds, and milliseconds.

C++ Examples:

```
/*
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Word Year, Month, Day, Hour, Min, Sec, MSec;
  TDateTime dtPresent = Now();
  DecodeDate(dtPresent, Year, Month, Day);
  Label1->Caption = AnsiString("Today is Day ") + IntToStr(Day) + AnsiString(" of Month ") +
IntToStr(Month) + AnsiString(" of Year ") + IntToStr(Year);
  DecodeTime(dtPresent, Hour, Min, Sec, MSec);
  Label2->Caption = AnsiString("The time is Minute ") + IntToStr(Min) + AnsiString(" of Hour
") + IntToStr(Hour);
}
```

Delphi Examples:

```
{
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Present: TDateTime;
  Year, Month, Day, Hour, Min, Sec, MSec: Word;
 begin
  Present:= Now;
  SysUtils.DecodeDate(Present, Year, Month, Day);
  Label1.Caption := 'Today is Day ' + IntToStr(Day) + ' of Month '
    + IntToStr(Month) + ' of Year ' + IntToStr(Year);
  SysUtils.DecodeTime(Present, Hour, Min, Sec, MSec);
  Label2.Caption := 'The time is Minute ' + IntToStr(Min) + ' of Hour '
    + IntToStr(Hour);
end;
```

37.3.70 SysUtils.DelegatesEqual Function

Pascal

```
function DelegatesEqual(A: Pointer; B: Pointer): Boolean;
```

C++

```
Boolean DelegatesEqual(void * A, void * B);
```

File

SysUtils

Description

This is function SysUtils.DelegatesEqual.

37.3.71 SysUtils.DeleteFile Function

Deletes a file from disk.

Pascal

```
function DeleteFile(const FileName: string): Boolean;
```

C++

```
Boolean DeleteFile(const UnicodeString FileName);
```

File

SysUtils

Description

DeleteFile deletes the file named by FileName from the disk. If the file cannot be deleted or does not exist, the function returns false.

C++ Examples:

```
/*
The following code prompts for confirmation before deleting
a file.  Create a file and then click on the button to select
the file with a TOpenDialog.  Click Yes to delete it.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenDialog1->Title = "Delete File";
  if (OpenDialog1->Execute())
  {
    if (FileExists(OpenDialog1->FileName))
    {
      if (MessageDlg(
        ("Do you really want to delete " + ExtractFileName(OpenDialog1->FileName) + "?"),
        mtConfirmation,
        TMsgDlgButtons() << mbYes << mbNo,
        0,
        mbNo) == mrYes)
        DeleteFile(OpenDialog1->FileName);
    }
    else
      MessageDlg(("File " + ExtractFileName(OpenDialog1->FileName) + " does not exist."),
mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  }
}
/*
Click the button to open a TOpenDialog, then select a file
to delete.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenDialog1->Title = "Delete File";
  if (OpenDialog1->Execute())
  {
    if (FileExists(OpenDialog1->FileName))
      DeleteFile(OpenDialog1->FileName);
  }
}
```

Delphi Examples:

```
{
The following code prompts for confirmation before deleting
a file.  Create a file and then enter the path and file name
in the textfields.  Click the button to delete it.
}
procedure TForm1.Button1Click(Sender: TObject);
var FileName: string;
begin
```

```
  Filename:= Edit1.Text;
  if SysUtils.FileExists(FileName) then
  begin
    if MessageDlg(('Do you really want to delete ' + ExtractFileName(FileName) + '?'),
mtConfirmation, [mbYes, mbNo], 0, mbNo) = IDYes then
      DeleteFile(FileName);
  end
  else
    MessageDlg(('File ' + ExtractFileName(FileName) + ' does not exist.'), mtConfirmation,
[mbOK], 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit2.Text:= ExtractFilePath(Application.ExeName);
end;
```

37.3.72 SysUtils.DirectoryExists Function

Determines whether a specified directory exists.

Pascal

```
function DirectoryExists(const Directory: string): Boolean;
```

C++

```
Boolean DirectoryExists(const UnicodeString Directory);
```

File

SysUtils

Description

Call DirectoryExists to determine whether the directory specified by the **Directory** parameter exists. If the directory exists, the function returns true. If the directory does not exist, the function returns false.

If a full path name is entered, DirectoryExists searches for the directory along the designated path. Otherwise, the **Directory** parameter is interpreted as a relative path name from the current directory.

Note: The FileCtrl unit (Windows only) also contains a DirectoryExists function. However, the FileCtrl version is deprecated, and the SysUtils (see page 3901) version preferred, even if the code does not need to be cross-platform.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("Cannot create C:\\temp again!");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
```

37.3.73 SysUtils.DiskFree Function

Returns the number of free bytes on a specified drive.

Pascal

```
function DiskFree(Drive: Byte): Int64;
```

C++

```
Int64 DiskFree(Byte Drive);
```

File

SysUtils

Description

DiskFree returns the number of free bytes on the specified drive, where 0 = Current, 1 = A, 2 = B, and so on.

DiskFree returns -1 if the drive number is invalid.

Note: DiskFree is only available on Windows.

C++ Examples:

```
/*
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  __int64 AmtFree = DiskFree(0);
  __int64 Total = DiskSize(0);
  AnsiString S;
  S.sprintf("%I64d percent of the space on drive 0 is free: %I64d KB", AmtFree*100/Total,
AmtFree/1024 );
  Label1->Caption = S;
}
```

```
/*
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ShowMessage(FormatFloat("#,##0 bytes", DiskFree(0)));
}
```

Delphi Examples:

```
{
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
  AmtFree: Int64;
  Total:   Int64;
begin
  AmtFree := SysUtils.DiskFree(0);
  Total := DiskSize(0);
  S := IntToStr((AmtFree  * 100) div Total) + ' percent of the space on drive 0 is free: ' +
IntToStr(AmtFree div 1024) + ' Kbytes free. ';
  Label1.Caption := S;
end;
{
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(FormatFloat('#,##0 bytes', DiskFree(0)));
end;
```

See Also

DiskSize (see page 4102)

37.3.74 SysUtils.DiskSize Function

Returns the size, in bytes, of a specified drive.

Pascal

```
function DiskSize(Drive: Byte): Int64;
```

C++

```
Int64 DiskSize(Byte Drive);
```

File

SysUtils

Description

DiskSize returns the size in bytes of the specified drive, where 0 = Current, 1 = A, 2 = B, etc. DiskSize returns -1 if the drive number is invalid.

Note: DiskSize is only available on Windows.

C++ Examples:

```
/*
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  __int64 AmtFree = DiskFree(0);
  __int64 Total = DiskSize(0);
  AnsiString S;
  S.sprintf("%I64d percent of the space on drive 0 is free: %I64d KB", AmtFree*100/Total,
AmtFree/1024 );
  Label1->Caption = S;
}
```

Delphi Examples:

```
{
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
  AmtFree: Int64;
  Total:   Int64;
begin
  AmtFree := SysUtils.DiskFree(0);
  Total := DiskSize(0);
  S := IntToStr((AmtFree  * 100) div Total) + ' percent of the space on drive 0 is free: ' +
IntToStr(AmtFree div 1024) + ' Kbytes free. ';
  Label1.Caption := S;
end;
```

See Also

DiskFree (see page 4101)

37.3.75 SysUtils.DisposeStr Function

Disposes of a string pointer that was allocated using NewStr (see page 4227).

Pascal

```
procedure DisposeStr(P: PAnsiString); deprecated;
```

C++

```
DisposeStr(PAnsiString P);
```

File

SysUtils

Description

DisposeStr is only provided for backward compatibility with existing code that allocated a string using NewStr (see page 4227). Both DisposeStr and NewStr (see page 4227) are obsolete.

See Also

NewStr (see page 4227)

37.3.76 SysUtils.ElementToCharIndex Function

Pascal

```
function ElementToCharIndex(const S: AnsiString; Index: Integer): Integer; overload;
```

C++

```
int ElementToCharIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

This is function SysUtils.ElementToCharIndex.

37.3.77 SysUtils.ElementToCharIndex Function

Pascal

```
function ElementToCharIndex(const S: UnicodeString; Index: Integer): Integer; overload;
```

C++

```
int ElementToCharIndex(const UnicodeString S, int Index);
```

File

SysUtils

Description

This is function SysUtils.ElementToCharIndex.

37.3.78 SysUtils.ElementToCharLen Function

Pascal

```
function ElementToCharLen(const S: AnsiString; MaxLen: Integer): Integer; overload;
```

C++

```
int ElementToCharLen(const AnsiString S, int MaxLen);
```

File

SysUtils

Description

This is function SysUtils.ElementToCharLen.

37.3.79 SysUtils.ElementToCharLen Function

Pascal

```
function ElementToCharLen(const S: UnicodeString; MaxLen: Integer): Integer; overload;
```

C++

```
int ElementToCharLen(const UnicodeString S, int MaxLen);
```

File

SysUtils

Description

This is function SysUtils.ElementToCharLen.

37.3.80 SysUtils.EncodeDate Function

Returns a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.

Pascal

```
function EncodeDate(Year: Word; Month: Word; Day: Word): TDateTime;
```

C++

```
TDateTime EncodeDate(Word Year, Word Month, Word Day);
```

File

SysUtils

Description

EncodeDate returns a TDateTime (see page 3323) value from the values specified as the Year, Month, and Day parameters.

The year must be between 1 and 9999.

Valid Month values are 1 through 12.

Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month value. For example, the possible Day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the Year value specifies a leap year.

If the specified values are not within range, EncodeDate raises an EConvertError (see page 3919) exception.

C++ Examples:

```
/*
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeDate((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
```

```
(Word)StrToInt(Edit3->Text));
    Label1->Caption = DateToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid day, month, or year.");
  }
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeDate(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text));
  Label1.Caption := DateToStr(MyDate);
end;
```

EncodeTime (see page 4106)

EncodeDateTime

TryEncodeDate (see page 4302)

37.3.81 SysUtils.EncodeTime Function

Returns a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.

Pascal

```
function EncodeTime(Hour: Word; Min: Word; Sec: Word; MSec: Word): TDateTime;
```

C++

```
TDateTime EncodeTime(Word Hour, Word Min, Word Sec, Word MSec);
```

File

SysUtils

Description

EncodeTime encodes the given hour, minute, second, and millisecond into a TDateTime (see page 3323) value.

Valid Hour values are 0 through 23.

Valid Min and Sec values are 0 through 59.

Valid MSec values are 0 through 999.

If the specified values are not within range, EncodeTime raises an EConvertError (see page 3919) exception.

The resulting value is a number between 0 and 1 (inclusive) that indicates the fractional part of a day given by the specified time or (if 1.0) midnight on the following day. The value 0 corresponds to midnight, 0.5 corresponds to noon, 0.75 corresponds to 6:00 pm, and so on.

C++ Examples:

```
/*
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeTime((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text), (Word)StrToInt(Edit4->Text));
    Label1->Caption = TimeToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid hour, minute, second, or millisecond.");
  }
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeTime(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text), StrToInt(Edit4.Text));
  Label1.Caption := TimeToStr(MyDate);
end;
```

EncodeDateTime

37.3.82 SysUtils.ExceptionErrorMessage Function

Formats a standard error message.

Pascal

```
function ExceptionErrorMessage(ExceptObject: TObject; ExceptAddr: Pointer; Buffer: PChar;
```

```
  Size: Integer): Integer;
```

C++

```
  int ExceptionErrorMessage(TObject * ExceptObject, void * ExceptAddr, const char * Buffer, int
  Size);
```

File

SysUtils

Description

Call ExceptionErrorMessage to assemble an error message that indicates the object associated with the current exception and the location at which the exception was raised. The assembled message is written into the buffer provided by the Buffer parameter. Specify the size of this buffer using the Size parameter.

ExceptionErrorMessage returns the number of bytes in the assembled error message.

See Also

ExceptAddr (see page 3562)

ExceptObject (see page 3562)

ShowException (see page 4240)

37.3.83 SysUtils.ExcludeTrailingBackslash Function

Returns a path name without a trailing delimiter.

Pascal

```
  function ExcludeTrailingBackslash(const S: string): string; overload; platform;
```

C++

```
  UnicodeString ExcludeTrailingBackslash(const UnicodeString S);
```

File

SysUtils

Description

ExcludeTrailingBackslash returns S with any trailing path delimiter ('\' on Windows, '/' on Linux) removed. This function is included for backward compatibility only. New (see page 3619) programs should use ExcludeTrailingPathDelimiter (see page 4109).

Note: ExcludeTrailingBackslash works with multibyte character sets.

See Also

IncludeTrailingBackslash (see page 4213)

IsPathDelimiter (see page 4222)

ExcludeTrailingPathDelimiter (see page 4109)

37.3.84 SysUtils.ExcludeTrailingPathDelimiter Function

Returns a path name without a trailing delimiter.

Pascal

```
function ExcludeTrailingPathDelimiter(const S: string): string; overload;
```

C++

```
UnicodeString ExcludeTrailingPathDelimiter(const UnicodeString S);
```

File

SysUtils

Description

ExcludeTrailingPathDelimiter returns S with any trailing path delimiter ('\' on Windows, '/' on Linux) removed. If the last character in S is a delimiter, the return value is S with the last character removed. Otherwise, S is returned unchanged.

Note: ExcludeTrailingPathDelimiter works with multibyte character sets.

See Also

IncludeTrailingPathDelimiter (see page 4213)

IsPathDelimiter (see page 4222)

37.3.85 SysUtils.ExpandFileName Function

Returns the full path name for a relative file name.

Pascal

```
function ExpandFileName(const FileName: string): string; overload;
```

C++

```
UnicodeString ExpandFileName(const UnicodeString FileName);
```

File

SysUtils

Description

ExpandFileName converts the relative file name into a fully qualified path name. ExpandFileName does not verify that the resulting fully qualified path name refers to an existing file, or even that the resulting path exists.

Note: ExpandFileName does not support UNC format. To expand to a UNC file name, use ExpandUNCFileName (see page 4111).

C++ Examples:

```
/*
The following example uses a listbox, an edit control, and a
button on a form. When the button is clicked, the filename
specified in the edit control is expanded to a fully
```

```
qualified filename and added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListBox1->Items->Add(ExpandFileName(Edit1->Text));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label2->Caption = ExtractFilePath(Application->ExeName);
}
```

Delphi Examples:

```
{
The following example uses a listbox, an edit control, and a
button on a form. When the button is clicked, the filename
specified in the edit control is expanded to a fully
qualified filename and added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items.Add(SysUtils.ExpandFileName(Edit1.Text));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Label2.Caption := ExtractFilePath(Application.ExeName);
end;
```

See Also

ExtractFileName (see page 4113)

ExpandUNCFileName (see page 4111)

ExpandFileNameCase (see page 4110)

37.3.86 SysUtils.ExpandFileNameCase Function

Returns the full path name for a relative file name on a case-sensitive file system.

Pascal

```
function ExpandFileNameCase(const FileName: string; out MatchFound: TFilenameCaseMatch):
string; overload;
```

C++

```
UnicodeString ExpandFileNameCase(const UnicodeString FileName, TFilenameCaseMatch MatchFound);
```

File

SysUtils

Description

ExpandFileNameCase expands a relative file name into a fully qualified path name, then attempts to find the file or a close case-insensitive match. This is useful when converting file name data from case-insensitive conventions (Windows) to case-sensitive conventions (Linux). It is also useful for validating file names entered by users unfamiliar with Linux conventions.

FileName is the relative file name to expand.

MatchFound indicates what match, if any, was found for FileName.

The return value is the fully qualified path name generated by ExpandFileNameCase. Its relationship to FileName depends on the value of MatchFound, as indicated in the following table:

MatchFound	Return value
mkNone	The fully qualified path name, as returned by ExpandFileName (see page 4109).
mkExactMatch	The fully qualified path name for the single case-sensitive match to FileName. This is the same value as the one returned when MatchFound is mkNone.
mkSingleMatch	(Linux only.) The fully qualified path name for the single file that matches FileName case-insensitively.
mkAmbiguous	(Linux only.) The fully qualified path name for one of the case-insensitve matches to FileName. This path name is not the same as the specified file, and not necessarily the closest match.

Note: ExpandFileNameCase is much slower than ExpandFileName (see page 4109), particularly when the specified file name is ambiguous or does not match an actual file.

See Also

ExpandFileName (see page 4109)

37.3.87 SysUtils.ExpandUNCFileName Function

Returns the full path of a file name in UNC format, if appropriate.

Pascal

```
function ExpandUNCFileName(const FileName: string): string; overload;
```

C++

```
UnicodeString ExpandUNCFileName(const UnicodeString FileName);
```

File

SysUtils

Description

ExpandUNCFileName returns the fully-qualified file name for a specified file name.

Note: On Windows, ExpandUNCFileName returns a fully qualified path name using Universal Naming Convention for network files. For files on local disks, ExpandUNCFileName is equivalent to ExpandFileName (see page 4109). In a UNC file name, the drive prefix is replaced with the name of the network resource to which the drive is mapped. For example, if the working directory is J:\ourdir and drive J is mapped to \\ourserver\ourshare, ExpandUNCFileName('ourfile') returns "\\ourserver\ourshare\ourdir\ourfile".

Note: On Linux, ExpandUNCFileName is always equivalent to ExpandFileName (see page 4109).

See Also

ExpandFileName (see page 4109)

ExtractFileDrive (see page 4112)

37.3.88 SysUtils.ExtractFileDir Function

Extracts the drive and directory parts from FileName.

Pascal

```
function ExtractFileDir(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractFileDir(const UnicodeString FileName);
```

File

SysUtils

Description

The resulting string is a directory name suitable for passing to the CreateDir (see page 4083), GetCurrentDir (see page 4202), RemoveDir (see page 4232), and SetCurrentDir (see page 4240) functions. This string is empty if FileName contains no drive and directory parts.

Note: This function works for multi-byte character systems (MBCS).

See Also

CreateDir (see page 4083)

GetCurrentDir (see page 4202)

RemoveDir (see page 4232)

SetCurrentDir (see page 4240)

37.3.89 SysUtils.ExtractFileDrive Function

Returns the drive portion of a file name.

Pascal

```
function ExtractFileDrive(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractFileDrive(const UnicodeString FileName);
```

File

SysUtils

Description

Note: On Windows, ExtractFileDrive returns a string containing the drive portion of a fully qualified path name for the file passed in the FileName. For file names with drive letters, the result is in the form "'<drive>'". For file names with a UNC path the result is in the form "'\\<servername>\<sharename>'". If the given path contains neither style of path prefix, the result is an empty string.

Note: On Linux, ExtractFileDrive always returns a zero-length string.

See Also

ExpandFileName (see page 4109)

ExpandUNCFileName (see page 4111)

37.3.90 SysUtils.ExtractFileExt Function

Returns the extension portions of a file name.

Pascal

```
function ExtractFileExt(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractFileExt(const UnicodeString FileName);
```

File

SysUtils

Description

Use ExtractFileExt to obtain the extension from a file name. For example, the following code returns the extension of the file name specified by a variable named MyFileName:

MyFilesExtension := ExtractFileExt(MyFileName); // Delphi

MyFilesExtension = ExtractFileExt(MyFileName); // C++

The resulting string includes the period character that separates the name and extension parts. This string is empty if the given file name has no extension.

Note: This function works for multi-byte character systems (MBCS).

See Also

ExtractFileName (see page 4113)

37.3.91 SysUtils.ExtractFileName Function

Extracts the name and extension parts of a file name.

Pascal

```
function ExtractFileName(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractFileName(const UnicodeString FileName);
```

File

SysUtils

Description

The resulting string is the rightmost characters of FileName, starting with the first character after the colon or backslash that separates the path information from the name and extension. The resulting string is equal to FileName if FileName contains no drive and directory parts.

Note: This function works for multi-byte character systems (MBCS).

Delphi Examples:

```
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
          FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
          GetMem(Buffer, StringLen); { allocate the buffer }
          cellString := StringGrid1.Cells[X,Y];
          for I := 1 to StringLen do
             Buffer[I - 1] := cellString[I];
          FileWrite(FileHandle, Buffer^, StringLen);
        finally
          FreeMem(Buffer, StringLen);
        end;
      end;
    end;
    FileClose(FileHandle);
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
```

```
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

ExpandFileName (see page 4109)

ExtractFilePath (see page 4115)

37.3.92 SysUtils.ExtractFilePath Function

Returns the drive and directory portions of a file name.

Pascal

```
function ExtractFilePath(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractFilePath(const UnicodeString FileName);
```

File

SysUtils

Description

The resulting string is the leftmost characters of FileName, up to and including the colon or backslash that separates the path information from the name and extension. The resulting string is empty if FileName contains no drive and directory parts.

This function works for multi-byte character systems (MBCS).

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Change
the Old Path and New Path to move files outside the Debug
directory, Old File and New File will not take a relative path.
*/

#include <memory>       //for STL auto_ptr class

  begin
    Edit2.Text:= ExtractFilePath(Application.ExeName);
  end;
```

See Also

ExtractFileName (see page 4113)

37.3.93 SysUtils.ExtractRelativePath Function

Returns a relative path name, relative to a specific base directory.

Pascal

```
function ExtractRelativePath(const BaseName: string; const DestName: string): string; overload;
```

C++

```
UnicodeString ExtractRelativePath(const UnicodeString BaseName, const UnicodeString DestName);
```

File

SysUtils

Description

Call ExtractRelativePath to convert a fully qualified path name into a relative path name. The `DestName` parameter specifies file name (including path) to be converted. `BaseName` is the fully qualified name of the base directory to which the returned path name should be relative. `BaseName` may or may not include a file name, but it must include the final path delimiter.

Note: If you send it what should be a directory without the trailing backslash (c:\foo

instead of `c:\foo\`), the function treats `foo` as a file and returns undesirable results. You should correctly call it like this:

```
ExtractRelativePath('c:\foo\', 'c:\bar\')
```

so that it would return

```
'..\bar\'
```

.

```
ExtractRelativePath('c:\foo\', 'c:\bar')
```

would return the incorrect result, probably like

```
'..'
```

.

See Also

ExpandFileName (see page 4109)

37.3.94 SysUtils.ExtractShortPathName Function

Converts a file name to the short 8.3 form.

Pascal

```
function ExtractShortPathName(const FileName: string): string; overload;
```

C++

```
UnicodeString ExtractShortPathName(const UnicodeString FileName);
```

File

SysUtils

Description

ExtractShortPathName converts the file name, FileName, to the short 8.3 form. ExtractShortPathName returns an empty string if the file or directory does not exist.

The first parameter, FileName, can be a full path name. For example, ExtractShortPathName would convert the full path name:

C:\Program Files\MyCompany\MyApp\MyApp.exe

to the short form:

C:\Progra~1\MyComp~1\MyApp\MyApp.exe

Note: ExtractShortPathName is only available on Windows.

See Also

ExpandFileName (see page 4109)

ExpandUNCFileName (see page 4111)

37.3.95 SysUtils.FileAge Function

Returns the OS timestamp of a file.

Pascal

```
function FileAge(const FileName: string): Integer; overload; deprecated;
function FileAge(const FileName: string; out FileDateTime: TDateTime): Boolean; overload;
```

C++

```
int FileAge(const UnicodeString FileName);
Boolean FileAge(const UnicodeString FileName, TDateTime FileDateTime);
```

File

SysUtils

Description

Call FileAge to obtain the OS timestamp of the file specified by `FileName`. The `FileDateTime` output parameter can be later converted to a TDateTime (see page 3323) using the FileDateToDateTime (see page 4130) function. The return value is **True** if the operation succeeded, or **False** otherwise.

Note: The first overloaded version of FileAge is deprecated. Use the second version of FileAge.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
```

```
      NewAttributes = Attributes;
      if (FileAttrDlg->ReadOnly->Checked)
        NewAttributes = NewAttributes | faReadOnly;
      else
         NewAttributes = NewAttributes & ~faReadOnly;

      if (FileAttrDlg->Archive->Checked)
        NewAttributes = NewAttributes | faArchive;
      else
        NewAttributes = NewAttributes & ~faArchive;

      if (FileAttrDlg->System->Checked)
        NewAttributes = NewAttributes | faSysFile;
      else
        NewAttributes = NewAttributes & ~faSysFile;

      if (FileAttrDlg->Hidden->Checked)
        NewAttributes = NewAttributes | faHidden;
      else
        NewAttributes = NewAttributes  & ~faHidden;
      if (NewAttributes != Attributes)
        FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
}

37.3.96 SysUtils.FileClose Function

Closes a specified file.

Pascal

```
procedure FileClose(Handle: Integer);
```

C++

```
FileClose(int Handle);
```

File

SysUtils

Description

FileClose closes a file given its handle. The handle is obtained when the file is opened using FileOpen (see page 4143) or FileCreate (see page 4128).

Note: : When working with Delphi language file variables, use the CloseFile (see page 3539) procedure instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a

37.3.97 SysUtils.FileCreate Function

Creates a new file.

Pascal

```
function FileCreate(const FileName: string): Integer; overload;
function FileCreate(const FileName: string; Rights: Integer): Integer; overload;
```

C++

```
int FileCreate(const UnicodeString FileName);
int FileCreate(const UnicodeString FileName, int Rights);
```

File

SysUtils

Description

FileCreate creates a new file with the specified name. If the return value is positive, the function was successful and the value is the file handle of the new file. A return value of -1 indicates that an error occurred.

Note: On Windows, the FileAccessRights variable and Rights parameter are ignored.

Note: On Linux, a file has a set of permission bits controlling access to the file. The first form of FileCreate takes the permission bits from the global FileAccessRights variable. The second form takes the permission bits from the Rights parameter. In either case, the permission bits are masked by the current process's umask value.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function. Verify
the file written after executing.

37.3.98 SysUtils.FileDateToDateTime Function

Converts an OS timestamp value to TDateTime (see page 3323) value.

Pascal

```
function FileDateToDateTime(FileDate: Integer): TDateTime;
```

C++

```
TDateTime FileDateToDateTime(int FileDate);
```

File

SysUtils

Description

A timestamp is a signed 32-bit integer, used by the OS to record information such as the date and time a file was modified. The precise format of a timestamp depends on the OS. Use FileDateToDateTime to convert a timestamp to a TDateTime (see page 3323) value.

You may need to use FileDateToDateTime to convert the Time (see page 4297) field of the TSearchRec (see page 4330) type used by the FindFirst (see page 4175) and FindNext (see page 4177) functions.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
     else
        NewAttributes = NewAttributes & ~faReadOnly;

     if (FileAttrDlg->Archive->Checked)
       NewAttributes = NewAttributes | faArchive;
     else
       NewAttributes = NewAttributes & ~faArchive;

     if (FileAttrDlg->System->Checked)
       NewAttributes = NewAttributes | faSysFile;
     else
       NewAttributes = NewAttributes & ~faSysFile;

     if (FileAttrDlg->Hidden->Checked)
       NewAttributes = NewAttributes | faHidden;
     else
       NewAttributes = NewAttributes  & ~faHidden;
```

```
      if (NewAttributes != Attributes)
        FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
    }
  }
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
}

37.3.99 SysUtils.FileExists Function

Tests if a specified file exists.

Pascal

```
function FileExists(const FileName: string): Boolean;
```

C++

```
Boolean FileExists(const UnicodeString FileName);
```

File

SysUtils

Description

FileExists returns true if the file specified by FileName exists. If the file does not exist, FileExists returns false.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function. Verify
the file written after executing.
*/

37.3.100 SysUtils.FileGetAttr Function

Returns the file attributes of FileName.

Pascal

```
function FileGetAttr(const FileName: string): Integer; platform;
```

C++

```
int FileGetAttr(const UnicodeString FileName);
```

File

SysUtils

Description

FileGetAttr returns the attributes of the file as a string of bits. This value is the same as the Attr field of a TSearchRec (see page 4330) type. Check for individual attributes with code such as the following:

Attrs := FileGetAttr('MyFile.sys');

```
if Attrs and faHidden <> 0 then
  FileSetAttr('MyFile.sys', Attrs – faHidden);
```

int Attrs = FileGetAttr("MyFile.sys");

```
if (Attrs & faHidden)
  FileSetAttr("MyFile.sys", Attrs & !faHidden);
```

A return value of INVALID_FILE_ATTRIBUTES indicates that an error occurred.

Note: See TSearchRec (see page 4330) for a description of the individual attribute constants.

Note: FileGetAttr is Windows-only.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
*/

     else
       NewAttributes = NewAttributes  & ~faHidden;
     if (NewAttributes != Attributes)
       FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
```

```
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
}
procedure TForm1.FileListMouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  Attributes, NewAttributes: Word;
begin
  with FileAttrForm do
  begin
    FileDirName.Caption := FileList.Items[FileList.ItemIndex];
    { set box caption }
    FilePathName.Caption := FileList.Directory;
    { show directory name }
    ChangeDate.Caption := DateTimeToStr(FileDateToDateTime(FileAge(FileList.FileName)));
    Attributes := SysUtils.FileGetAttr(FileDirName.Caption);
    { read file attributes }
    ReadOnly.Checked := (Attributes and SysUtils.faReadOnly) = faReadOnly;
    Archive.Checked := (Attributes and faArchive) = faArchive;
    System.Checked := (Attributes and faSysFile) = faSysFile;
    Hidden.Checked := (Attributes and faHidden) = faHidden;
    if ShowModal <> id_Cancel then    { execute dialog box }
    begin
      NewAttributes := Attributes;
      { start with original attributes }
      if ReadOnly.Checked then
        NewAttributes := NewAttributes or SysUtils.faReadOnly
      else
        NewAttributes := NewAttributes and not SysUtils.faReadOnly;
      if Archive.Checked then
        NewAttributes := NewAttributes or faArchive
      else
        NewAttributes := NewAttributes and not faArchive;
      if System.Checked then
        NewAttributes := NewAttributes or faSysFile
      else
        NewAttributes := NewAttributes and not faSysFile;
      if Hidden.Checked then

FileSetAttr (see page 4162)

37.3.101 SysUtils.FileGetDate Function

Returns an OS timestamp for a specified file.

Pascal

```
function FileGetDate(Handle: Integer): Integer;
```

C++

```
int FileGetDate(int Handle);
```

File

SysUtils

Description

Use FileGetDate to determine the timestamp of a file given its handle. The return value is -1 if the handle is invalid. The FileDateToDateTime (see page 4130) function can be used to convert the returned value to a TDateTime (see page 3323) value.

Note: :FileGetDate uses a file handle rather than a native Delphi file variable. To obtain the timestamp of a file that has not been opened using the FileOpen (see page 4143) or FileCreate (see page 4128) method, use the FileAge (see page 4119) function instead.

Note: :Under Linux, -1 is a valid timestamp. Use FileExists (see page 4133) to verify that the file does not exist.

See Also

FileSetDate (see page 4164)

FileDateToDateTime (see page 4130)

FileAge (see page 4119)

FileExists (see page 4133)

37.3.102 SysUtils.FileIsReadOnly Function

Reports whether a file is read-only.

Pascal

```
function FileIsReadOnly(const FileName: string): Boolean;
```

C++

```
Boolean FileIsReadOnly(const UnicodeString FileName);
```

File

SysUtils

Description

FileIsReadOnly returns **True** if FileName can be found and opened, but the current process does not have permission to write to it.

Note: On Windows XP, FileIsReadOnly returns **True** if the file does **not** exist.

37.3.103 SysUtils.FileOpen Function

Opens a specified file using a specified access mode.

Pascal

```
function FileOpen(const FileName: string; Mode: LongWord): Integer;
```

C++

```
int FileOpen(const UnicodeString FileName, LongWord Mode);
```

File

SysUtils

Description

Use FileOpen to open a file and obtain a file handle. The access mode value is constructed by or-ing one of the fmOpen constants with one of the fmShare constants defined in `File` open mode constants. If the return value is 0 or greater, the function was successful and the value is the file handle of the opened file. A return value of -1 indicates that an error occurred.

The Mode parameter consists of an open mode and (possibly) a share mode or'ed together. The open mode must be one of the following values:

Value	Meaning
fmOpenRead (see page 4377)	Open the file for reading only.
fmOpenWrite (see page 4378)	Open the file for writing only. Writing to the file completely replaces the current contents.
fmOpenReadWrite (see page 4378)	Open the file to modify the current contents rather than replace them.

The share mode must be one of the following values:

Value	Meaning
fmShareCompat (see page 4379)	Sharing is compatible with the way FCBs are opened.
fmShareExclusive (see page 4382)	Other applications can not open the file for any reason.
fmShareDenyWrite (see page 4381)	Other applications can open the file for reading but not for writing.
fmShareDenyRead (see page 4380)	Other applications can open the file for writing but not for reading.
fmShareDenyNone (see page 4380)	No attempt is made to prevent other applications from reading from or writing to the file.

Note: Use of the non-native Delphi language file handlers such as FileOpen is not encouraged. These routines map to system routines and return OS file handles, not normal Delphi file variables. These are low-level file access routines. For normal file operations use AssignFile (see page 3525), Rewrite (see page 3645), and Reset (see page 3643) instead.

C++ Examples:

```
/*
This example requires a TEdit, a button and a string grid.
Enter the file name in the TEdit and click the button to open
that file.  Notice that the file cannot be read.  Remove the
fmOpenWrite and the fmShareDenyNone access and the string
grid loads fine.

37.3.104 SysUtils.FileRead Function

Reads a specified number of bytes from a file.

Pascal

```
function FileRead(Handle: Integer; var Buffer; Count: LongWord): Integer;
```

C++

```
int FileRead(int Handle,  Buffer, LongWord Count);
```

File

SysUtils

Description

FileRead reads Count bytes from the file specified by Handle into the buffer. The Count parameter indicates the size, in bytes, of the buffer. The function result is the actual number of bytes read, which may be less than Count. The Handle that is passed to FileRead must be opened with FileOpen (see page 4143) or FileCreate (see page 4128).

Note: :In Delphi, do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To read from a file specified by a Delphi file variable, use the BlockRead (see page 3528) procedure or the Read (see page 3634) procedure instead.

C++ Examples:

```
/*

37.3.105 SysUtils.FileSearch Function

Searches a specified directory path for a file.

Pascal

```
function FileSearch(const Name: string; const DirList: string): string;
```

C++

```
UnicodeString FileSearch(const UnicodeString Name, const UnicodeString DirList);
```

File

SysUtils

Description

FileSearch searches through the directories passed in DirList for a file named Name. DirList is a list of path names delimited by semicolons on Windows, colons on Linux). If FileSearch locates a file matching Name, it returns a string specifying a path name for that file. If no matching file exists, FileSearch returns an empty string.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form. When the button is clicked, the current directory is
searched for the filename specified in the edit control. A
message box indicates whether the file is found.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString asFileName = FileSearch(Edit1->Text, GetCurrentDir());
  if (asFileName.IsEmpty())
    ShowMessage(AnsiString("Couldn't find ") + Edit1->Text + ".");
  else
    ShowMessage(AnsiString("Found ") + asFileName + ".");
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label2->Caption = GetCurrentDir();
}
```

Delphi Examples:

```
{
The following example uses an edit control and a button on a
form. When the button is clicked, the current directory is
searched for the filename specified in the edit control. A
message box indicates whether the file is found.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FileToFind: string;
begin
  FileToFind := SysUtils.FileSearch(Edit1.Text, GetCurrentDir);
  if FileToFind = '' then
    ShowMessage('Couldn''t find ' + Edit1.Text + '.')
  else
    ShowMessage('Found ' + FileToFind + '.');
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  Label2.Caption := GetCurrentDir;
end;
```

See Also

FileExists (see page 4133)

37.3.106 SysUtils.FileSeek Function

Repositions read/write point.

Pascal

```
function FileSeek(Handle: Integer; Offset: Integer; Origin: Integer): Integer; overload;
function FileSeek(Handle: Integer; const Offset: Int64; Origin: Integer): Int64; overload;
```

C++

```
int FileSeek(int Handle, int Offset, int Origin);
Int64 FileSeek(int Handle, const Int64 Offset, int Origin);
```

File

SysUtils

Description

Use FileSeek to reposition the read/write point in a file that was opened with FileOpen (see page 4143) or FileCreate (see page 4128). Handle is the file handle that was returned by FileOpen (see page 4143) or FileCreate (see page 4128).

Offset specifies the number of bytes from Origin where the file pointer should be positioned. Origin is a code with three possible values, denoting the beginning of the file, the end of the file, and the current position of the file pointer.

Origin	Action
0	The file pointer is positioned Offset bytes from the beginning of the file.
1	The file pointer is positioned Offset bytes from its current position.
2	The file pointer is positioned Offset bytes from the end of the file.

If FileSeek is successful, it returns the new position of the file pointer; otherwise, it returns -1.

Note: :Do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To move the file pointer in a file specified by a Delphi file variable, use the Seek (see page 3650) procedure instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first time you use this app, you should do a "Fill
Grid" and then "Write Grid to File".   Always use files
generated in this way to do a "Read File into Grid".
*/

37.3.107 SysUtils.FileSetAttr Function

Sets the file attributes of a specified file.

Pascal

```
function FileSetAttr(const FileName: string; Attr: Integer): Integer; platform;
```

C++

```
int FileSetAttr(const UnicodeString FileName, int Attr);
```

File

SysUtils

Description

FileSetAttr sets the file attributes of the file given by FileName to the value given by Attr. The value of Attr is formed by combining the appropriate file attribute constants, as in the following:

```
FileSetAttr('MyFile.sys', faReadOnly or faSysFile); // Delphi
FileSetAttr("MyFile.sys", faReadOnly | faSysFile); // C++
```

FileSetAttr returns zero if the function was successful. Otherwise the return value is an error code.

Note: See TSearchRec (see page 4330) for a description of the file attribute constants.

Note: FileSetAttr is only available on Windows.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
     else
        NewAttributes = NewAttributes & ~faReadOnly;

     if (FileAttrDlg->Archive->Checked)
       NewAttributes = NewAttributes | faArchive;
     else
       NewAttributes = NewAttributes & ~faArchive;

     if (FileAttrDlg->System->Checked)
       NewAttributes = NewAttributes | faSysFile;
     else
       NewAttributes = NewAttributes & ~faSysFile;

     if (FileAttrDlg->Hidden->Checked)
       NewAttributes = NewAttributes | faHidden;
     else
       NewAttributes = NewAttributes  & ~faHidden;
     if (NewAttributes != Attributes)
       FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings.  Click on a file to launch the dialog.
```

37.3.108 SysUtils.FileSetDate Function

Sets the OS time stamp for a specified file.

Pascal

```
function FileSetDate(const FileName: string; Age: Integer): Integer; overload;
function FileSetDate(Handle: Integer; Age: Integer): Integer; overload; platform;
```

C++

```
int FileSetDate(const UnicodeString FileName, int Age);
```

```
int FileSetDate(int Handle, int Age);
```

File

SysUtils

Description

FileSetDate sets the OS timestamp of the specified file to the value given by Age. The DateTimeToFileDate (see page 4088) function can be used to convert a TDateTime (see page 3323) value to a OS timestamp.

Handle is the Windows file handle of the file to alter. This syntax is only available on Windows.

FileName is the name of the file to alter.

Age is the timestamp to apply to the specified file.

The return value is zero if the function was successful. Otherwise the return value is an error code.

See Also

FileCreate (see page 4128)

FileGetDate (see page 4142)

FileOpen (see page 4143)

DateTimeToFileDate (see page 4088)

37.3.109 SysUtils.FileSetReadOnly Function

Sets the file permissions to read-only.

Pascal

```
function FileSetReadOnly(const FileName: string; ReadOnly: Boolean): Boolean;
```

C++

```
Boolean FileSetReadOnly(const UnicodeString FileName, Boolean ReadOnly);
```

File

SysUtils

Description

FileSetReadOnly attempts to set the read-only status of the specified file.

FileName is the name of the file to alter.

ReadOnly indicates the status to assign to the file.

FileSetReadOnly returns true if the operation was successful and false if an error occurred.

Note: On Windows, the ReadOnly parameter is assigned to the file's read-only flag.

Note: On Linux, the inverse of the ReadOnly parameter is assigned to the file's user write, group write, and other write permission bits. The active user must have permission to perform these operations.

FileSetReadOnly is designed to support cross-platform code. To manipulate permissions more specifically than FileSetReadOnly allows, use platform-specific functions.

37.3.110 SysUtils.FileWrite Function

Writes the contents of a buffer to the current position in a file.

Pascal

```
function FileWrite(Handle: Integer; const Buffer; Count: LongWord): Integer;
```

C++

```
int FileWrite(int Handle, const  Buffer, LongWord Count);
```

File

SysUtils

Description

FileWrite writes Count bytes to the file given by Handle from the buffer specified by Buffer. Handle is a file handle returned by the FileOpen (see page 4143) or FileCreate (see page 4128) method.

The return value is the number of bytes actually written, or -1 if an error occurred.

Note: :Do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To write to a file specified by a Delphi file variable, use Write (see page 3707), Writeln, or BlockWrite (see page 3530) instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function. Verify
the file written after executing.
*/

      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      PAnsiChar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PAnsiChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
          FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
          GetMem(Buffer, StringLen); { allocate the buffer }
          cellString := StringGrid1.Cells[X,Y];
          for I := 1 to StringLen do
             Buffer[I - 1] := cellString[I];
          FileWrite(FileHandle, Buffer^, StringLen);
        finally
          FreeMem(Buffer, StringLen);
        end;
      end;
    end;
    FileClose(FileHandle);
  end;
end;
```

37.3.111 SysUtils.FinalizePackage Function

Finalizes the specified package (.bpl file).

Pascal

```
procedure FinalizePackage(Module: HMODULE);
```

C++

```
FinalizePackage(HMODULE Module);
```

File

SysUtils

Description

Most applications do not need to call FinalizePackage, because UnloadPackage (see page 4310) calls FinalizePackage internally. FinalizePackage executes any finalization code in the specified package.

See Also

UnloadPackage (see page 4310)

37.3.112 SysUtils.FindClose Function

Releases memory allocated by FindFirst (see page 4175).

Pascal

```
procedure FindClose(var F: TSearchRec);
```

C++

```
FindClose(TSearchRec F);
```

File

SysUtils

Description

FindClose terminates a FindFirst (see page 4175)/FindNext (see page 4177) sequence.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory. Click at least one box before clicking the button.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;
  iAttributes |= faDirectory * CheckBox5->Checked;
  iAttributes |= faArchive * CheckBox6->Checked;
  iAttributes |= faAnyFile * CheckBox7->Checked;
  StringGrid1->RowCount = 0;
  if (FindFirst(Edit1->Text, iAttributes, sr) == 0)
  {
    do
    {
      if ((sr.Attr & iAttributes) == sr.Attr)
      {
        StringGrid1->RowCount = StringGrid1->RowCount + 1;
        StringGrid1->Cells[1][StringGrid1->RowCount-1] = sr.Name;
        StringGrid1->Cells[2][StringGrid1->RowCount-1] = IntToStr(sr.Size);
      }
    } while (FindNext(sr) == 0);
    FindClose(sr);
  }
}
```

37.3.113 SysUtils.FindCmdLineSwitch Function

Determines whether a string was passed as a command line argument to the application.

Pascal

```
function FindCmdLineSwitch(const Switch: string; const Chars: TSysCharSet; IgnoreCase:
Boolean): Boolean; overload;
function FindCmdLineSwitch(const Switch: string): Boolean; overload;
function FindCmdLineSwitch(const Switch: string; IgnoreCase: Boolean): Boolean; overload;
```

C++

```
Boolean FindCmdLineSwitch(const UnicodeString Switch, const TSysCharSet Chars, Boolean
IgnoreCase);
Boolean FindCmdLineSwitch(const UnicodeString Switch);
Boolean FindCmdLineSwitch(const UnicodeString Switch, Boolean IgnoreCase);
```

File

SysUtils

Description

FindCmdLineSwitch determines whether a string represents a command-line switch, based on the first character of the string.

Switch is a command line parameter, typically provided by the ParamStr (see page 3625) function.

Chars is the set of characters that distinguish switches from other parameters. If SwitchChars (see page 4398) is omitted, it defaults to '/' and '-' on Windows, and to '-' on Linux.

IgnoreCase determines whether case-insensitive character matching is used. The default is true on Windows, false on Linux.

ParamCount (see page 3623)

ParamStr (see page 3625)

37.3.114 SysUtils.FindFirst Function

Searches for the first instance of a file name with a given set of attributes in a specified directory.

Pascal

```
function FindFirst(const Path: string; Attr: Integer; var F: TSearchRec): Integer;
```

C++

```
int FindFirst(const UnicodeString Path, int Attr, TSearchRec F);
```

File

SysUtils

Description

FindFirst searches the directory specified by Path for the first file that matches the file name implied by Path and the attributes specified by the Attr parameter. The result is returned in the F parameter. Use the fields of this search record to extract the information needed. FindFirst returns 0 if a file was successfully located, otherwise, it returns an error code.

The Path constant parameter is the directory and file name mask, including wildcard characters. For example, '.\test*.*' specifies all files in the test subdirectory.

The Attr parameter specifies the special files to include in addition to all normal files. Choose from these file attribute constants when specifying the Attr parameter:

Constant	Description
faReadOnly (see page 4374)	Read (see page 3634)-only files
faHidden (see page 4373)	Hidden files
faSysFile (see page 4375)	System (see page 3159) files
faVolumeID (see page 4376)	Volume ID files
faDirectory (see page 4372)	Directory files
faArchive (see page 4372)	Archive files
faAnyFile (see page 4371)	Any file

Attributes can be combined by adding (Delphi) or or-ing (C++) their constants or values. For example, to search for read-only and hidden files in addition to normal files, pass (faReadOnly (see page 4374) + faHidden (see page 4373)) in Delphi or (faReadOnly (see page 4374) | faHidden (see page 4373)) in C++ as the Attr parameter. To include only normal files, pass zero for the Attr parameter.

Note: FindFirst allocates resources (memory) which must be released by calling FindClose (see page 4172).

Note: Some of the file attribute constants are not valid on all platforms. For example, faVolumeID (see page 4376) and faArchive (see page 4372) will not work on Linux.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the

37.3.115 SysUtils.FindNext Function

Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 4175).

Pascal

```
function FindNext(var F: TSearchRec): Integer;
```

C++

```
int FindNext(TSearchRec F);
```

File

SysUtils

Description

FindNext returns the next entry that matches the name and attributes specified in a previous call to FindFirst (see page 4175). The search record must be one that was passed to FindFirst (see page 4175). The return value is zero if the function was successful. Otherwise the return value is an error code.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The

37.3.116 SysUtils.FloatToCurr Function

Converts a floating-point value to a System::Currency (see page 3235) value.

Pascal

```
function FloatToCurr(const Value: Extended): Currency;
```

C++

```
Currency FloatToCurr(const Extended Value);
```

File

SysUtils

Description

FloatToCurr returns the System::Currency (see page 3235) value equivalent to Value. If Value is not within the valid range for a System::Currency (see page 3235) value, FloatToCurr raises an EConvertError (see page 3919) exception.

See Also

TryFloatToCurr (see page 4304)

37.3.117 SysUtils.FloatToDateTime Function

Converts a floating-point value to a TDateTime (see page 3323) value.

Pascal

```
function FloatToDateTime(const Value: Extended): TDateTime;
```

C++

```
TDateTime FloatToDateTime(const Extended Value);
```

File

SysUtils

Description

FloatToDateTime returns the TDateTime (see page 3323) value equivalent to Value. If Value is not within the valid range for TDateTime (see page 3323), FloatToDateTime raises an EConvertError (see page 3919) exception.

See Also

TryFloatToDateTime (see page 4304)

MinDateTime (see page 4384)

EConvertError (see page 3919)

37.3.118 SysUtils.FloatToDecimal Function

Converts a floating-point value to a decimal representation.

Pascal

```
procedure FloatToDecimal(var Result: TFloatRec; const Value; ValueType: TFloatValue;
Precision: Integer; Decimals: Integer);
```

C++

```
FloatToDecimal(TFloatRec Result, const  Value, TFloatValue ValueType, int Precision, int
Decimals);
```

File

SysUtils

Description

FloatToDecimal converts a floating-point value to a decimal representation that is suited for further formatting.

The Value parameter must be a variable of type Extended or System::Currency (see page 3235), as indicated by the ValueType parameter.

For values of type Extended, the Precision parameter specifies the requested number of significant digits in the result--the allowed range is 1..18. For values of type System::Currency (see page 3235), the Precision parameter is ignored, and the implied precision of the conversion is 19 digits.

The Decimals parameter specifies the requested maximum number of digits to the left of the decimal point in the result. Precision and Decimals together control how the result is rounded. To produce a result that always has a given number of significant digits regardless of the magnitude of the number, specify 9999 for the Decimals parameter.

37.3.119 SysUtils.FloatToStr Function

Converts a floating point value to a string.

Pascal

```
function FloatToStr(Value: Extended): string; overload;
function FloatToStr(Value: Extended; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
UnicodeString FloatToStr(Extended Value);
UnicodeString FloatToStr(Extended Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToStr converts the floating-point value given by Value to its string representation. The conversion uses general number format with 15 significant digits.

For greater control over the formatting of the string, use the FloatToStrF (see page 4182) function.

The first form of FloatToStr is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

C++ Examples:

```
/*
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Extended ex = 16 * ArcTan(1.0/5.0) - 4.0 * ArcTan(1.0/239.0); // Machin's formula
  String mystring = FloatToStr(ex);
  Edit2->Text = mystring;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Text = "3.14159265358979";
}
```

Delphi Examples:

```
{
This example displays the compiler version number in the
text field.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit1.Text := FloatToStr(System.CompilerVersion);
end;
{
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit3.Text := mystring;
  Str(ex:25:23, mystring);
  Edit4.Text := mystring;
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit2.Text := mystring;
  mystring := SysUtils.FormatFloat('#,##0.00000000000000000000000000;;Zero', ex);
  Edit5.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
```

```
  ex : Extended;
  myString : String;
begin
  ex := Pi;
//  mystring := FloatToStr(ex);
//  Str(ex:25:23, mystring);
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit1.Text := mystring;
end;
```

FloatToStrF (see page 4182)

FloatToText (see page 4183)

GetLocaleFormatSettings (see page 4206)

37.3.120 SysUtils.FloatToStrF Function

Converts a floating point value to a string, using a specified Format (see page 4188), Precision, and Digits.

Pascal

```
function FloatToStrF(Value: Extended; Format: TFloatFormat; Precision: Integer; Digits:
Integer): string; overload;
function FloatToStrF(Value: Extended; Format: TFloatFormat; Precision: Integer; Digits:
Integer; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
UnicodeString FloatToStrF(Extended Value, TFloatFormat Format, int Precision, int Digits);
UnicodeString FloatToStrF(Extended Value, TFloatFormat Format, int Precision, int Digits,
const TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToStrF converts the floating-point value given by Value to its string representation.

The Value parameter is the value to convert.

The Precision parameter specifies the precision of the given value. It should be 7 or less for values of type Single, 15 or less for values of type Double, and 18 or less for values of type Extended.

The Digits and Format (see page 4188) parameters together control how the value is formatted into a string. For details, see the description of TFloatFormat (see page 4323).

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

The first form of FloatToStrF is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToStrF, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToStrF, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

Delphi Examples:

```
{
This example shows how to use the ArcTan and FloatToStr
functions to approximate Pi.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit3.Text := mystring;
  Str(ex:25:23, mystring);
  Edit4.Text := mystring;
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit2.Text := mystring;
  mystring := SysUtils.FormatFloat('#,##0.00000000000000000000000000;;Zero', ex);
  Edit5.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
//  mystring := FloatToStr(ex);
//  Str(ex:25:23, mystring);
  mystring := FloatToStrF(ex, ffFixed, 35, 33);
  Edit1.Text := mystring;
end;
```

37.3.121 SysUtils.FloatToText Function

Converts a floating-point value to an unterminated character string, using a specified Format (see page 4188), Precision and Digits.

Pascal

```
function FloatToText(BufferArg: PAnsiChar; const Value; ValueType: TFloatValue; Format:
TFloatFormat; Precision: Integer; Digits: Integer): Integer; overload;
function FloatToText(BufferArg: PWideChar; const Value; ValueType: TFloatValue; Format:

int FloatToText(PWideChar BufferArg, const  Value, TFloatValue ValueType, TFloatFormat Format,
int Precision, int Digits, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToText converts the given floating-point value to its decimal representation using the specified format, precision, and digits.

The Value parameter must be a variable of type Extended or System::Currency (see page 3235), as indicated by the ValueType parameter. The resulting string of characters is stored in the given buffer, and the returned value is the number of characters stored. The resulting string is not null-terminated.

The first form of FloatToText is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToText, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToText, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.122 SysUtils.FloatToTextFmt Function

Converts a floating-point value to an unterminated character string, using a specified format.

Pascal

```
function FloatToTextFmt(Buf: PAnsiChar; const Value; ValueType: TFloatValue; Format:
PAnsiChar): Integer; overload;
function FloatToTextFmt(Buf: PAnsiChar; const Value; ValueType: TFloatValue; Format:
PAnsiChar; const FormatSettings: TFormatSettings): Integer; overload;
function FloatToTextFmt(Buf: PWideChar; const Value; ValueType: TFloatValue; Format:
PWideChar): Integer; overload;
function FloatToTextFmt(Buf: PWideChar; const Value; ValueType: TFloatValue; Format:
PWideChar; const FormatSettings: TFormatSettings): Integer; overload;
```

C++

```
int FloatToTextFmt(PAnsiChar Buf, const  Value, TFloatValue ValueType, PAnsiChar Format);
int FloatToTextFmt(PAnsiChar Buf, const  Value, TFloatValue ValueType, PAnsiChar Format, const
TFormatSettings FormatSettings);
int FloatToTextFmt(PWideChar Buf, const  Value, TFloatValue ValueType, PWideChar Format);
int FloatToTextFmt(PWideChar Buf, const  Value, TFloatValue ValueType, PWideChar Format, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use FloatToTextFmt to format a floating-point value using a format string rather than using a predefined format. To use a predefined format, use the FloatToText (see page 4183) or FloatToStrF (see page 4182) function instead.

The Value parameter must be a variable of type Extended or System::Currency (see page 3235), as indicated by the ValueType parameter. The resulting string of characters is stored in the given buffer, and the returned value is the number of characters stored. The resulting string is not null-terminated.

Formats supported are described as part of the FormatFloat (see page 4197) function.

The first form of FloatToTextFmt is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToTextFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToTextFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.123 SysUtils.FmtLoadStr Function

Returns formatted output using a resourced format string.

Pascal

```
function FmtLoadStr(Ident: Integer; const Args: array of const): string;
```

C++

```
UnicodeString FmtLoadStr(int Ident, const array of const Args);
```

File

SysUtils

Description

FmtLoadStr loads a string from a program's resource string table and uses that string, plus an array of arguments, as a parameter to Format (see page 4188).

Ident is the string resource ID of the desired format string.

Args is an array of arguments that replace the format specifiers in the string Ident designates.

Note: Args_Size is the index of the last element in the Args array (one less than the number of arguments).

FmtLoadStr returns the resourced string with the arguments applied. This is the same value that would result from calling Format (see page 4188), using the resourced string and the specified arguments.

See Also

Format (see page 4188)

37.3.124 SysUtils.FmtStr Function

Assembles a formatted string using a format string and an array of arguments.

Pascal

```
procedure FmtStr(var Result: string; const Format: string; const Args: array of const);
overload;
procedure FmtStr(var Result: string; const Format: string; const Args: array of const; const
FormatSettings: TFormatSettings); overload;
```

C++

```
FmtStr(UnicodeString Result, const UnicodeString Format, const array of const Args);
FmtStr(UnicodeString Result, const UnicodeString Format, const array of const Args, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the specified open (untyped) array.

StrResult returns the results of the operation.

Format (see page 4188) is the format string that determines how to generate StrResult. For information on the format strings, see Format (see page 4188) Strings.

Args is an array of arguments that replace the format specifiers in Format (see page 4188).

Note: Args_Size specifies the index of the last element of Args (one less than the number of elements).

The first form of FmtStr is not thread-safe, because it uses localization information contained in global variables. The second form of FmtStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FmtStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.125 SysUtils.ForceDirectories Function

Creates a new directory, including the creation of parent directories as needed.

Pascal

```
function ForceDirectories(Dir: string): Boolean;
```

C++

```
Boolean ForceDirectories(UnicodeString Dir);
```

File

SysUtils

Description

ForceDirectories creates a new directory as specified in Dir, which must be a fully-qualified path name. If the directories given in the path do not yet exist, ForceDirectories attempts to create them.

ForceDirectories returns true if it successfully creates all necessary directories, false if it could not create a needed directory.

Warning: Important:Do not call ForceDirectories with an empty string. Doing so causes ForceDirectories to raise an exception.

Note: The FileCtrl unit (Windows only) also contains a ForceDirectories function. However, the FileCtrl version is deprecated, and the SysUtils (see page 3901) version preferred, even if the code does not need to be cross-platform.

C++ Examples:

```
/*
The following sample code sets the directory of
DirectoryListBox1 to c:\\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
c:\\WINDOWS\\mytemp is added, but note that it is not updated
in DirectoryListBox1 until Button2 is pressed and Update is
called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current directory to see the magic happen.  Also,
capitalization matters in C++ and the file spearators must
be "\\".
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ForceDirectories(Edit1->Text);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  DirectoryListBox1->Update();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  DirectoryListBox1->Directory = "c:\\WINDOWS";
}
/*
This example uses a label and a button on a form. When the
user clicks the button, all the directories along the
specified path that don't exist are created. The results are
reported in the caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString Dir = "C:\\Apps\\Sales\\Local";
  if (ForceDirectories(Dir))
    Label1->Caption = Dir + " was created";
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, all the directories along the
specified path that don't exist are created. The results are
reported in the caption of the label:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Dir: string;
begin
  Dir := 'C:\APPS\SALES\LOCAL';
  if SysUtils.ForceDirectories(Dir) then
    Label1.Caption := Dir + ' was created'
end;
```

37.3.126 SysUtils.Format Function

Returns a formatted string assembled from a format string and an array of arguments.

Pascal

```
function Format(const Format: string; const Args: array of const): string; overload;
function Format(const Format: string; const Args: array of const; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
UnicodeString Format(const UnicodeString Format, const array of const Args);
UnicodeString Format(const UnicodeString Format, const array of const Args, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

The Format function formats the series of arguments in an open (untyped) array.

Format is the format string. For information on the format strings, see Format Strings, described in this topic.

Args is an array of arguments to apply to the format specifiers in Format. For C++, Args_Size specifies the index of the last element of Args (one less than the number of elements).

Format returns the results of applying the arguments in Args to the format string Format.

Two syntax forms are given for Format. The first form of Format is not thread-safe, because it uses localization information contained in global variables. The second form of Format, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of Format, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

Format Strings

Format strings specify required formats to general-purpose formatting routines. Format strings passed to the string formatting routines contain two types of objects -- literal characters and format specifiers. Literal characters are copied verbatim to the resulting string. Format specifiers fetch arguments from the argument list and apply formatting to them.

Format specifiers have the following form:

```
"%" [index ":"] ["-"] [width] ["." prec] type
```

A format specifier begins with a % character. After the % come the following elements, in this order:

An optional argument zero-offset index specifier (that is, the first item has index 0), `[index ":"]`

An optional left justification indicator, `["-"]`

An optional width specifier, `[width]`

An optional precision specifier, `["." prec]`

The conversion type character, `type`

The following table summarizes the possible values for type:

Value	Meaning
d	Decimal. The argument must be an integer value. The value is converted to a string of decimal digits. If the format string contains a precision specifier, it indicates that the resulting string must contain at least the specified number of digits; if the value has less digits, the resulting string is left-padded with zeros.
u	Unsigned decimal. Similar to 'd' but no sign is output.
e	Scientific. The argument must be a floating-point value. The value is converted to a string of the form "-d.ddd...E+ddd". The resulting string starts with a minus sign if the number is negative. One digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision specifier in the format string—a default precision of 15 is assumed if no precision specifier is present. The "E" exponent character in the resulting string is always followed by a plus or minus sign and at least three digits.
f	Fixed. The argument must be a floating-point value. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative. The number of digits after the decimal point is given by the precision specifier in the format string—a default of 2 decimal digits is assumed if no precision specifier is present.
g	General. The argument must be a floating-point value. The value is converted to the shortest possible decimal string using fixed or scientific format. The number of significant digits in the resulting string is given by the precision specifier in the format string—a default precision of 15 is assumed if no precision specifier is present. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format.
n	Number. The argument must be a floating-point value. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The "n" format corresponds to the "f" format, except that the resulting string contains thousand separators.
m	Money. The argument must be a floating-point value. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString (see page 4349), CurrencyFormat (see page 4348), NegCurrFormat (see page 4356), ThousandSeparator (see page 4362), DecimalSeparator (see page 4350), and CurrencyDecimals (see page 4348) global variables or their equivalent in a TFormatSettings (see page 4326) data structure. If the format string contains a precision specifier, it overrides the value given by the CurrencyDecimals (see page 4348) global variable or its TFormatSettings (see page 4326) equivalent.
p	Pointer. The argument must be a pointer value. The value is converted to an 8 character string that represents the pointers value in hexadecimal.
s	String. The argument must be a character, a string, or a PChar value. The string or character is inserted in place of the format specifier. The precision specifier, if present in the format string, specifies the maximum length of the resulting string. If the argument is a string that is longer than this maximum, the string is truncated.
x	Hexadecimal. The argument must be an integer value. The value is converted to a string of hexadecimal digits. If the format string contains a precision specifier, it indicates that the resulting string must contain at least the specified number of digits; if the value has fewer digits, the resulting string is left-padded with zeros.

Conversion characters may be specified in uppercase as well as in lowercase—both produce the same results.

For all floating-point formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator (see page 4350) and ThousandSeparator (see page 4362) global variables or their TFormatSettings (see page 4326) equivalent.

Index, width, and precision specifiers can be specified directly using decimal digit string (for example "%10d"), or indirectly using an asterisk character (for example "%*.*f"). When using an asterisk, the next argument in the argument list (which must be an integer value) becomes the value that is actually used. For example,

```
Format ('%*.*f', [8, 2, 123.456]);
```

is equivalent to

```
Format ('%8.2f', [123.456]);
```

Similarly:

```
TVarRec args[3] = {8,2,123.456};
Format ("%*.*f", args, 2);
```

is equivalent to

```
TVarRec args[1] = {123.456};
Format ("%8.2f", args, 0);
```

A width specifier sets the minimum field width for a conversion. If the resulting string is shorter than the minimum field width, it is padded with blanks to increase the field width. The default is to right-justify the result by adding blanks in front of the value, but if the format specifier contains a left-justification indicator (a "-" character preceding the width specifier), the result is left-justified by adding blanks after the value.

An index specifier sets the current argument list index to the specified value. The index of the first argument in the argument list is 0. Using index specifiers, it is possible to format the same argument multiple times. For example "Format('%d %d %0:d %1:d', [10, 20])" produces the string '10 20 10 20'.

Note: Setting the index specifier affects all subsequent formatting. That is, Format('%d %d %d %0:d %d', [1, 2, 3, 4]) returns '1 2 3 1 2', not '1 2 3 1 4'. To get the latter result, you must use Format('%d %d %d %0:d %3:d', [1, 2, 3, 4])

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Change
the Old Path and New Path to move files outside the Debug
directory, Old File and New File will not take a relative path.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Save1Click(TObject *Sender)
{
  AnsiString temp1 = Edit4->Text;
  AnsiString temp2 = ExtractFileName(Edit1->Text);
  AnsiString NewFileName = temp1 + temp2;
  AnsiString OldFileName =
    Edit3->Text + ExtractFileName(Edit2->Text);
  AnsiString Msg = Format("Copy %s to %s", ARRAYOFCONST((OldFileName, NewFileName)));
  if (MessageDlg(Msg, mtCustom, TMsgDlgButtons() << mbOK << mbCancel, 0) == mrOk)
  {
    std::auto_ptr<TFileStream> OldFile(new TFileStream(OldFileName, fmOpenRead |
fmShareDenyWrite));
    std::auto_ptr<TFileStream> NewFile(new TFileStream(NewFileName, fmCreate |
fmShareDenyRead));
    NewFile->CopyFrom(OldFile.get(), OldFile->Size);
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit3->Text = ExtractFilePath(Application->ExeName);
  Edit4->Text = Edit3->Text;
}
/*
This example displays a message on the form's status bar
indicating the record count after a record is deleted.  Set
the StatusBar SimplePanel property to True.
*/
void __fastcall TForm1::Table1AfterDelete(TDataSet *DataSet)
{
  StatusBar1->SimpleText = Format(
    "There are now %d records in the table",
    ARRAYOFCONST(((int)DataSet->RecordCount)));
}
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Table1->Delete();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Table1 = new TTable(Form1);
  Table1->Active = false; // The Table component must not be active
  Table1->DatabaseName = "DBDEMOS";
  Table1->TableType = ttParadox;
  Table1->TableName = "CustInfo";
  Table1->Active = False;
  if (!Table1->Exists) // Don't overwrite an existing table
  {
    Table1->Close();
    Table1->DeleteTable();
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Table1->FieldDefs->Clear();
  TFieldDef *pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Table1->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Table1->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Table1->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Table1->CreateTable();
  Table1->Active = True;
  for (int i = 1; i <= 20; i++)
    Table1->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Table1;
  DBGrid2->DataSource->DataSet = Table1;
  Table1->AfterDelete = Table1AfterDelete;
  Table1->Active = True;
}
```

Delphi Examples:

```
{
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Change
the Old Path and New Path to move files outside the Debug
directory, Old File and New File will not take a relative path.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit3.Text := ExtractFilePath(Application.ExeName);
  Edit4.Text := Edit3.Text;
end;

procedure TForm1.Save1Click(Sender: TObject);
var
  NewFileName, OldFileName: string;
  temp1, temp2: string;
```

```
    Msg: string;
    NewFile: TFileStream;
    OldFile: TFileStream;
  begin
    temp1 := Edit4.Text;
    temp2 := ExtractFileName(Edit1.Text);
    NewFileName := temp1 + temp2;
    OldFileName :=
      Edit3.Text + ExtractFileName(Edit2.Text);
    Msg := Format('Copy %s to %s?', [OldFileName, NewFileName]);
    if MessageDlg(Msg, mtCustom, mbOKCancel, 0) = mrOK then
    begin

```

File

SysUtils

Description

This function formats the series of arguments in the specified open array into a text buffer.

Buffer is the text buffer that receives the results.

BufLen is the number of bytes in Buffer.

Format (see page 4188) is the format string that determines how arguments are formatted. For information on the format strings, see Format (see page 4188) Strings.

FmtLen is the number of bytes in Format (see page 4188).

Args are the arguments that replace the format specifiers in Format (see page 4188).

Note: Args_Size is the index of the last element in Args (one less than the number of arguments).

FormatBuf function returns the length, in bytes, of the resulting string.

The first form of FormatBuf is not thread-safe, because it uses localization information contained in global variables. The second form of FormatBuf, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatBuf, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

GetLocaleFormatSettings (see page 4206)

37.3.128 SysUtils.FormatCurr Function

Formats a System::Currency (see page 3235) object.

Pascal

```
function FormatCurr(const Format: string; Value: Currency): string; overload;
function FormatCurr(const Format: string; Value: Currency; const FormatSettings:
```

```
TFormatSettings): string; overload;
```

C++

```
UnicodeString FormatCurr(const UnicodeString Format, Currency Value);
UnicodeString FormatCurr(const UnicodeString Format, Currency Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

FormatCurr formats the System::Currency (see page 3235) object given by Value using the format string given by Format (see page 4188).

For information on the format strings, see FormatFloat (see page 4197) Strings.

The first form of FormatCurr is not thread-safe, because it uses localization information contained in global variables. The second form of FormatCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.129 SysUtils.FormatDateTime Function

Formats a TDateTime (see page 3323) value.

Pascal

```
function FormatDateTime(const Format: string; DateTime: TDateTime): string; overload;
function FormatDateTime(const Format: string; DateTime: TDateTime; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
UnicodeString FormatDateTime(const UnicodeString Format, TDateTime DateTime);
UnicodeString FormatDateTime(const UnicodeString Format, TDateTime DateTime, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

FormatDateTime formats the TDateTime (see page 3323) value given by DateTime using the format given by Format (see page 4188). See the table below for information about the supported format strings.

If the string specified by the Format (see page 4188) parameter is empty, the TDateTime (see page 3323) value is formatted as if a 'c' format specifier had been given.

The first form of FormatDateTime is not thread-safe, because it uses localization information contained in global variables. The

second form of FormatDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

Date (see page 4087) Time (see page 4297) Format (see page 4188) Strings are composed from specifiers that represent values to be inserted into the formatted string. Some specifiers (such as "d"), simply format numbers or strings. Other specifiers (such as "/") refer to locale-specific strings from global variables.

In the following table, specifiers are given in lower case. Case is ignored in formats, except for the "am/pm" and "a/p" specifiers.

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat (see page 4358) global variable, followed by the time using the format given by the LongTimeFormat (see page 4356) global variable. The time is not displayed if the date-time value indicates midnight precisely.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames (see page 4359) global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames (see page 4355) global variable.
ddddd	Displays the date using the format given by the ShortDateFormat (see page 4358) global variable.
dddddd	Displays the date using the format given by the LongDateFormat (see page 4354) global variable.
e	(Windows only) Displays the year in the current period/era as a number without a leading zero (Japanese, Korean and Taiwanese locales only).
ee	(Windows only) Displays the year in the current period/era as a number with a leading zero (Japanese, Korean and Taiwanese locales only).
g	(Windows only) Displays the period/era as an abbreviation (Japanese and Taiwanese locales only).
gg	(Windows only) Displays the period/era as a full name. (Japanese and Taiwanese locales only).
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec (see page 3550)) using the strings given by the ShortMonthNames (see page 4359) global variable.
mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames (see page 4355) global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
z	Displays the millisecond without a leading zero (0-999).
zzz	Displays the millisecond with a leading zero (000-999).

t	Displays the time using the format given by the ShortTimeFormat (see page 4360) global variable.
tt\	Displays the time using the format given by the LongTimeFormat (see page 4356) global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString (see page 4362) global variable for any hour before noon, and the contents of the TimePMString (see page 4362) global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator (see page 4349) global variable.
:	Displays the time separator character given by the TimeSeparator (see page 4363) global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, and do not affect formatting.

C++ Examples:

```
/*
The following example uses FormatDateTime to set the string
variable S to a sentence indicating a meeting time in 3
hours. The sentence has the form "The meeting is on
Wednesday, February 15, 1995 at 2:30 PM."
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString S = "The meeting is on ";
  S = S + FormatDateTime("dddd, mmmm d, yyyy ' at ' hh:mm AM/PM", IncHour(Now(), 3));
  Label1->Caption = S;
}
```

Delphi Examples:

```
{
The following example uses FormatDateTime to set the string
variable S to a sentence indicating a meeting time in 3
hours. The sentence has the form "The meeting is on
Wednesday, February 15, 2008 at 2:30 PM."
}
procedure TForm1.Button1Click(Sender: TObject);
var S : string;
begin
  S := SysUtils.FormatDateTime(
    '"The meeting is on " dddd, mmmm d, yyyy, " at " hh:mm AM/PM', IncHour(Now(), 3));
  Label1.Caption := S;
end;
```

37.3.130 SysUtils.FormatFloat Function

Formats a floating point value.

Pascal

```
function FormatFloat(const Format: string; Value: Extended): string; overload;
function FormatFloat(const Format: string; Value: Extended; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
UnicodeString FormatFloat(const UnicodeString Format, Extended Value);
```

```
UnicodeString FormatFloat(const UnicodeString Format, Extended Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

FormatFloat formats the floating-point value given by Value using the format string given by Format (see page 4188). The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first '.' character in the format string determines the location of the decimal separator in the formatted value; any additional '.' characters are ignored. The actual character used as a the decimal separator in the output string is determined by the DecimalSeparator (see page 4350) global variable or its TFormatSettings (see page 4326) equivalent.
,	Thousand separator. If the format string contains one or more ',' characters, the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of ',' characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as a the thousand separator in the output is determined by the ThousandSeparator (see page 4362) global variable or its TFormatSettings (see page 4326) equivalent.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain between one and three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If the section for negative values or the section for zero values is empty, that is if there is nothing between the semicolons that delimit the section, the section for positive values is used instead.

If the section for positive values is empty, or if the entire format string is empty, the value is formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 4182) with the ffGeneral format. General

floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The first form of FormatFloat is not thread-safe, because it uses localization information contained in global variables. The second form of FormatFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int x = 1; x < StringGrid1->ColCount; x++)
  {
    for (int y = 1; y < StringGrid1->RowCount; y++)
    {
      StringGrid1->Cells[x][y] = FormatFloat(
      StringGrid1->Cells[0][y], StrToFloat(StringGrid1->Cells[x][0]));
    }
  }
}

int currCellCol, currCellRow;

void __fastcall TForm1::StringGrid1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  StringGrid1->MouseToCell(X, Y, currCellCol, currCellRow);
}

// Alter Cell
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  StringGrid1->Cells[currCellCol][currCellRow] = Edit1->Text;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "1234";
  StringGrid1->Cells[2][0] = "-1234";
  StringGrid1->Cells[3][0] = "0.5";
  StringGrid1->Cells[4][0] = "0";
  StringGrid1->Cells[0][1] = "";
  StringGrid1->Cells[0][2] = "0";
  StringGrid1->Cells[0][3] = "0.00";
  StringGrid1->Cells[0][4] = "#.##";
  StringGrid1->Cells[0][5] = "#,##0.00";
  StringGrid1->Cells[0][6] = "#,##0.00;(#,##0.00)";
  StringGrid1->Cells[0][7] = "#,##0.00;;Zero";
  StringGrid1->Cells[0][8] = "0.000E+00";
  StringGrid1->Cells[0][9] = "#.###E-0";
}
/*
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  ShowMessage(FormatFloat("#,##0 bytes", DiskFree(0)));
}
```

Delphi Examples:

```
{
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  X, Y, I: Integer;
begin
  for X := 1 to StringGrid1.ColCount - 1 do
  begin
    for Y := 0 to StringGrid1.RowCount - 1 do
    begin
      StringGrid1.Cells[X,Y] := SysUtils.FormatFloat(
        StringGrid1.Cells[0,Y], StrToFloat(StringGrid1.Cells[X,0]));
    end;
  end;

end;

var currCellCol, currCellRow: Integer;

// Alter Cell
procedure TForm1.Button2Click(Sender: TObject);
begin
  StringGrid1.Cells[currCellCol,currCellRow] := Edit1.Text;
end;

procedure TForm1.StringGrid1MouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
begin
  StringGrid1.MouseToCell(X, Y, &currCellCol, &currCellRow);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[1,0] := '1234';
  StringGrid1.Cells[2,0] := '-1234';
  StringGrid1.Cells[3,0] := '0.5';
  StringGrid1.Cells[4,0] := '0';
  StringGrid1.Cells[0,1] := '';
  StringGrid1.Cells[0,2] := '0';
  StringGrid1.Cells[0,3] := '0.00';
  StringGrid1.Cells[0,4] := '#.##';
  StringGrid1.Cells[0,5] := '#,##0.00';
  StringGrid1.Cells[0,6] := '#,##0.00;(#,##0.00)';
  StringGrid1.Cells[0,7] := '#,##0.00;;Zero';
  StringGrid1.Cells[0,8] := '0.000E+00';
  StringGrid1.Cells[0,9] := '#.###E-0';
end;
{
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(FormatFloat('#,##0 bytes', DiskFree(0)));
end;
```

37.3.131 SysUtils.FreeAndNil Function

Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).

Pascal

```
procedure FreeAndNil(var Obj);
```

C++

```
FreeAndNil( Obj);
```

File

SysUtils

Description

Use FreeAndNil to ensure that a variable is nil (Delphi) or NULL (C++) after you free the object it references. Pass any variable that represents an object as the Obj parameter.

Warning: Obj must be an instance of a TObject (see page 3354) descendant.

Delphi Examples:

```
{
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
}
procedure TForm1.Button1Click(Sender: TObject);
var NewFileName, OldFileName: string;
    NewFile, OldFile: TFileStream;
begin
  SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
  SavePictureDialog1.Filter := GraphicFilter(TBitmap);
  OldFileName := 'factory.bmp';
  if SavePictureDialog1.Execute then
  begin
    NewFileName := SavePictureDialog1.FileName;
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
```

```
      finally
        FreeAndNil(OldFile);
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Image1.Picture.LoadFromFile('factory.bmp');
  end;
```

See Also

System::TObject (see page 3354)

37.3.132 SysUtils.GDAL Function

Get Delphi Access Licence.

Pascal

```
function GDAL: LongWord;
```

C++

```
LongWord GDAL();
```

File

SysUtils

Description

GDAL retreives the access licences resource. It checks if it is valid, if not an Access Licence Violation exception with the message 'Application is not licenced to use this feature' is raised.

The returned value is the decrypted first Access Licence (AL1).

RCS (see page 4232)

RPR (see page 4237)

37.3.133 SysUtils.GetCurrentDir Function

Returns the name of the current directory.

Pascal

```
function GetCurrentDir: string;
```

C++

```
UnicodeString GetCurrentDir();
```

File

SysUtils

Description

GetCurrentDir returns the fully qualified name of the current directory.

C++ Examples:

```
/*
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
*/
void __fastcall TMyChDir::Button1Click(TObject *Sender)
{
  try
  {
    System::ChDir(Edit1->Text);
  }
  catch (...)
  {
    MessageDlg("Cannot find directory", mtWarning, TMsgDlgButtons() << mbOK, 0);
  }
  Edit2->Text = GetCurrentDir();
  FileListBox1->Directory = GetCurrentDir();
  DirectoryListBox1->Directory = GetCurrentDir();
}

void __fastcall TMyChDir::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  Edit2->Text = GetCurrentDir();
}

void __fastcall TMyChDir::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
  Edit2->Text = GetCurrentDir();
}
```

Delphi Examples:

```
{
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  System.ChDir(Edit1.Text);
  if IOResult <> 0 then
    MessageDlg('Cannot find directory', mtWarning, [mbOk], 0);
  Edit2.Text := GetCurrentDir;
  FileListBox1.Directory := GetCurrentDir;
  DirectoryListBox1.Directory := GetCurrentDir;
end;
```

```
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;
```

37.3.134 SysUtils.GetEnvironmentVariable Function

Retrieves an environment variable value.

Pascal

```
function GetEnvironmentVariable(const Name: string): string; overload;
```

C++

```
UnicodeString GetEnvironmentVariable(const UnicodeString Name);
```

File

SysUtils

Description

Call GetEnvironmentVariable to retrieve the value of an environment variable, passed as `Name`, for the current process.

Note: The case of the specified environment variable `Name` is ignored.

The following table defines the standard environment variables for Microsoft Windows.

Environment variable name	Environment value
ALLUSERSPROFILE	Generic user profile.
APPDATA	Path of the application data folder.
CLIENTNAME	Name of Client machine.
COMMONPROGRAMFILES	Path of common program files folder.
COMPUTERNAME	Name of Computer code is running on.
COMSPEC	Path of the cmd.exe program.
HOMEDRIVE	Current home drive designation, such as 'C:'
HOMEPATH	Path to current location for document storage.

LOGONSERVER	
NUMBER_OF_PROCESSORS	Number of processors on current machine.
OS	Base name of the Operating System (see page 3159). Note that Windows XP is given as Windows_NT.
PATH	The current program path.
PATHEXT	
PROCESSOR_ARCHITECTURE	Type of CPU architecture. For example, X86 for Intel Pentium processors.
PROCESSOR_IDENTIFIER	
PROCESSOR_LEVEL	More detailed description of the CPU architecture.
PROCESSOR_REVISION	Processor revision level.
PROGRAMFILES	Path of the program files folder.
SESSIONNAME	Name of the current OS session.
SYSTEMDRIVE	Drive the OS operates from.
SYSTEMROOT	
TEMP	Path of the temporary files folder.
TMP	
USERDOMAIN	
USERNAME	Name of the current user.
USERPROFILE	Path of the folder holding the current user's information.
WINDIR	Path of the Windows folder.

37.3.135 SysUtils.GetFileVersion Function

Returns file version.

Pascal

```
function GetFileVersion(const AFileName: string): Cardinal;
```

C++

```
unsigned GetFileVersion(const UnicodeString AFileName);
```

File

SysUtils

Description

GetFileVersion returns the most significant 32 bits of a file binary version number. AFileName specifies the name of the file, which is searched using the same path as the LoadLibrary function.

GetFileVersion is only available on Windows and must not be used in cross-platform code.

37.3.136 SysUtils.GetFormatSettings Function

Resets the date and number format parameters to initial values.

Pascal

```
procedure GetFormatSettings;
```

C++

```
GetFormatSettings();
```

File

SysUtils

Description

GetFormatSettings resets all date and number format variables to their initial values.

Note: On Windows, GetFormatSettings is called automatically in response to WM_WININICHANGE messages.

37.3.137 SysUtils.GetLocaleChar Function

Retrieves the first character of a localisation value.

Pascal

```
function GetLocaleChar(Locale: Integer; LocaleType: Integer; Default: Char): Char; platform;
```

C++

```
Char GetLocaleChar(int Locale, int LocaleType, Char Default);
```

File

SysUtils

Description

GetLocaleChar retrieves the first character of the passed LocaleType value, or the passed Default value if not found. The actual value is determined by the location specified by Locale. For example, on Windows, $0809 is the Locale for United Kingdom English, and $0409 is the Locale for US English. For the LOCALE_SCURRENCY LocaleType, these locales would yield '£' and '$' respectively.

Note: This is an OS specific function.

See Also

GetLocaleStr (see page 4207)

37.3.138 SysUtils.GetLocaleFormatSettings Function

Populates a TFormatSettings (see page 4326) data structure.

Pascal

```
procedure GetLocaleFormatSettings(LCID: Integer; var FormatSettings: TFormatSettings);
```

C++

```
GetLocaleFormatSettings(int LCID, TFormatSettings FormatSettings);
```

File

SysUtils

Description

GetLocaleFormatSettings populates FormatSettings based on the Windows locale ID specified in LCID. A TFormatSettings (see page 4326) data structure must be initialized by a call to GetLocaleFormatSettings before it can be used with any string formatting routines.

37.3.139 SysUtils.GetLocaleStr Function

Retrieves a localisation value.

Pascal

```
function GetLocaleStr(Locale: Integer; LocaleType: Integer; const Default: string): string;
platform;
```

C++

```
UnicodeString GetLocaleStr(int Locale, int LocaleType, const UnicodeString Default);
```

File

SysUtils

Description

GetLocaleStr retrieves the passed LocaleType value, or the passed Default value if not found. The actual value is determined by the location specified by Locale. For example, on Windows, $040c is the Locale for France French, and $0409 is the Locale for US English. For the LOCALE_SMONTHNAME1 LocaleType, these locales would yield 'janvier' and 'January' respectively.

Note: This is an OS specific function.

See Also

GetLocaleChar (see page 4206)

37.3.140 SysUtils.GetModuleName Function

Returns the fully qualified name for a module, given its handle.

Pascal

```
function GetModuleName(Module: HMODULE): string;
```

C++

```
UnicodeString GetModuleName(HMODULE Module);
```

File

SysUtils

Description

Call GetModuleName to obtain the fully qualified name of a module, given its handle.

Module is the handle of the module whose file name is required.

Warning: :On Linux, GetModuleName is not always successful. Depending on the way the application is called, the presence of the /proc file system, and other factors, there are times when GetModuleName may return a name that is not fully qualified or in some cases, no file name at all. Be sure to check the results of this function before using the returned value.

C++ Examples:

```
/*
This example requires a button and a label.  When the user clicks
the button, the GetModuleName function retieves the path and name
of the project executable using the file handle HInstance.
*/
AnsiString __fastcall GetUsersFileName(void)
{
  return GetModuleName(unsigned(HInstance));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = GetUsersFileName();
}
```

Delphi Examples:

```
{
This example requires a button and a label.  When the user clicks
the button, the GetModuleName function retieves the path and name
of the project executable using the file handle HInstance.
}
function GetUsersFileName: string;
begin
  Result := SysUtils.GetModuleName(HInstance);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := GetUsersFileName;
end;
```

37.3.141 SysUtils.GetPackageDescription Function

Returns the description resource from a package.

Pascal

```
function GetPackageDescription(ModuleName: PChar): string;
```

C++

```
UnicodeString GetPackageDescription(const char * ModuleName);
```

File

SysUtils

Description

Call GetPackageDescription to obtain the description stored with the named package. If the package does not have a description

resource, GetPackageDescription returns an empty string.

See Also

GetPackageInfo (see page 4209)

37.3.142 SysUtils.GetPackageInfo Function

Enumerates all the units and required packages for a package.

Pascal

```
procedure GetPackageInfo(Module: HMODULE; Param: Pointer; var Flags: Integer; InfoProc:
TPackageInfoProc);
```

C++

```
GetPackageInfo(HMODULE Module, void * Param, int Flags, TPackageInfoProc InfoProc);
```

File

SysUtils

Description

Call GetPackageInfo to process the information in a package's information table. The InfoProc callback is called for every unit included in the package and for every package required by the package. Module is the module handle for the package. GetPackageInfo passes any application-supplied information passed in the Param parameter to the InfoProc callback. The package's information flags are passed to the InfoProc and returned in the Flags parameter.

See Also

LoadPackage (see page 4224)

GetPackageDescription (see page 4208)

37.3.143 SysUtils.GetTime Function

Returns the current time.

Pascal

```
function GetTime: TDateTime;
```

C++

```
TDateTime GetTime();
```

File

SysUtils

Description

GetTime and Time (see page 4297) return the current time as a TDateTime (see page 3323) value. The two functions are completely equivalent.

Note: Time (see page 4297) clashes with an Xlib function of the same name. Use GetTime in Linux and cross-platform code.

See Also

Time (see page 4297)

Date (see page 4087)

DecodeTime (see page 4097)

Now (see page 4227)

TimeToStr (see page 4299)

37.3.144 SysUtils.GUIDToString Function

Converts a class identifier GUID to a string.

Pascal

```
function GUIDToString(const GUID: TGUID): string;
```

C++

```
UnicodeString GUIDToString(const TGUID GUID);
```

File

SysUtils

Description

GUIDToString converts a GUID into a string of printable characters. Each GUID always converts to a unique string.

If GUIDToString succeeds it returns a string for the requested GUID. If GUIDToString fails, it raises EConvertError (see page 3919).

C++ Examples:

```
/*
The following example manufactures a GUID and displays it in
a dialog box after translating it to a string.
*/
#include <ActiveX.hpp>
#include <ComObj.hpp>
#include <Sysutils.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
    TGUID g;
    OleCheck(CoCreateGuid(&g));
    ShowMessage(Sysutils::GUIDToString(g));
}
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
```

```
            "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
          ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
          myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
          myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7])));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));

    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
The following example manufactures a GUID and displays it in
a dialog box after translating it to a string.
}
uses ActiveX, ComObj;
procedure TForm1.Button1Click(Sender: TObject);
var
  G: TGUID;
begin
  OleCheck(CoCreateGuid(G));
  ShowMessage(SysUtils.GUIDToString(G));
end;
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));

  { Auto-generate a random GUID at runtime }
  if CreateGUID(MyGuid1) <> 0 then
     Memo1.Lines.Add('Creating GUID failed!')
  else
     Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

  { Generating second random GUID }
  CreateGUID(MyGuid0);

  { Testing if 2 guids are equal }
```

```
    if IsEqualGUID(MyGuid0, MyGuid1) then
       Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                       '2 randomly generated GUIDs cannot be equal!');
  end;
```

37.3.145 SysUtils.HashName Function

Pascal

```
function HashName(Name: PAnsiChar): Cardinal;
```

C++

```
unsigned HashName(PAnsiChar Name);
```

File

SysUtils

Description

This is function SysUtils.HashName.

37.3.146 SysUtils.IncAMonth Function

Increments date data by one month.

Pascal

```
procedure IncAMonth(var Year: Word; var Month: Word; var Day: Word; NumberOfMonths: Integer =
1);
```

C++

```
IncAMonth(Word Year, Word Month, Word Day, int NumberOfMonths = 1);
```

File

SysUtils

Description

IncAMonth modifies Year, Month, and Day parameters so the date they describe is incremented by NumberOfMonths months. NumberOfMonths can be negative, to return a date N months previous.

If the input day of month is greater than the last day of the resulting month, the day is set to the last day of the resulting month.

37.3.147 SysUtils.IncludeTrailingBackslash Function

Ensures path name ends with delimiter

Pascal

```
function IncludeTrailingBackslash(const S: string): string; overload; platform;
```

C++

```
UnicodeString IncludeTrailingBackslash(const UnicodeString S);
```

File

SysUtils

Description

IncludeTrailingBackslash ensures that a path name ends with a trailing path delimiter ('\' on Windows, '/' on Linux). This function is included for backward-compatibility only. New (see page 3619) programs should use IncludeTrailingPathDelimiter (see page 4213).

Note: IncludeTrailingBackslash works with multibyte character sets.

See Also

ExcludeTrailingBackslash (see page 4108)

IsPathDelimiter (see page 4222)

37.3.148 SysUtils.IncludeTrailingPathDelimiter Function

Ensures path name ends with delimiter.

Pascal

```
function IncludeTrailingPathDelimiter(const S: string): string; overload;
```

C++

```
UnicodeString IncludeTrailingPathDelimiter(const UnicodeString S);
```

File

SysUtils

Description

IncludeTrailingPathDelimiter ensures that a path name ends with a trailing path delimiter ('\" on Windows, '/' on Linux). If S already ends with a trailing delimiter character, it is returned unchanged; otherwise S with appended delimiter character is returned.

Note: IncludeTrailingPathDelimiter works with multibyte character sets.

See Also

ExcludeTrailingPathDelimiter (see page 4109)

IsPathDelimiter (see page 4222)

37.3.149 SysUtils.IncMonth Function

Returns a date shifted by a specified number of months.

Pascal

```
function IncMonth(const DateTime: TDateTime; NumberOfMonths: Integer = 1): TDateTime;
```

C++

```
TDateTime IncMonth(const TDateTime DateTime, int NumberOfMonths = 1);
```

File

SysUtils

Description

IncMonth returns the value of the Date (see page 4087) parameter, incremented by NumberOfMonths months. NumberOfMonths can be negative, to return a date N months previous.

If the input day of month is greater than the last day of the resulting month, the day is set to the last day of the resulting month. The time of day specified by the Date (see page 4087) parameter is copied to the result.

37.3.150 SysUtils.InitializePackage Function

Validates and initializes a given package.

Pascal

```
procedure InitializePackage(Module: HMODULE); overload;
procedure InitializePackage(Module: HMODULE; AValidatePackage: TValidatePackageProc); overload;
```

C++

```
InitializePackage(HMODULE Module);
InitializePackage(HMODULE Module, TValidatePackageProc AValidatePackage);
```

File

SysUtils

Description

InitializePackage checks for duplicate units in a package and calls the initialization blocks of the contained units.

Note: InitializePackage is called internally by the LoadPackage (see page 4224) function.

See Also

LoadPackage (see page 4224)

37.3.151 SysUtils.IntToHex Function

Returns the hex representation of an integer.

Pascal

```
function IntToHex(Value: Integer; Digits: Integer): string; overload;
function IntToHex(Value: Int64; Digits: Integer): string; overload;
```

C++

```
UnicodeString IntToHex(int Value, int Digits);
UnicodeString IntToHex(Int64 Value, int Digits);
```

File

SysUtils

Description

IntToHex converts a number into a string containing the number's hexadecimal (base 16) representation. Value is the number to convert. Digits indicates the minimum number of hexadecimal digits to return.

C++ Examples:

```
/*
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = "";
```

```
    for (int i = 1; i <= Edit1->Text.Length(); i++)
    {
      try
      {
        Label1->Caption =
          Label1->Caption +
          IntToHex(Byte(Edit1->Text[i]),2) + ' ';
      }
      catch (...)
      {
        Beep();
      }
    }
}
```

Delphi Examples:

```
{
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  Label1.Caption := '';
  for i := 1 to Length(Edit1.Text) do
  begin
    try
      Label1.Caption :=
        Label1.Caption +
        SysUtils.IntToHex(Byte(Edit1.Text[i]),2) + ' ';
    except
      Beep;
    end;
  end;
end;
```

See Also

IntToStr (see page 4216)

37.3.152 SysUtils.IntToStr Function

Converts an integer to a string.

Pascal

```
function IntToStr(Value: Integer): string; overload;
function IntToStr(Value: Int64): string; overload;
```

C++

```
UnicodeString IntToStr(int Value);
UnicodeString IntToStr(Int64 Value);
```

File

SysUtils

Description

IntToStr converts an integer into a string containing the decimal representation of that number.

C++ Examples:

```
/*
The following example uses two edit controls, a button, and
a label on a form. When the button is clicked, the integers
in the edit controls are multiplied together and the result
is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  try
  {
    Label1->Caption = IntToStr(StrToInt(Edit1->Text) * StrToInt(Edit2->Text));
  }
  catch(...)
  {
    ShowMessage("You must specify integer values. Please try again.");
  }
}
```

Delphi Examples:

```
{
The following example uses two edit controls, a button, and
a label on a form. When the button is clicked, the integers
in the edit controls are multiplied together and the result
is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  try
    Label1.Caption :=
      SysUtils.IntToStr(StrToInt(Edit1.Text) * StrToInt(Edit2.Text));
  except
    ShowMessage('You must specify integer values. Please try again.');
  end;
end;
```

37.3.153 SysUtils.IsAssembly Function

Determines whether a dll is an Assembly.

Pascal

```
function IsAssembly(const FileName: string): Boolean;
```

C++

```
Boolean IsAssembly(const UnicodeString FileName);
```

File

SysUtils

Description

Call IsAssembly to determine whether the passed FileName is that of a .Net Assembly or a traditional WIN32 DLL. The result is true if FileName is an Assembly.

37.3.154 SysUtils.IsDelimiter Function

Indicates whether a specified character in a string matches one of a set of delimiters.

Pascal

```
function IsDelimiter(const Delimiters: string; const S: string; Index: Integer): Boolean;
overload;
```

C++

```
Boolean IsDelimiter(const UnicodeString Delimiters, const UnicodeString S, int Index);
```

File

SysUtils

Description

Call IsDelimiter to determine whether the character at byte offset Index in the string S is one of the delimiters in the string Delimiters. Index is the index of the byte in question, where 1 is the first byte of the string, 2 is the second byte, and so on.

When working with a multi-byte character system (MBCS), IsDelimiter checks to make sure the indicated byte is not part of a double byte character. The delimiters in the Delimiters parameter must all be single byte characters.

See Also

AnsiStrRScan (see page 4060)

AnsiStrScan (see page 4061)

IsPathDelimiter (see page 4222)

LastDelimiter (see page 4223)

37.3.155 SysUtils.IsEqualGUID Function

Indicates whether two TGUID (see page 3718) values are the same.

Pascal

```
function IsEqualGUID(const guid1: TGUID; const guid2: TGUID): Boolean; stdcall;
```

C++

```
__stdcall Boolean IsEqualGUID(const TGUID guid1, const TGUID guid2);
```

File

SysUtils

Description

IsEqualGUID returns true if the TGUID (see page 3718) values are equal.

C++ Examples:

```
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
              "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
         ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
         myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
         myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7])));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));

    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));
```

```
    { Auto-generate a random GUID at runtime }
    if CreateGUID(MyGuid1) <> 0 then
       Memo1.Lines.Add('Creating GUID failed!')
    else
       Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

    { Generating second random GUID }
    CreateGUID(MyGuid0);

    { Testing if 2 guids are equal }
    if IsEqualGUID(MyGuid0, MyGuid1) then
       Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                       '2 randomly generated GUIDs cannot be equal!');
end;
```

37.3.156 SysUtils.IsLeadChar Function

Pascal

```
function IsLeadChar(C: AnsiChar): Boolean; overload;
```

C++

```
Boolean IsLeadChar(AnsiChar C);
```

File

SysUtils

Description

This is function SysUtils.IsLeadChar.

37.3.157 SysUtils.IsLeadChar Function

Pascal

```
function IsLeadChar(C: WideChar): Boolean; overload;
```

C++

```
Boolean IsLeadChar(WideChar C);
```

File

SysUtils

Description

This is function SysUtils.IsLeadChar.

37.3.158 SysUtils.IsLeapYear Function

Indicates whether a specified year is a leap year.

Pascal

```
function IsLeapYear(Year: Word): Boolean;
```

C++

```
Boolean IsLeapYear(Word Year);
```

File

SysUtils

Description

Call IsLeapYear to determine whether the year specified by the Year parameter is a leap year. Year specifies the calendar year.

Use YearOf to obtain the value of Year for IsLeapYear from a TDateTime (see page 3323) value.

C++ Examples:

```
/*
This example requires a button and a text edit. When the
user presses the button a message indicates if the year
specified in the text edit is a leap year.
*/
bool __fastcall IsThisLeapYear(int year)
{
  return IsLeapYear(year);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int year = StrToInt(Edit1->Text);
  if (IsThisLeapYear(year))
    ShowMessage(Edit1->Text + " is a leap year.");
  else
    ShowMessage(Edit1->Text + " is not a leap year.");
}
```

Delphi Examples:

```
{
This example requires a button and a text edit. When the
user presses the button a message indicates if the year
specified in the text edit is a leap year.
}
function IsThisLeapYear(year : Word): Boolean;
begin
  Result := SysUtils.IsLeapYear(year);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  year : integer;
begin
  year := StrToInt(Edit1.Text);
  if (IsThisLeapYear(year)) then
    ShowMessage(Edit1.Text + ' is a leap year.')
  else
    ShowMessage(Edit1.Text + ' is not a leap year.');
end;
```

See Also

Date (see page 4087)

YearOf

IsInLeapYear

37.3.159 SysUtils.IsPathDelimiter Function

Indicates whether the byte at a specified position in a string is the path delimiter.

Pascal

```
function IsPathDelimiter(const S: string; Index: Integer): Boolean; overload;
```

C++

```
Boolean IsPathDelimiter(const UnicodeString S, int Index);
```

File

SysUtils

Description

Call IsPathDelimiter to determine whether a position in the string S contains the path delimiter character ('/' on Linux, '\' on Windows). Positions are numbered from 1.

When working with a multi-byte character system (MBCS), IsPathDelimiter distinguishes between a true delimiter character, and the byte of the same value that can appear as the second byte of a double byte character.

To test for more characters than just the delimiter, use IsDelimiter (see page 4218).

See Also

IsDelimiter (see page 4218)

LastDelimiter (see page 4223)

37.3.160 SysUtils.IsValidIdent Function

Determines whether a string conforms to Delphi identifier rules.

Pascal

```
function IsValidIdent(const Ident: string; AllowDots: Boolean = False): Boolean;
```

C++

```
Boolean IsValidIdent(const UnicodeString Ident, Boolean AllowDots = False);
```

File

SysUtils

Description

Call IsValidIdent to determine whether the passed Ident is valid for use as an identifier, such as the name of a component.

An identifier is a sequence of letters, digits or underscores. Only the first 63 characters are used uniquely. Letters are limited to A-Z and a-z, although the case is ignored. The first character cannot be a digit.

37.3.161 SysUtils.Languages Function

Lists the locales for which support is available.

Pascal

```
function Languages: TLanguages;
```

C++

```
TLanguages Languages();
```

File

SysUtils

Description

Use the value returned by Languages to obtain information about the locales that the system supports. This function is only available on Windows.

See Also

TSysLocale (see page 4333)

37.3.162 SysUtils.LastDelimiter Function

Returns the byte index of the last character that matches any character in a specified set of delimiters.

Pascal

```
function LastDelimiter(const Delimiters: string; const S: string): Integer; overload;
```

C++

```
int LastDelimiter(const UnicodeString Delimiters, const UnicodeString S);
```

File

SysUtils

Description

Call LastDelimiter to locate the last delimiter in a specified string.

Delimiters is a string where each character is a valid delimiter.

S is the string to search for delimiters.

For example, the line

MyIndex := LastDelimiter('\.:','c:\filename.ext'); // Delphi

MyIndex = LastDelimiter("\\.:","c:\\filename.ext"); // C++

sets MyIndex to 12.

When working with multi-byte character sets (MBCS), S may contain double byte characters, but the delimiters listed in the Delimiters parameter must all be single byte non-null characters.

See Also

IsDelimiter (see page 4218)

AnsiStrRScan (see page 4060)

37.3.163 SysUtils.LoadPackage Function

Loads a specified package.

Pascal

```
function LoadPackage(const Name: string): HMODULE; overload;
function LoadPackage(const Name: string; AValidatePackage: TValidatePackageProc): HMODULE;
overload;
```

C++

```
HMODULE LoadPackage(const UnicodeString Name);
HMODULE LoadPackage(const UnicodeString Name, TValidatePackageProc AValidatePackage);
```

File

SysUtils

Description

LoadPackage loads the package specified by the Name parameter, checks for duplicate units, and calls the initialization blocks of all units contained in the package.

See Also

UnloadPackage (see page 4310)

37.3.164 SysUtils.LoadStr Function

Loads a string resource from the application's executable file.

Pascal

```
function LoadStr(Ident: Integer): string;
```

C++

```
UnicodeString LoadStr(int Ident);
```

File

SysUtils

Description

LoadStr loads the string resource given by Ident from the application's executable file or shared library. If the string resource does not exist, LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

Note: :LoadStr is provided primarily for backward compatibility. To isolate string resources in Delphi, use the resourcestring keyword in new applications.

37.3.165 SysUtils.LowerCase Function

Converts an ASCII string to lowercase.

Pascal

```
function LowerCase(const S: string): string; overload;
function LowerCase(const S: string; LocaleOptions: TLocaleOptions): string; overload;
```

C++

```
UnicodeString LowerCase(const UnicodeString S);
UnicodeString LowerCase(const UnicodeString S, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

LowerCase returns a string with the same text as the string passed in S, but with all letters converted to lowercase. The conversion affects only 7-bit ASCII characters between 'A' and 'Z'. To convert 8-bit international characters, use AnsiLowerCase (see page 4053).

C++ Examples:

```
/*
This example uses an edit control, a label, and a button on a
form. When the user clicks the button, the label shows the text of
the edit control in lower case.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = LowerCase(Edit1->Text);
}
/*
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    "System ParamStr = " + AnsiString(System::ParamStr(i)),
//    mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  for (int i=1;i<=ParamCount();i++)
  {
    if (LowerCase(ParamStr(i)) == "beep")
      Beep();
    else if (LowerCase(ParamStr(i)) == "exit")
      Application->Terminate();
  }
}
```

Delphi Examples:

```
{
This example uses an edit control, a label, and a button on a
form. When the user clicks the button, the label shows the text of
the edit control in lower case.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.LowerCase(Edit1.Text);
end;
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    'System ParamCount = ' + IntToStr(System.ParamCount),
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

See Also

AnsiLowerCase (see page 4053)

UpperCase (see page 4311)

37.3.166 SysUtils.MSecsToTimeStamp Function

Converts a specified number of milliseconds into a TTimeStamp (see page 4334) value.

Pascal

```
function MSecsToTimeStamp(MSecs: Comp): TTimeStamp;
```

C++

```
TTimeStamp MSecsToTimeStamp(Comp MSecs);
```

File

SysUtils

Description

Call MSecsToTimeStamp to convert MSecs, a number of milliseconds, into the number of days represented, plus the number of milliseconds remaining. The days and milliseconds are expressed as a TTimeStamp (see page 4334) value, where the Date (see page 4087) field is the number of days and the Time (see page 4297) field is the remainder in milliseconds.

See Also

TimeStampToMSecs (see page 4299)

TTimeStamp (see page 4334)

37.3.167 SysUtils.NewStr Function

Allocates a string on the heap.

Pascal

```
function NewStr(const S: AnsiString): PAnsiString; deprecated;
```

C++

```
PAnsiString NewStr(const AnsiString S);
```

File

SysUtils

Description

NewStr allocates a new string on the heap. Do not use NewStr in new applications. This function is provided for backward compatibility only.

Use normal Delphi operators instead. The string allocation will be performed automatically.

37.3.168 SysUtils.NextCharIndex Function

Returns the byte index of the next character.

Pascal

```
function NextCharIndex(const S: UnicodeString; Index: Integer): Integer; overload;
function NextCharIndex(const S: AnsiString; Index: Integer): Integer; overload;
```

C++

```
int NextCharIndex(const UnicodeString S, int Index);
int NextCharIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

NextCharIndex returns the byte index of the first byte of the character following the character starting at S[Index].

37.3.169 SysUtils.Now Function

Returns the current date and time.

Pascal

```
function Now: TDateTime;
```

C++

```
TDateTime Now();
```

File

SysUtils

Description

Returns the current date and time, corresponding to the sum of the value returned by the global Date (see page 4087) and Time (see page 4297) functions.

Note: Although TDateTime (see page 3323) values can represent milliseconds, Now is accurate only to the nearest second.

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateTimeToStr(Now());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.DateTimeToStr(Now);
end;
```

See Also

Date (see page 4087)

DateTimeToStr (see page 4089)

Time (see page 4297)

37.3.170 SysUtils.OutOfMemoryError Function

Raises an EOutOfMemory (see page 3942) exception.

Pascal

```
procedure OutOfMemoryError;
```

C++

```
OutOfMemoryError();
```

File

SysUtils

Description

Call OutOfMemoryError to raise the EOutOfMemory (see page 3942) exception. OutOfMemoryError runs without allocating additional memory.

See Also

EOutOfMemory (see page 3942)

37.3.171 SysUtils.PlatformBytesOf Function

Pascal

```
function PlatformBytesOf(const Value: string): TBytes;
```

C++

```
TBytes PlatformBytesOf(const UnicodeString Value);
```

File

SysUtils

Description

This is function SysUtils.PlatformBytesOf.

37.3.172 SysUtils.PlatformStringOf Function

Pascal

```
function PlatformStringOf(const Value: TBytes): UnicodeString;
```

C++

```
UnicodeString PlatformStringOf(const TBytes Value);
```

File

SysUtils

Description

This is function SysUtils.PlatformStringOf.

37.3.173 SysUtils.QuotedStr Function

Returns the quoted version of a string.

Pascal

```
function QuotedStr(const S: string): string; overload;
```

C++

```
UnicodeString QuotedStr(const UnicodeString S);
```

File

SysUtils

Description

Use QuotedStr to convert the string S to a quoted string. A single quote character (') is inserted at the beginning and end of S, and each single quote character in the string is repeated. To remove the quotes from a quoted string, use AnsiDequotedStr (see page 4051) routine.

Note: When working with multi-byte character systems (MBCS), use AnsiQuotedStr (see page 4054) instead.

See Also

QuotedStr

AnsiQuotedStr (see page 4054)

AnsiExtractQuotedStr (see page 4052)

37.3.174 SysUtils.RaiseLastOSError Function

Raises an exception for the last occurring OS or system library error.

Pascal

```
procedure RaiseLastOSError; overload;
procedure RaiseLastOSError(LastError: Integer); overload;
```

C++

```
RaiseLastOSError();
RaiseLastOSError(int LastError);
```

File

SysUtils

Description

Call RaiseLastOSError to raise an EOSError (see page 3939) exception for the last OS API call that failed. RaiseLastOSError retrieves the code for the last occurring API call error, if any. If this belongs to a previously occurring error, RaiseLastOSError raises an EOSError (see page 3939) exception with the error code and message associated with that error.

C++ Examples:

```
//
//This code demonstrates the use of system error codes
//and how to use transform them into C++ exceptions.
//
void __fastcall TForm2::btRaiseLastClick(TObject *Sender)
{
    /* Set the last OS error to a bogus value */
    System::SetLastError(ERROR_ACCESS_DENIED);

    try
    {
        RaiseLastOSError();
    }
    catch(EOSError* ex)
    {
        MessageDlg(String("Caught an OS error with code: ") +
            IntToStr((int)ex->ErrorCode), mtError,
            TMsgDlgButtons() << mbOK, 0);
```

```
    }

    /* Let the Delphi's Exception dialog pop-up */
    RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

    /* Finally set the last error to none */
    System::SetLastError(ERROR_SUCCESS);

    if (GetLastError() != ERROR_SUCCESS)
        MessageDlg(String("Whoops, something went wrong ") +
          " in the mean time!", mtError, TMsgDlgButtons() << mbOK, 0);

    /* No exception should be thrown here */
    RaiseLastOSError();
}
```

Delphi Examples:

```
{
This code demonstrates the use of system error codes
and how to transform them into Delphi exceptions.
}
procedure TForm2.btRaiseLastClick(Sender: TObject);
begin
  { Set the last OS error to a bogus value }
  System.SetLastError(ERROR_ACCESS_DENIED);

  try
    RaiseLastOSError();
  except
    on Ex : EOSError do
       MessageDlg('Caught an OS error with code: ' +
          IntToStr(Ex.ErrorCode), mtError, [mbOK], 0);
  end;

  { Let the Delphi's Exception dialog pop-up }
  RaiseLastOSError(ERROR_NOT_ENOUGH_MEMORY);

  { Finally set the last error to none }
  System.SetLastError(ERROR_SUCCESS);

  if GetLastError() <> ERROR_SUCCESS then
     MessageDlg('Whoops, something went wrong in the ' +
                'mean time!', mtError, [mbOK], 0);

  { No exception should be thrown here }
  RaiseLastOSError();
end;
```

See Also

EOSError (see page 3939)

37.3.175 SysUtils.RaiseLastWin32Error Function

Raises an exception for the last occurring Win32 error.

Pascal

```
procedure RaiseLastWin32Error; deprecated;
```

C++

```
RaiseLastWin32Error();
```

File

SysUtils

Description

Call RaiseLastWin32Error to raise an EWin32Error (see page 3949) exception for the last Windows API call that failed. RaiseLastWin32Error retrieves the code for the last occurring Win32 error, if any. If Windows returns a previously occurring error code, RaiseLastWin32Error raises an EWin32Error (see page 3949) exception with the error code and message associated with that error.

Note: RaiseLastWin32Error is a deprecated Windows-only procedure. New (see page 3619) applications should use RaiseLastOSError (see page 4230) instead.

See Also

EWin32Error (see page 3949)

Win32Check (see page 4318)

RaiseLastOSError (see page 4230)

37.3.176 SysUtils.RCS Function

Check for Delphi Client/Server Licence.

Pascal

```
procedure RCS;
```

C++

```
RCS();
```

File

SysUtils

Description

RCS is used by VCL components to check whether there is a Client/Server licence, raising an exception of not.

See Also

GDAL (see page 4202)

RPR (see page 4237)

37.3.177 SysUtils.RemoveDir Function

Deletes an existing empty directory.

Pascal

```
function RemoveDir(const Dir: string): Boolean;
```

C++

```
Boolean RemoveDir(const UnicodeString Dir);
```

File

SysUtils

Description

Call RemoveDir to remove the directory specified by the Dir parameter. The return value is true if a new directory was successfully deleted, false if an error occurred. The directory must be empty before it can be successfully deleted.

See Also

ExtractFileDir (see page 4112)

GetCurrentDir (see page 4202)

SetCurrentDir (see page 4240)

37.3.178 SysUtils.RenameFile Function

Changes a file name.

Pascal

```
function RenameFile(const OldName: string; const NewName: string): Boolean;
```

C++

```
Boolean RenameFile(const UnicodeString OldName, const UnicodeString NewName);
```

File

SysUtils

Description

RenameFile attempts to change the name of the file specified by OldFile to NewFile. If the operation succeeds, RenameFile returns true. If RenameFile cannot rename the file (for example, if the application does not have permission to modify the file), it returns false.

Note: If NewFile represents the name of an existing file, RenameFile behaves differently under Windows and Linux. Under Windows, the rename operation fails. Under Linux, RenameFile silently removes the other file.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function. Verify
the file written after executing.
*/

#include <dir.h>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  char szFileName[MAXFILE+4];
  int iFileHandle;
  int iLength;
  if (SaveDialog1->Execute())
  {
    if (FileExists(SaveDialog1->FileName))
    {
      fnsplit(AnsiString(SaveDialog1->FileName).c_str(), 0, 0, szFileName, 0);
      strcat(szFileName, ".BAK");
      RenameFile(SaveDialog1->FileName, szFileName);
    }
    iFileHandle = FileCreate(SaveDialog1->FileName);
    // Write out the number of rows and columns in the grid.
    FileWrite(iFileHandle, reinterpret_cast<char *>(&(StringGrid1->ColCount)),
sizeof(StringGrid1->ColCount));
    FileWrite(iFileHandle, reinterpret_cast<char *>(&(StringGrid1->RowCount)),
sizeof(StringGrid1->RowCount));
    for (int x=0;x<StringGrid1->ColCount;x++)
    {
      for (int y=0;y<StringGrid1->RowCount;y++)
      {
        // Write out the length of each string, followed by the string itself.
        iLength = StringGrid1->Cells[x][y].Length();
        FileWrite(iFileHandle, reinterpret_cast<char *>(&iLength), sizeof(iLength));
        FileWrite(iFileHandle, StringGrid1->Cells[x][y].t_str(),
StringGrid1->Cells[x][y].Length());
      }
    }
    FileClose(iFileHandle);
  }
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "Column 1";
  StringGrid1->Cells[2][0] = "Column 2";
  StringGrid1->Cells[3][0] = "Column 3";
  StringGrid1->Cells[4][0] = "Column 4";
  StringGrid1->Cells[0][1] = "Row 1";
  StringGrid1->Cells[1][1] = "Object";
  StringGrid1->Cells[2][1] = "Pascal";
  StringGrid1->Cells[3][1] = "is";
  StringGrid1->Cells[4][1] = "excellent";
  StringGrid1->Cells[0][2] = "Row 2";
  StringGrid1->Cells[1][2] = "Delphi";
  StringGrid1->Cells[2][2] = "is";
  StringGrid1->Cells[4][2] = "RAD";
};
```

Delphi Examples:

```
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
```

```
    cellString: string;
  begin
    if SaveDialog1.Execute then
    begin
      if FileExists(SaveDialog1.FileName) then
      begin
        BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
        BackupName := ChangeFileExt(BackupName, '.BAK');
        if not RenameFile(SaveDialog1.FileName, BackupName) then
          raise Exception.Create('Unable to create backup file.');
      end;
      FileHandle := FileCreate(SaveDialog1.FileName);
      { Write out the number of rows and columns in the grid. }
      colCountLength := SizeOf(StringGrid1.ColCount);
      FileWrite(FileHandle,
        Pchar(StringGrid1.ColCount), colCountLength);
      rowCountLength := SizeOf(StringGrid1.RowCount);
      FileWrite(FileHandle,
        PChar(StringGrid1.RowCount), rowCountLength);
      for X := 0 to StringGrid1.ColCount - 1 do
      begin
        for Y := 0 to StringGrid1.RowCount - 1 do
        begin
          try
            { Write out the length of each string, followed by the string itself. }
            StringLen := Length(StringGrid1.Cells[X,Y]);
            FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
            GetMem(Buffer, StringLen); { allocate the buffer }
            cellString := StringGrid1.Cells[X,Y];
            for I := 1 to StringLen do
               Buffer[I - 1] := cellString[I];
            FileWrite(FileHandle, Buffer^, StringLen);
          finally
            FreeMem(Buffer, StringLen);
          end;
        end;
      end;
      FileClose(FileHandle);
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    with StringGrid1 do
    begin
      Cells[1,0] := 'Column 1';
      Cells[2,0] := 'Column 2';
      Cells[3,0] := 'Column 3';
      Cells[4,0] := 'Column 4';
      Cells[0,1] := 'Row 1';
      Cells[1,1] := 'Object';
      Cells[2,1] := 'Pascal';
      Cells[3,1] := 'is';
      Cells[4,1] := 'excellent';
      Cells[0,2] := 'Row 2';
      Cells[1,2] := 'Delphi';
      Cells[2,2] := 'is';
      Cells[4,2] := 'RAD';
    end;
  end;
```

DeleteFile (see page 4098)

Rename (see page 3642)

37.3.179 SysUtils.ReplaceDate Function

Replaces the date portion of a TDateTime (see page 3323) value with a specified date.

Pascal

```
procedure ReplaceDate(var DateTime: TDateTime; const NewDate: TDateTime);
```

C++

```
ReplaceDate(TDateTime DateTime, const TDateTime NewDate);
```

File

SysUtils

Description

ReplaceDate changes the value of the DateTime parameter so that it has the same date as the NewDate parameter. The time portion of DateTime remains the same. ReplaceDate makes any necessary adjustments for negative dates (before 1900).

37.3.180 SysUtils.ReplaceTime Function

Replaces the time portion of a TDateTime (see page 3323) value with a specified time.

Pascal

```
procedure ReplaceTime(var DateTime: TDateTime; const NewTime: TDateTime);
```

C++

```
ReplaceTime(TDateTime DateTime, const TDateTime NewTime);
```

File

SysUtils

Description

ReplaceTime changes the value of the DateTime parameter so that it has the same time as the NewTime parameter. The date portion of DateTime remains the same. ReplaceTime makes any necessary adjustments for negative dates. (before 1900)

37.3.181 SysUtils.RPR Function

Check for Delphi Professional Licence.

Pascal

```
procedure RPR;
```

C++

```
RPR();
```

File

SysUtils

Description

RPR is used by VCL components to check whether there is a Professional licence, raising an exception of not.

See Also

GDAL (see page 4202)

RCS (see page 4232)

37.3.182 SysUtils.SafeLoadLibrary Function

Safe and simple library loading.

Pascal

```
function SafeLoadLibrary(const FileName: string; ErrorMode: UINT = SEM_NOOPENFILEERRORBOX):
HMODULE;
```

C++

```
HMODULE SafeLoadLibrary(const UnicodeString FileName, UINT ErrorMode = SEM_NOOPENFILEERRORBOX);
```

File

SysUtils

Description

SafeLoadLibrary loads a Windows DLL or Linux shared object file, as specified by Filename. SafeLoadLibrary preserves the current FPU control word, preventing library initialization code from permanently overwriting precision and exception masks.

Note: On Windows, SafeLoadLibrary temporarily sets the system error mode to ErrorMode. The default, SEM_NOOPENFILEERRORBOX, suppresses error dialogs. The previous error mode is restored before SafeLoadLibrary exits. For a list of error modes, refer to SetErrorMode in the Microsoft documentation.

Note: On Linux, the Dummy argument is ignored.

See Also

LoadPackage (see page 4224)

37.3.183 SysUtils.SameFileName Function

Compares file names based on the current locale.

Pascal

```
function SameFileName(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean SameFileName(const UnicodeString S1, const UnicodeString S2);
```

File

SysUtils

Description

SameFileName compares two file names in the same way as AnsiCompareFileName (see page 4049). SameFileName returns true if the file names match, false otherwise. Like AnsiCompareFileName (see page 4049), SameFileName supports locales and MBCS strings; see the AnsiCompareFileName (see page 4049) topic for more details.

See Also

AnsiCompareText (see page 4051)

37.3.184 SysUtils.SameStr Function

Compares two strings by ordinal value with case sensitivity.

Pascal

```
function SameStr(const S1: string; const S2: string): Boolean; overload;
function SameStr(const S1: string; const S2: string; LocaleOptions: TLocaleOptions): Boolean;
overload;
```

C++

```
Boolean SameStr(const UnicodeString S1, const UnicodeString S2);
Boolean SameStr(const UnicodeString S1, const UnicodeString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

SameStr compares S1 and S2 and returns true if they are identical. SameStr is case sensitive and is not affected by the current locale.

See Also

SameText (see page 4239)

CompareStr (see page 4078)

CompareText (see page 4079)

AnsiCompareStr (see page 4050)

AnsiCompareText (see page 4051)

CompareMem (see page 4078)

37.3.185 SysUtils.SameText Function

Compares two strings by ordinal value without case sensitivity.

Pascal

```
function SameText(const S1: string; const S2: string): Boolean; overload;
function SameText(const S1: string; const S2: string; LocaleOptions: TLocaleOptions): Boolean;
overload;
```

C++

```
Boolean SameText(const UnicodeString S1, const UnicodeString S2);
Boolean SameText(const UnicodeString S1, const UnicodeString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

SameText compares S1 and S2 and returns true if they are equal. SameText is not case sensitive and is not affected by the current locale.

See Also

CompareStr (see page 4078)

AnsiCompareText (see page 4051)

CompareMem (see page 4078)

CompareText (see page 4079)

37.3.186 SysUtils.SetCurrentDir Function

Sets the current directory.

Pascal

```
function SetCurrentDir(const Dir: string): Boolean;
```

C++

```
Boolean SetCurrentDir(const UnicodeString Dir);
```

File

SysUtils

Description

The SetCurrentDir function sets the current directory. The return value is true if the current directory was successfully changed, or false if an error occurred.

See Also

ChDir (see page 3534)

CreateDir (see page 4083)

ExtractFileDir (see page 4112)

GetCurrentDir (see page 4202)

RemoveDir (see page 4232)

37.3.187 SysUtils.ShowException Function

Displays an exception message with its physical address

Pascal

```
procedure ShowException(ExceptObject: TObject; ExceptAddr: Pointer);
```

C++

```
ShowException(TObject * ExceptObject, void * ExceptAddr);
```

File

SysUtils

Description

ShowException displays the message associated with an exception, together with the exception's physical address. The

exception's address can be used with Search | Find Error (see page 3560) menu command to find the statement that raised the exception.

See Also

ExceptionErrorMessage (see page 4107)

ExceptObject (see page 3562)

ExceptAddr (see page 3562)

37.3.188 SysUtils.Sleep Function

Delay program execution for a specified number of milliseconds.

Pascal

```
procedure Sleep(milliseconds: Cardinal); stdcall;
```

C++

```
__stdcall Sleep(unsigned milliseconds);
```

File

SysUtils

Description

Sleep pauses program executions as specified by the milliseconds parameter. Under Windows, Sleep is just a link to the Sleep function in the system API.

37.3.189 SysUtils.StrAlloc Function

Allocates a buffer for a null-terminated string and returns a pointer to its first character.

Pascal

```
function StrAlloc(Size: Cardinal): PChar;
```

C++

```
const char * StrAlloc(unsigned Size);
```

File

SysUtils

Description

StrAlloc allocates a buffer for a null-terminated string with a maximum length of Size - 1 (1 byte must be reserved for the termination character). The result points to the location where the first character of the string is to be stored. A 32-bit number giving the total amount of memory allocated is stored in the four bytes preceding the first character; it is equal to Size + 4. If space for a string is allocated with StrAlloc, it should be deallocated via StrDispose (see page 4247).

Because AnsiStrings (long strings) are implicitly null terminated and dynamically allocated, the use of StrAlloc is deprecated.

See Also

StrDispose (see page 4247)

StrNew (see page 4266)

StrBufSize (see page 4242)

37.3.190 SysUtils.StrBufSize Function

Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 4241).

Pascal

```
function StrBufSize(const Str: PAnsiChar): Cardinal; overload;
function StrBufSize(const Str: PWideChar): Cardinal; overload;
```

C++

```
unsigned StrBufSize(const PAnsiChar Str);
unsigned StrBufSize(const PWideChar Str);
```

File

SysUtils

Description

StrBufSize returns the number of bytes in Str (see page 3676), including the byte for the termination character.

Note: If Str (see page 3676) does not point to a string buffer allocated by StrAlloc (see page 4241) or StrNew (see page 4266), no error message is returned, and the result is unpredictable.

See Also

StrAlloc (see page 4241)

StrNew (see page 4266)

37.3.191 SysUtils.StrByteType Function

Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.

Pascal

```
function StrByteType(Str: PAnsiChar; Index: Cardinal): TMbcsByteType; overload;
function StrByteType(Str: PWideChar; Index: Cardinal): TMbcsByteType; overload;
```

C++

```
TMbcsByteType StrByteType(PAnsiChar Str, unsigned Index);
TMbcsByteType StrByteType(PWideChar Str, unsigned Index);
```

File

SysUtils

Description

Call StrByteType to determine the type of the byte specified by the Index parameter, where 0 specifies the first byte in the string Str (see page 3676), 1 specifies the second byte, and so on.

If the system is not using a multi-byte character system (MBCS), StrByteType always returns mbSingleByte. Otherwise, StrByteType returns mbSingleByte if the indicated byte represents a complete character in Str (see page 3676), mbLeadByte if

it represents the first byte of a double byte character, and mbTrailByte if it represents the second byte of a double byte character.

Note: No checking is done to ensure that Index is less than the length of Str (see page 3676). It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

ByteType (see page 4070)

LeadBytes (see page 4354)

37.3.192 SysUtils.StrCat Function

Appends a copy of Source to the end of Dest and returns the concatenated string.

Pascal

```
function StrCat(Dest: PAnsiChar; const Source: PAnsiChar): PAnsiChar; overload;
function StrCat(Dest: PWideChar; const Source: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrCat(PAnsiChar Dest, const PAnsiChar Source);
PWideChar StrCat(PWideChar Dest, const PWideChar Source);
```

File

SysUtils

Description

Use StrCat to concatenate Source to the end of Dest. StrCat does not perform any length checking. The destination buffer must have room for at least StrLen (see page 4260)(Dest)+StrLen (see page 4260)(Source)+1 characters.

To check length, use the StrLCat (see page 4255) function.

C++ Examples:

```
/*
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szBuffer(new char[Label1->Caption.Length() + Edit1->Text.Length() + 1]);
  // The following 2 lines are used in VCL applications
  StrCopy(szBuffer.get(), AnsiString(Label1->Caption).c_str());
  StrCat(szBuffer.get(), AnsiString(Edit1->Text).c_str());
  Label1->Caption = szBuffer.get();
  Edit1->Clear();
}
```

Delphi Examples:

```
{
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
begin
  GetMem(Buffer,Length(Label1.Caption) + Length(Edit1.Text) + 1);
  StrCopy(Buffer, PChar(Label1.Caption));
  SysUtils.StrCat(Buffer, PChar(Edit1.Text));
  Label1.Caption := Buffer;
  Edit1.Clear;
  FreeMem(Buffer);
end;
```

See Also

StrLCat (see page 4255)

StrLen (see page 4260)

37.3.193 SysUtils.StrCharLength Function

Returns the length, in bytes, of a character.

Pascal

```
function StrCharLength(const Str: PAnsiChar): Integer; overload;
function StrCharLength(const Str: PWideChar): Integer; overload;
```

C++

```
int StrCharLength(const PAnsiChar Str);
int StrCharLength(const PWideChar Str);
```

File

SysUtils

Description

StrCharLength returns the size, in bytes, of the first character in Str (see page 3676). This value can be 1 or 2 under Windows, 1 to 6 under Linux.

See Also

ByteType (see page 4070)

LeadBytes (see page 4354)

37.3.194 SysUtils.StrComp Function

Compares two strings with case sensitivity.

Pascal

```
function StrComp(const Str1: PAnsiChar; const Str2: PAnsiChar): Integer; overload;
function StrComp(const Str1: PWideChar; const Str2: PWideChar): Integer; overload;
```

C++

```
int StrComp(const PAnsiChar Str1, const PAnsiChar Str2);
int StrComp(const PWideChar Str1, const PWideChar Str2);
```

File

SysUtils

Description

Call StrComp to compare two null-terminated strings, with case sensitivity. The return value is indicated in the following table:

Return value	Condition
<0	Str1 sorts before Str2
=0	Str1is the same as Str2
>0	Str1 sorts after Str2

Note: When working with International characters, use AnsiStrComp (see page 4056) instead.

C++ Examples:

```
/*
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szResult(new char[Edit1->Text.Length() + Edit2->Text.Length() + 20]);
  int iResult = StrComp(Edit1->Text.t_str(), Edit2->Text.t_str());
  StrCopy(szResult.get(), Edit1->Text.t_str());
  if (iResult < 0)
    StrCat(szResult.get(), " is less than ");
  else if (iResult > 0)
    StrCat(szResult.get(), " is greater than ");
  else
    StrCat(szResult.get(), " is equal to ");

  StrCat(szResult.get(), AnsiString(Edit2->Text).c_str());
  ShowMessage(AnsiString(szResult.get()));
}
```

Delphi Examples:

```
{
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Msg: string;
  CompResult: Integer;
begin
  Msg := Edit1.Text;
  CompResult := SysUtils.StrComp(PChar(Edit1.Text), PChar(Edit2.Text));
  if CompResult < 0 then
    Msg := Msg + ' is less than '
  else if CompResult > 0 then
    Msg := Msg + ' is greater than '
  else
    Msg := Msg + ' is equal to ';
  Msg := Msg + Edit2.Text;
```

```
  ShowMessage(Msg);
end;
```

StrIComp (see page 4251)

StrLComp (see page 4257)

StrLIComp (see page 4262)

37.3.195 SysUtils.StrCopy Function

Copies a null-terminated string.

Pascal

```
function StrCopy(Dest: PAnsiChar; const Source: PAnsiChar): PAnsiChar; overload;
function StrCopy(Dest: PWideChar; const Source: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrCopy(PAnsiChar Dest, const PAnsiChar Source);
PWideChar StrCopy(PWideChar Dest, const PWideChar Source);
```

File

SysUtils

Description

Use StrCopy to copy Source to Dest. StrCopy returns Dest.

StrCpy does not perform any length checking. The destination buffer must have room for at least StrLen (see page 4260)(Source)+1 characters.

For length checking, use the StrLCopy (see page 4258) function.

C++ Examples:

```
/*
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szBuffer(new char[Label1->Caption.Length() + Edit1->Text.Length() + 1]);
  // The following 2 lines are used in VCL applications
  StrCopy(szBuffer.get(), AnsiString(Label1->Caption).c_str());
  StrCat(szBuffer.get(), AnsiString(Edit1->Text).c_str());
  Label1->Caption = szBuffer.get();
  Edit1->Clear();
}
```

Delphi Examples:

```
{
The following example uses an edit control, a label, and a button
```

```
  on a form. When the button is clicked, the label's caption and the
  edit control's text are combined in a buffer. Then the buffer is
  displayed in the label's caption.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    Buffer: PChar;
  begin
    GetMem(Buffer,Length(Label1.Caption) + Length(Edit1.Text) + 1);
    StrCopy(Buffer, PChar(Label1.Caption));
    SysUtils.StrCat(Buffer, PChar(Edit1.Text));
    Label1.Caption := Buffer;
    Edit1.Clear;
    FreeMem(Buffer);
  end;
```

See Also

StrECopy (see page 4248)

StrLCopy (see page 4258)

37.3.196 SysUtils.StrDispose Function

Disposes of a string.

Pascal

```
procedure StrDispose(Str: PAnsiChar); overload;
procedure StrDispose(Str: PWideChar); overload;
```

C++

```
StrDispose(PAnsiChar Str);
StrDispose(PWideChar Str);
```

File

SysUtils

Description

StrDispose is provided for backward compatibility. StrDispose disposes of a string on a heap that was previously allocated with StrAlloc (see page 4241) or StrNew (see page 4266).

If Str (see page 3676) is nil (Delphi) or NULL (C++), StrDispose does nothing.

C++ Examples:

```
/*
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Allocate memory.
  char* psz = StrNew(Edit1->Text.t_str());
  Application->MessageBox(
    Edit1->Text.c_str(),
    L"StrNew, StrDispose example",
    MB_OK);
  // Deallocate memory.
  StrDispose(psz);
```

```
}
```

Delphi Examples:

```
{
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Temp: PChar;
begin
  // Allocate memory.
  Temp := StrNew(PChar(Edit1.Text));
  Application.MessageBox(Temp, 'StrNew, StrDispose example', MB_OK);
  // Deallocate memory.
  SysUtils.StrDispose(Temp);
end;
```

See Also

StrAlloc (see page 4241)

StrNew (see page 4266)

37.3.197 SysUtils.StrECopy Function

Copies null-terminated string.

Pascal

```
function StrECopy(Dest: PAnsiChar; const Source: PAnsiChar): PAnsiChar; overload;
function StrECopy(Dest: PWideChar; const Source: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrECopy(PAnsiChar Dest, const PAnsiChar Source);
PWideChar StrECopy(PWideChar Dest, const PWideChar Source);
```

File

SysUtils

Description

StrECopy copies Source to Dest and returns StrEnd (see page 4249)(Dest).

StrECopy does not perform any length checking. The destination buffer must have room for at least StrLen (see page 4260)(Source)+1 characters.

Nested calls to StrECopy to concatenate a sequence of strings run more efficiently than multiple calls to StrCat (see page 4243).

C++ Examples:

```
/*
The following example uses an edit control, a label, and a
button on a form. When the button is clicked, the edit
control's text is appended to a static buffer. Then the
buffer is displayed in the label's caption.
*/
const static int MAX_LENGTH = 15;
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  static char szBuffer[MAX_LENGTH];
  static char* pszBuffer = szBuffer;

  if (StrLen(pszBuffer) + StrLen(Edit1->Text.c_str()) < MAX_LENGTH)
    pszBuffer = StrECopy(pszBuffer, Edit1->Text.t_str());
  else
    ShowMessage("Can't fit new string in allocated memory space.");
  Label1->Caption = szBuffer;
}
```

Delphi Examples:

```
{
This example uses a button on a form.  Since StrECopy returns
the destination char array, nested calls are possible and
actually more efficient than repeated calls.  StrECopy does
no bounds checking. When the button is clicked, the inline
text is appended to a static buffer. Then the buffer is
displayed in the form's canvas.
}

procedure TForm1.Button1Click(Sender: TObject);
const
  Turbo: PChar = 'Object';
  Pascal: PChar = 'Pascal';
 var
  S: array[0..15] of Char;
begin
  SysUtils.StrECopy(SysUtils.StrECopy(SysUtils.StrECopy(S, Turbo), ' '), Pascal);
  Canvas.TextOut(10, 10, string(S));
end;
```

See Also

StrCat (see page 4243)

StrCopy (see page 4246)

StrEnd (see page 4249)

StrLen (see page 4260)

37.3.198 SysUtils.StrEnd Function

Returns a pointer to the end of a null terminated string.

Pascal

```
function StrEnd(const Str: PAnsiChar): PAnsiChar; overload;
function StrEnd(const Str: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrEnd(const PAnsiChar Str);
PWideChar StrEnd(const PWideChar Str);
```

File

SysUtils

Description

StrEnd returns a pointer to the null character at the end of Str (see page 3676).

C++ Examples:

```
/*
The following example uses an edit control, a label, and a
button on a form. When the button is clicked, the edit
control's text is copied into a buffer. Then the buffer is
displayed backwards in the label.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> pszEditText(new char[Edit1->Text.Length()+1]);
  char *psz;
  StrCopy(pszEditText.get(), Edit1->Text.t_str());
  psz = StrEnd(pszEditText.get());
  Label1->Caption = "";
  while (psz >= &pszEditText.get()[0])
  {
    psz--;
    Label1->Caption = Label1->Caption + *psz;
  }
}
```

Delphi Examples:

```
{
The following example uses an edit control, a label, and a
button on a form. When the button is clicked, the edit
control's text is copied into a buffer. Then the buffer is
displayed backwards in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TextBuffer: PChar;
  Ptr: PChar;
begin
  GetMem(TextBuffer, Length(Edit1.Text)+1);
  StrCopy(TextBuffer, PChar(Edit1.Text));
  Ptr := StrEnd(TextBuffer);
  Label1.Caption := '';
  while Ptr > TextBuffer do
  begin
    Dec(Ptr);
    Label1.Caption := Label1.Caption + Ptr^;
  end;
  FreeMem(TextBuffer);
end;
```

See Also

AnsiStrLastChar (see page 4057)

StrLen (see page 4260)

37.3.199 SysUtils.StrFmt Function

Formats entries in an array.

Pascal

```
function StrFmt(Buffer: PAnsiChar; Format: PAnsiChar; const Args: array of const): PAnsiChar;
overload;
```

```
function StrFmt(Buffer: PAnsiChar; Format: PAnsiChar; const Args: array of const; const
FormatSettings: TFormatSettings): PAnsiChar; overload;
function StrFmt(Buffer: PWideChar; Format: PWideChar; const Args: array of const): PWideChar;
overload;
function StrFmt(Buffer: PWideChar; Format: PWideChar; const Args: array of const; const
FormatSettings: TFormatSettings): PWideChar; overload;
```

C++

```
PAnsiChar StrFmt(PAnsiChar Buffer, PAnsiChar Format, const array of const Args);
PAnsiChar StrFmt(PAnsiChar Buffer, PAnsiChar Format, const array of const Args, const
TFormatSettings FormatSettings);
PWideChar StrFmt(PWideChar Buffer, PWideChar Format, const array of const Args);
PWideChar StrFmt(PWideChar Buffer, PWideChar Format, const array of const Args, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

StrFmt formats the series of arguments from an open array into a buffer.

Buffer is a buffer that receives the results.

Format (see page 4188) is a null-terminated format string that indicates how to generate the results. For more information about how the result is formatted, see Format (see page 4188) Strings.

Args is an array of arguments that replace the format specifiers in Format (see page 4188).

Note: Args_Size gives the index of the last argument (one less than the number of elements in Args).

StrFmt returns a pointer to the destination buffer.

The first form of StrFmt is not thread-safe, because it uses localization information contained in global variables. The second form of StrFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

See Also

Format (see page 4188)

GetLocaleFormatSettings (see page 4206)

37.3.200 SysUtils.StrIComp Function

Compares two strings without case sensitivity.

Pascal

```
function StrIComp(const Str1: PAnsiChar; const Str2: PAnsiChar): Integer; overload;
function StrIComp(const Str1: PWideChar; const Str2: PWideChar): Integer; overload;
```

C++

```
int StrIComp(const PAnsiChar Str1, const PAnsiChar Str2);
int StrIComp(const PWideChar Str1, const PWideChar Str2);
```

File

SysUtils

Description

Call StrIComp to compare two strings without case sensitivity. StrIComp returns a value greater than 0 if Str1 > Str2, less than 0 if Str1 < Str2, and returns 0 if the strings are equal except for differences in case.

When working with international characters, use AnsiStrIComp (see page 4057) instead.

C++ Examples:

```
/*
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared case-insensitively.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szResult(new char[Edit1->Text.Length() + Edit2->Text.Length() + 20]);
  int iResult = StrIComp(Edit1->Text.c_str(), Edit2->Text.c_str());

  StrCopy(szResult.get(), Edit1->Text.t_str());
  if (iResult < 0)
    StrCat(szResult.get(), " is less than ");
  else if (iResult > 0)
    StrCat(szResult.get(), " is greater than ");
  else
    StrCat(szResult.get(), " is equal to ");
  StrCat(szResult.get(), Edit2->Text.t_str());
  ShowMessage(AnsiString(szResult.get()));
}
```

Delphi Examples:

```
{
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared case-insensitively.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Msg: string;
  CompResult: Integer;
begin
  Msg := Edit1.Text;
  CompResult := StrIComp(PChar(Edit1.Text), PChar(Edit2.Text));
  if CompResult < 0 then
    Msg := Msg + ' is less than '
  else if CompResult > 0 then
    Msg := Msg + ' is greater than '
  else
    Msg := Msg + ' is equal to ';
  Msg := Msg + Edit2.Text;
  ShowMessage(Msg);
end;
```

37.3.201 SysUtils.StringOf Function

Pascal

```
function StringOf(const Bytes: TBytes): UnicodeString;
```

C++

```
UnicodeString StringOf(const TBytes Bytes);
```

File

SysUtils

Description

This is function SysUtils.StringOf.

37.3.202 SysUtils.StringReplace Function

Replaces occurrences of a substring within a string.

Pascal

```
function StringReplace(const S: string; const OldPattern: string; const NewPattern: string;
Flags: TReplaceFlags): string; overload;
```

C++

```
UnicodeString StringReplace(const UnicodeString S, const UnicodeString OldPattern, const
UnicodeString NewPattern, TReplaceFlags Flags);
```

File

SysUtils

Description

StringReplace replaces occurrences of the substring specified by `OldPattern` with the substring specified by `NewPattern` in the string S.

`Flags` is a TReplaceFlags (see page 4343) type parameter. If `rfIgnoreCase` is set, the replacement is case-sensitive; otherwise case is ignored. If `rfReplaceAll` is on, all occurrences of `OldPattern` are replaced; if not, only the first occurrence is replaced.

Note: The parameters `S`, `OldPattern`, `NewPattern`, and the return value are of type `UnicodeString` (see page 3381). To do the replacement in an `AnsiString` context, use the StringReplace function. Also, to do the replacement in a `WideString` (see page 3467) context, use the WideStringReplace function.

Note: Recursive replacement of substrings is not supported. This means that if the substitution of `OldPattern` results in a new match for `NewPattern`, that match is not replaced.

To replace all occurrences of the substring within the string, you may also use the ReplaceStr function to do a case-sensitive search, or ReplaceText to do a case-insensitive search.

37.3.203 SysUtils.StringToGUID Function

Converts a string to a GUID.

Pascal

```
function StringToGUID(const S: string): TGUID;
```

C++

```
TGUID StringToGUID(const UnicodeString S);
```

File

SysUtils

Description

StringToGUID converts the string representation of a GUID, S, into an equivalent TGUID (see page 3718) data structure.

If StringToGUID succeeds it returns the requested GUID. If StringToGUID fails an EConvertError (see page 3919) exception is raised.

C++ Examples:

```
//
//This example demonstrates the usage of some GUID related routines along with
//the type itself.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    TGUID myGuid0, myGuid1;

    /* Create a new GUID from the string representation */
    myGuid0 = StringToGUID("{00020400-0000-0000-C000-000000000046}");
    Memo1->Lines->Add("The GUID is: " + GUIDToString(myGuid0));

    /*
    Accessing GUID's internal fields. Using Format function to
    obtain the same output as GUIDToString
    */
    Memo1->Lines->Add(Format(String("GUID using formatting is: ") +
              "{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}",
         ARRAYOFCONST((myGuid0.Data1, myGuid0.Data2, myGuid0.Data3,
         myGuid0.Data4[0], myGuid0.Data4[1], myGuid0.Data4[2], myGuid0.Data4[3],
         myGuid0.Data4[4], myGuid0.Data4[5], myGuid0.Data4[6], myGuid0.Data4[7]))));

    /* Auto-generate a random GUID at runtime */
    if (CreateGUID(myGuid1) != 0)
        Memo1->Lines->Add("Creating GUID failed!");
    else
        Memo1->Lines->Add("The generated guid is: " + GUIDToString(myGuid1));
```

```
    /* Generating second random GUID */
    CreateGUID(myGuid0);

    /* Testing if 2 guids are equal */
    if (IsEqualGUID(myGuid0, myGuid1))
       Memo1->Lines->Add("This cannot happen! CreateGUID guarantees that 2 " +
                "String("randomly generated GUIDs cannot be equal!"));
}
```

Delphi Examples:

```
{
This example demonstrates the usage of some GUID related routines along with
the type itself.
}
procedure TForm2.FormCreate(Sender: TObject);
var
  MyGuid0, MyGuid1 : TGUID;

begin
  { Create a new GUID from the string representation }
  MyGuid0 := StringToGUID('{00020400-0000-0000-C000-000000000046}');
  Memo1.Lines.Add('The GUID is: ' + GUIDToString(MyGuid0));

  {
  Accessing GUID's internal fields. Using Format function to obtain the
  same output as GUIDToString
  }
  Memo1.Lines.Add(Format('GUID using formatting is: ' +
       '{%0.8X-%0.4X-%0.4X-%0.2X%0.2X-%0.2X%0.2X%0.2X%0.2X%0.2X%0.2X}',
       [MyGuid0.D1, MyGuid0.D2, MyGuid0.D3,
       MyGuid0.D4[0], MyGuid0.D4[1], MyGuid0.D4[2], MyGuid0.D4[3],
       MyGuid0.D4[4], MyGuid0.D4[5], MyGuid0.D4[6], MyGuid0.D4[7]]));

  { Auto-generate a random GUID at runtime }
  if CreateGUID(MyGuid1) <> 0 then
     Memo1.Lines.Add('Creating GUID failed!')
  else
     Memo1.Lines.Add('The generated guid is: ' + GUIDToString(MyGuid1));

  { Generating second random GUID }
  CreateGUID(MyGuid0);

  { Testing if 2 guids are equal }
  if IsEqualGUID(MyGuid0, MyGuid1) then
     Memo1.Lines.Add('This cannot happen! CreateGUID guarantees that ' +
                     '2 randomly generated GUIDs cannot be equal!');
end;
```

See Also

GUIDToString (see page 4210)

37.3.204 SysUtils.StrLCat Function

Appends up to a specified maximum number of characters to string.

Pascal

```
function StrLCat(Dest: PAnsiChar; const Source: PAnsiChar; MaxLen: Cardinal): PAnsiChar;
overload;
function StrLCat(Dest: PWideChar; const Source: PWideChar; MaxLen: Cardinal): PWideChar;
```

```
  overload;
```

C++

```
PAnsiChar StrLCat(PAnsiChar Dest, const PAnsiChar Source, unsigned MaxLen);
PWideChar StrLCat(PWideChar Dest, const PWideChar Source, unsigned MaxLen);
```

File

SysUtils

Description

StrLCat appends at most MaxLen - StrLen (see page 4260)(Dest) characters from Source to the end of Dest and returns Dest. That is, MaxLen indicates the maximum length that is allowed in the result string.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form in an application. When the button is clicked, the edit
control's text is split in halves that are copied into
separate buffers. Then the contents of the buffers are
displayed in a message box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString EditText = AnsiString(Edit1->Text);
  char* szFirstHalf = new char[StrLen(EditText.c_str())/2+2];
  char* szSecondHalf = new char[StrLen(EditText.c_str())/2+2];
  char* pszSecondHalf = &EditText[StrLen(EditText.c_str())/2+1];

  *szFirstHalf = 0;
  *szSecondHalf = 0;

  StrLCat(szFirstHalf, EditText.c_str(), StrLen(EditText.c_str())/2);
  StrCat(szSecondHalf, pszSecondHalf);

  Application->MessageBox(WideString(szFirstHalf).c_bstr(), L"First Half", MB_OKCANCEL);
  Application->MessageBox(WideString(szSecondHalf).c_bstr(), L"Second Half", MB_OKCANCEL);

  delete [] szFirstHalf;
  delete [] szSecondHalf;
}
```

Delphi Examples:

```
{
The following example uses an edit control and a button on a
form in an application. When the button is clicked, the edit
control's text is split in halves that are copied into
separate buffers. Then the contents of the buffers are
displayed in a message box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FirstHalf: PChar;
  SecondHalf: PChar;
  HalfLen: Integer;
begin
  HalfLen := StrLen(PChar(string(Edit1.Text))) div 2;
  GetMem(FirstHalf,HalfLen+2);
  GetMem(SecondHalf,HalfLen+2);
  FirstHalf^ := Chr(0);
  SecondHalf^ := Chr(0);
  StrLCat(FirstHalf, PChar(string(Edit1.Text)), HalfLen);
  StrCat(SecondHalf, PChar(string(Edit1.Text)) + HalfLen);
//  Application.MessageBox(FirstHalf, 'First Half', [smbOK], smsInformation, smbOK, smbCancel);
```

```
  Application.MessageBox(FirstHalf, 'First Half', MB_OKCANCEL);
  Application.MessageBox(SecondHalf, 'Second Half', MB_OKCANCEL);
  FreeMem(FirstHalf);
  FreeMem(SecondHalf);
end;
```

SizeOf (see page 3670)

StrCat (see page 4243)

StrLen (see page 4260)

37.3.205 SysUtils.StrLComp Function

Compares up to a specified maximum number of characters in two strings.

Pascal

```
function StrLComp(const Str1: PAnsiChar; const Str2: PAnsiChar; MaxLen: Cardinal): Integer;
overload;
function StrLComp(const Str1: PWideChar; const Str2: PWideChar; MaxLen: Cardinal): Integer;
overload;
```

C++

```
int StrLComp(const PAnsiChar Str1, const PAnsiChar Str2, unsigned MaxLen);
int StrLComp(const PWideChar Str1, const PWideChar Str2, unsigned MaxLen);
```

File

SysUtils

Description

StrLComp compares Str1 to Str2, up to a maximum length of MaxLen characters. The return value is indicated in the following table:

Return value	Condition
<0	Str1 sorts before Str2
=0	Str1 is the same as Str2
>0	Str1 sorts after Str2

Note: When working with international characters, use AnsiStrLComp (see page 4058) instead.

C++ Examples:

```
/*
This example requires two text edits and a button.
Enter text in the two text edits and click the button
to compare the strings.
*/
#include <algorithm>  // for the min function
#include <memory>       // for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szResult(new char[Edit1->Text.Length() + Edit2->Text.Length() + 65]);
  int len = std::min(Edit1->Text.Length(), Edit2->Text.Length());
```

```
  int iResult = Sysutils::StrLComp(
    Edit1->Text.c_str(), Edit2->Text.c_str(), len + 1);
  StrCopy(szResult.get(), "The first ");
  StrCat(szResult.get(), IntToStr(len).t_str());
  StrCat(szResult.get(), " characters of ");
  StrCat(szResult.get(), Edit1->Text.t_str());
  if (iResult < 0)
    StrCat(szResult.get(), " are less than the first ");
  else if (iResult > 0)
    StrCat(szResult.get(), " are greater than the first ");
  else
    StrCat(szResult.get(), " are equal to the first ");
  StrCat(szResult.get(), IntToStr(len).t_str());
  StrCat(szResult.get(), " characters of ");
  StrCat(szResult.get(), Edit2->Text.t_str());

  ShowMessage(szResult.get());
}
```

Delphi Examples:

```
{
This example requires two text edits and a button.
Enter text in the two text edits and click the button
to compare the strings.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S1, S2: String;
  Pos: Integer;
  Equal: Boolean;
begin
  Pos := 1;
  Equal := True;
  S1 := Edit1.Text;
  S2 := Edit2.Text;
  Form1.Repaint;
  while (Equal = True) do
  begin
    if StrLComp(PChar(S1), PChar(S2), Pos) = 0 then
      Inc(Pos)
    else
      Equal := False;
  end;
  Canvas.TextOut(10, 10, 'The first ' + IntToStr(Pos - 1) +
    ' characters are equal.');
end;
```

StrLIComp (see page 4262)

37.3.206 SysUtils.StrLCopy Function

Copies up to a specified maximum number of characters from Source to Dest.

Pascal

```
function StrLCopy(Dest: PAnsiChar; const Source: PAnsiChar; MaxLen: Cardinal): PAnsiChar;
overload;
function StrLCopy(Dest: PWideChar; const Source: PWideChar; MaxLen: Cardinal): PWideChar;
overload;
```

C++

```
PAnsiChar StrLCopy(PAnsiChar Dest, const PAnsiChar Source, unsigned MaxLen);
PWideChar StrLCopy(PWideChar Dest, const PWideChar Source, unsigned MaxLen);
```

File

SysUtils

Description

StrLCopy copies at most MaxLen characters from Source to Dest, then adds a null terminator to Dest and returns Dest. The SizeOf (see page 3670) standard function (Delphi) or the sizeof operator (C++) can be used to determine the MaxLen parameter. Usually MaxLen equals SizeOf (see page 3670)(Dest)-1.

Note: StrLCopy copies a null terminator as well as MaxLen characters. Be sure that Dest is large enough to accommodate the null terminator at the end.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form. When the button is clicked, the first X bytes of the
edit control are copied into a buffer, where X is a
predefined number.
*/
const MAX_BUFFER = 10;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char szBuffer[MAX_BUFFER+1];
  StrLCopy(szBuffer, Edit1->Text.t_str(), MAX_BUFFER);
  Application->MessageBox(WideString(szBuffer).c_bstr(), L"StrLCopy example", MB_OKCANCEL);
}
```

Delphi Examples:

```
{
The following example uses an edit control and a button on a
form. When the button is clicked, the first X bytes of the
edit control are copied into a buffer, where X is a
predefined number.
}
const MAX_BUFFER = 10;
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: array [0..MAX_BUFFER] of char;
begin
  StrLCopy(Buffer, PChar(Edit1.Text), MAX_BUFFER);
  Application.MessageBox(Buffer, 'StrLCopy example', MB_OKCANCEL);
end;
```

See Also

SizeOf (see page 3670)

StrCopy (see page 4246)

StrLen (see page 4260)

37.3.207 SysUtils.StrLen Function

Returns number of characters in a string excluding the null terminator.

Pascal

```
function StrLen(const Str: PAnsiChar): Cardinal; overload;
function StrLen(const Str: PWideChar): Cardinal; overload;
```

C++

```
unsigned StrLen(const PAnsiChar Str);
unsigned StrLen(const PWideChar Str);
```

File

SysUtils

Description

StrLen returns the number of characters in Str (see page 3676), not counting the null terminator.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form in an application. When the button is clicked, the edit
control's text is split in halves that are copied into
separate buffers. Then the contents of the buffers are
displayed in a message box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString EditText = AnsiString(Edit1->Text);
  char* szFirstHalf = new char[StrLen(EditText.c_str())/2+2];
  char* szSecondHalf = new char[StrLen(EditText.c_str())/2+2];
  char* pszSecondHalf = &EditText[StrLen(EditText.c_str())/2+1];

  *szFirstHalf = 0;
  *szSecondHalf = 0;

  StrLCat(szFirstHalf, EditText.c_str(), StrLen(EditText.c_str())/2);
  StrCat(szSecondHalf, pszSecondHalf);

  Application->MessageBox(WideString(szFirstHalf).c_bstr(), L"First Half", MB_OKCANCEL);
  Application->MessageBox(WideString(szSecondHalf).c_bstr(), L"Second Half", MB_OKCANCEL);

  delete [] szFirstHalf;
  delete [] szSecondHalf;
}
```

Delphi Examples:

```
{
The following example uses an edit control and a button on a
form in an application. When the button is clicked, the edit
control's text is split in halves that are copied into
separate buffers. Then the contents of the buffers are
displayed in a message box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FirstHalf: PChar;
  SecondHalf: PChar;
  HalfLen: Integer;
```

```
begin
  HalfLen := StrLen(PChar(string(Edit1.Text))) div 2;
  GetMem(FirstHalf,HalfLen+2);
  GetMem(SecondHalf,HalfLen+2);
  FirstHalf^ := Chr(0);
  SecondHalf^ := Chr(0);
  StrLCat(FirstHalf, PChar(string(Edit1.Text)), HalfLen);
  StrCat(SecondHalf, PChar(string(Edit1.Text)) + HalfLen);
//  Application.MessageBox(FirstHalf, 'First Half', [smbOK], smsInformation, smbOK, smbCancel);
  Application.MessageBox(FirstHalf, 'First Half', MB_OKCANCEL);
  Application.MessageBox(SecondHalf, 'Second Half', MB_OKCANCEL);
  FreeMem(FirstHalf);
  FreeMem(SecondHalf);
end;
```

See Also

StrEnd (see page 4249)

37.3.208 SysUtils.StrLFmt Function

Formats a series of arguments from a specified open array into a buffer.

Pascal

```
function StrLFmt(Buffer: PAnsiChar; MaxBufLen: Cardinal; Format: PAnsiChar; const Args: array
of const): PAnsiChar; overload;
function StrLFmt(Buffer: PAnsiChar; MaxBufLen: Cardinal; Format: PAnsiChar; const Args: array
of const; const FormatSettings: TFormatSettings): PAnsiChar; overload;
function StrLFmt(Buffer: PWideChar; MaxBufLen: Cardinal; Format: PWideChar; const Args: array
of const): PWideChar; overload;
function StrLFmt(Buffer: PWideChar; MaxBufLen: Cardinal; Format: PWideChar; const Args: array
of const; const FormatSettings: TFormatSettings): PWideChar; overload;
```

C++

```
PAnsiChar StrLFmt(PAnsiChar Buffer, unsigned MaxBufLen, PAnsiChar Format, const array of const
Args);
PAnsiChar StrLFmt(PAnsiChar Buffer, unsigned MaxBufLen, PAnsiChar Format, const array of const
Args, const TFormatSettings FormatSettings);
PWideChar StrLFmt(PWideChar Buffer, unsigned MaxBufLen, PWideChar Format, const array of const
Args);
PWideChar StrLFmt(PWideChar Buffer, unsigned MaxBufLen, PWideChar Format, const array of const
Args, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

StrLFmt formats the series of arguments in and open array and writes the results to a buffer.

Buffer is the buffer that receives the results.

MaxLen is the maximum number of bytes that can be written to Buffer. This value does not include the terminating null character.

Format (see page 4188) is the format string that governs the operation.

Args is an array of arguments that replace the format specifiers in Format (see page 4188).

Note: Args_Size is the index of the last argument in Args (one less than the number of arguments).

StrLFmt returns a pointer to the destination buffer.

The first form of StrLFmt is not thread-safe, because it uses localization information contained in global variables. The second form of StrLFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrLFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

StrFmt (see page 4250)

FmtStr (see page 4185)

GetLocaleFormatSettings (see page 4206)

37.3.209 SysUtils.StrLIComp Function

Compares strings up to a specified maximum number of characters, without case sensitivity.

Pascal

```
function StrLIComp(const Str1: PAnsiChar; const Str2: PAnsiChar; MaxLen: Cardinal): Integer;
overload;
function StrLIComp(const Str1: PWideChar; const Str2: PWideChar; MaxLen: Cardinal): Integer;
overload;
```

C++

```
int StrLIComp(const PAnsiChar Str1, const PAnsiChar Str2, unsigned MaxLen);
int StrLIComp(const PWideChar Str1, const PWideChar Str2, unsigned MaxLen);
```

File

SysUtils

Description

StrLIComp compares Str1 to Str2, up to a maximum length of MaxLen characters, without case sensitivity. The return value is indicated in the following table:

Return value	Condition
<0	Str1 sorts before Str2
=0	Str1 is the same as Str2
>0	Str1 sorts after Str2

Note: When working with international characters, use AnsiStrLIComp (see page 4058) instead.

C++ Examples:

```
/*
This example requires two text edits and a button.
Enter text in the two text edits and click the button
to compare the strings without case sensitivity.
*/
#include <algorithm>  // for the min function
#include <memory>       // for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  std::auto_ptr<char> szResult(new char[Edit1->Text.Length() + Edit2->Text.Length() + 65]);
  int len = std::min(Edit1->Text.Length(), Edit2->Text.Length());
  int iResult = StrLIComp(
    Edit1->Text.c_str(), Edit2->Text.c_str(), len);

  StrCopy(szResult.get(), "The first ");
  StrCat(szResult.get(), IntToStr(len).t_str());
  StrCat(szResult.get(), " characters of ");
  StrCat(szResult.get(), Edit1->Text.t_str());
  if (iResult < 0)
    StrCat(szResult.get(), " are less than the first ");
  else if (iResult > 0)
    StrCat(szResult.get(), " are greater than the first ");
  else
    StrCat(szResult.get(), " are equal to the first ");
  StrCat(szResult.get(), IntToStr(len).t_str());
  StrCat(szResult.get(), " characters of ");
  StrCat(szResult.get(), Edit2->Text.t_str());

  ShowMessage(szResult.get());
}
```

Delphi Examples:

```
{
This example requires two text edits and a button.
Enter text in the two text edits and click the button
to compare the strings, without case sensitivity.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S1, S2: String;
  Pos: Integer;
  Equal: Boolean;
begin
  Pos := 1;
  Equal := True;
  S1 := Edit1.Text;
  S2 := Edit2.Text;
  Form1.Repaint;
  while (Equal = True) do
  begin
    if StrLIComp(PChar(S1), PChar(S2), Pos) = 0 then
      Inc(Pos)
    else
      Equal := False;
  end;
  Canvas.TextOut(10, 10, 'The first ' + IntToStr(Pos - 1) +
    ' characters are equal.');
end;
```

37.3.210 SysUtils.StrLower Function

Converts a string to lowercase.

Pascal

```
function StrLower(Str: PAnsiChar): PAnsiChar; overload;
function StrLower(Str: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrLower(PAnsiChar Str);
PWideChar StrLower(PWideChar Str);
```

File

SysUtils

Description

StrLower converts Str (see page 3676) to lowercase and returns Str (see page 3676).

Note: If the source string contains international characters, use AnsiStrLower (see page 4059) instead. If the source string is an AnsiString (long string), use LowerCase (see page 4225) (or AnsiLowerCase (see page 4053)) instead.

C++ Examples:

```
/*
The following example uses an edit box, two labels, and a
button on a form. When the button is clicked, the text in
the edit control is displayed in lower case in label1's
caption and upper case in label2's caption.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = StrLower(Edit1->Text.c_str());
  Label2->Caption = StrUpper(Edit1->Text.c_str());
}
```

Delphi Examples:

```
{
The following example uses an edit box, a label, and a
button on a form. When the button is clicked, the text in
the edit control is displayed in lower case in the label's
caption.
}
var
  S: array[0..20] of Char = 'A fUnNy StRiNg';

procedure TForm1.Button1Click(Sender: TObject);
var
  lower, upper : string;
begin
  lower := string(StrLower(S));
  upper := string(StrUpper(S));
  Canvas.TextOut(5, 10, lower + ' ' + upper);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
  Label1.Caption := S;
end;
```

LowerCase (see page 4225)

StrUpper (see page 4292)

37.3.211 SysUtils.StrMove Function

Copies specified number of characters to string.

Pascal

```
function StrMove(Dest: PAnsiChar; const Source: PAnsiChar; Count: Cardinal): PAnsiChar;
overload;
function StrMove(Dest: PWideChar; const Source: PWideChar; Count: Cardinal): PWideChar;
overload;
```

C++

```
PAnsiChar StrMove(PAnsiChar Dest, const PAnsiChar Source, unsigned Count);
PWideChar StrMove(PWideChar Dest, const PWideChar Source, unsigned Count);
```

File

SysUtils

Description

StrMove copies exactly Count characters from Source to Dest and returns Dest. Source and Dest can overlap.

C++ Examples:

```
/*
This example shows two functions that do the same thing as
StrNew and StrDispose.
*/
char * AHeapaString(char *S)
{
// Allocate string on heap
  if ((S != NULL) && (S[0] != '\0'))
  {
    int L = StrLen(S) + 1;
    char *p = (char *)malloc(L);
    return StrMove(p, S, L);
  }
  return NULL;
}
void DisposeDaString(char *S)
{
// Dispose string on heap
  if (S != NULL)
    free(S);
}
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char *S = "Now you see it.";
  char *otherS = AHeapaString(S);
  Canvas->TextOut(5, 10, otherS);
```

```
  Canvas->Refresh();
  Sleep(5000);
  DisposeDaString(otherS);
}
```

Delphi Examples:

```
{
This example shows two functions that do the same thing as
StrNew and StrDispose.
}
function AHeapaString(S: PChar): PChar;
{ Allocate string on heap }
 var
  L: Cardinal;
  P: PChar;
  StrNew: PChar;
begin
  StrNew := nil;
  if (S <> nil) and (S[0] <> #0) then
  begin
    L := StrLen(S) + 1;
    GetMem(P, L);
    StrNew := StrMove(P, S, L);
  end;
  Result := StrNew;
end;

procedure DisposeDaString(S: PChar);
{ Dispose string on heap }
begin
  if S <> nil then FreeMem(S, StrLen(S) + 1);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  S, otherS: PChar;
begin
  S := 'Now you see it';
  otherS := AHeapaString(S);
  Canvas.TextOut(5, 10, otherS);
  Canvas.Refresh;
  Sleep(5000);
  DisposeDaString(otherS);
end;
```

Move (see page 3617)

37.3.212 SysUtils.StrNew Function

Allocates space on and copies a string to the heap; returning a pointer to the string.

Pascal

```
function StrNew(const Str: PAnsiChar): PAnsiChar; overload;
function StrNew(const Str: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrNew(const PAnsiChar Str);
PWideChar StrNew(const PWideChar Str);
```

File

SysUtils

Description

StrNew allocates a copy of Str (see page 3676) on the heap.

If Str (see page 3676) is nil (Delphi) or NULL (C++) or points to an empty string, StrNew returns a pointer to a new empty string.

Otherwise, StrNew makes a duplicate of Str (see page 3676), obtaining space with a call to StrAlloc (see page 4241), and returns a pointer to the duplicated string.

The allocated space is the length of Str (see page 3676) + 5 bytes.

C++ Examples:

```
/*
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Allocate memory.
  char* psz = StrNew(Edit1->Text.t_str());
  Application->MessageBox(
    Edit1->Text.c_str(),
    L"StrNew, StrDispose example",
    MB_OK);
  // Deallocate memory.
  StrDispose(psz);
}
```

Delphi Examples:

```
{
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Temp: PChar;
begin
  // Allocate memory.
  Temp := StrNew(PChar(Edit1.Text));
  Application.MessageBox(Temp, 'StrNew, StrDispose example', MB_OK);
  // Deallocate memory.
  SysUtils.StrDispose(Temp);
end;
```

See Also

GetMem (see page 3584)

StrDispose (see page 4247)

StrAlloc (see page 4241)

37.3.213 SysUtils.StrNextChar Function

Returns pointer to following character.

Pascal

```
function StrNextChar(const Str: PAnsiChar): PAnsiChar; overload;
function StrNextChar(const Str: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrNextChar(const PAnsiChar Str);
PWideChar StrNextChar(const PWideChar Str);
```

File

SysUtils

Description

Note: StrNextChar returns a pointer to the second character in Str (see page 3676), allowing for multi-byte characters.

37.3.214 SysUtils.StrPas Function

Converts null-terminated string to an AnsiString (long string).

Pascal

```
function StrPas(const Str: PAnsiChar): AnsiString; overload;
```

C++

```
AnsiString StrPas(const PAnsiChar Str);
```

File

SysUtils

Description

This function is provided for backwards compatibility only. To convert a null terminated string to an AnsiString or native Delphi language string, use a typecast or an assignment.

C++ Examples:

```
/*
The following code locks the memory for text on the Clipboard, then
reads the text.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
      AnsiString MyString;

      int TextHandle;
      PChar pText;

      Clipboard()->Open();
      try
      {
```

```
            TextHandle = Clipboard()->GetAsHandle(CF_UNICODETEXT);
            pText = (PChar)GlobalLock((HGLOBAL)TextHandle);
            MyString = pText;
            ListBox1->Items->Add(StrPas(pText));
            GlobalUnlock((HGLOBAL)TextHandle);
      }
      catch (...)
      {
            Clipboard()->Close();
            throw;
      }
      Clipboard()->Close();
}
```

Delphi Examples:

```
{
The following code locks the memory for text on the Clipboard, then reads the text.
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
      MyHandle: THandle;
      TextPtr: PChar;
begin
      ClipBoard.Open;
      try
      {$IFNDEF UNICODE}
            MyHandle := Clipboard.GetAsHandle(CF_TEXT);
      {$ELSE}
            MyHandle := Clipboard.GetAsHandle(CF_UNICODETEXT);
      {$ENDIF}

            TextPtr := GlobalLock(MyHandle);
            ListBox1.Items.Add(StrPas(TextPtr));
            GlobalUnlock(MyHandle);
      finally
            Clipboard.Close;
      end;
end;
```

See Also

StrPCopy (see page 4271)

37.3.215 SysUtils.StrPas Function

Converts null-terminated string to an AnsiString (long string).

Pascal

```
function StrPas(const Str: PWideChar): UnicodeString; overload;
```

C++

```
UnicodeString StrPas(const PWideChar Str);
```

File

SysUtils

Description

This function is provided for backwards compatibility only. To convert a null terminated string to an AnsiString or native Delphi language string, use a typecast or an assignment.

C++ Examples:

```
/*
The following code locks the memory for text on the Clipboard, then
reads the text.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
      AnsiString MyString;

      int TextHandle;
      PChar pText;

      Clipboard()->Open();
      try
      {
            TextHandle = Clipboard()->GetAsHandle(CF_UNICODETEXT);
            pText = (PChar)GlobalLock((HGLOBAL)TextHandle);
            MyString = pText;
            ListBox1->Items->Add(StrPas(pText));
            GlobalUnlock((HGLOBAL)TextHandle);
      }
      catch (...)
      {
            Clipboard()->Close();
            throw;
      }
      Clipboard()->Close();
}
```

Delphi Examples:

```
{
The following code locks the memory for text on the Clipboard, then reads the text.
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
      MyHandle: THandle;
      TextPtr: PChar;
begin
      ClipBoard.Open;
      try
      {$IFNDEF UNICODE}
            MyHandle := Clipboard.GetAsHandle(CF_TEXT);
      {$ELSE}
            MyHandle := Clipboard.GetAsHandle(CF_UNICODETEXT);
      {$ENDIF}

            TextPtr := GlobalLock(MyHandle);
            ListBox1.Items.Add(StrPas(TextPtr));
            GlobalUnlock(MyHandle);
      finally
            Clipboard.Close;
      end;
end;
```

See Also

StrPCopy (see page 4271)

37.3.216 SysUtils.StrPCopy Function

Copies an AnsiString (long string) to a null-terminated string.

Pascal

```
function StrPCopy(Dest: PAnsiChar; const Source: AnsiString): PAnsiChar; overload;
function StrPCopy(Dest: PWideChar; const Source: UnicodeString): PWideChar; overload;
```

C++

```
PAnsiChar StrPCopy(PAnsiChar Dest, const AnsiString Source);
PWideChar StrPCopy(PWideChar Dest, const UnicodeString Source);
```

File

SysUtils

Description

StrPCopy copies Source into a null-terminated string Dest. It returns a pointer to Dest.

StrPCopy does not perform any length checking.

The destination buffer must have room for at least Length (see page 3607)(Source)+1 characters.

C++ Examples:

```
/*
The following example uses an edit control, a label, and a
button on a form. When the button is clicked, the label's
caption and the edit control's text are combined in a buffer.
Then the buffer is displayed in the label's caption.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<char> szBuffer(new char[Label1->Caption.Length() + Edit1->Text.Length() + 1]);
  StrPCopy(szBuffer.get(), Label1->Caption);
  StrCat(szBuffer.get(), Edit1->Text.t_str());
  Label1->Caption = szBuffer.get();
  Edit1->Clear();
}
```

Delphi Examples:

```
{
This example requires a button on a form and uses StrPCopy
to copy a string into an array and then display the character
array on the form canvas.  StrPCopy does not do length checking.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  A: array[0..79] of Char;
  S: String;
begin
  S := 'Honk if you know Blaise.';
  StrPCopy(A, S);
```

```
  Canvas.TextOut(10, 10, string(A));
end;
```

See Also

StrCopy (see page 4246)

37.3.217 SysUtils.StrPLCopy Function

Copies characters from an AnsiString (long string) into a null-terminated string.

Pascal

```
function StrPLCopy(Dest: PAnsiChar; const Source: AnsiString; MaxLen: Cardinal): PAnsiChar;
overload;
function StrPLCopy(Dest: PWideChar; const Source: UnicodeString; MaxLen: Cardinal): PWideChar;
overload;
```

C++

```
PAnsiChar StrPLCopy(PAnsiChar Dest, const AnsiString Source, unsigned MaxLen);
PWideChar StrPLCopy(PWideChar Dest, const UnicodeString Source, unsigned MaxLen);
```

File

SysUtils

Description

StrPLCopy copies up to a maximum of MaxLen characters from Source into the null-terminated string Dest. StrPLCopy returns a pointer to Dest.

Note: Dest should point to a location with room for MaxLen + 1 characters, including the null terminator.

37.3.218 SysUtils.StrPos Function

Returns a pointer to the first occurrence of STR2 in STR1.

Pascal

```
function StrPos(const Str1: PAnsiChar; const Str2: PAnsiChar): PAnsiChar; overload;
```

C++

```
PAnsiChar StrPos(const PAnsiChar Str1, const PAnsiChar Str2);
```

File

SysUtils

Description

StrPos returns a pointer to the first occurrence of Str2 in Str1. If Str2 does not occur in Str1, StrPos returns nil (Delphi) or NULL (C++).

Note: If the source string contains international characters, use AnsiStrPos (see page 4060) instead.

Delphi Examples:

```
{
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the first
```

```
edit control is searched for the text in the second edit control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
      if StrPos(PChar(Edit1.Text), PChar(Edit2.Text)) <> nil then
         ShowMessage('Substring found')
      else
         ShowMessage('Substring not found');
end;
```

C++ Examples:

```
/*
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the first
edit control is searched for the text in the second edit control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
      if (StrPos(Edit1->Text.c_str(), Edit2->Text.c_str()))
         ShowMessage("Substring found.");
      else
         ShowMessage("Substring not found.");
}
```

See Also

AnsiStrPos (see page 4060)

37.3.219 SysUtils.StrPos Function

Returns a pointer to the first occurrence of STR2 in STR1.

Pascal

```
function StrPos(const Str1: PWideChar; const Str2: PWideChar): PWideChar; overload;
```

C++

```
PWideChar StrPos(const PWideChar Str1, const PWideChar Str2);
```

File

SysUtils

Description

StrPos returns a pointer to the first occurrence of Str2 in Str1. If Str2 does not occur in Str1, StrPos returns nil (Delphi) or NULL (C++).

Note: If the source string contains international characters, use AnsiStrPos (see page 4060) instead.

Delphi Examples:

```
{
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the first
edit control is searched for the text in the second edit control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
      if StrPos(PChar(Edit1.Text), PChar(Edit2.Text)) <> nil then
         ShowMessage('Substring found')
      else
         ShowMessage('Substring not found');
```

```
end;
```

C++ Examples:

```
/*
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the first
edit control is searched for the text in the second edit control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
      if (StrPos(Edit1->Text.c_str(), Edit2->Text.c_str()))
         ShowMessage("Substring found.");
      else
         ShowMessage("Substring not found.");
}
```

See Also

AnsiStrPos (see page 4060)

37.3.220 SysUtils.StrRScan Function

Returns a pointer to the last occurrence of a specified character in a string.

Pascal

```
function StrRScan(const Str: PAnsiChar; Chr: AnsiChar): PAnsiChar; overload;
function StrRScan(const Str: PWideChar; Chr: WideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrRScan(const PAnsiChar Str, AnsiChar Chr);
PWideChar StrRScan(const PWideChar Str, WideChar Chr);
```

File

SysUtils

Description

StrRScan returns a pointer to the last occurrence of Chr (see page 3536) in Str (see page 3676).

If Chr (see page 3536) does not occur in Str (see page 3676), StrRScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Note: If the source string contains international characters, use AnsiStrRScan (see page 4060) instead.

C++ Examples:

```
/*
The following example uses an Open dialog box and a button
on a form. When the button is clicked, the user is prompted
for a filename. Then the filename, minus its path, is
displayed in a message box.
Note:   This technique will not work with multi-byte
character sets (MBCS). To be more general, use ExtractFileName.
*/
char *__fastcall GetFileName(char *pszFilePath)
{
  char *pszFileName = StrRScan(pszFilePath, '\\');
  if (!pszFileName)
    pszFileName = pszFilePath;
```

```
    else
      pszFileName++;
    return pszFileName;
  }
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    if (OpenDialog1->Execute())
    {
      char *name = GetFileName(OpenDialog1->FileName.t_str());
      Application->MessageBox(
        WideString(name).c_bstr(),
        L"File Name",
        MB_OK);
    }
  }
```

Delphi Examples:

```
{
This function behaves much like ExtractFileName except that
it uses null-terminated strings and it will not work with
multi-byte character sets (MBCS).
}
function NamePart(FileName: PAnsiChar): PAnsiChar;
 var
  P: PAnsiChar;
  sep: Char;
begin
  sep := '/';
  P := StrRScan(FileName, '/');
  if P = nil then
  begin
    P := StrRScan(FileName, ':');
    if P = nil then P := FileName;
  end;
  NamePart := P;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  S : string;
begin
  S := string(NamePart('C:\Test.fil'));
  Canvas.TextOut(10, 10, S);
end;
```

See Also

AnsiStrRScan (see page 4060)

StrScan (see page 4275)

37.3.221 SysUtils.StrScan Function

Returns a pointer to first occurrence of a specified character in a string.

Pascal

```
function StrScan(const Str: PAnsiChar; Chr: AnsiChar): PAnsiChar; overload;
function StrScan(const Str: PWideChar; Chr: WideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrScan(const PAnsiChar Str, AnsiChar Chr);
```

```
PWideChar StrScan(const PWideChar Str, WideChar Chr);
```

File

SysUtils

Description

StrScan returns a pointer to the first occurrence of Chr (see page 3536) in Str (see page 3676). If Chr (see page 3536) does not occur in Str (see page 3676), StrScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Note: If the source string contains international characters, use AnsiStrScan (see page 4061) instead.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form. When the button is clicked, the text in the edit
control is searched for a wildcard (asterisk character).
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (StrScan(Edit1->Text.c_str(), '*'))
    ShowMessage("Wildcard found.");
  else
    ShowMessage("Wildcard not found.");
}
```

Delphi Examples:

```
{
The following example uses a button on a form. When the
button is clicked, the text is searched for a wildcard
(asterisk character).
}
function HasWildcards(FileName: PChar): Boolean;
{ Return true if file name has wildcards in it }
begin
  HasWildcards := (StrScan(FileName, '*') <> nil) or
    (StrScan(FileName, '?') <> nil);
end;

procedure TForm1.Button1Click(Sender: TObject);
const
  P: PChar = 'C:\Test.* ';
begin
  if HasWildcards(P) then
    ShowMessage('The string has wildcards')
  else
    ShowMessage('The string does not have wildcards');
end;
```

See Also

AnsiStrScan (see page 4061)

StrRScan (see page 4274)

37.3.222 SysUtils.StrToBool Function

Converts a string to a Boolean value.

Pascal

```
function StrToBool(const S: string): Boolean; overload;
```

C++

```
Boolean StrToBool(const UnicodeString S);
```

File

SysUtils

Description

StrToBool converts the string specified by S to a Boolean. If S can be converted to a number, StrToBool returns false if that number is 0, true otherwise. If S can't be converted to a number, StrToBool returns true if S is any of the strings listed in TrueBoolStrs (see page 4363) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 4352) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 4363) or FalseBoolStrs (see page 4352), StrToBool raises an EConvertError (see page 3919) exception.

Note: If you do not assign a value to TrueBoolStrs (see page 4363), it is treated as if it contains the single string 'True'. Similarly, if you do not assign a value to FalseBoolStrs (see page 4352), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 4363) and FalseBoolStrs (see page 4352) variables are undefined when an application starts. Any use of StrToBool, BoolToStr (see page 4066) or TryStrToBool (see page 4305) will cause these variables to be initialised with the default values above.

See Also

BoolToStr (see page 4066)

TrueBoolStrs (see page 4363)

FalseBoolStrs (see page 4352)

37.3.223 SysUtils.StrToBoolDef Function

Converts a string to a Boolean value, with error default.

Pascal

```
function StrToBoolDef(const S: string; const Default: Boolean): Boolean; overload;
```

C++

```
Boolean StrToBoolDef(const UnicodeString S, const Boolean Default);
```

File

SysUtils

Description

StrToBoolDef converts the string specified by S to a Boolean. If S can be converted to a number, StrToBoolDef returns false if that number is 0, true otherwise. If S can't be converted to a number, StrToBoolDef returns true if S is any of the strings listed in TrueBoolStrs (see page 4363) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 4352) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 4363) or FalseBoolStrs (see page 4352), StrToBoolDef returns Default.

Note: If you do not assign a value to TrueBoolStrs (see page 4363), it is treated as if it contains the single string 'True'.

Similarly, if you do not assign a value to FalseBoolStrs (see page 4352), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 4363) and FalseBoolStrs (see page 4352) variables are undefined when an application starts. Any use of StrToBool (see page 4276), BoolToStr (see page 4066) or TryStrToBool (see page 4305) will cause these variables to be initialised with the default values above.

FalseBoolStrs (see page 4352)

StrToBool (see page 4276)

37.3.224 SysUtils.StrToCurr Function

Converts a string to a System::Currency (see page 3235) value.

Pascal

```
function StrToCurr(const S: string): Currency; overload;
function StrToCurr(const S: string; const FormatSettings: TFormatSettings): Currency; overload;
```

C++

```
Currency StrToCurr(const UnicodeString S);
Currency StrToCurr(const UnicodeString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToCurr to convert a string that represents a floating-point value to the corresponding System::Currency (see page 3235) value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, StrToCurr raises an EConvertError (see page 3919) exception.

The first form of StrToCurr is not thread-safe, because it uses localization information contained in global variables. The second form of StrToCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.225 SysUtils.StrToCurrDef Function

Converts a string to a System::Currency (see page 3235) value, with error default.

Pascal

```
function StrToCurrDef(const S: string; const Default: Currency): Currency; overload;
function StrToCurrDef(const S: string; const Default: Currency; const FormatSettings:
```

```
TFormatSettings): Currency; overload;
```

C++

```
Currency StrToCurrDef(const UnicodeString S, const Currency Default);
Currency StrToCurrDef(const UnicodeString S, const Currency Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToCurrDef to convert a string that represents a floating-point value to the corresponding System::Currency (see page 3235) value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, StrToCurrDef returns Default.

The first form of StrToCurrDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToCurrDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToCurrDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.226 SysUtils.StrToDate Function

Converts a string to a TDateTime (see page 3323) value.

Pascal

```
function StrToDate(const S: string): TDateTime; overload;
function StrToDate(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToDate(const UnicodeString S);
TDateTime StrToDate(const UnicodeString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToDate to parse a string that specifies a date. If S does not contain a valid date, StrToDate raises an EConvertError (see page 3919) exception.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 4349) global variable or its TFormatSettings (see page 4326) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 4358) global variable or its TFormatSettings (see page 4326) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of StrToDate is not thread-safe, because it uses localization information contained in global variables. The second

form of StrToDate, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDate, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char days[7][10] = {"Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday",
"Saturday" };
  TDateTime dtDate = StrToDate(Edit1->Text);
  ShowMessage(Edit1->Text + AnsiString(" is a ") + days[dtDate.DayOfWeek() - 1]);
}
```

Delphi Examples:

```
{
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ADate: TDateTime;
  days: array[1..7] of string;
begin
  days[1] := 'Sunday';
  days[2] := 'Monday';
  days[3] := 'Tuesday';
  days[4] := 'Wednesday';
  days[5] := 'Thursday';
  days[6] := 'Friday';
  days[7] := 'Saturday';
  ADate := StrToDate(Edit1.Text);
  ShowMessage(Edit1.Text + ' is a ' + days[SysUtils.DayOfWeek(ADate)]);
end;
```

37.3.227 SysUtils.StrToDateDef Function

Converts a string to a TDateTime (see page 3323) value, with error default.

Pascal

```
function StrToDateDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToDateDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToDateDef(const UnicodeString S, const TDateTime Default);
TDateTime StrToDateDef(const UnicodeString S, const TDateTime Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToDateDef to parse a string that specifies a date. If S does not contain a valid date, StrToDateDef returns Default.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 4349) global variable or its TFormatSettings (see page 4326) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 4358) global variable or its TFormatSettings (see page 4326) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of StrToDateDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.228 SysUtils.StrToDateTime Function

Converts a string to a TDateTime (see page 3323) value.

Pascal

```
function StrToDateTime(const S: string): TDateTime; overload;
function StrToDateTime(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToDateTime(const UnicodeString S);
TDateTime StrToDateTime(const UnicodeString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToDateTime to parse a string that specifies a date and time value. If S does not contain a valid date, StrToDateTime raises an EConvertError (see page 3919) exception.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of StrToDateTime is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.229 SysUtils.StrToDateTimeDef Function

Converts a string to a TDateTime (see page 3323) value with error default.

Pascal

```
function StrToDateTimeDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToDateTimeDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToDateTimeDef(const UnicodeString S, const TDateTime Default);
TDateTime StrToDateTimeDef(const UnicodeString S, const TDateTime Default, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToDateTimeDef to parse a string that specifies a date and time value. If S does not contain a valid date, StrToDateTimeDef returns Default.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of StrToDateTimeDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateTimeDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateTimeDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.230 SysUtils.StrToFloat Function

Converts a given string to a floating-point value.

Pascal

```
function StrToFloat(const S: string): Extended; overload;
function StrToFloat(const S: string; const FormatSettings: TFormatSettings): Extended;
overload;
```

C++

```
Extended StrToFloat(const UnicodeString S);
Extended StrToFloat(const UnicodeString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use StrToFloat to convert a string, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 4350) global variable or its TFormatSettings (see page 4326) equivalent defines the character that is used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, StrToFloat raises an EConvertError (see page 3919) exception.

The first form of StrToFloat is not thread-safe, because it uses localization information contained in global variables. The second form of StrToFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int x = 1; x < StringGrid1->ColCount; x++)
  {
    for (int y = 1; y < StringGrid1->RowCount; y++)
    {
      StringGrid1->Cells[x][y] = FormatFloat(
      StringGrid1->Cells[0][y], StrToFloat(StringGrid1->Cells[x][0]));
    }
  }
}

int currCellCol, currCellRow;

void __fastcall TForm1::StringGrid1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  StringGrid1->MouseToCell(X, Y, currCellCol, currCellRow);
}

// Alter Cell
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  StringGrid1->Cells[currCellCol][currCellRow] = Edit1->Text;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "1234";
  StringGrid1->Cells[2][0] = "-1234";
  StringGrid1->Cells[3][0] = "0.5";
```

```
  StringGrid1->Cells[4][0] = "0";
  StringGrid1->Cells[0][1] = "";
  StringGrid1->Cells[0][2] = "0";
  StringGrid1->Cells[0][3] = "0.00";
  StringGrid1->Cells[0][4] = "#.##";
  StringGrid1->Cells[0][5] = "#,##0.00";
  StringGrid1->Cells[0][6] = "#,##0.00;(#,##0.00)";
  StringGrid1->Cells[0][7] = "#,##0.00;;Zero";
  StringGrid1->Cells[0][8] = "0.000E+00";
  StringGrid1->Cells[0][9] = "#.###E-0";
}
```

Delphi Examples:

```
{
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  X, Y, I: Integer;
begin
  for X := 1 to StringGrid1.ColCount - 1 do
  begin
    for Y := 0 to StringGrid1.RowCount - 1 do
    begin
      StringGrid1.Cells[X,Y] := SysUtils.FormatFloat(
        StringGrid1.Cells[0,Y], StrToFloat(StringGrid1.Cells[X,0]));
    end;
  end;

end;

var currCellCol, currCellRow: Integer;

// Alter Cell
procedure TForm1.Button2Click(Sender: TObject);
begin
  StringGrid1.Cells[currCellCol,currCellRow] := Edit1.Text;
end;

procedure TForm1.StringGrid1MouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
begin
  StringGrid1.MouseToCell(X, Y, &currCellCol, &currCellRow);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[1,0] := '1234';
  StringGrid1.Cells[2,0] := '-1234';
  StringGrid1.Cells[3,0] := '0.5';
  StringGrid1.Cells[4,0] := '0';
  StringGrid1.Cells[0,1] := '';
  StringGrid1.Cells[0,2] := '0';
  StringGrid1.Cells[0,3] := '0.00';
  StringGrid1.Cells[0,4] := '#.##';
  StringGrid1.Cells[0,5] := '#,##0.00';
  StringGrid1.Cells[0,6] := '#,##0.00;(#,##0.00)';
  StringGrid1.Cells[0,7] := '#,##0.00;;Zero';
  StringGrid1.Cells[0,8] := '0.000E+00';
  StringGrid1.Cells[0,9] := '#.###E-0';
end;
```

```
{
This example uses a form with a combo box, two list boxes,
an edit control, and a button.  The user selects a
conversion family from the combo box, which causes the list
boxes to fill with the conversion types registered with that
family. When the user clicks the button, a message box
appears showing the value in the edit control converted from
the units selected in the first list box to the units
selected in the second list box.
Note:   If you have not registered your own conversion families,
include the stdconvs unit in your uses clause to use the
standard conversion families.
}

{
The following OnCreate event handler for the form initializes
the combo box and list boxes:
}

procedure TForm1.FormCreate(Sender: TObject);
var
  FamilyList: TConvFamilyArray;
  i: Integer;
begin
  GetConvFamilies(FamilyList);
  for i := 0 to (Length(FamilyList) - 1) do
    ComboBox1.Items.Add(ConvFamilyToDescription(FamilyList[i]));
  ComboBox1.ItemIndex := 0; { select the first item }
  ComboBox1Select(ComboBox1); {trigger the event to initialize lists}
end;

{
The following OnClick event handler for the button reads the
value entered in the edit box and converts it between the
measurement units selected in the list boxes:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  newVal: Double;
  CurFamily: TConvFamily;
  FromType, ToType: TConvType;
begin
  DescriptionToConvFamily(ComboBox1.Items[ComboBox1.ItemIndex], CurFamily);
  DescriptionToConvType(CurFamily, ListBox1.Items[ListBox1.ItemIndex], FromType);
  DescriptionToConvType(CurFamily, ListBox2.Items[ListBox2.ItemIndex], ToType);
  newVal := Convert(StrToFloat(Edit1.Text), FromType, ToType);
  ShowMessage(Format('%g %s', [newVal, ConvTypeToDescription(ToType)]));
end;

{
The following OnSelect event handler for the combo box
initializes the list boxes with the registered conversion
types for the selected family:
}
procedure TForm1.ComboBox1Select(Sender: TObject);
var
  TypeList: TConvTypeArray;
  i: Integer;
  CurFamily: TConvFamily;Description:string;
beginDescription := ComboBox1.Items[ComboBox1.ItemIndex];
  if DescriptionToConvFamily(Description, CurFamily) then
  begin
    GetConvTypes(CurFamily, TypeList);
    ListBox1.Items.Clear;
    ListBox2.Items.Clear;
    for i := 0 to Length(TypeList) -1 do
```

```
      ListBox1.Items.Add(ConvTypeToDescription(TypeList[i]));
    ListBox2.Items := ListBox1.Items;
    ListBox1.ItemIndex := 0;
    ListBox2.ItemIndex := 0;
  end;
end;
```

37.3.231 SysUtils.StrToFloatDef Function

Converts a given string to a floating-point value with error default.

Pascal

```
function StrToFloatDef(const S: string; const Default: Extended): Extended; overload;
function StrToFloatDef(const S: string; const Default: Extended; const FormatSettings:
TFormatSettings): Extended; overload;
```

C++

```
Extended StrToFloatDef(const UnicodeString S, const Extended Default);
Extended StrToFloatDef(const UnicodeString S, const Extended Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Use StrToFloatDef to convert a string, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 4350) global variable or its TFormatSettings (see page 4326) equivalent defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, StrToFloatDef returns Default.

The first form of StrToFloatDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToFloatDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToFloatDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.232 SysUtils.StrToInt Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt(const S: string): Integer; overload;
```

C++

```
int StrToInt(const UnicodeString S);
```

File

SysUtils

Description

StrToInt converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a

number. If S does not represent a valid number, StrToInt raises an EConvertError (see page 3919) exception.

C++ Examples:

```
/*
This example uses two edit boxes and a button on a form. When the user clicks
the button, the code converts the values in the edit boxes to numbers, adds them,
and displays a message indicating the sum:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int i1, i2;
  i1 = StrToInt(Edit1->Text);
  i2 = StrToInt(Edit2->Text);
  ShowMessage(IntToStr(i1 + i2));
}
```

Delphi Examples:

```
{
This example uses two edit boxes and a button on a form. When the user clicks
the button, the code converts the values in the edit boxes to numbers, adds them,
and displays a message indicating the sum:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
  J: Integer;
begin
  I := StrToInt(Edit1.Text);
  J := StrToInt(Edit2.Text);
  ShowMessage(IntToStr(I + J));
end;
```

37.3.233 SysUtils.StrToInt64 Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt64(const S: string): Int64; overload;
```

C++

```
Int64 StrToInt64(const UnicodeString S);
```

File

SysUtils

Description

StrToInt64 converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToInt64 raises an EConvertError (see page 3919) exception.

See Also

IntToHex (see page 4215)

37.3.234 SysUtils.StrToInt64Def Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt64Def(const S: string; const Default: Int64): Int64; overload;
```

C++

```
Int64 StrToInt64Def(const UnicodeString S, const Int64 Default);
```

File

SysUtils

Description

StrToInt64Def converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToInt64Def returns the number passed in Default.

See Also

IntToStr (see page 4216)

TryStrToInt64 (see page 4309)

37.3.235 SysUtils.StrToIntDef Function

Converts a string that represents an integer (decimal or hex notation) to a number with error default.

Pascal

```
function StrToIntDef(const S: string; Default: Integer): Integer; overload;
```

C++

```
int StrToIntDef(const UnicodeString S, int Default);
```

File

SysUtils

Description

StrToIntDef converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToIntDef returns Default.

C++ Examples:

```
/*
This example uses two edit boxes and a button on a form. The
user enters a number in the first edit box and clicks the
button. If the number entered was a valid integer, the same
value appears in the second edit box. If the number was not
a valid integer, the default value of 1000 appears in the
second edit box:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Number = StrToIntDef(Edit1->Text, 1000);
  Edit2->Text = IntToStr(Number);
}
```

Delphi Examples:

```
{
  This example uses the FetchParams method to sync the params
  with the server.
}
procedure TForm1.SaveParamsClick(Sender: TObject);
begin
  { Save the parameters for the TDataSet }
  SavedParams.Assign(CDS.Params);
end;

procedure TForm1.AlterParamsClick(Sender: TObject);
var
  I : Integer;
  ListItem: string;
begin
  CDS.Params.CreateParam(ftString, 'stringParam', ptInput);  // you can also edit the params
in the CDS dynamically
  CDS.Params.CreateParam(ftSmallInt, 'smallIntParam', ptInput);
  CDS.Params.CreateParam(ftInteger, 'intParam', ptInput);

            Items[I].AsDate := StrToDate(ListItem);
          ftTime:
            Items[I].AsTime := StrToTime(ListItem);
          ftDateTime:
            Items[I].AsDateTime := StrToDateTime(ListItem);
        end;
      end;
    end;
  end;

  procedure TForm1.RestoreParamsClick(Sender: TObject);
  begin
    { Restore the parameters to TDataSet }
    CDS.Params.AssignValues(SavedParams);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    { Initialize SavedParams }
    SavedParams := TParams.Create;
    ListBox1.Items.Add('Here is a string');
    ListBox1.Items.Add('4');
    ListBox1.Items.Add('3456789');
    ListBox1.Items.Add('34');
    ListBox1.Items.Add('0');
    ListBox1.Items.Add('12.56');
    ListBox1.Items.Add('4.23');
    ListBox1.Items.Add('99.5');
    ListBox1.Items.Add('4/12/53');
    ListBox1.Items.Add('7:45:00');
    ListBox1.Items.Add('4/12/53 7:45:00');
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    SavedParams.Free;
  end;
  {
  This example uses two edit boxes and a button on a form. The
  user enters a number in the first edit box and clicks the
  button. If the number entered was a valid integer, the same
  value appears in the second edit box. If the number was not
  a valid integer, the default value of 1000 appears in the
  second edit box:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    Number: Integer;
  begin
    Number := StrToIntDef(Edit1.Text, 1000);
    Edit2.Text := IntToStr(Number);
  end;
```

37.3.236 SysUtils.StrToTime Function

Converts a string to a TDateTime (see page 3323) value.

Pascal

```
function StrToTime(const S: string): TDateTime; overload;
function StrToTime(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToTime(const UnicodeString S);
TDateTime StrToTime(const UnicodeString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToTime to parse a string that specifies a time value. If S does not contain a valid time, StrToTime raises an EConvertError (see page 3919) exception.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 4363) global variable or its TFormatSettings (see page 4326) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of StrToTime is not thread-safe, because it uses localization information contained in global variables. The second form of StrToTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user enters a time in the edit box in the HH:MM:SS
format, the string entered is converted to a TDateTime value.
A message then appears that says "Good Morning" or "Good
Afternoon", depending on whether the time entered was in the
morning or afternoon.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dtTime = StrToTime(Edit1->Text);
  if (dtTime < (TDateTime) 0.50 )
    ShowMessage("Good Morning");
  else
    ShowMessage("Good Afternoon");
}
```

Delphi Examples:

```
{
This example uses an edit box and a button on a form. When
the user enters a time in the edit box in the HH:MM:SS
format, the string entered is converted to a TDateTime value.
A message then appears that says "Good Morning" or "Good
Afternoon", depending on whether the time entered was in the
morning or afternoon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ATime: TDateTime;
begin
  ATime := StrToTime(Edit1.Text);
  if ATime < 0.50 then
    ShowMessage('Good Morning')
  else
    ShowMessage('Good Afternoon');
end;
```

37.3.237 SysUtils.StrToTimeDef Function

Converts a string to a TDateTime (see page 3323) value with error default.

Pascal

```
function StrToTimeDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToTimeDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToTimeDef(const UnicodeString S, const TDateTime Default);
TDateTime StrToTimeDef(const UnicodeString S, const TDateTime Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToTimeDef to parse a string that specifies a time value. If S does not contain a valid time, StrToTimeDef returns Default.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 4363) global variable or its TFormatSettings (see page 4326) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of StrToTimeDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToTimeDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToTimeDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.238 SysUtils.StrUpper Function

Returns a string in upper case.

Pascal

```
function StrUpper(Str: PAnsiChar): PAnsiChar; overload;
function StrUpper(Str: PWideChar): PWideChar; overload;
```

C++

```
PAnsiChar StrUpper(PAnsiChar Str);
PWideChar StrUpper(PWideChar Str);
```

File

SysUtils

Description

StrUpper converts Str (see page 3676) to uppercase and returns Str (see page 3676).

Note: If the source string contains international characters, use AnsiStrUpper (see page 4061) instead. If the source string is an AnsiString (long string), use UpperCase (see page 4311) (or AnsiUpperCase (see page 4062)) instead.

C++ Examples:

```
/*
The following example uses an edit box, two labels, and a
button on a form. When the button is clicked, the text in
the edit control is displayed in lower case in label1's
caption and upper case in label2's caption.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = StrLower(Edit1->Text.c_str());
  Label2->Caption = StrUpper(Edit1->Text.c_str());
}
```

Delphi Examples:

```
{
The following example uses an edit box, a label, and a
button on a form. When the button is clicked, the text in
the edit control is displayed in lower case in the label's
caption.
}
var
  S: array[0..20] of Char = 'A fUnNy StRiNg';

procedure TForm1.Button1Click(Sender: TObject);
var
  lower, upper : string;
begin
  lower := string(StrLower(S));
  upper := string(StrUpper(S));
  Canvas.TextOut(5, 10, lower + ' ' + upper);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Label1.Caption := S;
end;
```

See Also

AnsiUpperCase (see page 4062)

UpperCase (see page 4311)

StrLower (see page 4264)

37.3.239 SysUtils.Supports Function

Indicates whether a given object or interface supports a specified interface.

Pascal

```
function Supports(const Instance: IInterface; const IID: TGUID; out Intf): Boolean; overload;
function Supports(const Instance: TObject; const IID: TGUID; out Intf): Boolean; overload;
function Supports(const Instance: IInterface; const IID: TGUID): Boolean; overload;
function Supports(const Instance: TObject; const IID: TGUID): Boolean; overload;
function Supports(const AClass: TClass; const IID: TGUID): Boolean; overload;
```

C++

```
Boolean Supports(const IInterface Instance, const TGUID IID,  Intf);
Boolean Supports(const TObject * Instance, const TGUID IID,  Intf);
Boolean Supports(const IInterface Instance, const TGUID IID);
Boolean Supports(const TObject * Instance, const TGUID IID);
Boolean Supports(const TClass AClass, const TGUID IID);
```

File

SysUtils

Description

Call Supports to determine whether the object or interface specified by Instance, or the class specified by AClass, supports the interface identified by the IID parameter. If Instance supports the interface, Supports returns the interface as the Intf parameter and returns true. If AClass supports the interface, Supports does not return an interface, but still returns true. If the interface specified by IID is not supported, Supports returns false.

On the Win32 platform, to determine whether the interface specified by IID is supported, Supports calls the QueryInterface method of the supplied interface (or the interface of the supplied object). However, unlike calling QueryInterface directly, Supports lets you pass a nil (Delphi) or NULL (C++) value as the instance.

On the .NET platform, Supports uses the typecasting facilities of the .NET framework.

TComponent

37.3.240 SysUtils.SysErrorMessage Function

Converts OS error codes into strings.

Pascal

```
function SysErrorMessage(ErrorCode: Cardinal): string;
```

C++

```
UnicodeString SysErrorMessage(unsigned ErrorCode);
```

File

SysUtils

Description

SysErrorMessage returns an error message string that corresponds to the specified OS error code.

See Also

RaiseLastOSError (see page 4230)

EWin32Error (see page 3949)

37.3.241 SysUtils.SystemTimeToDateTime Function

Converts a system time value into a TDateTime (see page 3323) value.

Pascal

```
function SystemTimeToDateTime(const SystemTime: TSystemTime): TDateTime;
```

C++

```
TDateTime SystemTimeToDateTime(const TSystemTime SystemTime);
```

File

SysUtils

Description

Call SystemTimeToDateTime to convert a value from Windows 32's TSystemTime (Delphi) or _SYSTEMTIME (C++) API format to a TDateTime (see page 3323) value. SystemTimeToDateTime is available on Windows only.

C++ Examples:

```
/*
The following code retrieves the current date and time using
the Windows GetLocalTime API call, and converts this value
to a TDateTime value.
*/
TDateTime __fastcall GetCurrentDateTime()
{
  SYSTEMTIME SystemTime;
  GetLocalTime(&SystemTime);
  return SystemTimeToDateTime(SystemTime);
}
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateTimeToStr(GetCurrentDateTime());
}
```

Delphi Examples:

```
{
The following code retrieves the current date and time using
the Windows GetLocalTime API call, and converts this value
to a TDateTime value.
}
function GetCurrentDateTime: TDateTime;
var
  SystemTime: TSystemTime;
begin
  GetLocalTime(SystemTime);
  Result := SysUtils.SystemTimeToDateTime(SystemTime);
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.DateTimeToStr(GetCurrentDateTime);
end;
```

See Also

DateTimeToSystemTime (see page 4091)

37.3.242 SysUtils.TextPos Function

Pascal

```
function TextPos(Str: PAnsiChar; SubStr: PAnsiChar): PAnsiChar; overload;
```

C++

```
PAnsiChar TextPos(PAnsiChar Str, PAnsiChar SubStr);
```

File

SysUtils

Description

This is function SysUtils.TextPos.

37.3.243 SysUtils.TextPos Function

Pascal

```
function TextPos(Str: PWideChar; SubStr: PWideChar): PWideChar; overload;
```

C++

```
PWideChar TextPos(PWideChar Str, PWideChar SubStr);
```

File

SysUtils

Description

This is function SysUtils.TextPos.

37.3.244 SysUtils.TextToFloat Function

Converts a null-terminated string to a floating-point value.

Pascal

```
function TextToFloat(Buffer: PAnsiChar; var Value; ValueType: TFloatValue): Boolean; overload;
function TextToFloat(Buffer: PAnsiChar; var Value; ValueType: TFloatValue; const
FormatSettings: TFormatSettings): Boolean; overload;
function TextToFloat(Buffer: PWideChar; var Value; ValueType: TFloatValue): Boolean; overload;
function TextToFloat(Buffer: PWideChar; var Value; ValueType: TFloatValue; const
FormatSettings: TFormatSettings): Boolean; overload;
```

C++

```
Boolean TextToFloat(PAnsiChar Buffer,  Value, TFloatValue ValueType);
Boolean TextToFloat(PAnsiChar Buffer,  Value, TFloatValue ValueType, const TFormatSettings
FormatSettings);
Boolean TextToFloat(PWideChar Buffer,  Value, TFloatValue ValueType);
Boolean TextToFloat(PWideChar Buffer,  Value, TFloatValue ValueType, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Use TextToFloat to convert a null-terminated string, Buffer, to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The converted value is assigned to the Value parameter, which must be of type Extended or System::Currency (see page 3235), as indicated by the ValueType parameter.

TextToFloat returns true if the conversion is successful, or false if the Buffer does not contain a valid floating-point value.

The first form of TextToFloat is not thread-safe, because it uses localization information contained in global variables. The second form of TextToFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TextToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.245 SysUtils.Time Function

Returns the current time.

Pascal

```
function Time: TDateTime;
```

C++

```
TDateTime Time();
```

File

SysUtils

Description

Time and GetTime (see page 4209) return the current time as a TDateTime (see page 3323) value. The two functions are completely equivalent.

Note: Time clashes with an Xlib function of the same name. Use GetTime (see page 4209) in Linux and cross-platform code.

C++ Examples:

```
/*
This procedure displays the current time in the form's
caption every time the Timer's OnClick event fires, based upon
the Interval Property (default: 1000 = 1 sec)
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
```

```
  TDateTime DateTime = Time();  // store the current date and time
  AnsiString str = TimeToStr(DateTime); // convert the time to a string
  Caption = str;  // display the time on the form's caption
  // Note This could have been done with the following line of code:
  //  Caption = TimeToStr(Time());
}
```

Delphi Examples:

```
{
This procedure displays the current time in the form's
caption every time the Timer's OnClick event fires, based upon
the Interval Property (default: 1000 = 1 sec)
}
procedure TForm1.Timer1Timer(Sender: TObject);
var
  DateTime : TDateTime;
  str : string;
begin
  DateTime := Time;  // store the current date and time
  str := TimeToStr(DateTime); // convert the time into a string
  Caption := str;  // display the time on the form's caption
  { Note This could have been done with the following line of code:
    Caption := TimeToStr(Time); }
end;
```

Date (see page 4087)

DecodeTime (see page 4097)

Now (see page 4227)

TimeToStr (see page 4299)

37.3.246 SysUtils.TimeStampToDateTime Function

Converts a TTimeStamp (see page 4334) value into the corresponding TDateTime (see page 3323) value.

Pascal

```
function TimeStampToDateTime(const TimeStamp: TTimeStamp): TDateTime;
```

C++

```
TDateTime TimeStampToDateTime(const TTimeStamp TimeStamp);
```

File

SysUtils

Description

Call TimeStampToDateTime to convert a TTimeStamp (see page 4334) value into a TDateTime (see page 3323) value. TTimeStamp (see page 4334) values represent time as separate date and time values, where the date is the number of calendar days since the start of the current calendar (that is, January 1, 0001 would have a value of 1), and time is the number of milliseconds since midnight. TDateTime (see page 3323) values represent time as the number of days (including fractional days) that have elapsed since 12:00 am on December 30, 1899.

See Also

DateTimeToTimeStamp (see page 4092)

37.3.247 SysUtils.TimeStampToMSecs Function

Converts a TTimeStamp (see page 4334) value into an absolute number of milliseconds.

Pascal

```
function TimeStampToMSecs(const TimeStamp: TTimeStamp): Comp;
```

C++

```
Comp TimeStampToMSecs(const TTimeStamp TimeStamp);
```

File

SysUtils

Description

Call TimeStampToMSecs to convert a TTimeStamp (see page 4334) value, into the total number of milliseconds that comprise the Date (see page 4087) field plus the number of milliseconds given in the Time (see page 4297) field.

See Also

MSecsToTimeStamp (see page 4226)

TimeStampToDateTime (see page 4298)

37.3.248 SysUtils.TimeToStr Function

Returns a string that represents a TDateTime (see page 3323) value.

Pascal

```
function TimeToStr(const DateTime: TDateTime): string; overload;
function TimeToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings): string;
overload;
```

C++

```
UnicodeString TimeToStr(const TDateTime DateTime);
UnicodeString TimeToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

TimeToStr converts the Time (see page 4297) parameter, a TDateTime (see page 3323) value, to a string. The conversion uses the format specified by the LongTimeFormat (see page 4356) global variable or its TFormatSettings (see page 4326) equivalent. Change the format of the string by changing the values of some of the date and time variables.

The first form of TimeToStr is not thread-safe, because it uses localization information contained in global variables. The second form of TimeToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TimeToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

C++ Examples:

```
/*
```

```
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeTime((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text), (Word)StrToInt(Edit4->Text));
    Label1->Caption = TimeToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid hour, minute, second, or millisecond.");
  }
}
/*
This procedure displays the current time in the form's
caption every time the Timer's OnClick event fires, based upon
the Interval Property (default: 1000 = 1 sec)
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  TDateTime DateTime = Time();  // store the current date and time
  AnsiString str = TimeToStr(DateTime); // convert the time to a string
  Caption = str;  // display the time on the form's caption
  // Note This could have been done with the following line of code:
  //  Caption = TimeToStr(Time());
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeTime(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text), StrToInt(Edit4.Text));
  Label1.Caption := TimeToStr(MyDate);
end;
{
This procedure displays the current time in the form's
caption every time the Timer's OnClick event fires, based upon
the Interval Property (default: 1000 = 1 sec)
}
procedure TForm1.Timer1Timer(Sender: TObject);
var
  DateTime : TDateTime;
  str : string;
begin
  DateTime := Time;  // store the current date and time
  str := TimeToStr(DateTime); // convert the time into a string
  Caption := str;  // display the time on the form's caption
  { Note This could have been done with the following line of code:
    Caption := TimeToStr(Time); }
end;
```

See Also

StrToDateTime (see page 4281)

Time (see page 4297)

GetLocaleFormatSettings (see page 4206)

37.3.249 SysUtils.Trim Function

Trims leading and trailing spaces and control characters from a string.

Pascal

```
function Trim(const S: string): string; overload;
```

C++

```
UnicodeString Trim(const UnicodeString S);
```

File

SysUtils

Description

Trim removes leading and trailing spaces and control characters from the given string S.

In the 7-bit ASCII character set defined in ANSI X3.4-1977 (C0 and G0), "control codes" are defined as all characters whose code is between 0 and 31.

See Also

TrimLeft (see page 4301)

TrimRight (see page 4302)

37.3.250 SysUtils.TrimLeft Function

Trims leading spaces and control characters from a string.

Pascal

```
function TrimLeft(const S: string): string; overload;
```

C++

```
UnicodeString TrimLeft(const UnicodeString S);
```

File

SysUtils

Description

TrimLeft returns a copy of the string S with leading spaces and control characters removed.

See Also

Trim (see page 4301)

TrimRight (see page 4302)

37.3.251 SysUtils.TrimRight Function

Trims trailing spaces and control characters from a string.

Pascal

```
function TrimRight(const S: string): string; overload;
```

C++

```
UnicodeString TrimRight(const UnicodeString S);
```

File

SysUtils

Description

TrimRight returns a copy of the string S with trailing spaces and control characters removed.

See Also

TrimLeft (see page 4301)

Trim (see page 4301)

37.3.252 SysUtils.TryEncodeDate Function

Creates a TDateTime (see page 3323) value that represents a specified Year, Month, and Day.

Pascal

```
function TryEncodeDate(Year: Word; Month: Word; Day: Word; out Date: TDateTime): Boolean;
```

C++

```
Boolean TryEncodeDate(Word Year, Word Month, Word Day, TDateTime Date);
```

File

SysUtils

Description

TryEncodeDate generates a TDateTime (see page 3323) value from the values specified as the Year, Month, and Day parameters.

The year must be between 1 and 9999.

Valid Month values are 1 through 12.

Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month value. For example, the possible Day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the Year value specifies a leap year.

The Date (see page 4087) parameter returns the generated value if TryEncodeDate returns true.

If the specified values are not within range, TryEncodeDate returns false.

See Also

DateToStr (see page 4092)

DecodeDate (see page 4095)

TryEncodeTime (see page 4303)

TryEncodeDateTime

EncodeDate (see page 4105)

37.3.253 SysUtils.TryEncodeTime Function

Creates a TDateTime (see page 3323) value for a specified Hour, Min, Sec, and MSec.

Pascal

```
function TryEncodeTime(Hour: Word; Min: Word; Sec: Word; MSec: Word; out Time: TDateTime):
Boolean;
```

C++

```
Boolean TryEncodeTime(Word Hour, Word Min, Word Sec, Word MSec, TDateTime Time);
```

File

SysUtils

Description

EncodeTime (see page 4106) encodes the given hour, minute, second, and millisecond into a TDateTime (see page 3323) value.

Valid Hour values are 0 through 24. If Hour is 24, Min, Sec, and MSec must all be 0, and the resulting TDateTime (see page 3323) value represents midnight (12:00:00:000 AM) of the following day.

Valid Min and Sec values are 0 through 59.

Valid MSec values are 0 through 999.

The Time (see page 4297) paremter returns the generated TDateTime (see page 3323) value of the specifies values are in range. This value is a number between 0 and 1 (inclusive) that indicates the fractional part of a day given by the specified time or (if 1.0) midnight on the following day. The value 0 corresponds to midnight, 0.5 corresponds to noon, 0.75 corresponds to 6:00 pm, and so on.

See Also

DecodeTime (see page 4097)

TryEncodeDate (see page 4302)

TryEncodeDateTime

EncodeTime (see page 4106)

37.3.254 SysUtils.TryFloatToCurr Function

Converts a floating-point value to a System::Currency (see page 3235) value.

Pascal

```
function TryFloatToCurr(const Value: Extended; out AResult: Currency): Boolean;
```

C++

```
Boolean TryFloatToCurr(const Extended Value, Currency AResult);
```

File

SysUtils

Description

TryFloatToCurr converts the specified floating-point value into a System::Currency (see page 3235) value.

Value is the floating-point value to convert.

AResult returns the equivalent System::Currency (see page 3235) value, if possible.

If TryFloatToCurr is successful, it returns true. If Value is not within the valid range for a System::Currency (see page 3235) value, TryFloatToCurr returns false.

See Also

FloatToCurr (see page 4179)

37.3.255 SysUtils.TryFloatToDateTime Function

Converts a floating-point value to a TDateTime (see page 3323) value.

Pascal

```
function TryFloatToDateTime(const Value: Extended; out AResult: TDateTime): Boolean;
```

C++

```
Boolean TryFloatToDateTime(const Extended Value, TDateTime AResult);
```

File

SysUtils

Description

TryFloatToDateTime converts a floating-point value into the corresponding TDateTime (see page 3323) value.

Value is the floating-point value to convert.

AResult returns the corresponding TDateTime (see page 3323) value if possible.

TryFloatToDateTime returns true if the conversion was successful, false otherwise.

See Also

MinDateTime (see page 4384)

FloatToDateTime (see page 4179)

37.3.256 SysUtils.TryStrToBool Function

Converts a string to a Boolean value, with a Boolean success code.

Pascal

```
function TryStrToBool(const S: string; out Value: Boolean): Boolean; overload;
```

C++

```
Boolean TryStrToBool(const UnicodeString S, Boolean Value);
```

File

SysUtils

Description

TryStrToBool converts the string specified by S to a Boolean and sets Value to the result. If S can be converted to a number, TryStrToBool sets Value to false if that number is 0, true otherwise. If S can't be converted to a number, TryStrToBool returns true if S is any of the strings listed in TrueBoolStrs (see page 4363) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 4352) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 4363) or FalseBoolStrs (see page 4352), TryStrToBool returns false to indicate that the conversion failed. If the conversion is successful, TryStrToBool returns true.

Note: If you do not assign a value to TrueBoolStrs (see page 4363), it is treated as if it contains the single string 'True'. Similarly, if you do not assign a value to FalseBoolStrs (see page 4352), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 4363) and FalseBoolStrs (see page 4352) variables are undefined when an application starts. Any use of StrToBool (see page 4276), BoolToStr (see page 4066) or TryStrToBool will cause these variables to be initialised with the default values above.

See Also

BoolToStr (see page 4066)

TrueBoolStrs (see page 4363)

FalseBoolStrs (see page 4352)

StrToBool (see page 4276)

37.3.257 SysUtils.TryStrToCurr Function

Converts a string to a System::Currency (see page 3235) value, with a Boolean success code.

Pascal

```
function TryStrToCurr(const S: string; out Value: Currency): Boolean; overload;
function TryStrToCurr(const S: string; out Value: Currency; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToCurr(const UnicodeString S, Currency Value);
Boolean TryStrToCurr(const UnicodeString S, Currency Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToCurr to convert a string that represents a floating-point value to the corresponding System::Currency (see page 3235) value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 4350) global variable or its TFormatSettings (see page 4326) equivalent defines the character that is used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, TryStrToCurr returns Default.

The first form of TryStrToCurr is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.258 SysUtils.TryStrToDate Function

Converts a string to a TDateTime (see page 3323) value, with a Boolean success code.

Pascal

```
function TryStrToDate(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToDate(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToDate(const UnicodeString S, TDateTime Value);
Boolean TryStrToDate(const UnicodeString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToDate to parse a string that specifies a date. If S does not contain a valid date, TryStrToDate returns false.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 4349) global variable or its TFormatSettings (see page 4326) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 4358) global variable or its TFormatSettings (see page 4326) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of TryStrToDate is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToDate, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToDate, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.259 SysUtils.TryStrToDateTime Function

Converts a string to a TDateTime (see page 3323) value with a Boolean success code.

Pascal

```
function TryStrToDateTime(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToDateTime(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToDateTime(const UnicodeString S, TDateTime Value);
Boolean TryStrToDateTime(const UnicodeString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToDateTime to parse a string that specifies a date and time value. If S does not contain a valid date, TryStrToDateTime returns false.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 4364). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency (see page 3235) and Date (see page 4087)-Time (see page 4297) Formatting Variables" for more information.

The first form of TryStrToDateTime is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.260 SysUtils.TryStrToFloat Function

Converts a given string to a floating-point value with a boolean success code.

Pascal

```
function TryStrToFloat(const S: string; out Value: Extended): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Extended; const FormatSettings:
TFormatSettings): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Double): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Double; const FormatSettings:
TFormatSettings): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Single): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Single; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToFloat(const UnicodeString S, Extended Value);
Boolean TryStrToFloat(const UnicodeString S, Extended Value, const TFormatSettings
```

```
FormatSettings);
Boolean TryStrToFloat(const UnicodeString S, Double Value);
Boolean TryStrToFloat(const UnicodeString S, Double Value, const TFormatSettings
FormatSettings);
Boolean TryStrToFloat(const UnicodeString S, Single Value);
Boolean TryStrToFloat(const UnicodeString S, Single Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Use TryStrToFloat to convert a astring, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 4350) global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, TryStrToFloat returns Default.

TryStrToFloat places the result in Value, and returns true if the conversion was successful, false otherwise.

The first three forms of TryStrToFloat are not thread-safe, because they use localization information contained in global variables. The second three forms of TryStrToFloat, which are thread-safe, refer to localization information contained in the FormatSettings parameter. Before calling the thread-safe forms of TryStrToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.261 SysUtils.TryStrToInt Function

Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.

Pascal

```
function TryStrToInt(const S: string; out Value: Integer): Boolean; overload;
```

C++

```
Boolean TryStrToInt(const UnicodeString S, int Value);
```

File

SysUtils

Description

TryStrToInt converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number, which is assigned to Value. If S does not represent a valid number, TryStrToInt returns false; otherwise TryStrToInt returns true.

To accept decimal but not hexadecimal values in the input string, you may use code like this:

```
function TryDecimalStrToInt( const S: string; out Value: Integer): Boolean;
begin
   result := ( pos( '$', S ) = 0 ) and TryStrToInt( S, Value );
end;
```

See Also

IntToHex (see page 4215)

IntToStr (see page 4216)

StrToInt (see page 4286)

StrToIntDef (see page 4288)

37.3.262 SysUtils.TryStrToInt64 Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function TryStrToInt64(const S: string; out Value: Int64): Boolean; overload;
```

C++

```
Boolean TryStrToInt64(const UnicodeString S, Int64 Value);
```

File

SysUtils

Description

TryStrToInt64 converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number, which is assigned to Value. If S does not represent a valid number, TryStrToInt64 returns false; otherwise TryStrToInt64 returns true.

To accept decimal but not hexadecimal values in the input string, you may use code like this:

```
function TryDecimalStrToInt( const S: string; out Value: Integer): Boolean;
begin
   result := ( pos( '$', S ) = 0 ) and TryStrToInt( S, Value );
end;
```

See Also

IntToStr (see page 4216)

StrToInt (see page 4286)

StrToInt64 (see page 4287)

37.3.263 SysUtils.TryStrToTime Function

Converts a string to a TDateTime (see page 3323) value with an error default.

Pascal

```
function TryStrToTime(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToTime(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToTime(const UnicodeString S, TDateTime Value);
Boolean TryStrToTime(const UnicodeString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToTime to parse a string that specifies a time value. If S does not contain a valid time, TryStrToTime returns false.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 4363) global variable or its TFormatSettings (see page 4326) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of TryStrToTime is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.264 SysUtils.UIntToStr Function

Pascal

```
function UIntToStr(Value: Cardinal): string; overload;
```

C++

```
UnicodeString UIntToStr(unsigned Value);
```

File

SysUtils

Description

This is function SysUtils.UIntToStr.

37.3.265 SysUtils.UIntToStr Function

Pascal

```
function UIntToStr(Value: UInt64): string; overload;
```

C++

```
UnicodeString UIntToStr(UInt64 Value);
```

File

SysUtils

Description

This is function SysUtils.UIntToStr.

37.3.266 SysUtils.UnloadPackage Function

Unloads a package.

Pascal

```
procedure UnloadPackage(Module: HMODULE);
```

C++

```
UnloadPackage(HMODULE Module);
```

File

SysUtils

Description

Call UnloadPackage to unload a package that was loaded using the LoadPackage (see page 4224) function. UnloadPackage performs any finalization of units contained in the package and then unloads the package BPL.

See Also

LoadPackage (see page 4224)

37.3.267 SysUtils.UpperCase Function

Returns a copy of a string in uppercase.

Pascal

```
function UpperCase(const S: string): string; overload;
function UpperCase(const S: string; LocaleOptions: TLocaleOptions): string; overload;
```

C++

```
UnicodeString UpperCase(const UnicodeString S);
UnicodeString UpperCase(const UnicodeString S, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

UpperCase returns a copy of the string S, with the same text but with all 7-bit ASCII characters between 'a' and 'z' converted to uppercase. To convert 8-bit international characters, use AnsiUpperCase (see page 4062) instead.

C++ Examples:

```
/*
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int I = 0; I < ListBox1->Items->Count; I++)
    ListBox1->Items->Strings[I] = UpperCase(ListBox1->Items->Strings[I]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
```

```
}
```

Delphi Examples:

```
{
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to ListBox1.Items.Count -1 do
    ListBox1.Items[I] := SysUtils.UpperCase(ListBox1.Items[I]);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  Listbox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;
```

See Also

AnsiUpperCase (see page 4062)

LowerCase (see page 4225)

37.3.268 SysUtils.WideBytesOf Function

Converts an Unicode string to an array of bytes.

Pascal

```
function WideBytesOf(const Value: UnicodeString): TBytes;
```

C++

```
TBytes WideBytesOf(const UnicodeString Value);
```

File

SysUtils

Description

Call WideBytesOf to convert an Unicode string to an array of bytes. Strings are converted using the UTF-16 encoding, represented by the Unicode property of the TEncoding (see page 3969) class.

Unlike the BytesOf (see page 4068) routine, the resulting array of bytes contains two bytes per character in the input string.

See Also

BytesOf (see page 4068)

StringCodePage (see page 3676)

TEncoding (see page 3969)

37.3.269 SysUtils.WideCompareStr Function

Compares Unicode strings based on the current locale with case sensitivity.

Pascal

```
function WideCompareStr(const S1: WideString; const S2: WideString): Integer;
```

C++

```
int WideCompareStr(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideCompareStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters. with S1 set to 'a' and S2 set to 'A', WideCompareStr returns a value lsess than zero, while CompareStr (see page 4078) returns a value greater than zero.

See Also

WideCompareText (see page 4313)

WideSameStr (see page 4316)

37.3.270 SysUtils.WideCompareText Function

Compares Unicode strings based on the current locale without case sensitivity.

Pascal

```
function WideCompareText(const S1: WideString; const S2: WideString): Integer;
```

C++

```
int WideCompareText(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideCompareText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. WideCompareText returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

WideCompareStr (see page 4313)

WideSameText (see page 4316)

37.3.271 SysUtils.WideFmtStr Function

Assembles a formatted Unicode string using a format string and an array of arguments.

Pascal

```
procedure WideFmtStr(var Result: WideString; const Format: WideString; const Args: array of
const); overload;
procedure WideFmtStr(var Result: WideString; const Format: WideString; const Args: array of
const; const FormatSettings: TFormatSettings); overload;
```

C++

```
WideFmtStr(BSTR Result, const BSTR Format, const array of const Args);
WideFmtStr(BSTR Result, const BSTR Format, const array of const Args, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args into a Unicode string. Formatting is controlled by the format string Format (see page 4188); the results are returned in the parameter Result.

For information on the format strings, see Format (see page 4188) Strings.

The first form of WideFmtStr is not thread-safe, because it uses localization information contained in global variables. The second form of WideFmtStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFmtStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

See Also

GetLocaleFormatSettings (see page 4206)

37.3.272 SysUtils.WideFormat Function

Returns a formatted Unicode string assembled from a format string and an array of arguments.

Pascal

```
function WideFormat(const Format: WideString; const Args: array of const): WideString;
overload;
function WideFormat(const Format: WideString; const Args: array of const; const
FormatSettings: TFormatSettings): WideString; overload;
```

C++

```
BSTR WideFormat(const BSTR Format, const array of const Args);
BSTR WideFormat(const BSTR Format, const array of const Args, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args. Formatting is controlled by the format string Format (see page 4188); the results are returned in the function result as a Unicode string.

For information on the format strings, see Format (see page 4188) Strings.

The first form of WideFormat is not thread-safe, because it uses localization information contained in global variables. The second form of WideFormat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFormat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

See Also

GetLocaleFormatSettings (see page 4206)

37.3.273 SysUtils.WideFormatBuf Function

Formats the arguments from an array, placing the result in a buffer.

Pascal

```
function WideFormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const
Args: array of const): Cardinal; overload;
function WideFormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const
Args: array of const; const FormatSettings: TFormatSettings): Cardinal; overload;
```

C++

```
unsigned WideFormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array
of const Args);
unsigned WideFormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array
of const Args, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args. Formatting is controlled by the Unicode format string Format (see page 4188) (whose length is given by FmtLen); the results are returned in Buffer (whose length is given by BufLen). The function returns the number of Unicode characters in the formatted string.

Note: Both buffers contain wide (Unicode) characters. BufLen and FmtLen must specify the number of Unicode characters in their respective buffers, not the number of bytes.

For information on the format strings, see Format (see page 4188) Strings.

The first form of WideFormatBuf is not thread-safe, because it uses localization information contained in global variables. The second form of WideFormatBuf, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFormatBuf, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 4206).

37.3.274 SysUtils.WideLowerCase Function

Returns Unicode string converted to lower case.

Pascal

```
function WideLowerCase(const S: WideString): WideString;
```

C++

```
BSTR WideLowerCase(const BSTR S);
```

File

SysUtils

Description

WideLowerCase returns S converted to lower case. The conversion uses the current locale.

See Also

WideUpperCase (see page 4318)

LowerCase (see page 4225)

37.3.275 SysUtils.WideSameStr Function

Compares Unicode strings based on the current locale with case sensitivity.

Pascal

```
function WideSameStr(const S1: WideString; const S2: WideString): Boolean;
```

C++

```
Boolean WideSameStr(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideSameStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, Ffalse otherwise.

See Also

WideSameText (see page 4316)

WideCompareStr (see page 4313)

37.3.276 SysUtils.WideSameText Function

Compares Unicode strings based on the current locale without case sensitivity.

Pascal

```
function WideSameText(const S1: WideString; const S2: WideString): Boolean;
```

C++

```
Boolean WideSameText(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideSameText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

WideSameStr (see page 4316)

WideCompareText (see page 4313)

37.3.277 SysUtils.WideStrAlloc Function

Pascal

```
function WideStrAlloc(Size: Cardinal): PWideChar;
```

C++

```
PWideChar WideStrAlloc(unsigned Size);
```

File

SysUtils

Description

This is function SysUtils.WideStrAlloc.

37.3.278 SysUtils.WideStringOf Function

Pascal

```
function WideStringOf(const Value: TBytes): UnicodeString;
```

C++

```
UnicodeString WideStringOf(const TBytes Value);
```

File

SysUtils

Description

This is function SysUtils.WideStringOf.

37.3.279 SysUtils.WideUpperCase Function

Returns Unicode string converted to upper case.

Pascal

```
function WideUpperCase(const S: WideString): WideString;
```

C++

```
BSTR WideUpperCase(const BSTR S);
```

File

SysUtils

Description

WideUpperCase returns S converted to upper case. The conversion uses the current locale.

See Also

WideLowerCase (see page 4316)

UpperCase (see page 4311)

37.3.280 SysUtils.Win32Check Function

Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.

Pascal

```
function Win32Check(RetVal: BOOL): BOOL; platform;
```

C++

```
BOOL Win32Check(BOOL RetVal);
```

File

SysUtils

Description

Call Win32Check with the return value of a Windows API call that returns a Boolean to indicate success or failure. If the Windows API returns false (indicating failure), Win32Check calls RaiseLastOSError (see page 4230) to raise an exception. If the Windows function returns true, Win32Check returns true.

Win32Check is available on Windows only.

See Also

RaiseLastOSError (see page 4230)

37.3.281 SysUtils.WrapText Function

Splits a string into multiple lines as its length approaches a specified size.

Pascal

```
function WrapText(const Line: string; const BreakStr: string; const BreakChars: TSysCharSet;
MaxCol: Integer): string; overload;
function WrapText(const Line: string; MaxCol: Integer = 45): string; overload;
```

C++

```
UnicodeString WrapText(const UnicodeString Line, const UnicodeString BreakStr, const
TSysCharSet BreakChars, int MaxCol);
UnicodeString WrapText(const UnicodeString Line, int MaxCol = 45);
```

File

SysUtils

Description

WrapText scans a string for occurrences of any of the characters specified by nBreakChars and inserts a line-break, specified by BreakStr, at the last occurrence of a character in nBreakChars before MaxCol. Line is the text WrapText scans. MaxCol is the maximum line length.

If the BreakStr and nBreakChars parameters are omitted, WrapText searches for space, hyphen, or tab characters on which to break the line and inserts a carriage return/line feed pair (Windows) or a linefeed (Linux) at the break points.

WrapText does not insert a break into an embedded quoted string (both single quotes and double quotes are supported).

For example, the following call wraps the text into two lines at the last space character:

WrapText('The rain in Spain falls mainly on the plain.', #13#10, ['.',' ',#9,'-'], 42);

TSysCharSet (see page 4344) bchars

bchars << '.' << '-' << ' ';

WrapText("The rain in Spain falls mainly on the plain.", "\r\n", bchars, 42);

The result:

The rain in Spain falls mainly on the

plain.

37.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TFilenameCaseMatch (see page 4323)	TFilenameCaseMatch indicates how close a match was found to a specified file name.
	TFloatFormat (see page 4323)	TFloatFormat is an enumerated list of formatting codes for float functions.
	TFloatValue (see page 4325)	TFloatValue is an enumeration of two basic floating point types.
	TLocaleOptions (see page 4328)	TLocaleOptions defines a choice of dependent and independent locale options.
	TMbcsByteType (see page 4329)	TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).
	TNameType (see page 4329)	This is record SysUtils.TNameType.

Records

	Name	Description
	Int64Rec (see page 4320)	Int64Rec declares a utility record to provide access to the bytes of an Int64 value.
	LongRec (see page 4321)	LongRec declares a utility record to provide access to the bytes of a LongWord value.
	TCharSearch (see page 4321)	This is record SysUtils.TCharSearch.
	TExceptionRecord (see page 4322)	TExceptionRecord holds information about an exception in an application.
	TFloatRec (see page 4325)	TFloatRec declares a utility record that provides access to the attributes of a floating point number.
	TFormatSettings (see page 4326)	TFormatSettings defines a thread-safe string formatting context.
	TLangRec (see page 4327)	TLangRec declares a record used to describe a Windows locale.
	TSearchRec (see page 4330)	TSearchRec defines file information searched for by FindFirst (see page 4175) or FindNext (see page 4177).
	TSysLocale (see page 4333)	TSysLocale represents locale information.
	TThreadInfo (see page 4334)	This is record SysUtils.TThreadInfo.
	TTimeStamp (see page 4334)	TTimeStamp represents time and date values.
	WordRec (see page 4335)	WordRec declares a utility record to store high and low order bytes of a variable.

37.4.1 SysUtils.Int64Rec Record

Int64Rec declares a utility record to provide access to the bytes of an Int64 value.

Pascal

```
Int64Rec = packed record
  case Integer of
    0: (Hi: Cardinal;
        Lo: Cardinal;);
    1: (Cardinals: array [0..1] of Cardinal);
        Words: array [0..3] of Word);
        Bytes: array [0..7] of Byte););
end;
```

C++

```
struct Int64Rec {
  unsigned Hi;
  unsigned Lo;
  array [0..1] of Cardinal) Cardinals;
```

```
  array [0..3] of Word) Words;
  array [0..7] of Byte) Bytes;
};
```

File

SysUtils

Description

The Int64Rec type declares a utility record that stores 8 contiguous (packed) bytes of data. Int64Rec is used primarily for typecasting, where Int64 data needs to be dissected.

The 8 bytes may be accessed individually via the `Bytes` array, or as an array of 4 `Words`, or an array of 2 `Cardinals`. And finally, the value may be accessed via the `Hi` and `Lo` order Cardinals.

37.4.2 SysUtils.LongRec Record

LongRec declares a utility record to provide access to the bytes of a LongWord value.

Pascal

```
LongRec = packed record
  case Integer of
    0: (Hi: Word;
        Lo: Word;);
    1: (Words: array [0..1] of Word);
        Bytes: array [0..3] of Byte););
end;
```

C++

```
struct LongRec {
  Word Hi;
  Word Lo;
  array [0..1] of Word) Words;
  array [0..3] of Byte) Bytes;
};
```

File

SysUtils

Description

The LongRec type declares a utility record that stores 4 contiguous (packed) bytes of data. LongRec is used primarily for typecasting, where LongWord data needs to be dissected.

The 4 bytes may be accessed individually via the `Bytes` array, or as an array of 2 `Words`, or the value may be accessed via the `Hi` and `Lo` order Words.

37.4.3 SysUtils.TCharSearch Record

Pascal

```
TCharSearch = record
  ArrayPtr: PChar;
  MatchPtr: PChar;
end;
```

C++

```
struct TCharSearch {
  const char * ArrayPtr;
  const char * MatchPtr;
};
```

File

SysUtils

Description

This is record SysUtils.TCharSearch.

37.4.4 SysUtils.TExceptionRecord Record

TExceptionRecord holds information about an exception in an application.

Pascal

```
TExceptionRecord = record
  ExceptionCode: Cardinal;
  ExceptionFlags: Cardinal;
  ExceptionRecord: PExceptionRecord;
  ExceptionAddress: Pointer;
  NumberParameters: Cardinal;
  case Boolean of
    True: (ExceptionInformation: array [0..14] of Longint);
          False: (ExceptAddr: Pointer; ExceptObject: Pointer;);
end;
```

C++

```
struct TExceptionRecord {
  unsigned ExceptionCode;
  unsigned ExceptionFlags;
  PExceptionRecord ExceptionRecord;
  void * ExceptionAddress;
  unsigned NumberParameters;
  array [0..14] of Longint) ExceptionInformation;
  (ExceptAddr: Pointer; ExceptObject: Pointer False;
};
```

File

SysUtils

Description

TExceptionRecord holds information about an exception in an application. It is furnished by the Delphi exception handling process.

The record comprises the following elements :

Element	Meaning
ExceptionCode	The exception code, such as EXCEPTION_INT_OVERFLOW.
ExceptionFlags	Comprises one flag : EXCEPTION_NONCONTINUABLE_EXCEPTION. If 0, then the exception is allowed to continue.
ExceptionRecord	Pointer to subsequent exception records, if any.
ExceptionAddress	Address where the exception occured.

`NumberParameters`	Number of elements in the `ExceptionInformation` array.
`ExceptionInformation`	An array of numbers that describe the exception.

37.4.5 SysUtils.TFilenameCaseMatch Enumeration

TFilenameCaseMatch indicates how close a match was found to a specified file name.

Pascal

```
TFilenameCaseMatch = (
  mkNone,
  mkExactMatch,
  mkSingleMatch,
  mkAmbiguous
);
```

C++

```
enum TFilenameCaseMatch {
  mkNone,
  mkExactMatch,
  mkSingleMatch,
  mkAmbiguous
};
```

File

SysUtils

Description

These are the possible values of the TFilenameCaseMatch type:

Value	Meaning
mkNone	No actual file matches the file name.
mkExactMatch	A single file matches the file name.
mkSingleMatch	No file matches the file name, but a single match can be found by ignoring differences in case.
mkAmbiguous	No file matches the file name, but two or more matches can be found by ignoring differences in case.

37.4.6 SysUtils.TFloatFormat Enumeration

TFloatFormat is an enumerated list of formatting codes for float functions.

Pascal

```
TFloatFormat = (
  ffGeneral,
  ffExponent,
  ffFixed,
  ffNumber,
  ffCurrency
);
```

C++

```
enum TFloatFormat {
  ffGeneral,
  ffExponent,
  ffFixed,
  ffNumber,
  ffCurrency
};
```

File

SysUtils

Description

TFloatFormat defines an enumerated list of formatting codes for the float functions.

Format (see page 4188)	Defines
ffGeneral	General number format. The value is converted to the shortest possible decimal string using scientific format. Trailing zeros are removed from the resulting string.
ffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits before the exponent in the resulting string (including the one before the decimal point) is given by the Precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The Digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
ffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffFixed with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.
ffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The ffNumber format corresponds to the ffFixed format, except that the resulting string contains thousandth separators. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffNumber with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.
ffCurrency	Currency (see page 3235) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString (see page 4349), CurrencyFormat (see page 4348), NegCurrFormat (see page 4356), ThousandSeparator (see page 4362), and DecimalSeparator (see page 4350) global variables, all of which are initialized from the System::Currency (see page 3235) Format (see page 4188) in the International section of the Windows Control Panel. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffCurrency with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.

FloatToTextFmt (see page 4184)

37.4.7 SysUtils.TFloatRec Record

TFloatRec declares a utility record that provides access to the attributes of a floating point number.

Pascal

```
TFloatRec = packed record
  Exponent: Smallint;
  Negative: Boolean;
  Digits: array[0..20] of AnsiChar;
end;
```

C++

```
struct TFloatRec {
  Smallint Exponent;
  Boolean Negative;
  array[0..20] of AnsiChar Digits;
};
```

File

SysUtils

Description

The TFloatRec type declares a record that holds the attributes of a floating point number. The record makes the attributes accessible for easy formatting or specialised numerical processing.

`Exponent` holds the floating point number exponent value.

`Negative` is set true if the floating point number has a negative value.

`Digits` is a 21 element array of numeric characters representing the floating point number mantissa value : its significant digits.

TFloatRec is used by the FloatToDecimal (see page 4180) function to hold the results of the conversion of a floating point value to its decimal representation.

See Also

FloatToDecimal (see page 4180)

37.4.8 SysUtils.TFloatValue Enumeration

TFloatValue is an enumeration of two basic floating point types.

Pascal

```
TFloatValue = (
  fvExtended,
  fvCurrency
);
```

C++

```
enum TFloatValue {
  fvExtended,
  fvCurrency
};
```

File

SysUtils

Description

TFloatValue is used by a number of data conversion routines, where it is used to indicate what type of floating point number is being handled.

These are the possible values of the TFloatValue type:

Value	Meaning
fvExtended	An extended floating point number. These are the highest capacity floating point numbers in Delphi : they support the largest mantissa and exponent sizes.
fvDecimal	A decimal floating point number. Decimals have a fixed exponent size of 4 digits.

See Also

FloatToDecimal (see page 4180)

FloatToText (see page 4183)

FloatToTextFmt (see page 4184)

TextToFloat (see page 4296)

37.4.9 SysUtils.TFormatSettings Record

TFormatSettings defines a thread-safe string formatting context.

Pascal

```
TFormatSettings = record
  CurrencyFormat: Byte;
  NegCurrFormat: Byte;
  ThousandSeparator: Char;
  DecimalSeparator: Char;
  CurrencyDecimals: Byte;
  DateSeparator: Char;
  TimeSeparator: Char;
  ListSeparator: Char;
  CurrencyString: string;
  ShortDateFormat: string;
  LongDateFormat: string;
  TimeAMString: string;
  TimePMString: string;
  ShortTimeFormat: string;
  LongTimeFormat: string;
  ShortMonthNames: array[1..12] of string;
  LongMonthNames: array[1..12] of string;
  ShortDayNames: array[1..7] of string;
  LongDayNames: array[1..7] of string;
  TwoDigitYearCenturyWindow: Word;
end;
```

C++

```
struct TFormatSettings {
  Byte CurrencyFormat;
  Byte NegCurrFormat;
  Char ThousandSeparator;
```

```
    Char DecimalSeparator;
    Byte CurrencyDecimals;
    Char DateSeparator;
    Char TimeSeparator;
    Char ListSeparator;
    UnicodeString CurrencyString;
    UnicodeString ShortDateFormat;
    UnicodeString LongDateFormat;
    UnicodeString TimeAMString;
    UnicodeString TimePMString;
    UnicodeString ShortTimeFormat;
    UnicodeString LongTimeFormat;
    array[1..12] of string ShortMonthNames;
    array[1..12] of string LongMonthNames;
    array[1..7] of string ShortDayNames;
    array[1..7] of string LongDayNames;
    Word TwoDigitYearCenturyWindow;
  };
```

File

SysUtils

Description

TFormatSettings defines a data structure containing locale information used by string formatting routine. Each member of TFormatSettings is equivalent to the global variable with the same name. A variable of type TFormatSettings defines a thread-safe context that formatting functions can use in place of the default global context, which is not thread-safe.

To create and use the thread-safe environment defined by TFormatSettings, follow these steps:

Define a variable of type TFormatSettings

Call GetLocaleFormatSettings (see page 4206) to populate the TFormatSettings variable with locale information.

Pass the TFormatSettings variable as the last parameter of the string formatting routine.

Each routine that accepts a TFormatSettings parameter is thread-safe, and is an overload of an equivalent function that refers to the global formatting variables.

37.4.10 SysUtils.TLangRec Record

TLangRec declares a record used to describe a Windows locale.

Pascal

```
  TLangRec = packed record
    FName: string;
    FLCID: LCID;
    FExt: string;
  end;
```

C++

```
  struct TLangRec {
    UnicodeString FName;
    LCID FLCID;
    UnicodeString FExt;
  };
```

File

SysUtils

Description

The TLangRec type declares a record that holds the attributes of a Windows language. The record is principally used internally by TLanguages (see page 3987).

`FName` holds the Windows locale name.

`FLCID` holds the local id for the Windows locale.

`FExt` holds the recommended filename extension for the Windows locale.

See Also

TLanguages (see page 3987)

37.4.11 SysUtils.TLocaleOptions Enumeration

TLocaleOptions defines a choice of dependent and independent locale options.

Pascal

```
TLocaleOptions = (
  loInvariantLocale,
  loUserLocale
);
```

C++

```
enum TLocaleOptions {
  loInvariantLocale,
  loUserLocale
};
```

File

SysUtils

Description

The TLocaleOptions type is an enumeration of two choices for dealing with the operating locale of an application. This Microsoft Windows specific type is used in a number of string handling routines, where the locale language may have a bearing on the routine.

Format (see page 4188)	Defines
loInvariantLocale	Use this option where a consistent inter-application operation is desired, inedependent of the actual locale.
loUserLocale	Use this option where the user locale is taken into account.

See Also

CompareStr (see page 4078)

CompareText (see page 4079)

LowerCase (see page 4225)

SameStr (see page 4239)

SameText (see page 4239)

UpperCase (see page 4311)

37.4.12 SysUtils.TMbcsByteType Enumeration

TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).

Pascal

```
TMbcsByteType = (
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
);
```

C++

```
enum TMbcsByteType {
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
};
```

File

SysUtils

Description

TMbcsByteType represents the possible return values of the ByteType (see page 4070) and StrByteType (see page 4242) functions. Possible values are as follows:

Values	Meaning
mbSingleByte	The char is used to represent an entire character in the string. The value of Char can not be included in the LeadBytes (see page 4354) set.
mbLeadByte	The char is used to represent the first byte of a multi-byte character. The value of Char must be included in the LeadBytes (see page 4354) set.
mbTrailByte	The char is used to represent one of the trailing bytes in a multi-byte character. There are no a priori restrictions on the value of char.

See Also

ByteType (see page 4070)

LeadBytes (see page 4354)

StrByteType (see page 4242)

37.4.13 SysUtils.TNameType Enumeration

Pascal

```
TNameType = (
  ntContainsUnit,
  ntRequiresPackage,
  ntDcpBpiName
);
```

C++

```
enum TNameType {
  ntContainsUnit,
  ntRequiresPackage,
  ntDcpBpiName
};
```

File

SysUtils

Description

This is record SysUtils.TNameType.

37.4.14 SysUtils.TSearchRec Record

TSearchRec defines file information searched for by FindFirst (see page 4175) or FindNext (see page 4177).

Pascal

```
TSearchRec = record
  Time: Integer;
  Size: Int64;
  Attr: Integer;
  Name: TFileName;
  ExcludeAttr: Integer;
  FindHandle: THandle platform;
  FindData: TWin32FindData platform;
end;
```

C++

```
struct TSearchRec {
  int Time;
  Int64 Size;
  int Attr;
  TFileName Name;
  int ExcludeAttr;
  THandle platform FindHandle;
  TWin32FindData platform FindData;
};
```

File

SysUtils

Description

The TSearchRec type defines file information searched for by a FindFirst (see page 4175) or FindNext (see page 4177) function call. If a file is found, the fields of the TSearchRec type parameter are modified to specify the found file.

Attr represents the file attributes of the file. Test Attr against the following attribute constants or values to determine if a file attribute matches the file's properties.

Note: On Windows, attribute constants map directly to DOS file attributes.

Note: On Linux, attribute constants map to sets of file characteristics; use the Mode field to access the specific permission mode.

Constant	Value	Description	Linux Meaning
faReadOnly (see page 4374)	1	Read (see page 3634)-only files	Current user does not have write access.
faHidden (see page 4373)	2	Hidden files	File name begins with ".".
faSysFile (see page 4375)	4	System (see page 3159) files	File is socket, symbolic link, device file, or FIFO.
faVolumeID (see page 4376)	8	Volume ID files	Not used.
faDirectory (see page 4372)	16	Directory files	Directory.
faArchive (see page 4372)	32	Archive files	Not used.
faSymLink (see page 4375)	64	Symbolic link	File is a symbolic link.
faAnyFile (see page 4371)	71	Any file	Any file.

The faReadOnly (see page 4374) constant has the same name as the enumerated value that is defined by the TFieldAttribute type. If both the SysUtils (see page 3901) and the Db units are used in your source files, you must disambiguate by specifying the unit to qualify the use of faReadOnly (see page 4374). That is, write SysUtils.faReadOnly (see page 4374) (Delphi) or SysUtils::faReadOnly (see page 4374) (C++).

To test for an attribute, combine the value of the Attr field with the attribute constant with the and operator. If the file has that attribute, the result will be greater than 0. For example, if the found file is a hidden file, the following expression will evaluate to true:

(SearchRec.Attr and faHidden (see page 4373)) <> 0.

(SearchRec.Attr & faHidden (see page 4373)) != 0.

Time contains the time stamp of the file. It can be converted to a TDateTime (see page 3323) value using FileDateToDateTime (see page 4130).

Size contains the size of the file in bytes.

Name contains the base file name, including extension.

FindHandle is an internal handle used to track find state.

FindData (Windows only) contains additional information such as the file creation time, last access time, and both the long and short file names.

Mode (Linux only) is the file's permission mask.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
```

```
directory. Click at least one box before clicking the button.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;
  iAttributes |= faDirectory * CheckBox5->Checked;
  iAttributes |= faArchive * CheckBox6->Checked;
  iAttributes |= faAnyFile * CheckBox7->Checked;
  StringGrid1->RowCount = 0;
  if (FindFirst(Edit1->Text, iAttributes, sr) == 0)
  {
    do
    {
      if ((sr.Attr & iAttributes) == sr.Attr)
      {
        StringGrid1->RowCount = StringGrid1->RowCount + 1;
        StringGrid1->Cells[1][StringGrid1->RowCount-1] = sr.Name;
        StringGrid1->Cells[2][StringGrid1->RowCount-1] = IntToStr(sr.Size);
      }
    } while (FindNext(sr) == 0);
    FindClose(sr);
  }
}
```

Delphi Examples:

```
{
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory. Click at least one box before clicking the button.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sr: TSearchRec;
  FileAttrs: Integer;
begin
  StringGrid1.RowCount := 1;
  if CheckBox1.Checked then
    FileAttrs := faReadOnly
  else
    FileAttrs := 0;
  if CheckBox2.Checked then
    FileAttrs := FileAttrs + faHidden;
  if CheckBox3.Checked then
    FileAttrs := FileAttrs + faSysFile;
  if CheckBox4.Checked then
    FileAttrs := FileAttrs + faVolumeID;
  if CheckBox5.Checked then
    FileAttrs := FileAttrs + faDirectory;
  if CheckBox6.Checked then
    FileAttrs := FileAttrs + faArchive;
  if CheckBox7.Checked then
    FileAttrs := FileAttrs + faAnyFile;
  with StringGrid1 do
```

```
    begin
      RowCount := 0;
      if SysUtils.FindFirst(Edit1.Text, FileAttrs, sr) = 0 then
      begin
        repeat
          if (sr.Attr and FileAttrs) = sr.Attr then
          begin
          RowCount := RowCount + 1;
          Cells[1,RowCount-1] := sr.Name;
          Cells[2,RowCount-1] := IntToStr(sr.Size);
          end;
        until FindNext(sr) <> 0;
        FindClose(sr);
      end;
    end;
  end;
```

37.4.15 SysUtils.TSysLocale Record

TSysLocale represents locale information.

Pascal

```
  TSysLocale = packed record
    DefaultLCID: Integer;
    PriLangID: Integer;
    SubLangID: Integer;
    FarEast: Boolean;
    MiddleEast: Boolean;
  end;
```

C++

```
  struct TSysLocale {
    int DefaultLCID;
    int PriLangID;
    int SubLangID;
    Boolean FarEast;
    Boolean MiddleEast;
  };
```

File

SysUtils

Description

The TSysLocale type represents a locale. The locale determines how dates and times are formatted, how items are alphabetically sorted, and how strings are compared.

The **DefaultLCID** field represents the locale identifier. This is a 32-bit value that specifies a default sort order and a default language identifier.

The **PirLangID** field specifies the primary type of the language identifier. This is one of the constants that identify a language group, such as **LANG_ENGLISH** or **LANG_FRENCH**.

The **SubLangID** field specifies the subtype of the language identifier. This is one of the constants that identify a language subgroup, such as **SUBLANG_ENGLISH_US** or **SUBLANG_FRENCH_CANADIAN**.

FarEast is true or nonzero if User32.dll supports DBCS; false or zero otherwise. In other words, **FarEast** is true or nonzero if the double-byte character-set (DBCS) version of User.exe is installed; false or zero otherwise.

MiddleEast is true if the system is enabled for Hebrew and Arabic languages; false otherwise.

37.4.16 SysUtils.TThreadInfo Record

Pascal

```
TThreadInfo = record
  Next: PThreadInfo;
  ThreadID: Cardinal;
  Active: Integer;
  RecursionCount: Cardinal;
end;
```

C++

```
struct TThreadInfo {
  PThreadInfo Next;
  unsigned ThreadID;
  int Active;
  unsigned RecursionCount;
};
```

File

SysUtils

Description

This is record SysUtils.TThreadInfo.

37.4.17 SysUtils.TTimeStamp Record

TTimeStamp represents time and date values.

Pascal

```
TTimeStamp = record
  Time: Integer;
  Date: Integer;
end;
```

C++

```
struct TTimeStamp {
  int Time;
  int Date;
};
```

File

SysUtils

Description

Use TTimeStamp to represent date and time values when a great deal of accuracy is required for the time portion. When the time values do not need to be precise to the millisecond, use the more compact TDateTime (see page 3323) representation. If additional precision is needed, use TSQLTimeStamp (but do NOT assign it to a Variant (see page 3421)).

The Time field indicates the number of milliseconds that have elapsed since midnight.

The Date field indicates the number of calendar days since the start of the calendar (the number of days since 1/1/0001 plus one).

See Also

DateTimeToTimeStamp (see page 4092)

TDateTime (see page 3787)

TimeStampToDateTime (see page 4298)

TSQLTimeStamp (see page 1737)

37.4.18 SysUtils.WordRec Record

WordRec declares a utility record to store high and low order bytes of a variable.

Pascal

```
WordRec = packed record
  case Integer of
    0: (Hi: Byte;
        Lo: Byte;);
    1: (Bytes: array [0..1] of Byte););
end;
```

C++

```
struct WordRec {
  Byte Hi;
  Byte Lo;
  array [0..1] of Byte) Bytes;
};
```

File

SysUtils

Description

The WordRec type declares a utility record that stores the high and low order bytes of the specified variable as type Byte. WordRec is used primarily for typecasting.

37.5 Types

The following table lists types in this documentation.

Types

Name	Description
ExceptClass (see page 4336)	ExceptClass declares an Exception (see page 3949) class.
PByteArray (see page 4337)	PByteArray declares a pointer to an array of Bytes.
PDayTable (see page 4337)	PDayTable is a pointer to a TDayTable (see page 4340) type.
PExceptionRecord (see page 4338)	PExceptionRecord is a pointer to a TExceptionRecord (see page 4322) type.
PThreadInfo (see page 4338)	This is type SysUtils.PThreadInfo.
PWordArray (see page 4338)	PWordArray is a pointer to a TWordArray (see page 4345) type.
TByteArray (see page 4339)	TByteArray declares an array of Bytes.
TBytes (see page 4339)	TBytes declares an array of Bytes.
TCharArray (see page 4340)	This is type SysUtils.TCharArray.
TDayTable (see page 4340)	TDayTable is used to hold the number of days of each month of a year.
TFileName (see page 4340)	TFileName is a string that represents a file name.
TFunc (see page 4341)	This is type SysUtils.TFunc.
TIntegerSet (see page 4341)	TIntegerSet is used to treat an integer as a set of bits.
TMREWSync (see page 4341)	TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 3997).
TPackageInfoProc (see page 4342)	TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 4209).
TPredicate (see page 4342)	This is type SysUtils.TPredicate.
TProc (see page 4343)	This is type SysUtils.TProc.
TProcedure (see page 4343)	TProcedure declares a procedure.
TReplaceFlags (see page 4343)	TReplaceFlags indicates how to perform a search-and-replace operation
TSysCharSet (see page 4344)	TSysCharSet is a set or characters.
TTerminateProc (see page 4344)	TTerminateProc is a call-back function invoked by CallTerminateProcs (see page 4071).
TValidatePackageProc (see page 4345)	TValidatePackageProc is a call-back function invoked by LoadPackage (see page 4224).
TWordArray (see page 4345)	TWordArray declares an array of Words.

37.5.1 SysUtils.ExceptClass Type

ExceptClass declares an Exception (see page 3949) class.

Pascal

```
ExceptClass = class of Exception;
```

C++

```
Exception ExceptClass;
```

File

SysUtils

Description

The ExceptClass type declares an Exception (see page 3949) class. This class encapsulates the fundamental properties and methods for all exceptions. Use Exception (see page 3949) as the base class for creating custom exceptions.

See Also

Exception (see page 3949)

37.5.2 SysUtils.PByteArray Type

PByteArray declares a pointer to an array of Bytes.

Pascal

```
PByteArray = ^TByteArray;
```

C++

```
^TByteArray PByteArray;
```

File

SysUtils

Description

The PByteArray type declares a pointer to a TByteArray (see page 4339) : a static array of Bytes. The array size is 32,768 (2**15) elements.

Note: Static arrays are declared with an immutable size.

See Also

TByteArray (see page 4339)

37.5.3 SysUtils.PDayTable Type

PDayTable is a pointer to a TDayTable (see page 4340) type.

Pascal

```
PDayTable = ^TDayTable;
```

C++

```
^TDayTable PDayTable;
```

File

SysUtils

Description

The TDayTable (see page 4340) type points to a TDayTable (see page 4340) variable. TDayTable (see page 4340) declares a static array of 12 Words. It is principally used by the MonthDays (see page 4386) constant to hold the number of days in a month for normal and leap years.

Note: Static arrays are declared with an immutable size.

See Also

TDayTable (see page 4340)

37.5.4 SysUtils.PExceptionRecord Type

PExceptionRecord is a pointer to a TExceptionRecord (see page 4322) type.

Pascal

```
PExceptionRecord = ^TExceptionRecord;
```

C++

```
^TExceptionRecord PExceptionRecord;
```

File

SysUtils

Description

The PExceptionRecord type points to a TExceptionRecord (see page 4322) variable. TExceptionRecord (see page 4322) holds information about an exception in an application.

See Also

TExceptionRecord (see page 4322)

37.5.5 SysUtils.PThreadInfo Type

Pascal

```
PThreadInfo = ^TThreadInfo;
```

C++

```
^TThreadInfo PThreadInfo;
```

File

SysUtils

Description

This is type SysUtils.PThreadInfo.

37.5.6 SysUtils.PWordArray Type

PWordArray is a pointer to a TWordArray (see page 4345) type.

Pascal

```
PWordArray = ^TWordArray;
```

C++

```
^TWordArray PWordArray;
```

File

SysUtils

Description

The PWordArray type points to a TWordArray (see page 4345) variable. The TWordArray (see page 4345) type declares a static array of Words. The array size is 16,384 (2**14) elements.

See Also

TWordArray (see page 4345)

37.5.7 SysUtils.TByteArray Type

TByteArray declares an array of Bytes.

Pascal

```
TByteArray = array[0..32767] of Byte;
```

C++

```
array[0..32767] of Byte TByteArray;
```

File

SysUtils

Description

The TByteArray type declares a static array of Bytes. The array size is 32,768 (2**15) elements.

Note: Static arrays are declared with an immutable size.

37.5.8 SysUtils.TBytes Type

TBytes declares an array of Bytes.

Pascal

```
TBytes = array of Byte;
```

C++

```
array of Byte TBytes;
```

File

SysUtils

Description

The TBytes type declares a dynamic array of Bytes.

Note: Dynamic arrays have no intrinsic size. SetLength (see page 3657) is used to allocate storage for the defined array size desired. Dynamic arrays are always integer-indexed, starting at 0.

37.5.9 SysUtils.TCharArray Type

Pascal

```
TCharArray = array of Char;
```

C++

```
array of Char TCharArray;
```

File

SysUtils

Description

This is type SysUtils.TCharArray.

37.5.10 SysUtils.TDayTable Type

TDayTable is used to hold the number of days of each month of a year.

Pascal

```
TDayTable = array[1..12] of Word;
```

C++

```
array[1..12] of Word TDayTable;
```

File

SysUtils

Description

The TDayTable type declares a static array of 12 Words. It is principally used by the MonthDays (see page 4386) constant to hold the number of days in a month for normal and leap years.

Note: Static arrays are declared with an immutable size.

See Also

MonthDays (see page 4386)

37.5.11 SysUtils.TFileName Type

TFileName is a string that represents a file name.

Pascal

```
TFileName = type string;
```

C++

```
type string TFileName;
```

File

SysUtils

Description

Use TFileName to represent strings that are only used for file names.

37.5.12 SysUtils.TFunc Type

Pascal

```
TFunc<T1,T2,T3,T4,TResult> = reference to function (Arg1: T1; Arg2: T2; Arg3: T3; Arg4: T4):
TResult;
```

C++

```
reference to function (Arg1: T1; Arg2: T2; Arg3: T3; Arg4: T4): TResult TFunc;
```

File

SysUtils

Description

This is type SysUtils.TFunc.

37.5.13 SysUtils.TIntegerSet Type

TIntegerSet is used to treat an integer as a set of bits.

Pascal

```
TIntegerSet = set of 0..SizeOf(Integer) * 8 - 1;
```

C++

```
0..SizeOf(Integer) * 8 - 1 TIntegerSet;
```

File

SysUtils

Description

Type TIntegerSet = set of 0 .. Integer-bit-size-1;

Assuming that an integer is 4 bytes (=32 bits), the set will 0 .. 31. TIntegerSet is typically used to treat an integer as a set of bits. To do so, an integer variable value is assigned to a TIntegerSet variable using TIntegerSet casting.

37.5.14 SysUtils.TMREWSync Type

TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 3997).

Pascal

```
TMREWSync = TMultiReadExclusiveWriteSynchronizer;
```

C++

```
TMultiReadExclusiveWriteSynchronizer TMREWSync;
```

File

SysUtils

Description

The TMREWSync type is used instead of TMultiReadExclusiveWriteSynchronizer (see page 3997).

Note: TMultiReadExclusiveWriteSynchronizer (see page 3997) is a class that minimizes thread serialization to gain read access to a resource shared among threads while still providing complete exclusivity to callers needing write access to the shared resource.

37.5.15 SysUtils.TPackageInfoProc Type

TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 4209).

Pascal

```
TPackageInfoProc = procedure (const Name: string; NameType: TNameType; Flags: Byte; Param:
Pointer);
```

C++

```
(const Name: string; NameType: TNameType; Flags: Byte; Param: Pointer) ( TPackageInfoProc)();
```

File

SysUtils

Description

The TPackageInfoProc type declares the procedure that is invoked by GetPackageInfo (see page 4209) to retrieve package information. It is called for every unit in the package, and every package required by that package.

The following table lists the information provided in these call back invocations of your TPackageInfoProc variable.

Parameter name	Parameter value
Name	Unit or required package name
NameType	Indicates if this call is for a contained unit, required package or DcpBpiName.
Flags	
Param	

See Also

GetPackageInfo (see page 4209)

37.5.16 SysUtils.TPredicate Type

Pascal

```
TPredicate<T> = reference to function (Arg1: T): Boolean;
```

C++

```
reference to function (Arg1: T): Boolean TPredicate;
```

File

SysUtils

Description

This is type SysUtils.TPredicate.

37.5.17 SysUtils.TProc Type

Pascal

```
TProc<T1,T2,T3,T4> = reference to procedure (Arg1: T1; Arg2: T2; Arg3: T3; Arg4: T4);
```

C++

```
reference to procedure (Arg1: T1; Arg2: T2; Arg3: T3; Arg4: T4) TProc;
```

File

SysUtils

Description

This is type SysUtils.TProc.

37.5.18 SysUtils.TProcedure Type

TProcedure declares a procedure.

Pascal

```
TProcedure = procedure;
```

C++

```
( TProcedure)();
```

File

SysUtils

Description

Use the TProcedure type as a generic Procedure pointer.

37.5.19 SysUtils.TReplaceFlags Type

TReplaceFlags indicates how to perform a search-and-replace operation

Pascal

```
TReplaceFlags = set of (rfReplaceAll, rfIgnoreCase);
```

C++

```
(rfReplaceAll, rfIgnoreCase) TReplaceFlags;
```

File

SysUtils

Description

TReplaceFlags is a set of flags that govern how to locate and replace a substring within a string. This set can contain the following values:

Value	Meaning
rfReplaceAll	Replace all occurrences. If this flag is not present, only the first occurrence of the target substring is replaced.
rfIgnoreCase	Match occurrences of the substring case-insensitively. If this flag is not present, only case-sensitive matches are considered.

See Also

StringReplace (see page 4253)

37.5.20 SysUtils.TSysCharSet Type

TSysCharSet is a set or characters.

Pascal

```
TSysCharSet = set of AnsiChar;
```

C++

```
AnsiChar TSysCharSet;
```

File

SysUtils

Description

TSysCharSet is a set containing ANSI characters. TSysCharSet is useful when passing a set of characters to various functions that require them. TSysCharSet is primarily used in the CharInSet (see page 4073) routine, which detects whether a given character is contained within the set.

Note: You cannot use TSysCharSet to group Unicode characters. This means that TSysCharSet cannot be used to check whether an Unicode character is a part of TSysCharSet.

See Also

CharInSet (see page 4073)

TCharacter

37.5.21 SysUtils.TTerminateProc Type

TTerminateProc is a call-back function invoked by CallTerminateProcs (see page 4071).

Pascal

```
TTerminateProc = function : Boolean;
```

C++

```
: Boolean ( TTerminateProc)();
```

File

SysUtils

Description

CallTerminateProcs (see page 4071) is called internally when an application is about to terminate. It invokes TTerminateProc for each defined termination function. Termination functions are added using AddTerminateProc (see page 4048). The application only terminates if all termination routines return true.

See Also

AddTerminateProc (see page 4048)

CallTerminateProcs (see page 4071)

37.5.22 SysUtils.TValidatePackageProc Type

TValidatePackageProc is a call-back function invoked by LoadPackage (see page 4224).

Pascal

```
TValidatePackageProc = function (Module: HMODULE): Boolean;
```

C++

```
(Module: HMODULE): Boolean ( TValidatePackageProc)();
```

File

SysUtils

Description

TValidatePackageProc is optionally invoked by LoadPackage (see page 4224) when a package is loaded. The package is not loaded if TValidatePackageProc determines that it is not valid and hence returns false.

See Also

LoadPackage (see page 4224)

37.5.23 SysUtils.TWordArray Type

TWordArray declares an array of Words.

Pascal

```
TWordArray = array[0..16383] of Word;
```

C++

```
array[0..16383] of Word TWordArray;
```
