Pascal

```
procedure RemoveNotify(ANotify: TObject);
```

C++

```
__fastcall RemoveNotify(TObject * ANotify);
```

Description

Call RemoveNotify to unregister interest in change notifications. After a call to RemoveNotify, the object is no longer notified when the component changes.

ANotify is the object to unregister. It must be an object that previously registered interest by calling the AddNotify (see page 1059) method.

See Also

AddNotify (see page 1059)

11.2.50 IPageDispatcher Interface

IPageDispatcher is the interface for interacting with the page dispatcher.

Class Hierarchy

Pascal

```
IPageDispatcher = interface(IWebRequestHandler);
```

C++

```
__interface IPageDispatcher : public IWebRequestHandler;
```

File

SiteComp

Description

The TPageDispatcher component implements IPageDispatcher. This interface, which the TWebAppComponents object publishes, allows the WebSnap application to dispatch request messages. The request messages identify a target Web page using the pathinfo portion of their target URL. If the request is not addressed to an URL with a pathinfo portion, the IPageDispatcher forwards the request to the Web page module identified by the DefaultPageName (see page 1064) property.

In addition to dispatching requests for Web pages, IPageDispatcher includes methods that check whether the current user needs to log in, check whether the current user has rights to view the requested page, and to redirect requests.

Note: In C++, method declarations that use IPageDispatcher use the _di_IPageDispatcher type instead. This type is a DelphiInterface (see page 3256) wrapper around the IPageDispatcher interface:

Note: typedef System::DelphiInterface (see page 3256)< IPageDispatcher > _di_IPageDispatcher;

See Also

TPageDispatcher (see page 6236)

TCustomWebAppComponents (see page 6201)

TWebAppComponents (see page 6243)

11.2.50.1 IPageDispatcher Members

The following tables list the members exposed by IPageDispatcher.

Public Methods

	Name	Description
	DispatchPageName (see page 1061)	Checks whether a specified user has a given access rights string.

	GetCanView (see page 1062)	Indicates whether the current user is permitted to view a specified Web page.
	GetDefaultPageName (see page 1062)	Returns the value of the DefaultPageName (see page 1064) property.
	GetLoginRequired (see page 1062)	Indicates whether a user must log in before accessing a specified Web page.
	PageNameOfRequest (see page 1063)	Returns the name of the Web page to which an HTTP request is addressed.
	RedirectToPageName (see page 1063)	Fills out a response message so that it redirects the caller to another page in the application.

Public Properties

	Name	Description
R	DefaultPageName (see page 1064)	Indicates the Web page module that should handle requests that do not include a Web page module name in the pathinfo portion of their target URL.

11.2.50.2 IPageDispatcher Methods

The methods of the IPageDispatcher class are listed here.

Public Methods

	Name	Description
	DispatchPageName (see page 1061)	Checks whether a specified user has a given access rights string.
	GetCanView (see page 1062)	Indicates whether the current user is permitted to view a specified Web page.
	GetDefaultPageName (see page 1062)	Returns the value of the DefaultPageName (see page 1064) property.
	GetLoginRequired (see page 1062)	Indicates whether a user must log in before accessing a specified Web page.
	PageNameOfRequest (see page 1063)	Returns the name of the Web page to which an HTTP request is addressed.
	RedirectToPageName (see page 1063)	Fills out a response message so that it redirects the caller to another page in the application.

11.2.50.2.1 IPageDispatcher.DispatchPageName Method

Checks whether a specified user has a given access rights string.

Pascal

```
function DispatchPageName(const APageName: string; AResponse: TWebResponse; AFlags:
TDispatchPageFlags): Boolean;
```

C++

```
__fastcall Boolean DispatchPageName(const UnicodeString APageName, TWebResponse AResponse,
TDispatchPageFlags AFlags);
```

Description

Call DispatchPageName to fill out a response message with the Web page that a specified Web page module provides. DispatchPageName locates the Web page module that produces the requested Web page and uses it to fill out the content of a response object.

APageName is the name of the Web page to fetch. If APageName is an empty string, DispatchPageName uses the first Web page module that is registered with the current Web context.

AResponse is the response object whose Content property receives the requested Web page.

AFlags indicates the attributes that must be present on the Web page module. For example, if AFlags includes dpPublished, APageName must specify a published Web page module or the page dispatcher won't fetch the Web page.

DispatchPageName returns true if it successfully fetches the requested page, false if it fails to obtain the requested page.

See Also

RedirectToPageName (see page 1063)

HandleRequest

Content

WebContext (see page 6003)

11.2.50.2.2 IPageDispatcher.GetCanView Method

Indicates whether the current user is permitted to view a specified Web page.

Pascal

```
function GetCanView(const APageName: string): Boolean;
```

C++

```
__fastcall Boolean GetCanView(const UnicodeString APageName);
```

Description

Call GetCanView to check whether the current user should be allowed to view a specified Web page. Typically, this method is called after the user logs in.

APageName is the name of the Web page the user wants to view.

See Also

GetLoginRequired (see page 1062)

HasViewRights (see page 5992)

OnCanViewPage (see page 6198)

11.2.50.2.3 IPageDispatcher.GetDefaultPageName Method

Returns the value of the DefaultPageName (see page 1064) property.

Pascal

```
function GetDefaultPageName: string;
```

C++

```
__fastcall UnicodeString GetDefaultPageName();
```

Description

GetDefaultPageName is the read implementation of the DefaultPageName (see page 1064) property.

See Also

DefaultPageName (see page 1064)

11.2.50.2.4 IPageDispatcher.GetLoginRequired Method

Indicates whether a user must log in before accessing a specified Web page.

Pascal

```
function GetLoginRequired(const APageName: string): Boolean;
```

C++

```
__fastcall Boolean GetLoginRequired(const UnicodeString APageName);
```

Description

Call GetLoginRequired to check whether users must log in before accessing a specified Web page. GetLoginRequired can check the Web page information object for the target Web page, but can also use other means (such as an event handler) to obtain this information.

APageName is the name of the Web page to check whether it requires users to first log in.

See Also

GetCanView (see page 1062)

IsLoginRequired

OnIsLoginRequired (see page 6199)

11.2.50.2.5 IPageDispatcher.PageNameOfRequest Method

Returns the name of the Web page to which an HTTP request is addressed.

Pascal

```
function PageNameOfRequest(ARequest: TWebRequest): string;
```

C++

```
__fastcall UnicodeString PageNameOfRequest(TWebRequest ARequest);
```

Description

Call PageNameOfRequest to obtain the name of the Web page that a request message is trying to fetch.

ARequest is the request object that describes the HTTP request message.

PageNameOfRequest returns the last string in the path info portion of the request message's target URL.

See Also

DefaultPageName (see page 1064)

11.2.50.2.6 IPageDispatcher.RedirectToPageName Method

Fills out a response message so that it redirects the caller to another page in the application.

Pascal

```
function RedirectToPageName(const APageName: string; AParams: TStrings; AResponse:
TWebResponse; AFlags: TDispatchPageFlags): Boolean;
```

C++

```
__fastcall Boolean RedirectToPageName(const UnicodeString APageName, TStrings AParams,
TWebResponse AResponse, TDispatchPageFlags AFlags);
```

Description

Call RedirectToPageName to generate a response that redirects the caller to another Web page in the WebSnap application.

APageName is the name of the Web page to which the request should be redirected. If APageName is an empty string, RedirectToPageName uses the first Web page module that is registered with the current Web context.

AParams is a string list containing application-defined name-value pairs. These name-value pairs supply the query fields of the redirected request message, and are added to the URL that is the target of the SendRedirect call.

AResponse is the response object that the WebSnap uses to make the SendRedirect call.

AFlags indicates the attributes that must be present on the Web page module to which the current request is redirected. For example, if AFlags includes dpPublished, APageName must specify a published Web page module.

RedirectToPageName returns true if it successfully redirects to the specified page.

DispatchPageName (see page 1061)

HandleRequest

Content

WebContext (see page 6003)

11.2.50.3 IPageDispatcher Properties

The properties of the IPageDispatcher class are listed here.

Public Properties

	Name	Description
	DefaultPageName (see page 1064)	Indicates the Web page module that should handle requests that do not include a Web page module name in the pathinfo portion of their target URL.

11.2.50.3.1 IPageDispatcher.DefaultPageName Property

Indicates the Web page module that should handle requests that do not include a Web page module name in the pathinfo portion of their target URL.

Pascal

```
property DefaultPageName: string;
```

C++

```
__property UnicodeString DefaultPageName;
```

Description

DefaultPageName is the name of the registered Web page module that should handle incoming request messages that do not have a pathinfo portion on their target URL. This is the name that is supplied to the Web page module wizard when you created the default Web page module. It forms the basis of that Web page module's class name. For example, if the default Web page module has the name MyDefaultPage, the Web page module class is of type TMyDefaultPage.

If DefaultPageName is an empty string, the page dispatcher uses the Web application module as a default Web page module, as long as it is a TWebAppPageModule object.

See Also

DispatchPageName (see page 1061)

TWebAppPageModule (see page 6588)

11.2.51 IPageResult Interface

Class Hierarchy

Pascal

```
IPageResult = interface;
```

C++

```
__interface IPageResult;
```

File

SiteComp

Description

This is class SiteComp.IPageResult.

11.2.51.1 IPageResult Members

The following tables list the members exposed by IPageResult.

Public Methods

	Name	Description
	DispatchPage (see page 1065)	This is DispatchPage, a member of class IPageResult.
	IncludePage (see page 1065)	This is IncludePage, a member of class IPageResult.
	RedirectToPage (see page 1066)	This is RedirectToPage, a member of class IPageResult.

11.2.51.2 IPageResult Methods

The methods of the IPageResult class are listed here.

Public Methods

	Name	Description
	DispatchPage (see page 1065)	This is DispatchPage, a member of class IPageResult.
	IncludePage (see page 1065)	This is IncludePage, a member of class IPageResult.
	RedirectToPage (see page 1066)	This is RedirectToPage, a member of class IPageResult.

11.2.51.2.1 IPageResult.DispatchPage Method

Pascal

```
function DispatchPage(const APageName: string; AWebResponse: TWebResponse): Boolean;
```

C++

```
__fastcall Boolean DispatchPage(const UnicodeString APageName, TWebResponse AWebResponse);
```

Description

This is DispatchPage, a member of class IPageResult.

11.2.51.2.2 IPageResult.IncludePage Method

Pascal

```
function IncludePage(const APageName: string; var AOwned: Boolean): TStream;
```

C++

```
__fastcall TStream IncludePage(const UnicodeString APageName, Boolean AOwned);
```

Description

This is IncludePage, a member of class IPageResult.

11.2.51.2.3 IPageResult.RedirectToPage Method

Pascal

```
function RedirectToPage(const APageName: string; AParams: TStrings; AWebResponse:
TWebResponse): Boolean;
```

C++

```
__fastcall Boolean RedirectToPage(const UnicodeString APageName, TStrings AParams,
TWebResponse AWebResponse);
```

Description

This is RedirectToPage, a member of class IPageResult.

11.2.52 ISessionsService Interface

ISessionsService is the interface for controlling a TSessionsService object.

Class Hierarchy

Pascal

```
ISessionsService = interface;
```

C++

```
__interface ISessionsService;
```

File

SiteComp

Description

The TSessionsService component implements ISessionsService. Most applications do not need to use this interface directly. Instead, the TWebAppComponents component uses this interface to drive the orderly management of sessions. In addition, Web session objects (TWebSession) use this interface to update the sessions service when they are terminated.

Note: In C++, method declarations that use ISessionsService use the _di_ISessionsService type instead. This type is a DelphiInterface (see page 3256) wrapper around the ISessionsService interface:

Note: typedef System::DelphiInterface (see page 3256)< ISessionsService > _di_ISessionsService;

See Also

TSessionsService (see page 6756)

TWebAppComponents (see page 6243)

TWebSession (see page 6251)

11.2.52.1 ISessionsService Members

The following tables list the members exposed by ISessionsService.

Public Methods

	Name	Description
	CheckStatusChange (see page 1067)	Checks whether any sessions have started or terminated.
	Clear (see page 1067)	Deletes all sessions from memory.
	NewSession (see page 1068)	Starts a new session.
	NotifyStatusChange (see page 1068)	Generates an OnEndSession or OnStartSession event, as apprORpriate.

11.2.52.2 ISessionsService Methods

The methods of the ISessionsService class are listed here.

Public Methods

	Name	Description
	CheckStatusChange (see page 1067)	Checks whether any sessions have started or terminated.
	Clear (see page 1067)	Deletes all sessions from memory.
	NewSession (see page 1068)	Starts a new session.
	NotifyStatusChange (see page 1068)	Generates an OnEndSession or OnStartSession event, as apprORpriate.

11.2.52.2.1 ISessionsService.CheckStatusChange Method

Checks whether any sessions have started or terminated.

Pascal

```
function CheckStatusChange: Boolean;
```

C++

```
__fastcall Boolean CheckStatusChange();
```

Description

CheckStatusChange examines the sessions currently in memory to see if any sessions have been started or terminated since the last call to NotifyStatusChange (see page 1068). If a session has started or terminated since the last call, CheckStatusChange returns true. Otherwise, it returns false.

See Also

NotifyStatusChange (see page 1068)

11.2.52.2.2 ISessionsService.Clear Method

Deletes all sessions from memory.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the sessions service of all the sessions it has stored in memory. Clear does not terminate active sessions in an orderly fashion (for example, it omits the call to NotifyStatusChange (see page 1068)), it merely frees all memory used to store sessions.

See Also

NotifyStatusChange (see page 1068)

11.2.52.2.3 ISessionsService.NewSession Method

Starts a new session.

Pascal

```
function NewSession: IWebSession;
```

C++

```
__fastcall IWebSession NewSession();
```

Description

Call NewSession to generate a new session. NewSession starts a new session and returns an interface that can be used to terminate that session.

See Also

NotifyStatusChange (see page 1068)

11.2.52.2.4 ISessionsService.NotifyStatusChange Method

Generates an OnEndSession or OnStartSession event, as approrpriate.

Pascal

```
procedure NotifyStatusChange;
```

C++

```
__fastcall NotifyStatusChange();
```

Description

Call NotifyStatusChange to generate the OnStartSession event for any new sessions that have been created since the last call and to generate the OnEndSession event for any sessions that terminated since the last call. For any terminated sessions, NotifyStatusChange frees the memory allocated to the session after the OnEndSession event handler exits.

See Also

OnEndSession (see page 6755)

OnStartSession (see page 6755)

CheckStatusChange (see page 1067)

11.2.53 ISessionsServiceConnectID Interface

Class Hierarchy

Pascal

```
ISessionsServiceConnectID = interface;
```

C++

```
__interface ISessionsServiceConnectID;
```

File

SiteComp

Description

This is class SiteComp.ISessionsServiceConnectID.

11.2.53.1 ISessionsServiceConnectID Members

The following tables list the members exposed by ISessionsServiceConnectID.

Public Methods

	Name	Description
	Connect (see page 1069)	This is Connect, a member of class ISessionsServiceConnectID.
	ConnectActive (see page 1069)	This is ConnectActive, a member of class ISessionsServiceConnectID.

11.2.53.2 ISessionsServiceConnectID Methods

The methods of the ISessionsServiceConnectID class are listed here.

Public Methods

	Name	Description
	Connect (see page 1069)	This is Connect, a member of class ISessionsServiceConnectID.
	ConnectActive (see page 1069)	This is ConnectActive, a member of class ISessionsServiceConnectID.

11.2.53.2.1 ISessionsServiceConnectID.Connect Method

Pascal

```
function Connect(AID: TSessionID): IWebSession;
```

C++

```
__fastcall IWebSession Connect(TSessionID AID);
```

Description

This is Connect, a member of class ISessionsServiceConnectID.

11.2.53.2.2 ISessionsServiceConnectID.ConnectActive Method

Pascal

```
function ConnectActive(AID: TSessionID): IWebSession;
```

C++

```
__fastcall IWebSession ConnectActive(TSessionID AID);
```

Description

This is ConnectActive, a member of class ISessionsServiceConnectID.

11.2.54 ISessionsServicePersist Interface

Class Hierarchy

SiteComp.ISessionsServicePersist

Pascal

```
ISessionsServicePersist = interface;
```

C++

```
__interface ISessionsServicePersist;
```

File

SiteComp

Description

This is class SiteComp.ISessionsServicePersist.

11.2.54.1 ISessionsServicePersist Members

The following tables list the members exposed by ISessionsServicePersist.

Public Methods

	Name	Description
	LoadFromFile (see page 1070)	This is LoadFromFile, a member of class ISessionsServicePersist.
	LoadFromStream (see page 1071)	This is LoadFromStream, a member of class ISessionsServicePersist.
	SaveToFile (see page 1071)	This is SaveToFile, a member of class ISessionsServicePersist.
	SaveToStream (see page 1071)	This is SaveToStream, a member of class ISessionsServicePersist.

11.2.54.2 ISessionsServicePersist Methods

The methods of the ISessionsServicePersist class are listed here.

Public Methods

	Name	Description
	LoadFromFile (see page 1070)	This is LoadFromFile, a member of class ISessionsServicePersist.
	LoadFromStream (see page 1071)	This is LoadFromStream, a member of class ISessionsServicePersist.
	SaveToFile (see page 1071)	This is SaveToFile, a member of class ISessionsServicePersist.
	SaveToStream (see page 1071)	This is SaveToStream, a member of class ISessionsServicePersist.

11.2.54.2.1 ISessionsServicePersist.LoadFromFile Method

Pascal

```
procedure LoadFromFile(const Filename: string);
```

C++

```
__fastcall LoadFromFile(const UnicodeString Filename);
```

Description

This is LoadFromFile, a member of class ISessionsServicePersist.

11.2.54.2.2 ISessionsServicePersist.LoadFromStream Method

Pascal

```
procedure LoadFromStream(S: TStream);
```

C++

```
__fastcall LoadFromStream(TStream S);
```

Description

This is LoadFromStream, a member of class ISessionsServicePersist.

11.2.54.2.3 ISessionsServicePersist.SaveToFile Method

Pascal

```
procedure SaveToFile(const Filename: string);
```

C++

```
__fastcall SaveToFile(const UnicodeString Filename);
```

Description

This is SaveToFile, a member of class ISessionsServicePersist.

11.2.54.2.4 ISessionsServicePersist.SaveToStream Method

Pascal

```
procedure SaveToStream(S: TStream);
```

C++

```
__fastcall SaveToStream(TStream S);
```

Description

This is SaveToStream, a member of class ISessionsServicePersist.

11.2.55 ISessionsServiceStoreID Interface

Class Hierarchy

Pascal

```
ISessionsServiceStoreID = interface;
```

C++

```
__interface ISessionsServiceStoreID;
```

File

SiteComp

Description

This is class SiteComp.ISessionsServiceStoreID.

11.2.55.1 ISessionsServiceStoreID Members

The following tables list the members exposed by ISessionsServiceStoreID.

Public Methods

	Name	Description
	ReadSessionID (see page 1072)	This is ReadSessionID, a member of class ISessionsServiceStoreID.
	WriteSessionID (see page 1072)	This is WriteSessionID, a member of class ISessionsServiceStoreID.

11.2.55.2 ISessionsServiceStoreID Methods

The methods of the ISessionsServiceStoreID class are listed here.

Public Methods

	Name	Description
	ReadSessionID (see page 1072)	This is ReadSessionID, a member of class ISessionsServiceStoreID.
	WriteSessionID (see page 1072)	This is WriteSessionID, a member of class ISessionsServiceStoreID.

11.2.55.2.1 ISessionsServiceStoreID.ReadSessionID Method

Pascal

```
function ReadSessionID(ARequest: TWebRequest; AResponse: TWebResponse; out AID: TSessionID):
Boolean;
```

C++

```
__fastcall Boolean ReadSessionID(TWebRequest ARequest, TWebResponse AResponse, TSessionID AID);
```

Description

This is ReadSessionID, a member of class ISessionsServiceStoreID.

11.2.55.2.2 ISessionsServiceStoreID.WriteSessionID Method

Pascal

```
procedure WriteSessionID(AResponse: TWebResponse; AID: TSessionID);
```

C++

```
__fastcall WriteSessionID(TWebResponse AResponse, TSessionID AID);
```

Description

This is WriteSessionID, a member of class ISessionsServiceStoreID.

11.2.56 IValuesListAdapter Interface

IValuesListAdapter is the interface for supplying name/value pairs.

Class Hierarchy

Pascal

```
IValuesListAdapter = interface;
```

C++

```
__interface IValuesListAdapter;
```

File

SiteComp

Description

Values list adapters such as TStringsValuesList and TDataSetValuesList implement the IValuesListAdapter interface. This allows adapter fields to use the values list adapter for supplying an associated list of name/value pairs. Typically, this list is used to enumerate the possible values for the adapter field so that they can be added to a selection control such as a list box in an HTML form.

The IValuesListAdapter interface introduces methods to read the current name or value, and to look up the name (or image) associated with a specified value. If the adapter that implements IValuesListAdapter does not also support iteration, server-side script can't change the current name/value pair. However, it can still look up the name or image for a specified value.

Note: In C++, method declarations that use IValuesListAdapter use the _di_IValuesListAdapter type instead. This type is a DelphiInterface (see page 3256) wrapper around the IValuesListAdapter interface:

Note: typedef System::DelphiInterface (see page 3256)< IValuesListAdapter > _di_IValuesListAdapter;

See Also

TAdapterUpdateField (see page 5419)

TCustomDataSetAdapterField

TStringsValuesList (see page 5857)

TDataSetValuesList

IIteratorSupport (see page 1054)

11.2.56.1 IValuesListAdapter Members

The following tables list the members exposed by IValuesListAdapter.

Public Methods

	Name	Description
	GetListImage (see page 1074)	Returns the image object associated with the current name/value pair.
	GetListImageOfValue (see page 1074)	Returns the image object associated with a specified value.
	GetListName (see page 1075)	Returns the name part of the current name/value pair.
	GetListNameOfValue (see page 1075)	Returns the name associated with a specified value.
	GetListValue (see page 1076)	Returns the value of the current name/value pair.

11.2.56.2 IValuesListAdapter Methods

The methods of the IValuesListAdapter class are listed here.

Public Methods

	Name	Description
	GetListImage (see page 1074)	Returns the image object associated with the current name/value pair.
	GetListImageOfValue (see page 1074)	Returns the image object associated with a specified value.
	GetListName (see page 1075)	Returns the name part of the current name/value pair.
	GetListNameOfValue (see page 1075)	Returns the name associated with a specified value.
	GetListValue (see page 1076)	Returns the value of the current name/value pair.

11.2.56.2.1 IValuesListAdapter.GetListImage Method

Returns the image object associated with the current name/value pair.

Pascal

```
function GetListImage: TComponent;
```

C++

```
__fastcall TComponent * GetListImage();
```

Description

GetListImage returns the object that represents an image associated with the current name/value pair. The image object is the component that responds to request messages which originate from an anchor tag in an HTML form that refers to the image.

If the current name/value pair does not have an associated image, GetListImage returns nil (Delphi) or NULL (C++).

Note: GetListImage provides the support for the Image property of the values list adapter, which can be addressed by server-side script.

See Also

GetListImageOfValue (see page 1074)

GetListName (see page 1075)

GetListValue (see page 1076)

TWebRequestFile

11.2.56.2.2 IValuesListAdapter.GetListImageOfValue Method

Returns the image object associated with a specified value.

Pascal

```
function GetListImageOfValue(Value: Variant): TComponent;
```

C++

```
__fastcall TComponent * GetListImageOfValue(Variant Value);
```

Description

GetListImageOfValue looks for a name/value pair with the specified value and returns the object that represents an image associated with that value. The image object is the component that responds to request messages which originate from an anchor tag in an HTML form that refers to the image.

Value is the value part of the name/value pair whose image you want.

If Value does not identify a name/value pair with an associated image, GetListImageOfValue returns nil (Delphi) or NULL (C++).

See Also

GetListImage (see page 1074)

GetListNameOfValue (see page 1075)

GetListValue (see page 1076)

TWebRequestFile

11.2.56.2.3 IValuesListAdapter.GetListName Method

Returns the name part of the current name/value pair.

Pascal

```
function GetListName: string;
```

C++

```
__fastcall UnicodeString GetListName();
```

Description

GetListName returns the name part of the current name/value pair. This method provides the support for the Name property of the values list adapter, which can be addressed by server-side script.

If the current name/value pair does not have a name, GetListName returns an empty string.

See Also

GetListNameOfValue (see page 1075)

GetListImage (see page 1074)

GetListValue (see page 1076)

11.2.56.2.4 IValuesListAdapter.GetListNameOfValue Method

Returns the name associated with a specified value.

Pascal

```
function GetListNameOfValue(Value: Variant): string;
```

C++

```
__fastcall UnicodeString GetListNameOfValue(Variant Value);
```

Description

GetListNameOfValue looks for a name/value pair with the specified value and returns the name part.

Value is the value part of the name/value pair whose name you want.

If Value does not identify a name/value pair with a name, GetListNameOfValue returns an empty string.

See Also

GetListName (see page 1075)

GetListImageOfValue (see page 1074)

GetListValue (see page 1076)

11.2.56.2.5 IValuesListAdapter.GetListValue Method

Returns the value of the current name/value pair.

Pascal

```
function GetListValue: Variant;
```

C++

```
__fastcall Variant GetListValue();
```

Description

GetListValue returns the value part of the current name/value pair. This method provides the support for the Value property of the values list adapter, which can be addressed by server-side script.

If the current name/value pair does not have a value, GetListValue returns either the name part, or an unassigned Variant (see page 3421), depending on the type of values list adapter.

GetListName (see page 1075)

GetListImage (see page 1074)

11.2.57 IWebActionsList Interface

Class Hierarchy

Pascal

```
IWebActionsList = interface;
```

C++

```
__interface IWebActionsList;
```

File

SiteComp

Description

This is class SiteComp.IWebActionsList.

11.2.57.1 IWebActionsList Members

The following tables list the members exposed by IWebActionsList.

Public Methods

	Name	Description
	FindAction (see page 1077)	This is FindAction, a member of class IWebActionsList.
	GetActionsList (see page 1077)	This is GetActionsList, a member of class IWebActionsList.
	GetVisibleActions (see page 1077)	This is GetVisibleActions, a member of class IWebActionsList.
	IsActionInUse (see page 1078)	This is IsActionInUse, a member of class IWebActionsList.

Public Properties

	Name	Description
	VisibleActions (see page 1078)	This is VisibleActions, a member of class IWebActionsList.

11.2.57.2 IWebActionsList Methods

The methods of the IWebActionsList class are listed here.

Public Methods

	Name	Description
	FindAction (see page 1077)	This is FindAction, a member of class IWebActionsList.
	GetActionsList (see page 1077)	This is GetActionsList, a member of class IWebActionsList.
	GetVisibleActions (see page 1077)	This is GetVisibleActions, a member of class IWebActionsList.
	IsActionInUse (see page 1078)	This is IsActionInUse, a member of class IWebActionsList.

11.2.57.2.1 IWebActionsList.FindAction Method

Pascal

```
function FindAction(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindAction(const UnicodeString AName);
```

Description

This is FindAction, a member of class IWebActionsList.

11.2.57.2.2 IWebActionsList.GetActionsList Method

Pascal

```
procedure GetActionsList(AList: TStrings);
```

C++

```
__fastcall GetActionsList(TStrings AList);
```

Description

This is GetActionsList, a member of class IWebActionsList.

11.2.57.2.3 IWebActionsList.GetVisibleActions Method

Pascal

```
function GetVisibleActions: TWebComponentList;
```

C++

```
__fastcall TWebComponentList GetVisibleActions();
```

Description

This is GetVisibleActions, a member of class IWebActionsList.

11.2.57.2.4 IWebActionsList.IsActionInUse Method

Pascal

```
function IsActionInUse(const AName: string): Boolean;
```

C++

```
__fastcall Boolean IsActionInUse(const UnicodeString AName);
```

Description

This is IsActionInUse, a member of class IWebActionsList.

11.2.57.3 IWebActionsList Properties

The properties of the IWebActionsList class are listed here.

Public Properties

	Name	Description
	VisibleActions (see page 1078)	This is VisibleActions, a member of class IWebActionsList.

11.2.57.3.1 IWebActionsList.VisibleActions Property

Pascal

```
property VisibleActions: TWebComponentList;
```

C++

```
__property TWebComponentList VisibleActions;
```

Description

This is VisibleActions, a member of class IWebActionsList.

11.2.58 IWebApplicationInfo Interface

IWebApplicationInfo is the interface for the application adapter.

Class Hierarchy

Pascal

```
IWebApplicationInfo = interface;
```

C++

```
__interface IWebApplicationInfo;
```

File

SiteComp

Description

The TApplicationAdapter component implements IWebApplicationInfo. This interface, which the TWebAppComponents object publishes, allows the WebSnap application to obtain application. IWebApplicationInfo declares an ApplicationTitle (see page

1080) property, which allows server-side scripts to use the title of the application. It also provides access to the application adapter object, which may provide additional application-level information.

Note: In C++, method declarations that use IWebApplicationInfo use the _di_IWebApplicationInfo type instead. This type is a DelphiInterface (see page 3256) wrapper around the IWebApplicationInfo interface:

Note: typedef System::DelphiInterface (see page 3256)< IWebApplicationInfo > _di_IWebApplicationInfo;

See Also

TApplicationAdapter (see page 5439)

TCustomWebAppComponents (see page 6201)

TWebAppComponents (see page 6243)

11.2.58.1 IWebApplicationInfo Members

The following tables list the members exposed by IWebApplicationInfo.

Public Methods

	Name	Description
	GetApplicationAdapter (see page 1079)	Returns the value of the ApplicationAdapter (see page 1080) property.
	GetApplicationTitle (see page 1080)	Returns the value of the ApplicationTitle (see page 1080) property.

Public Properties

	Name	Description
R	ApplicationAdapter (see page 1080)	Provides access to the adapter that implements the fields and actions of the Application variable in server-side scripts.
R	ApplicationTitle (see page 1080)	Indicates the title of the WebSnap application.

11.2.58.2 IWebApplicationInfo Methods

The methods of the IWebApplicationInfo class are listed here.

Public Methods

	Name	Description
	GetApplicationAdapter (see page 1079)	Returns the value of the ApplicationAdapter (see page 1080) property.
	GetApplicationTitle (see page 1080)	Returns the value of the ApplicationTitle (see page 1080) property.

11.2.58.2.1 IWebApplicationInfo.GetApplicationAdapter Method

Returns the value of the ApplicationAdapter (see page 1080) property.

Pascal

```
function GetApplicationAdapter: TComponent;
```

C++

```
__fastcall TComponent * GetApplicationAdapter();
```

Description

GetApplicationAdapter is the read implementation of the ApplicationAdapter (see page 1080) property.

See Also

ApplicationAdapter (see page 1080)

11.2.58.2.2 IWebApplicationInfo.GetApplicationTitle Method

Returns the value of the ApplicationTitle (see page 1080) property.

Pascal

```
function GetApplicationTitle: string;
```

C++

```
__fastcall UnicodeString GetApplicationTitle();
```

Description

GetApplicationTitle is the read implementation of the ApplicationTitle (see page 1080) property.

See Also

ApplicationTitle (see page 1080)

11.2.58.3 IWebApplicationInfo Properties

The properties of the IWebApplicationInfo class are listed here.

Public Properties

	Name	Description
R	ApplicationAdapter (see page 1080)	Provides access to the adapter that implements the fields and actions of the Application variable in server-side scripts.
R	ApplicationTitle (see page 1080)	Indicates the title of the WebSnap application.

11.2.58.3.1 IWebApplicationInfo.ApplicationAdapter Property

Provides access to the adapter that implements the fields and actions of the Application variable in server-side scripts.

Pascal

```
property ApplicationAdapter: TComponent;
```

C++

```
__property TComponent * ApplicationAdapter;
```

Description

Read (see page 3634) ApplicationAdapter to access the application adapter component. This is the adapter that implements the fields and actions of the Application variable in server-side scripts. Typically, this is an instance of TApplicationAdapter.

See Also

TApplicationAdapter (see page 5439)

11.2.58.3.2 IWebApplicationInfo.ApplicationTitle Property

Indicates the title of the WebSnap application.

Pascal

```
property ApplicationTitle: string;
```

C++

```
__property UnicodeString ApplicationTitle;
```

Description

Read (see page 3634) ApplicationTitle to obtain the title of the WebSnap application. This property is the value of the Title field in the Application variable in server-side scripts.

See Also

Title (see page 5940)

11.2.59 IWebContainerSubComponent Interface

Class Hierarchy

Pascal

```
IWebContainerSubComponent = interface;
```

C++

```
__interface IWebContainerSubComponent;
```

File

SiteComp

Description

This is class SiteComp.IWebContainerSubComponent.

11.2.60 IWebDataFields Interface

Class Hierarchy

Pascal

```
IWebDataFields = interface;
```

C++

```
__interface IWebDataFields;
```

File

SiteComp

Description

This is class SiteComp.IWebDataFields.

11.2.60.1 IWebDataFields Members

The following tables list the members exposed by IWebDataFields.

Public Methods

	Name	Description
	FindField (see page 1082)	This is FindField, a member of class IWebDataFields.
	GetFieldsList (see page 1082)	This is GetFieldsList, a member of class IWebDataFields.
	GetVisibleFields (see page 1083)	This is GetVisibleFields, a member of class IWebDataFields.
	IsFieldInUse (see page 1083)	This is IsFieldInUse, a member of class IWebDataFields.

Public Properties

	Name	Description
	VisibleFields (see page 1083)	This is VisibleFields, a member of class IWebDataFields.

11.2.60.2 IWebDataFields Methods

The methods of the IWebDataFields class are listed here.

Public Methods

	Name	Description
	FindField (see page 1082)	This is FindField, a member of class IWebDataFields.
	GetFieldsList (see page 1082)	This is GetFieldsList, a member of class IWebDataFields.
	GetVisibleFields (see page 1083)	This is GetVisibleFields, a member of class IWebDataFields.
	IsFieldInUse (see page 1083)	This is IsFieldInUse, a member of class IWebDataFields.

11.2.60.2.1 IWebDataFields.FindField Method

Pascal

```
function FindField(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindField(const UnicodeString AName);
```

Description

This is FindField, a member of class IWebDataFields.

11.2.60.2.2 IWebDataFields.GetFieldsList Method

Pascal

```
procedure GetFieldsList(AList: TStrings);
```

C++

```
__fastcall GetFieldsList(TStrings AList);
```

Description

This is GetFieldsList, a member of class IWebDataFields.

11.2.60.2.3 IWebDataFields.GetVisibleFields Method

Pascal

```
function GetVisibleFields: TWebComponentList;
```

C++

```
__fastcall TWebComponentList GetVisibleFields();
```

Description

This is GetVisibleFields, a member of class IWebDataFields.

11.2.60.2.4 IWebDataFields.IsFieldInUse Method

Pascal

```
function IsFieldInUse(const AName: string): Boolean;
```

C++

```
__fastcall Boolean IsFieldInUse(const UnicodeString AName);
```

Description

This is IsFieldInUse, a member of class IWebDataFields.

11.2.60.3 IWebDataFields Properties

The properties of the IWebDataFields class are listed here.

Public Properties

	Name	Description
	VisibleFields (see page 1083)	This is VisibleFields, a member of class IWebDataFields.

11.2.60.3.1 IWebDataFields.VisibleFields Property

Pascal

```
property VisibleFields: TWebComponentList;
```

C++

```
__property TWebComponentList VisibleFields;
```

Description

This is VisibleFields, a member of class IWebDataFields.

11.2.61 IWebEnabled Interface

Class Hierarchy

SiteComp.IWebEnabled

Pascal

```
IWebEnabled = interface;
```

C++

```
__interface IWebEnabled;
```

File

SiteComp

Description

This is class SiteComp.IWebEnabled.

11.2.61.1 IWebEnabled Members

The following tables list the members exposed by IWebEnabled.

Public Methods

	Name	Description
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

11.2.61.2 IWebEnabled Methods

The methods of the IWebEnabled class are listed here.

Public Methods

	Name	Description
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

11.2.61.2.1 IWebEnabled.WebEnabled Method

Pascal

```
function WebEnabled: Boolean;
```

C++

```
__fastcall Boolean WebEnabled();
```

Description

This is WebEnabled, a member of class IWebEnabled.

11.2.62 IWebFormComponentContainer Interface

Class Hierarchy

SiteComp.IWebFormComponentContainer

Pascal

```
IWebFormComponentContainer = interface;
```

C++

```
__interface IWebFormComponentContainer;
```

File

SiteComp

Description

This is class SiteComp.IWebFormComponentContainer.

11.2.62.1 IWebFormComponentContainer Members

The following tables list the members exposed by IWebFormComponentContainer.

Public Methods

	Name	Description
	GetCount (see page 1085)	This is GetCount, a member of class IWebFormComponentContainer.
	GetItem (see page 1085)	This is GetItem, a member of class IWebFormComponentContainer.

Public Properties

	Name	Description
R	Count (see page 1086)	This is Count, a member of class IWebFormComponentContainer.
R	Items (see page 1086)	This is Items, a member of class IWebFormComponentContainer.

11.2.62.2 IWebFormComponentContainer Methods

The methods of the IWebFormComponentContainer class are listed here.

Public Methods

	Name	Description
	GetCount (see page 1085)	This is GetCount, a member of class IWebFormComponentContainer.
	GetItem (see page 1085)	This is GetItem, a member of class IWebFormComponentContainer.

11.2.62.2.1 IWebFormComponentContainer.GetCount Method

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

This is GetCount, a member of class IWebFormComponentContainer.

11.2.62.2.2 IWebFormComponentContainer.GetItem Method

Pascal

```
function GetItem(I: Integer): TComponent;
```

C++

```
__fastcall TComponent * GetItem(int I);
```

Description

This is GetItem, a member of class IWebFormComponentContainer.

11.2.62.3 IWebFormComponentContainer Properties

The properties of the IWebFormComponentContainer class are listed here.

Public Properties

	Name	Description
	Count (see page 1086)	This is Count, a member of class IWebFormComponentContainer.
	Items (see page 1086)	This is Items, a member of class IWebFormComponentContainer.

11.2.62.3.1 IWebFormComponentContainer.Count Property

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

This is Count, a member of class IWebFormComponentContainer.

11.2.62.3.2 IWebFormComponentContainer.Items Property

Pascal

```
property Items [I: Integer]: TComponent;
```

C++

```
__property TComponent * Items[int I];
```

Description

This is Items, a member of class IWebFormComponentContainer.

11.2.63 IWebGetActionName Interface

Class Hierarchy

Pascal

```
IWebGetActionName = interface;
```

C++

```
__interface IWebGetActionName;
```

File

SiteComp

Description

This is class SiteComp.IWebGetActionName.

11.2.63.1 IWebGetActionName Members

The following tables list the members exposed by IWebGetActionName.

Public Methods

	Name	Description
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.

Public Properties

	Name	Description
R	ActionName (see page 1087)	This is ActionName, a member of class IWebGetActionName.

11.2.63.2 IWebGetActionName Methods

The methods of the IWebGetActionName class are listed here.

Public Methods

	Name	Description
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.

11.2.63.2.1 IWebGetActionName.GetActionName Method

Pascal

```
function GetActionName: string;
```

C++

```
__fastcall UnicodeString GetActionName();
```

Description

This is GetActionName, a member of class IWebGetActionName.

11.2.63.3 IWebGetActionName Properties

The properties of the IWebGetActionName class are listed here.

Public Properties

	Name	Description
R	ActionName (see page 1087)	This is ActionName, a member of class IWebGetActionName.

11.2.63.3.1 IWebGetActionName.ActionName Property

Pascal

```
property ActionName: string;
```

C++

```
__property UnicodeString ActionName;
```

Description

This is ActionName, a member of class IWebGetActionName.

11.2.64 IWebGetDisplayLabel Interface

Class Hierarchy

SiteComp.IWebGetDisplayLabel

Pascal

```
IWebGetDisplayLabel = interface;
```

C++

```
__interface IWebGetDisplayLabel;
```

File

SiteComp

Description

This is class SiteComp.IWebGetDisplayLabel.

11.2.64.1 IWebGetDisplayLabel Members

The following tables list the members exposed by IWebGetDisplayLabel.

Public Methods

	Name	Description
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.

11.2.64.2 IWebGetDisplayLabel Methods

The methods of the IWebGetDisplayLabel class are listed here.

Public Methods

	Name	Description
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.

11.2.64.2.1 IWebGetDisplayLabel.GetDisplayLabel Method

Pascal

```
function GetDisplayLabel: string;
```

C++

```
__fastcall UnicodeString GetDisplayLabel();
```

Description

This is GetDisplayLabel, a member of class IWebGetDisplayLabel.

11.2.65 IWebGetDisplayWidth Interface

Class Hierarchy

Pascal

```
IWebGetDisplayWidth = interface;
```

C++

```
__interface IWebGetDisplayWidth;
```

File

SiteComp

Description

This is class SiteComp.IWebGetDisplayWidth.

11.2.65.1 IWebGetDisplayWidth Members

The following tables list the members exposed by IWebGetDisplayWidth.

Public Methods

	Name	Description
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.

11.2.65.2 IWebGetDisplayWidth Methods

The methods of the IWebGetDisplayWidth class are listed here.

Public Methods

	Name	Description
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.

11.2.65.2.1 IWebGetDisplayWidth.GetDisplayWidth Method

Pascal

```
function GetDisplayWidth: Integer;
```

C++

```
__fastcall int GetDisplayWidth();
```

Description

This is GetDisplayWidth, a member of class IWebGetDisplayWidth.

11.2.66 IWebGetFieldName Interface

Class Hierarchy

Pascal

```
IWebGetFieldName = interface;
```

C++

```
__interface IWebGetFieldName;
```

File

SiteComp

Description

This is class SiteComp.IWebGetFieldName.

11.2.66.1 IWebGetFieldName Members

The following tables list the members exposed by IWebGetFieldName.

Public Methods

	Name	Description
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.

Public Properties

	Name	Description
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.

11.2.66.2 IWebGetFieldName Methods

The methods of the IWebGetFieldName class are listed here.

Public Methods

	Name	Description
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.

11.2.66.2.1 IWebGetFieldName.GetFieldName Method

Pascal

```
function GetFieldName: string;
```

C++

```
__fastcall UnicodeString GetFieldName();
```

Description

This is GetFieldName, a member of class IWebGetFieldName.

11.2.66.3 IWebGetFieldName Properties

The properties of the IWebGetFieldName class are listed here.

Public Properties

	Name	Description
	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.

11.2.66.3.1 IWebGetFieldName.FieldName Property

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;
```

Description

This is FieldName, a member of class IWebGetFieldName.

11.2.67 IWebGetFieldValue Interface

Class Hierarchy

SiteComp.IWebGetFieldValue

Pascal

```
IWebGetFieldValue = interface;
```

C++

```
__interface IWebGetFieldValue;
```

File

SiteComp

Description

This is class SiteComp.IWebGetFieldValue.

11.2.67.1 IWebGetFieldValue Members

The following tables list the members exposed by IWebGetFieldValue.

Public Methods

	Name	Description
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.

Public Properties

	Name	Description
	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.

11.2.67.2 IWebGetFieldValue Methods

The methods of the IWebGetFieldValue class are listed here.

Public Methods

	Name	Description
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.

11.2.67.2.1 IWebGetFieldValue.GetValue Method

Pascal

```
function GetValue: Variant;
```

C++

```
__fastcall Variant GetValue();
```

Description

This is GetValue, a member of class IWebGetFieldValue.

11.2.67.3 IWebGetFieldValue Properties

The properties of the IWebGetFieldValue class are listed here.

Public Properties

	Name	Description
	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.

11.2.67.3.1 IWebGetFieldValue.Value Property

Pascal

```
property Value: Variant;
```

C++

```
__property Variant Value;
```

Description

This is Value, a member of class IWebGetFieldValue.

11.2.68 IWebGetFieldValues Interface

IWebGetFieldValues is used to iterate over multiple values associated with an adapter field.

Class Hierarchy

SiteComp.IWebGetFieldValues

Pascal

```
IWebGetFieldValues = interface;
```

C++

```
__interface IWebGetFieldValues;
```

File

SiteComp

Description

IWebGetFieldValues is implemented by adapter fields that may have zero or more associated values. Server-side script accesses these values using the adapter field's Values property.

11.2.68.1 IWebGetFieldValues Members

The following tables list the members exposed by IWebGetFieldValues.

Public Methods

	Name	Description
	EndValueIterator (see page 1093)	Indicate the iteration is finished.
	GetCurrentValue (see page 1094)	Retrieves the current value as a variant.
	HasValue (see page 1094)	Indicates whether the adapter field has a matching value.
	NextValueIteration (see page 1094)	Position the iteration pointer on the next value.
	StartValueIterator (see page 1095)	Reset (see page 3643) the iteration pointer to the first item.

11.2.68.2 IWebGetFieldValues Methods

The methods of the IWebGetFieldValues class are listed here.

Public Methods

	Name	Description
	EndValueIterator (see page 1093)	Indicate the iteration is finished.
	GetCurrentValue (see page 1094)	Retrieves the current value as a variant.
	HasValue (see page 1094)	Indicates whether the adapter field has a matching value.
	NextValueIteration (see page 1094)	Position the iteration pointer on the next value.
	StartValueIterator (see page 1095)	Reset (see page 3643) the iteration pointer to the first item.

11.2.68.2.1 IWebGetFieldValues.EndValueIterator Method

Indicate the iteration is finished.

Pascal

```
procedure EndValueIterator(OwnerData: Pointer);
```

C++

```
__fastcall EndValueIterator(void * OwnerData);
```

Description

EndValueIterator is used with StartValueIterator (see page 1095) and NextValueIteration (see page 1094) to loop through the values associated with an adapter field. EndValueIterator should be called when iteration is complete. The OwnerData parameter can be used to pass a value between the three iteration functions.

See Also

StartValueIterator (see page 1095)

NextValueIteration (see page 1094)

11.2.68.2.2 IWebGetFieldValues.GetCurrentValue Method

Retrieves the current value as a variant.

Pascal

```
function GetCurrentValue: Variant;
```

C++

```
__fastcall Variant GetCurrentValue();
```

Description

GetCurrentValue retrieves the value associated with internal iteration pointer. The FirstValueIterator and NextValueIteration (see page 1094) are called to position the internal iteration pointer. Server-side script accesses this value using the Values.Value property.

See Also

StartValueIterator (see page 1095)

NextValueIteration (see page 1094)

11.2.68.2.3 IWebGetFieldValues.HasValue Method

Indicates whether the adapter field has a matching value.

Pascal

```
function HasValue(const AValue: Variant): Boolean;
```

C++

```
__fastcall Boolean HasValue(const Variant AValue);
```

Description

Server-side script accesses this value using the Values.HasValue method. Server-side script to generate an HTML select list or check box group can use this method to determine whether an item should be selected or checked.

See Also

ViewMode (see page 6475)

11.2.68.2.4 IWebGetFieldValues.NextValueIteration Method

Position the iteration pointer on the next value.

Pascal

```
function NextValueIteration(var OwnerData: Pointer): Boolean;
```

C++

```
__fastcall Boolean NextValueIteration(void * OwnerData);
```

Description

NextValueIteration is used with StartValueIterator (see page 1095) and EndValueIterator (see page 1093) to loop through the values associated with an adapter field. NextValueIteration returns False if there are no more values. The OwnerData parameter can be used to pass a value between the three iteration functions.

See Also

StartValueIterator (see page 1095)

EndValueIterator (see page 1093)

GetCurrentValue (see page 1094)

11.2.68.2.5 IWebGetFieldValues.StartValueIterator Method

Reset (see page 3643) the iteration pointer to the first item.

Pascal

```
function StartValueIterator(var OwnerData: Pointer): Boolean;
```

C++

```
__fastcall Boolean StartValueIterator(void * OwnerData);
```

Description

StartValueIterator is used with NextValueIteration (see page 1094) and EndValueIterator (see page 1093) to loop through the values associated with an adapter field. StartValueIterator returns false if there are no values. The OwnerData parameter can be used to pass a value between the three iteration functions.

See Also

NextValueIteration (see page 1094)

EndValueIterator (see page 1093)

GetCurrentValue (see page 1094)

11.2.69 IWebGetMaxLength Interface

Class Hierarchy

Pascal

```
IWebGetMaxLength = interface;
```

C++

```
__interface IWebGetMaxLength;
```

File

SiteComp

Description

This is class SiteComp.IWebGetMaxLength.

11.2.69.1 IWebGetMaxLength Members

The following tables list the members exposed by IWebGetMaxLength.

Public Methods

	Name	Description
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.

11.2.69.2 IWebGetMaxLength Methods

The methods of the IWebGetMaxLength class are listed here.

Public Methods

	Name	Description
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.

11.2.69.2.1 IWebGetMaxLength.GetMaxLength Method

Pascal

```
function GetMaxLength: integer;
```

C++

```
__fastcall int GetMaxLength();
```

Description

This is GetMaxLength, a member of class IWebGetMaxLength.

11.2.70 IWebGetSessionIDs Interface

Class Hierarchy

SiteComp.IWebGetSessionIDs

Pascal

```
IWebGetSessionIDs = interface;
```

C++

```
__interface IWebGetSessionIDs;
```

File

SiteComp

Description

This is class SiteComp.IWebGetSessionIDs.

11.2.70.1 IWebGetSessionIDs Members

The following tables list the members exposed by IWebGetSessionIDs.

Public Methods

	Name	Description
	GetSessionIDs (see page 1097)	This is GetSessionIDs, a member of class IWebGetSessionIDs.

11.2.70.2 IWebGetSessionIDs Methods

The methods of the IWebGetSessionIDs class are listed here.

Public Methods

	Name	Description
	GetSessionIDs (see page 1097)	This is GetSessionIDs, a member of class IWebGetSessionIDs.

11.2.70.2.1 IWebGetSessionIDs.GetSessionIDs Method

Pascal

```
function GetSessionIDs: IWebSessionIDs;
```

C++

```
__fastcall IWebSessionIDs GetSessionIDs();
```

Description

This is GetSessionIDs, a member of class IWebGetSessionIDs.

11.2.71 IWebImageHREF Interface

IWebImageHREF is the interface for obtaining an HREF that addresses an image.

Class Hierarchy

Pascal

```
IWebImageHREF = interface;
```

C++

```
__interface IWebImageHREF;
```

File

SiteComp

Description

IWebImageHREF defines a single method, WebImageHREF (see page 1098), which supplies a URL for an image that should appear in HTML forms. This interface is used when server-side script addresses the Image.AsHREF property of an adapter.

Adapter field objects that represent images (that is, adapter fields with an Image property) implement IWebImageHREF so that the image reference can be obtained from server-side script. Such adapter fields include TAdapterImageField and TDataSetAdapterImageField.

Note: Method declarations that use IWebImageHREF use the _di_IWebImageHREF type instead. This type is a DelphiInterface (see page 3256) wrapper around the IWebImageHREF interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IWebImageHREF >  _di_IWebImageHREF;
```

See Also

TAdapterImageField (see page 5308)

TDataSetAdapterImageField

11.2.71.1 IWebImageHREF Members

The following tables list the members exposed by IWebImageHREF.

Public Methods

	Name	Description
	WebImageHREF (see page 1098)	Retrieves a URL for an external image file.

11.2.71.2 IWebImageHREF Methods

The methods of the IWebImageHREF class are listed here.

Public Methods

	Name	Description
	WebImageHREF (see page 1098)	Retrieves a URL for an external image file.

11.2.71.2.1 IWebImageHREF.WebImageHREF Method

Retrieves a URL for an external image file.

Pascal

```
function WebImageHREF(var AHREF: string): Boolean;
```

C++

```
__fastcall Boolean WebImageHREF(UnicodeString AHREF);
```

Description

WebImageHREF is called when server-side script uses the Image.AsHREF property. WebImageHREF returns a URL that identifies a specific image that is available as a simple file reference. If images must be generated dynamically in response to requests, then WebImageHREF returns false and the adapter dispatcher generates an HREF based on the request parameters supplied by the object that implements this interface.

AHREF returns the URL that identifies the image of this field.

WebImageHREF returns true if it supplies a URL as the value of the AHREF parameter, false if the HTML form must request images using a set of request parameters instead.

EncodeAdapterItemRequestAsHREF (see page 6173)

11.2.72 IWebInputName Interface

Class Hierarchy

SiteComp.IWebInputName

Pascal

```
IWebInputName = interface;
```

C++

```
__interface IWebInputName;
```

File

SiteComp

Description

This is class SiteComp.IWebInputName.

11.2.72.1 IWebInputName Members

The following tables list the members exposed by IWebInputName.

Public Methods

	Name	Description
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.

Public Properties

	Name	Description
	InputName (see page 1100)	This is InputName, a member of class IWebInputName.

11.2.72.2 IWebInputName Methods

The methods of the IWebInputName class are listed here.

Public Methods

	Name	Description
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.

11.2.72.2.1 IWebInputName.GetInputName Method

Pascal

```
function GetInputName: string;
```

C++

```
__fastcall UnicodeString GetInputName();
```

Description

This is GetInputName, a member of class IWebInputName.

11.2.72.3 IWebInputName Properties

The properties of the IWebInputName class are listed here.

Public Properties

	Name	Description
	InputName (see page 1100)	This is InputName, a member of class IWebInputName.

11.2.72.3.1 IWebInputName.InputName Property

Pascal

```
property InputName: string;
```

C++

```
__property UnicodeString InputName;
```

Description

This is InputName, a member of class IWebInputName.

11.2.73 IWebIsDefaultAction Interface

Class Hierarchy

Pascal

```
IWebIsDefaultAction = interface;
```

C++

```
__interface IWebIsDefaultAction;
```

File

SiteComp

Description

This is class SiteComp.IWebIsDefaultAction.

11.2.73.1 IWebIsDefaultAction Members

The following tables list the members exposed by IWebIsDefaultAction.

Public Methods

	Name	Description
	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.

11.2.73.2 IWebIsDefaultAction Methods

The methods of the IWebIsDefaultAction class are listed here.

Public Methods

	Name	Description
	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.

11.2.73.2.1 IWebIsDefaultAction.IsDefaultAction Method

Pascal

```
function IsDefaultAction(ADisplay: TObject): Boolean;
```

C++

```
__fastcall Boolean IsDefaultAction(TObject * ADisplay);
```

Description

This is IsDefaultAction, a member of class IWebIsDefaultAction.

11.2.74 IWebIsDefaultField Interface

Class Hierarchy

SiteComp.IWebIsDefaultField

Pascal

```
IWebIsDefaultField = interface;
```

C++

```
__interface IWebIsDefaultField;
```

File

SiteComp

Description

This is class SiteComp.IWebIsDefaultField.

11.2.74.1 IWebIsDefaultField Members

The following tables list the members exposed by IWebIsDefaultField.

Public Methods

	Name	Description
	IsDefaultField (see page 1102)	This is IsDefaultField, a member of class IWebIsDefaultField.

11.2.74.2 IWebIsDefaultField Methods

The methods of the IWebIsDefaultField class are listed here.

Public Methods

	Name	Description
	IsDefaultField (see page 1102)	This is IsDefaultField, a member of class IWebIsDefaultField.

11.2.74.2.1 IWebIsDefaultField.IsDefaultField Method

Pascal

```
function IsDefaultField(ADisplay: TObject): Boolean;
```

C++

```
__fastcall Boolean IsDefaultField(TObject * ADisplay);
```

Description

This is IsDefaultField, a member of class IWebIsDefaultField.

11.2.75 IWebSession Interface

IWebSession allows an application to terminate a Web session.

Class Hierarchy

Pascal

```
IWebSession = interface;
```

C++

```
__interface IWebSession;
```

File

SiteComp

Description

Use IWebSession to terminate an active Web session. When you add a new session to a TSessionsService component using the ISessionsService (see page 1066) interface, it returns an IWebSession interface for the new session. You can use this interface to terminate the session. Once a session terminates, the application can no longer access its named values.

Note: In C++, method declarations that use IWebSession use the _di_IWebSession type instead. This type is a DelphiInterface (see page 3256) wrapper around the IWebSession interface:

Note: typedef System::DelphiInterface (see page 3256)< IWebSession > _di_IWebSession;

See Also

TWebSession (see page 6251)

TSessionsService (see page 6756)

ISessionsService (see page 1066)

11.2.75.1 IWebSession Members

The following tables list the members exposed by IWebSession.

Public Methods

	Name	Description
	Terminate (see page 1103)	Terminates the session.

11.2.75.2 IWebSession Methods

The methods of the IWebSession class are listed here.

Public Methods

	Name	Description
	Terminate (see page 1103)	Terminates the session.

11.2.75.2.1 IWebSession.Terminate Method

Terminates the session.

Pascal

```
procedure Terminate;
```

C++

```
__fastcall Terminate();
```

Description

Call Terminate to terminate a session. Once a session terminates, the application can no longer access its Values.

Sessions are terminated automatically when the application does not receive any requests for the session for TimeOutMinutes minutes.

TimeoutMinutes

Values

11.2.76 IWebSessionAttributes Interface

Class Hierarchy

Pascal

```
IWebSessionAttributes = interface;
```

C++

```
__interface IWebSessionAttributes;
```

File

SiteComp

Description

This is class SiteComp.IWebSessionAttributes.

11.2.76.1 IWebSessionAttributes Members

The following tables list the members exposed by IWebSessionAttributes.

Public Methods

	Name	Description
	GetExpirationTime (see page 1104)	This is GetExpirationTime, a member of class IWebSessionAttributes.
	GetExpired (see page 1105)	This is GetExpired, a member of class IWebSessionAttributes.
	GetIsActive (see page 1105)	This is GetIsActive, a member of class IWebSessionAttributes.
	GetStartTime (see page 1105)	This is GetStartTime, a member of class IWebSessionAttributes.
	GetTerminated (see page 1105)	This is GetTerminated, a member of class IWebSessionAttributes.
	GetTimeoutMinutes (see page 1105)	This is GetTimeoutMinutes, a member of class IWebSessionAttributes.
	GetTouchTime (see page 1106)	This is GetTouchTime, a member of class IWebSessionAttributes.
	SetTimeoutMinutes (see page 1106)	This is SetTimeoutMinutes, a member of class IWebSessionAttributes.

Public Properties

	Name	Description
R	ExpirationTime (see page 1106)	This is ExpirationTime, a member of class IWebSessionAttributes.
R	Expired (see page 1107)	This is Expired, a member of class IWebSessionAttributes.
R	IsActive (see page 1107)	This is IsActive, a member of class IWebSessionAttributes.
R	StartTime (see page 1107)	This is StartTime, a member of class IWebSessionAttributes.
R	Terminated (see page 1107)	This is Terminated, a member of class IWebSessionAttributes.
	TimeoutMinutes (see page 1107)	This is TimeoutMinutes, a member of class IWebSessionAttributes.
R	TouchTime (see page 1108)	This is TouchTime, a member of class IWebSessionAttributes.

11.2.76.2 IWebSessionAttributes Methods

The methods of the IWebSessionAttributes class are listed here.

Public Methods

	Name	Description
	GetExpirationTime (see page 1104)	This is GetExpirationTime, a member of class IWebSessionAttributes.
	GetExpired (see page 1105)	This is GetExpired, a member of class IWebSessionAttributes.
	GetIsActive (see page 1105)	This is GetIsActive, a member of class IWebSessionAttributes.
	GetStartTime (see page 1105)	This is GetStartTime, a member of class IWebSessionAttributes.
	GetTerminated (see page 1105)	This is GetTerminated, a member of class IWebSessionAttributes.
	GetTimeoutMinutes (see page 1105)	This is GetTimeoutMinutes, a member of class IWebSessionAttributes.
	GetTouchTime (see page 1106)	This is GetTouchTime, a member of class IWebSessionAttributes.
	SetTimeoutMinutes (see page 1106)	This is SetTimeoutMinutes, a member of class IWebSessionAttributes.

11.2.76.2.1 IWebSessionAttributes.GetExpirationTime Method

Pascal

```
function GetExpirationTime: TDateTime;
```

C++

```
__fastcall TDateTime GetExpirationTime();
```

Description

This is GetExpirationTime, a member of class IWebSessionAttributes.

11.2.76.2.2 IWebSessionAttributes.GetExpired Method

Pascal

```
function GetExpired: Boolean;
```

C++

```
__fastcall Boolean GetExpired();
```

Description

This is GetExpired, a member of class IWebSessionAttributes.

11.2.76.2.3 IWebSessionAttributes.GetIsActive Method

Pascal

```
function GetIsActive: Boolean;
```

C++

```
__fastcall Boolean GetIsActive();
```

Description

This is GetIsActive, a member of class IWebSessionAttributes.

11.2.76.2.4 IWebSessionAttributes.GetStartTime Method

Pascal

```
function GetStartTime: TDateTime;
```

C++

```
__fastcall TDateTime GetStartTime();
```

Description

This is GetStartTime, a member of class IWebSessionAttributes.

11.2.76.2.5 IWebSessionAttributes.GetTerminated Method

Pascal

```
function GetTerminated: Boolean;
```

C++

```
__fastcall Boolean GetTerminated();
```

Description

This is GetTerminated, a member of class IWebSessionAttributes.

11.2.76.2.6 IWebSessionAttributes.GetTimeoutMinutes Method

Pascal

```
function GetTimeoutMinutes: Integer;
```

C++

```
__fastcall int GetTimeoutMinutes();
```

Description

This is GetTimeoutMinutes, a member of class IWebSessionAttributes.

11.2.76.2.7 IWebSessionAttributes.GetTouchTime Method

Pascal

```
function GetTouchTime: TDateTime;
```

C++

```
__fastcall TDateTime GetTouchTime();
```

Description

This is GetTouchTime, a member of class IWebSessionAttributes.

11.2.76.2.8 IWebSessionAttributes.SetTimeoutMinutes Method

Pascal

```
procedure SetTimeoutMinutes(AValue: Integer);
```

C++

```
__fastcall SetTimeoutMinutes(int AValue);
```

Description

This is SetTimeoutMinutes, a member of class IWebSessionAttributes.

11.2.76.3 IWebSessionAttributes Properties

The properties of the IWebSessionAttributes class are listed here.

Public Properties

	Name	Description
R	ExpirationTime (see page 1106)	This is ExpirationTime, a member of class IWebSessionAttributes.
R	Expired (see page 1107)	This is Expired, a member of class IWebSessionAttributes.
R	IsActive (see page 1107)	This is IsActive, a member of class IWebSessionAttributes.
R	StartTime (see page 1107)	This is StartTime, a member of class IWebSessionAttributes.
R	Terminated (see page 1107)	This is Terminated, a member of class IWebSessionAttributes.
	TimeoutMinutes (see page 1107)	This is TimeoutMinutes, a member of class IWebSessionAttributes.
R	TouchTime (see page 1108)	This is TouchTime, a member of class IWebSessionAttributes.

11.2.76.3.1 IWebSessionAttributes.ExpirationTime Property

Pascal

```
property ExpirationTime: TDateTime;
```

C++

```
__property TDateTime ExpirationTime;
```

Description

This is ExpirationTime, a member of class IWebSessionAttributes.

11.2.76.3.2 IWebSessionAttributes.Expired Property

Pascal

```
property Expired: Boolean;
```

C++

```
__property Boolean Expired;
```

Description

This is Expired, a member of class IWebSessionAttributes.

11.2.76.3.3 IWebSessionAttributes.IsActive Property

Pascal

```
property IsActive: Boolean;
```

C++

```
__property Boolean IsActive;
```

Description

This is IsActive, a member of class IWebSessionAttributes.

11.2.76.3.4 IWebSessionAttributes.StartTime Property

Pascal

```
property StartTime: TDateTime;
```

C++

```
__property TDateTime StartTime;
```

Description

This is StartTime, a member of class IWebSessionAttributes.

11.2.76.3.5 IWebSessionAttributes.Terminated Property

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

This is Terminated, a member of class IWebSessionAttributes.

11.2.76.3.6 IWebSessionAttributes.TimeoutMinutes Property

Pascal

```
property TimeoutMinutes: Integer;
```

C++

```
__property int TimeoutMinutes;
```

Description

This is TimeoutMinutes, a member of class IWebSessionAttributes.

11.2.76.3.7 IWebSessionAttributes.TouchTime Property

Pascal

```
property TouchTime: TDateTime;
```

C++

```
__property TDateTime TouchTime;
```

Description

This is TouchTime, a member of class IWebSessionAttributes.

11.2.77 IWebSessionID Interface

Class Hierarchy

Pascal

```
IWebSessionID = interface;
```

C++

```
__interface IWebSessionID;
```

File

SiteComp

Description

This is class SiteComp.IWebSessionID.

11.2.77.1 IWebSessionID Members

The following tables list the members exposed by IWebSessionID.

Public Methods

	Name	Description
	GetID (see page 1109)	This is GetID, a member of class IWebSessionID.

Public Properties

	Name	Description
R	ID (see page 1109)	This is ID, a member of class IWebSessionID.

11.2.77.2 IWebSessionID Methods

The methods of the IWebSessionID class are listed here.

Public Methods

	Name	Description
	GetID (see page 1109)	This is GetID, a member of class IWebSessionID.

11.2.77.2.1 IWebSessionID.GetID Method

Pascal

```
function GetID: TSessionID;
```

C++

```
__fastcall TSessionID GetID();
```

Description

This is GetID, a member of class IWebSessionID.

11.2.77.3 IWebSessionID Properties

The properties of the IWebSessionID class are listed here.

Public Properties

	Name	Description
	ID (see page 1109)	This is ID, a member of class IWebSessionID.

11.2.77.3.1 IWebSessionID.ID Property

Pascal

```
property ID: TSessionID;
```

C++

```
__property TSessionID ID;
```

Description

This is ID, a member of class IWebSessionID.

11.2.78 IWebSessionIDs Interface

IWebSessionIDs lists the session IDs (see page 1111) for all sessions that TSessionsService stores in memory.

Class Hierarchy

SiteComp.IWebSessionIDs

Pascal

```
IWebSessionIDs = interface;
```

C++

```
__interface IWebSessionIDs;
```

File

SiteComp

Description

Use IWebSessionIDs to obtain the session IDs (see page 1111) for all the sessions in a sessions service.

Note: In C++, method declarations that use IWebSessionIDs use the _di_IWebSessionIDs type instead. This type is a DelphiInterface (see page 3256) wrapper around the IWebSessionIDs interface:

Note: typedef System::DelphiInterface (see page 3256)< IWebSessionIDs > _di_IWebSessionIDs;

See Also

TSessionsService (see page 6756)

11.2.78.1 IWebSessionIDs Members

The following tables list the members exposed by IWebSessionIDs.

Public Methods

	Name	Description
	GetID (see page 1110)	Returns the value of the IDs (see page 1111) property.
	GetIDCount (see page 1111)	Returns the value of the IDCount (see page 1111) property.

Public Properties

	Name	Description
R	IDCount (see page 1111)	Indicates the number of session IDs (see page 1111) available.
R	IDs (see page 1111)	Lists the session IDs for all the sessions stored by the sessions service.

11.2.78.2 IWebSessionIDs Methods

The methods of the IWebSessionIDs class are listed here.

Public Methods

	Name	Description
	GetID (see page 1110)	Returns the value of the IDs (see page 1111) property.
	GetIDCount (see page 1111)	Returns the value of the IDCount (see page 1111) property.

11.2.78.2.1 IWebSessionIDs.GetID Method

Returns the value of the IDs (see page 1111) property.

Pascal

```
function GetID(I: Integer): TSessionID;
```

C++

```
__fastcall TSessionID GetID(int I);
```

Description

GetID is the read implementation of the IDs (see page 1111) property.

I is the index of the session ID to return.

See Also

IDs (see page 1111)

11.2.78.2.2 IWebSessionIDs.GetIDCount Method

Returns the value of the IDCount (see page 1111) property.

Pascal

```
function GetIDCount: Integer;
```

C++

```
__fastcall int GetIDCount();
```

Description

GetIDCount is the read implementation of the IDCount (see page 1111) property.

See Also

IDCount (see page 1111)

11.2.78.3 IWebSessionIDs Properties

The properties of the IWebSessionIDs class are listed here.

Public Properties

	Name	Description
	IDCount (see page 1111)	Indicates the number of session IDs (see page 1111) available.
	IDs (see page 1111)	Lists the session IDs for all the sessions stored by the sessions service.

11.2.78.3.1 IWebSessionIDs.IDCount Property

Indicates the number of session IDs (see page 1111) available.

Pascal

```
property IDCount: Integer;
```

C++

```
__property int IDCount;
```

Description

Read (see page 3634) IDCount to obtain an upper bound for the Index parameter of the IDs (see page 1111) property. IDCount is the number of session IDs (see page 1111) (hence, the number of sessions) that the sessions service has stored in memory.

See Also

IDs (see page 1111)

11.2.78.3.2 IWebSessionIDs.IDs Property

Lists the session IDs for all the sessions stored by the sessions service.

Pascal

```
property IDs [I: Integer]: TSessionID;
```

C++

```
__property TSessionID IDs[int I];
```

Description

Use IDs to iterate over the session IDs of all the sessions that the sessions service stores.

I is the index of the session ID. It can be any value from 0 to IDCount (see page 1111) – 1.

See Also

IDCount (see page 1111)

11.2.79 IWebSessionValues Interface

Class Hierarchy

SiteComp.IWebSessionValues

Pascal

```
IWebSessionValues = interface;
```

C++

```
__interface IWebSessionValues;
```

File

SiteComp

Description

This is class SiteComp.IWebSessionValues.

11.2.79.1 IWebSessionValues Members

The following tables list the members exposed by IWebSessionValues.

Public Methods

	Name	Description
	GetItemCount (see page 1113)	This is GetItemCount, a member of class IWebSessionValues.
	GetItems (see page 1113)	This is GetItems, a member of class IWebSessionValues.
	GetValue (see page 1113)	This is GetValue, a member of class IWebSessionValues.
	SetValue (see page 1113)	This is SetValue, a member of class IWebSessionValues.

Public Properties

	Name	Description
	Values (see page 1114)	This is Values, a member of class IWebSessionValues.

11.2.79.2 IWebSessionValues Methods

The methods of the IWebSessionValues class are listed here.

Public Methods

	Name	Description
	GetItemCount (see page 1113)	This is GetItemCount, a member of class IWebSessionValues.
	GetItems (see page 1113)	This is GetItems, a member of class IWebSessionValues.

	GetValue (see page 1113)	This is GetValue, a member of class IWebSessionValues.
	SetValue (see page 1113)	This is SetValue, a member of class IWebSessionValues.

11.2.79.2.1 IWebSessionValues.GetItemCount Method

Pascal

```
function GetItemCount: Integer;
```

C++

```
__fastcall int GetItemCount();
```

Description

This is GetItemCount, a member of class IWebSessionValues.

11.2.79.2.2 IWebSessionValues.GetItems Method

Pascal

```
procedure GetItems(var AItems: TAbstractNamedVariants);
```

C++

```
__fastcall GetItems(TAbstractNamedVariants AItems);
```

Description

This is GetItems, a member of class IWebSessionValues.

11.2.79.2.3 IWebSessionValues.GetValue Method

Pascal

```
function GetValue(const AName: string): Variant;
```

C++

```
__fastcall Variant GetValue(const UnicodeString AName);
```

Description

This is GetValue, a member of class IWebSessionValues.

11.2.79.2.4 IWebSessionValues.SetValue Method

Pascal

```
procedure SetValue(const AName: string; const AValue: Variant);
```

C++

```
__fastcall SetValue(const UnicodeString AName, const Variant AValue);
```

Description

This is SetValue, a member of class IWebSessionValues.

11.2.79.3 IWebSessionValues Properties

The properties of the IWebSessionValues class are listed here.

Public Properties

	Name	Description
	Values (see page 1114)	This is Values, a member of class IWebSessionValues.

11.2.79.3.1 IWebSessionValues.Values Property

Pascal

```
property Values [const AName: string]: Variant;
```

C++

```
__property Variant Values[UnicodeString const AName];
```

Description

This is Values, a member of class IWebSessionValues.

11.2.80 IWebSetActionName Interface

Class Hierarchy

SiteComp.IWebSetActionName

Pascal

```
IWebSetActionName = interface;
```

C++

```
__interface IWebSetActionName;
```

File

SiteComp

Description

This is class SiteComp.IWebSetActionName.

11.2.80.1 IWebSetActionName Members

The following tables list the members exposed by IWebSetActionName.

Public Methods

	Name	Description
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.

11.2.80.2 IWebSetActionName Methods

The methods of the IWebSetActionName class are listed here.

Public Methods

	Name	Description
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.

11.2.80.2.1 IWebSetActionName.SetActionName Method

Pascal

```
procedure SetActionName(const AFieldName: string);
```

C++

```
__fastcall SetActionName(const UnicodeString AFieldName);
```

Description

This is SetActionName, a member of class IWebSetActionName.

11.2.81 IWebSetFieldName Interface

Class Hierarchy

Pascal

```
IWebSetFieldName = interface;
```

C++

```
__interface IWebSetFieldName;
```

File

SiteComp

Description

This is class SiteComp.IWebSetFieldName.

11.2.81.1 IWebSetFieldName Members

The following tables list the members exposed by IWebSetFieldName.

Public Methods

	Name	Description
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.

11.2.81.2 IWebSetFieldName Methods

The methods of the IWebSetFieldName class are listed here.

Public Methods

	Name	Description
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.

11.2.81.2.1 IWebSetFieldName.SetFieldName Method

Pascal

```
procedure SetFieldName(const AFieldName: string);
```

C++

```
__fastcall SetFieldName(const UnicodeString AFieldName);
```

Description

This is SetFieldName, a member of class IWebSetFieldName.

11.2.82 IWebUserList Interface

IWebUserList is the interface for validating user logins and access rights.

Class Hierarchy

Pascal

```
IWebUserList = interface;
```

C++

```
__interface IWebUserList;
```

File

SiteComp

Description

The TWebUserList component implements IWebUserList. This interface, which the TWebAppComponents object publishes, allows the WebSnap application to check whether a user supplied the correct password when logging in and whether the user has rights to perform the operation requested in an HTTP request message.

Note: In C++, method declarations that use IWebUserList use the _di_IWebUserList type instead. This type is a DelphiInterface (see page 3256) wrapper around the IWebUserList interface:

Note: typedef System::DelphiInterface (see page 3256)< IWebUserList > _di_IWebUserList;

See Also

TWebUserList (see page 6796)

TCustomWebAppComponents (see page 6201)

TWebAppComponents (see page 6243)

11.2.82.1 IWebUserList Members

The following tables list the members exposed by IWebUserList.

Public Methods

	Name	Description
	CheckAccessRights (see page 1117)	Checks whether a specified user has a given access rights string.
	ValidateUser (see page 1117)	Validates a user login.

11.2.82.2 IWebUserList Methods

The methods of the IWebUserList class are listed here.

Public Methods

	Name	Description
	CheckAccessRights (see page 1117)	Checks whether a specified user has a given access rights string.
	ValidateUser (see page 1117)	Validates a user login.

11.2.82.2.1 IWebUserList.CheckAccessRights Method

Checks whether a specified user has a given access rights string.

Pascal

```
function CheckAccessRights(UserID: Variant; Rights: string): Boolean;
```

C++

```
__fastcall Boolean CheckAccessRights(Variant UserID, UnicodeString Rights);
```

Description

Call CheckAccessRights to determine whether the current end user is authorized to view Web pages or adapters whose access rights string is Rights. The end user must be logged in before CheckAccessRights can determine the user's access rights.

UserID is the user ID of the user to check.

Rights is the access rights string that CheckAccessRights must look for. Typically, this is the value of the ViewRights property on a Web page information object that describes the page the user wants to access or on an adapter that the user wants to call.

See Also

HasViewRights (see page 5510)

HasModifyRights (see page 5509)

HasExecuteRights (see page 5509)

ViewAccess

ViewAccess (see page 5574)

11.2.82.2.2 IWebUserList.ValidateUser Method

Validates a user login.

Pascal

```
function ValidateUser(Strings: TStrings): Variant;
```

C++

```
__fastcall Variant ValidateUser(TStrings Strings);
```

Description

Call ValidateUser to check whether the information a user supplies on login matches a user in the user list.

Strings is a string list that lists the information that the user supplied when logging in. Each entry in the string list is of the form Name=Value. Typically, the names of strings in the list are 'UserName' and 'Password'.

If the login information is valid, ValidateUser returns the UserID of the identified user. Otherwise, ValidateUser returns an unassigned Variant (see page 3421).

See Also

CheckAccessRights (see page 1117)

11.2.83 IWebValueIsEqual Interface

Class Hierarchy

Pascal

```
IWebValueIsEqual = interface;
```

C++

```
__interface IWebValueIsEqual;
```

File

SiteComp

Description

This is class SiteComp.IWebValueIsEqual.

11.2.83.1 IWebValueIsEqual Members

The following tables list the members exposed by IWebValueIsEqual.

Public Methods

	Name	Description
	IsEqual (see page 1119)	This is IsEqual, a member of class IWebValueIsEqual.

11.2.83.2 IWebValueIsEqual Methods

The methods of the IWebValueIsEqual class are listed here.

Public Methods

	Name	Description
	IsEqual (see page 1119)	This is IsEqual, a member of class IWebValueIsEqual.

11.2.83.2.1 IWebValueIsEqual.IsEqual Method

Pascal

```
function IsEqual(const Value: Variant): Boolean;
```

C++

```
__fastcall Boolean IsEqual(const Variant Value);
```

Description

This is IsEqual, a member of class IWebValueIsEqual.

11.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FullyQualifiedFieldName (see page 1120)	This is function SiteComp.FullyQualifiedFieldName.
	FullyQualifiedName (see page 1120)	This is function SiteComp.FullyQualifiedName.

11.3.1 SiteComp.FullyQualifiedFieldName Function

Pascal

```
function FullyQualifiedFieldName(AComponent: TComponent): string;
```

C++

```
UnicodeString FullyQualifiedFieldName(TComponent * AComponent);
```

File

SiteComp

Description

This is function SiteComp.FullyQualifiedFieldName.

11.3.2 SiteComp.FullyQualifiedName Function

Pascal

```
function FullyQualifiedName(AComponent: TComponent; AOption: TQualifyOption): string;
```

C++

```
UnicodeString FullyQualifiedName(TComponent * AComponent, TQualifyOption AOption);
```

File

SiteComp

Description

This is function SiteComp.FullyQualifiedName.

11.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAdapterActionHTMLElementType (see page 1121)	TAdapterActionHTMLElementType identifies the HTML type that is generated to let a user execute an adapter action.
	TAdapterDisplayCharacteristic (see page 1122)	TAdapterDisplayCharacteristics (see page 1128) describes the characteristics of the HTML generated to display information from an adapter.
	TAdapterDisplayHTMLElementType (see page 1123)	TAdapterDisplayHTMLElementType identifies an HTML type that can be used to display the value(s) associated with an adapter field.
	TAdapterDisplayViewModeType (see page 1123)	TAdapterDisplayViewModeType identifies how an HTML control for the associated adapter field should behave.
	TAdapterInputHTMLElementType (see page 1124)	TAdapterInputHTMLElementType identifies an HTML input type that can be used to edit the value(s) associated with an adapter field.
	TAdapterItemRequestParamOption (see page 1125)	TAdapterItemRequestParamOptions (see page 1128) identifies what parameter values to include when encoding the hidden fields and HREF values that represent calls to adapter fields and actions.
	TDispatchPageFlag (see page 1126)	TDiapatchPageFlags indicates the attributes that must be present on a Web page module for it to handle a request.
	TQualifyOption (see page 1126)	This is record SiteComp.TQualifyOption.

11.4.1 SiteComp.TAdapterActionHTMLElementType Enumeration

TAdapterActionHTMLElementType identifies the HTML type that is generated to let a user execute an adapter action.

Pascal

```
TAdapterActionHTMLElementType = (
  htmlaButton,
  htmlaImage,
  htmlaAnchor,
  htmlaEventImages
);
```

C++

```
enum TAdapterActionHTMLElementType {
  htmlaButton,
  htmlaImage,
  htmlaAnchor,
  htmlaEventImages
};
```

File

SiteComp

Description

Each element type indicates a different HTML element. TAdapterActionHTMLElementType defines executable HTML elements.

The following table lists the possible values:

Value	Meaning
htmlaButton	Push button control
htmlaImage	Image control that user can click.
htmlaAnchor	Anchor tag (hypertext link).
htmlaEventImages	Multiple images that change based on associated script.

See Also

TAdapterInputHTMLElementType (see page 1124)

11.4.2 SiteComp.TAdapterDisplayCharacteristic Enumeration

TAdapterDisplayCharacteristics (see page 1128) describes the characteristics of the HTML generated to display information from an adapter.

Pascal

```
TAdapterDisplayCharacteristic = (
  dcMultipleRecordView,
  dcCurrentRecordView,
  dcChangeCurrentRecordView
);
```

C++

```
enum TAdapterDisplayCharacteristic {
  dcMultipleRecordView,
  dcCurrentRecordView,
  dcChangeCurrentRecordView
};
```

File

SiteComp

Description

The components that generate HTML to represent the fields or actions of an adapter return a TAdapterDisplayCharacteristics (see page 1128) value to indicate what types of actions are appropriate to accompany the generated HTML. TAdapterDisplayCharacteristics (see page 1128) is a set of TAdapterDisplayCharacteristic values.

The following table lists the TAdapterDisplayCharacteristic values:

Value	Appropriate Actions
dcMultipleRecordView	Actions that operate on or display multiple records are appropriate.
dcCurrentRecordView	Actions that operate on the current adapter record are appropriate.
dcChangeCurrentRecordView	Actions that change the current record are appropriate.

11.4.3 SiteComp.TAdapterDisplayHTMLElementType Enumeration

TAdapterDisplayHTMLElementType identifies an HTML type that can be used to display the value(s) associated with an adapter field.

Pascal

```
TAdapterDisplayHTMLElementType = (
  htmldText,
  htmldImage,
  htmldList,
  htmldNone
);
```

C++

```
enum TAdapterDisplayHTMLElementType {
  htmldText,
  htmldImage,
  htmldList,
  htmldNone
};
```

File

SiteComp

Description

Each element type indicates a different HTML element. TAdapterDisplayHTMLElementType defines read-only HTML elements. TAdapterInputHTMLElementType (see page 1124) defines editable HTML elements.

The following table lists the possible values:

Value	Meaning
htmldText	Display as a text block.
htmldImage	Display as an image.
htmldList	Display as a list of values.
htmldNone	No display type specified.

See Also

GetDisplayStyleType (see page 5347)

TAdapterInputHTMLElementType (see page 1124)

11.4.4 SiteComp.TAdapterDisplayViewModeType Enumeration

TAdapterDisplayViewModeType identifies how an HTML control for the associated adapter field should behave.

Pascal

```
TAdapterDisplayViewModeType = (
  htmlvmInput,
  htmlvmDisplay,
  htmlvmToggleOnAccess,
  htmlvmNone
);
```

C++

```
enum TAdapterDisplayViewModeType {
  htmlvmInput,
  htmlvmDisplay,
  htmlvmToggleOnAccess,
  htmlvmNone
};
```

File

SiteComp

Description

Each view mode type indicates how an HTML element is to be used. The following table lists the possible values:

Value	Meaning
htmlvmInput	The HTML control is used for editing values.
htmlvmDisplay	The HTML control is used for read-only display.
htmlvmToggleOnAccess	The HTML control is used for editing if the user has modify rights, otherwise for read-only display.
htmlvmNone	No view mode type specified.

See Also

TAdapterNamedDisplayField (see page 5343)

11.4.5 SiteComp.TAdapterInputHTMLElementType Enumeration

TAdapterInputHTMLElementType identifies an HTML input type that can be used to edit the value(s) associated with an adapter field.

Pascal

```
TAdapterInputHTMLElementType = (
  htmliNone,
  htmliTextInput,
  htmliPasswordInput,
  htmliSelect,
  htmliSelectMultiple,
  htmliRadio,
  htmliCheckBox,
  htmliTextArea,
  htmliFile
);
```

C++

```
enum TAdapterInputHTMLElementType {
  htmliNone,
  htmliTextInput,
  htmliPasswordInput,
  htmliSelect,
  htmliSelectMultiple,
  htmliRadio,
  htmliCheckBox,
  htmliTextArea,
  htmliFile
};
```

File

SiteComp

Description

Each element type indicates a different HTML element. TAdapterDisplayHTMLElementType (see page 1123) defines read-only HTML elements. TAdapterInputHTMLElementType defines editable HTML elements.

The following table lists the possible values:

Value	Meaning
htmliNone	No type specified
htmliTextInput	Single line input element
htmliPasswordInput	Single line password input element
htmliSelect	Single selection list
htmliSelectMultiple	Multiple select list
htmliRadio	Group of radio buttons
htmliCheckBox	Group of check boxes
htmliTextArea	Multi-line input element
htmliFile	File upload element

See Also

GetInputStyleType (see page 5347)

TAdapterDisplayHTMLElementType (see page 1123)

11.4.6 SiteComp.TAdapterItemRequestParamOption Enumeration

TAdapterItemRequestParamOptions (see page 1128) identifies what parameter values to include when encoding the hidden fields and HREF values that represent calls to adapter fields and actions.

Pascal

```
TAdapterItemRequestParamOption = (
  roExcludeID
);
```

C++

```
enum TAdapterItemRequestParamOption {
  roExcludeID
};
```

File

SiteComp

Description

TAdapterItemRequestParamOptions (see page 1128) is the set of flags that an adapter dispatcher uses when encoding parameter values for a call to an adapter action. It represents zero or more TAdapterItemRequestParamOption values.

The following table lists the possible values:

Value	Meaning
roExcludeID	Do not include a parameter that identifies the action or image field that is the target of the request.

11.4.7 SiteComp.TDispatchPageFlag Enumeration

TDiapatchPageFlags indicates the attributes that must be present on a Web page module for it to handle a request.

Pascal

```
TDispatchPageFlag = (
  dpPublished
);
```

C++

```
enum TDispatchPageFlag {
  dpPublished
};
```

File

SiteComp

Description

TDispatchPageFlags (see page 1129) is a set of TDispatchPageFlag values. This type is used to supply flags to methods that dispatch request messages to a page module for handling. The following table lists the possible values:

Option	Meaning
dpPublished	The request can only be dispatched to the Web page module if it is published.

See Also

IPageDispatcher (see page 1060)

11.4.8 SiteComp.TQualifyOption Enumeration

Pascal

```
TQualifyOption = (
```

```
    qaUseModulesVar,
    qaNoModulesVar,
    qaNoModuleName
  );
```

C++

```
  enum TQualifyOption {
    qaUseModulesVar,
    qaNoModulesVar,
    qaNoModuleName
  };
```

File

SiteComp

Description

This is record SiteComp.TQualifyOption.

11.5 Types

The following table lists types in this documentation.

Types

Name	Description
TAdapterDisplayCharacteristics (see page 1128)	This is type SiteComp.TAdapterDisplayCharacteristics.
TAdapterItemRequestParamOptions (see page 1128)	This is type SiteComp.TAdapterItemRequestParamOptions.
TDispatchPageFlags (see page 1129)	This is type SiteComp.TDispatchPageFlags.
TSessionID (see page 1129)	TSessionID is the type of the session identifier in a WebSnap application.

11.5.1 SiteComp.TAdapterDisplayCharacteristics Type

Pascal

```
TAdapterDisplayCharacteristics = set of TAdapterDisplayCharacteristic;
```

C++

```
TAdapterDisplayCharacteristic TAdapterDisplayCharacteristics;
```

File

SiteComp

Description

This is type SiteComp.TAdapterDisplayCharacteristics.

11.5.2 SiteComp.TAdapterItemRequestParamOptions Type

Pascal

```
TAdapterItemRequestParamOptions = set of TAdapterItemRequestParamOption;
```

C++

```
TAdapterItemRequestParamOption TAdapterItemRequestParamOptions;
```

File

SiteComp

Description

This is type SiteComp.TAdapterItemRequestParamOptions.

11.5.3 SiteComp.TDispatchPageFlags Type

Pascal

```
TDispatchPageFlags = set of TDispatchPageFlag;
```

C++

```
TDispatchPageFlag TDispatchPageFlags;
```

File

SiteComp

Description

This is type SiteComp.TDispatchPageFlags.

11.5.4 SiteComp.TSessionID Type

TSessionID is the type of the session identifier in a WebSnap application.

Pascal

```
TSessionID = type string;
```

C++

```
type string TSessionID;
```

File

SiteComp

Description

TSessionID is the type that TSessionsService uses to uniquely identify the sessions in a WebSnap application.

See Also

TWebSession (see page 6251)

TInvalidWebSession (see page 6216)

TSessionsService (see page 6756)

11.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ExecuteScript (see page 1130)	This is variable SiteComp.ExecuteScript.
GetHTMLSampleImage (see page 1130)	This is variable SiteComp.GetHTMLSampleImage.
IDEFileManager (see page 1131)	This is variable SiteComp.IDEFileManager.
InetFileTypes (see page 1131)	This is variable SiteComp.InetFileTypes.
InternetEnvOptions (see page 1131)	This is variable SiteComp.InternetEnvOptions.
ScriptDebugger (see page 1132)	This is variable SiteComp.ScriptDebugger.

11.6.1 SiteComp.ExecuteScript Variable

Pascal

```
ExecuteScript: IInternetExecuteScript = nil;
```

C++

```
IInternetExecuteScript ExecuteScript = nil;
```

File

SiteComp

Description

This is variable SiteComp.ExecuteScript.

11.6.2 SiteComp.GetHTMLSampleImage Variable

Pascal

```
GetHTMLSampleImage: function: string = nil;
```

C++

```
function: string GetHTMLSampleImage = nil;
```

File

SiteComp

Description

This is variable SiteComp.GetHTMLSampleImage.

11.6.3 SiteComp.IDEFileManager Variable

Pascal

```
IDEFileManager: IIDEFileManager = nil;
```

C++

```
IIDEFileManager IDEFileManager = nil;
```

File

SiteComp

Description

This is variable SiteComp.IDEFileManager.

11.6.4 SiteComp.InetFileTypes Variable

Pascal

```
InetFileTypes: IInternetFileTypes = nil;
```

C++

```
IInternetFileTypes InetFileTypes = nil;
```

File

SiteComp

Description

This is variable SiteComp.InetFileTypes.

11.6.5 SiteComp.InternetEnvOptions Variable

Pascal

```
InternetEnvOptions: IInternetEnvOptions = nil;
```

C++

```
IInternetEnvOptions InternetEnvOptions = nil;
```

File

SiteComp

Description

This is variable SiteComp.InternetEnvOptions.

11.6.6 SiteComp.ScriptDebugger Variable

Pascal

```
ScriptDebugger: IInternetScriptDebugger = nil;
```

C++

```
IInternetScriptDebugger ScriptDebugger = nil;
```

File

SiteComp

Description

This is variable SiteComp.ScriptDebugger.

11.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
AdapterActionHTMLElementTypeNames (see page 1133)	This is constant SiteComp.AdapterActionHTMLElementTypeNames.
AdapterDisplayHTMLElementTypeNames (see page 1133)	This is constant SiteComp.AdapterDisplayHTMLElementTypeNames.
AdapterDisplayViewModeTypeNames (see page 1134)	This is constant SiteComp.AdapterDisplayViewModeTypeNames.
AdapterInputHTMLElementTypeNames (see page 1134)	This is constant SiteComp.AdapterInputHTMLElementTypeNames.

11.7.1 SiteComp.AdapterActionHTMLElementTypeNames Constant

Pascal

```
AdapterActionHTMLElementTypeNames: array[TAdapterActionHTMLElementType] of string = ('Button',
'Image', 'Anchor', 'EventImages');
```

C++

```
array[TAdapterActionHTMLElementType] of string AdapterActionHTMLElementTypeNames = ('Button',
'Image', 'Anchor', 'EventImages');
```

File

SiteComp

Description

This is constant SiteComp.AdapterActionHTMLElementTypeNames.

11.7.2 SiteComp.AdapterDisplayHTMLElementTypeNames Constant

Pascal

```
AdapterDisplayHTMLElementTypeNames: array[TAdapterDisplayHTMLElementType] of string = ('Text',
'Image', 'List', '');
```

C++

```
array[TAdapterDisplayHTMLElementType] of string AdapterDisplayHTMLElementTypeNames = ('Text',
'Image', 'List', '');
```

File

SiteComp

Description

This is constant SiteComp.AdapterDisplayHTMLElementTypeNames.

11.7.3 SiteComp.AdapterDisplayViewModeTypeNames Constant

Pascal

```
AdapterDisplayViewModeTypeNames: array[TAdapterDisplayViewModeType] of string = ('Input',
'Display', 'ToggleOnAccess', '');
```

C++

```
array[TAdapterDisplayViewModeType] of string AdapterDisplayViewModeTypeNames = ('Input',
'Display', 'ToggleOnAccess', '');
```

File

SiteComp

Description

This is constant SiteComp.AdapterDisplayViewModeTypeNames.

11.7.4 SiteComp.AdapterInputHTMLElementTypeNames Constant

Pascal

```
AdapterInputHTMLElementTypeNames: array[TAdapterInputHTMLElementType] of string = ('',
'TextInput', 'PasswordInput', 'Select', 'SelectMultiple', 'Radio', 'CheckBox', 'TextArea',
'File');
```

C++

```
array[TAdapterInputHTMLElementType] of string AdapterInputHTMLElementTypeNames = ('',
'TextInput', 'PasswordInput', 'Select', 'SelectMultiple', 'Radio', 'CheckBox', 'TextArea',
'File');
```

File

SiteComp

Description

This is constant SiteComp.AdapterInputHTMLElementTypeNames.

12 SiteProd Namespace

This is namespace SiteProd.

Topics

Name	Description
Classes (see page 1136)	The following table lists classes in this documentation.

Classes

	Name	Description
	TAdapterPageProducer (see page 1136)	TAdapterPageProducer generates the proper HTML and server-side script needed to display adapter fields and execute adapter actions.
	TBaseAdapterPageProducer (see page 1143)	TBaseAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.
	TCustomAdapterPageProducer (see page 1159)	TCustomAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.
	TSitePageElements (see page 1167)	TSitePageElements stores part of the content that page producers generate.

12.1 Classes

The following table lists classes in this documentation.

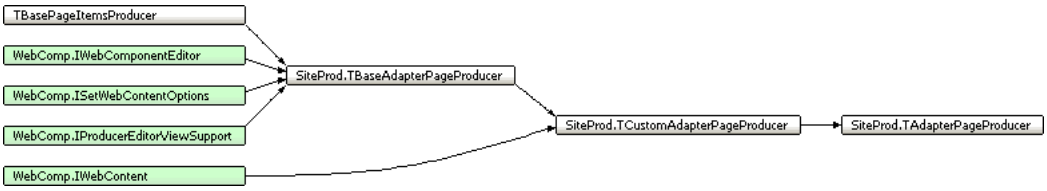
Classes

	Name	Description
	TAdapterPageProducer (see page 1136)	TAdapterPageProducer generates the proper HTML and server-side script needed to display adapter fields and execute adapter actions.
	TBaseAdapterPageProducer (see page 1143)	TBaseAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.
	TCustomAdapterPageProducer (see page 1159)	TCustomAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.
	TSitePageElements (see page 1167)	TSitePageElements stores part of the content that page producers generate.

12.1.1 TAdapterPageProducer Class

TAdapterPageProducer generates the proper HTML and server-side script needed to display adapter fields and execute adapter actions.

Class Hierarchy



Pascal

```
TAdapterPageProducer = class(TCustomAdapterPageProducer);
```

C++

```
class TAdapterPageProducer : public TCustomAdapterPageProducer;
```

File

SiteProd

Description

TAdapterPageProducer creates an HTML page using content it obtains from a hierarchy of components called Web items. Add components to this hierarchy to define HTML forms and tables. For example, to create an HTML form with a grid, add a TAdapterForm (see page 6404) and TAdapterGrid (see page 6419) components. The Web items that appear in the TAdapterPageProducer's hierarchy use Adapter components to fetch the information that they display.

Use the Web Page Module wizard to create a web page that uses the TAdapterPageProducer. You can select TAdapterPageProducer from the drop-down list at the top of the Web Page Module wizard, or add a TAdapterPageProducer component to an existing web page modue.

Web page modules that use the TAdapterPageProducer provide an editor view called HTML Script. Use this view to see the HTML Script that TAdapterPageProducer generates. The script generated by TAdapterPageProducer is not editable. However, you can copy the generated script from the HTML Script view to a new Web Page Module. You can then edit the copy of the

script in the code editor or with an external HTML editor that supports embedded script tags (for example <% %>).

TAdapterPageProducer uses a template that contains the following special tags:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1140) or StylesFile (see page 1141) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with the generated HTML/JavaScript. The TAdapterPageProducer will not generate any content if this tag is missing.

See Also

TAdapter (see page 5190)

TAdapterForm (see page 6404)

TAdapterGrid (see page 6419)

Page Producers

Server-side Scripting in WebSnap

12.1.1.1 TAdapterPageProducer Members

The following tables list the members exposed by TAdapterPageProducer.

Protected Methods

	Name	Description
	CanAddClass (see page 1146)	Specifies whether a Web item of a specified type can be added to the WebPageItems property list.
V	CreatePageElements (see page 1147)	Creates the object that implements the PageElements (see page 1157) property.
V	DeclareStyles (see page 1148)	Returns an HTML Styles (see page 1157) tag that declares the styles specified by the Styles (see page 1157) or StylesFile (see page 1158) property.
V	DeclareWarnings (see page 1148)	Returns the formatted warnings that appear at design time to indicate the status of content generation.
	DoAfterGetContent (see page 1148)	Generates an OnAfterGetContent (see page 1158) event.
	DoBeforeGetContent (see page 1149)	Generates an OnBeforeGetContent (see page 1159) event.
V	DoTagEvent (see page 1149)	Translates HTML-transparent tags in the template.
V	GeneratePageElements (see page 1150)	Fills the PageElements (see page 1157) property with information based on the other properties of the adapter Page Producer.
V	GetContentOptions (see page 1150)	Returns an object that influences how the page producer generates its content.
V	GetDefaultTemplate (see page 1150)	Returns the default template that the page producer can use to generate content.
V	GetTemplateFileName (see page 1162)	Returns the value of the HTMLFile (see page 1166) property.
	GetTemplateFileType (see page 1152)	Returns the type of file that can store the templates this object uses to generate its content.
V	GetTemplateStream (see page 1163)	Returns a stream from which to read the HTML template that this producer uses.
	GetXMLData (see page 1152)	Returns a stream for reading any XML data associated with the page producer.
	GetXSLData (see page 1152)	Returns a stream for reading an XSL template associated with the page producer.
V	HandleScriptTag (see page 1153)	Translates HTML-transparent tags for an associated server-side script.
	HasHTMLBrowserView (see page 1153)	Indicates whether the IDE should display an HTML browser view for the producer's content.
	HasScriptView (see page 1154)	Indicates whether the IDE should display an associated server-side script.
	HasXMLBrowserView (see page 1154)	Indicates whether the IDE should display an XML tree view for any XML data associated with the page producer.
	HasXSLBrowserView (see page 1154)	Indicates whether the IDE should display an XSL tree view for an XSL template associated with the page producer.

	ImplCanAddClass (see page 1155)	Provides the underlying implementation for the CanAddClass (see page 1146) method.
	SetHTMLDoc (see page 1163)	Sets the HTMLDoc (see page 1165) property.
	SetHTMLFile (see page 1164)	Sets the HTMLFile (see page 1166) property.
	SetWebContentOptions (see page 1156)	Sets the options that limit how the page producer creates its generated HTML.
	WebContent (see page 1164)	Returns the HTML document assembled by the Adapter page producer.

Protected Properties

	Name	Description
	PageElements (see page 1157)	Stores information that the Adapter page producer uses when generating its content.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
	Content (see page 6104)	Returns the HTML that the Web item generates.
	ContentFromStream (see page 1147)	Returns the content produced using a template read from a stream.
	Create (see page 1145)	Creates and initializes an instance of TBaseAdapterPageProducer (see page 1143).
	Create (see page 1161)	Creates and initializes an instance of TCustomAdapterPageProducer (see page 1159).
	Destroy (see page 1145)	Frees an instance of TBaseAdapterPageProducer (see page 1143).
	Destroy (see page 1162)	Frees an instance of TCustomAdapterPageProducer (see page 1159).
	GetRequiredTags (see page 1151)	Returns the HTML-transparent tags that the adapter page producer requires to have present in its template.
	GetScriptEngines (see page 1151)	Returns a list of script engines that can work with server-side scripts that produce content for the page producer.
	GetTemplateFileType (see page 6090)	This is GetTemplateFileType, a member of class IProducerEditorViewSupport.
	GetXMLData (see page 6090)	This is GetXMLData, a member of class IProducerEditorViewSupport.
	GetXSLData (see page 6090)	This is GetXSLData, a member of class IProducerEditorViewSupport.
	HasHTMLBrowserView (see page 6091)	This is HasHTMLBrowserView, a member of class IProducerEditorViewSupport.
	HasScriptView (see page 6091)	This is HasScriptView, a member of class IProducerEditorViewSupport.
	HasXMLBrowserView (see page 6091)	This is HasXMLBrowserView, a member of class IProducerEditorViewSupport.
	HasXSLBrowserView (see page 6091)	This is HasXSLBrowserView, a member of class IProducerEditorViewSupport.
	SetStyles (see page 1155)	Assigns a value to the Styles (see page 1157) property.
	SetStylesFile (see page 1156)	Assigns a value to the StylesFile (see page 1158) property.
	SetWebContentOptions (see page 6092)	This is SetWebContentOptions, a member of class ISetWebContentOptions.

Published Events

	Name	Description
	OnAfterGetContent (see page 1142)	Occurs after the page producer generates its content.
	OnBeforeGetContent (see page 1142)	Occurs before the page producer generates its content.

Published Properties

	Name	Description
	HTMLDoc (see page 1139)	Specifies the HTML template used to generate the value that the Content method returns.
	HTMLFile (see page 1140)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	Styles (see page 1140)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 1141)	Specifies a file containing the individual styles for the page producer's style sheet.
	WebPageItems (see page 1141)	Maintains a list of components that generate HTML content for the producer.

12.1.1.2 TAdapterPageProducer Properties

The properties of the TAdapterPageProducer class are listed here.

Published Properties

	Name	Description
	HTMLDoc (see page 1139)	Specifies the HTML template used to generate the value that the Content method returns.
	HTMLFile (see page 1140)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	Styles (see page 1140)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 1141)	Specifies a file containing the individual styles for the page producer's style sheet.
	WebPageItems (see page 1141)	Maintains a list of components that generate HTML content for the producer.

12.1.1.2.1 TAdapterPageProducer.HTMLDoc Property

Specifies the HTML template used to generate the value that the Content method returns.

Pascal

```
property HTMLDoc: TStrings;
```

C++

```
__property TStrings HTMLDoc;
```

Description

Set HTMLDoc to a set of strings that make up the HTML template. By default, HTMLDoc is initialized to the following template:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#STYLES> <#WARNINGS> <#SERVERSCRIPT>
</BODY>
</HTML>
```

Each string is a sequence of one or more HTML commands or HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. TCustomAdapterPageProducer automatically handles the conversion of the HTML-transparent tags in the default template as follows:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles or StylesFile property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items. TCustomAdapterPageProducer will not generate any content if this tag is missing.

If you set HTMLDoc to include other HTML-transparent tags, you must translate these in an OnHTMLTag event handler.

Note: Setting HTMLDoc clears the HTMLFile property.

Content

HTMLFile (see page 1166)

OnHTMLTag

12.1.1.2.2 TAdapterPageProducer.HTMLFile Property

Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLFile: TFileName;
```

C++

```
__property TFileName HTMLFile;
```

Description

Set HTMLFile to the name of the file that contains an HTML template. The HTML template is a sequence of HTML commands and HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLFile clears the HTMLDoc property.

Note: When distributing applications that contain page producers which use the HTMLFile property, be sure to distribute the file along with the application. Also, be sure that the value of HTMLFile does not include a hard-coded path name that will not be available on the user's disk.

Content

HTMLDoc (see page 1165)

OnHTMLTag

12.1.1.2.3 TAdapterPageProducer.Styles Property

Defines the styles that can be used by the page producer and its Web items.

Pascal

```
property Styles: TStrings;
```

C++

```
__property TStrings Styles;
```

Description

Use Styles to define a style sheet for the HTML document produced by TBaseAdapterPageProducer. Each string in the TStrings object specifies a specific style by giving a style selector followed by a set of attributes in curly braces. These definitions can define styles for standard HTML elements such as

```
H2 B  {color: red}
```

or they can define styles that you name, such as

```
.MyStyle  {font-family: arial; font-weight: bold; font-size: 18px }
```

Note that user-defined style names must begin with a dot.

Styles for standard elements are applied automatically to HTML that uses the tag or tags that form the style selector. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector.

Note: If you are sharing a set of styles between multiple page producers or multiple applications, you can define the styles in a file. To define the styles in a file, use the StylesFile property instead. If StylesFile is defined, it takes precedence over the Styles property.

See Also

StylesFile (see page 1158)

Content

12.1.1.2.4 TAdapterPageProducer.StylesFile Property

Specifies a file containing the individual styles for the page producer's style sheet.

Pascal

```
property StylesFile: TFileName;
```

C++

```
__property TFileName StylesFile;
```

Description

Set StylesFile to the name of a file containing the style definitions used by the page producer. The page producer uses these style definitions to declare a style sheet in the HTML document it generates.

Styles for standard elements are applied automatically to HTML in the document. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector of a style definition.

Note: If the StylesFile property is not set, you can specify the style definitions using the Styles property instead.

See Also

Styles (see page 1157)

Content

12.1.1.2.5 TAdapterPageProducer.WebPageItems Property

Maintains a list of components that generate HTML content for the producer.

Pascal

```
property WebPageItems;
```

C++

```
__property WebPageItems;
```

Description

WebPageItems lists the components that generate content for the page items producer. Each of these components supports the IWebContent interface, and can contain its own list of Web items that help it generate its content.

The type of items that can be added to the WebPageItems list are restricted by a protected method that is abstract or, in C++ terminology, pure virtual in TBasePageItemsProducer. Descendant classes implement this protected method to indicate what types of items can be added to the list.

At design time, use the Web page editor to add components to the WebPageItems property.

Note: Typically, WebPageItems lists all the components that generate content for the page items producer, in the order that the generated content appears in the final HTML document. However, the page items producer can transform COMPONENT tags in its template using components that are not in this list, as long as they have the same owner as the page items producer..

12.1.1.3 TAdapterPageProducer Events

The events of the TAdapterPageProducer class are listed here.

Published Events

	Name	Description
	OnAfterGetContent (see page 1142)	Occurs after the page producer generates its content.
	OnBeforeGetContent (see page 1142)	Occurs before the page producer generates its content.

12.1.1.3.1 TAdapterPageProducer.OnAfterGetContent Event

Occurs after the page producer generates its content.

Pascal

```
property OnAfterGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAfterGetContent;
```

Description

Write an OnAfterGetContent event handler to take specific action immediately after the producer generates its content.

See Also

ContentFromStream (see page 1147)

OnBeforeGetContent (see page 1159)

12.1.1.3.2 TAdapterPageProducer.OnBeforeGetContent Event

Occurs before the page producer generates its content.

Pascal

```
property OnBeforeGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBeforeGetContent;
```

Description

Write an OnBeforeGetContent event handler to take specific action immediately before the producer generates its content.

See Also

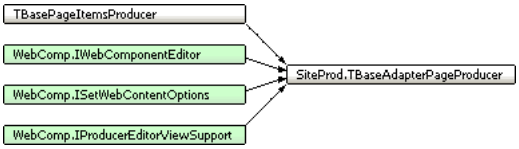
ContentFromStream (see page 1147)

OnAfterGetContent (see page 1158)

12.1.2 TBaseAdapterPageProducer Class

TBaseAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.

Class Hierarchy



Pascal

```
TBaseAdapterPageProducer = class(TBasePageItemsProducer, IWebComponentEditor,
ISetWebContentOptions, IProducerEditorViewSupport);
```

C++

```
class TBaseAdapterPageProducer : public TBasePageItemsProducer, public IWebComponentEditor,
public ISetWebContentOptions, public IProducerEditorViewSupport;
```

File

SiteProd

Description

TBaseAdapterPageProducer creates an HTML page using content it obtains from a hierarchy of components called Web items. The Web items that appear in the TBaseAdapterPageProducer's hierarchy use Adapter components to fetch the information that they display.

Use TBaseAdapterPageProducer as a base class for page producer components that assemble their content from Web items that use Adapter components. TBaseAdapterPageProducer implements the logic for converting an HTML template into content it assembles from its hierarchy of Web items.

TBaseAdapterPageProducer implements the logic to translate the following special HTML-transparent tags:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1157) or StylesFile (see page 1158) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items.

12.1.2.1 TBaseAdapterPageProducer Members

The following tables list the members exposed by TBaseAdapterPageProducer.

Protected Methods

	Name	Description
	CanAddClass (see page 1146)	Specifies whether a Web item of a specified type can be added to the WebPageItems property list.
V	CreatePageElements (see page 1147)	Creates the object that implements the PageElements (see page 1157) property.
V	DeclareStyles (see page 1148)	Returns an HTML Styles (see page 1157) tag that declares the styles specified by the Styles (see page 1157) or StylesFile (see page 1158) property.
V	DeclareWarnings (see page 1148)	Returns the formatted warnings that appear at design time to indicate the status of content generation.
	DoAfterGetContent (see page 1148)	Generates an OnAfterGetContent (see page 1158) event.
	DoBeforeGetContent (see page 1149)	Generates an OnBeforeGetContent (see page 1159) event.
V	DoTagEvent (see page 1149)	Translates HTML-transparent tags in the template.
V	GeneratePageElements (see page 1150)	Fills the PageElements (see page 1157) property with information based on the other properties of the adapter Page Producer.
V	GetContentOptions (see page 1150)	Returns an object that influences how the page producer generates its content.
V	GetDefaultTemplate (see page 1150)	Returns the default template that the page producer can use to generate content.
	GetTemplateFileType (see page 1152)	Returns the type of file that can store the templates this object uses to generate its content.
	GetXMLData (see page 1152)	Returns a stream for reading any XML data associated with the page producer.
	GetXSLData (see page 1152)	Returns a stream for reading an XSL template associated with the page producer.
V	HandleScriptTag (see page 1153)	Translates HTML-transparent tags for an associated server-side script.
	HasHTMLBrowserView (see page 1153)	Indicates whether the IDE should display an HTML browser view for the producer's content.
	HasScriptView (see page 1154)	Indicates whether the IDE should display an associated server-side script.
	HasXMLBrowserView (see page 1154)	Indicates whether the IDE should display an XML tree view for any XML data associated with the page producer.
	HasXSLBrowserView (see page 1154)	Indicates whether the IDE should display an XSL tree view for an XSL template associated with the page producer.
V	ImplCanAddClass (see page 1155)	Provides the underlying implementation for the CanAddClass (see page 1146) method.
	SetWebContentOptions (see page 1156)	Sets the options that limit how the page producer creates its generated HTML.

Protected Properties

	Name	Description
R	PageElements (see page 1157)	Stores information that the Adapter page producer uses when generating its content.

Public Events

	Name	Description
	OnAfterGetContent (see page 1158)	Occurs after the page producer generates its content.
	OnBeforeGetContent (see page 1159)	Occurs before the page producer generates its content.

Public Methods

	Name	Description
V	ContentFromStream (see page 1147)	Returns the content produced using a template read from a stream.
V	Create (see page 1145)	Creates and initializes an instance of TBaseAdapterPageProducer (see page 1143).
V	Destroy (see page 1145)	Frees an instance of TBaseAdapterPageProducer (see page 1143).
	GetRequiredTags (see page 1151)	Returns the HTML-transparent tags that the adapter page producer requires to have present in its template.

	GetScriptEngines (see page 1151)	Returns a list of script engines that can work with server-side scripts that produce content for the page producer.
	SetStyles (see page 1155)	Assigns a value to the Styles (see page 1157) property.
	SetStylesFile (see page 1156)	Assigns a value to the StylesFile (see page 1158) property.

Public Properties

	Name	Description
	Styles (see page 1157)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 1158)	Specifies a file containing the individual styles for the page producer's style sheet.

12.1.2.2 TBaseAdapterPageProducer.Create Constructor

Creates and initializes an instance of TBaseAdapterPageProducer (see page 1143).

Pascal

```
constructor Create(AComponent: TComponent); override;
```

C++

```
virtual __fastcall TBaseAdapterPageProducer(TComponent * AComponent);
```

Description

Call Create to instantiate an adapter page producer at runtime. Adapter page producers placed in a Web page module at design time (or by the Web page module wizard) are instantiated automatically.

AOwner is a component, typically a Web page module, that becomes the value of the Owner property. The Owner is responsible for freeing the TBaseAdapterPageProducer (see page 1143) instance.

See Also

Owner

12.1.2.3 TBaseAdapterPageProducer.Destroy Destructor

Frees an instance of TBaseAdapterPageProducer (see page 1143).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBaseAdapterPageProducer();
```

Description

Do not call Destroy directly. Instead, call the Free method, which checks whether the reference to the producer is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

12.1.2.4 TBaseAdapterPageProducer Methods

The methods of the TBaseAdapterPageProducer class are listed here.

Protected Methods

	Name	Description
	CanAddClass (see page 1146)	Specifies whether a Web item of a specified type can be added to the WebPageItems property list.
V	CreatePageElements (see page 1147)	Creates the object that implements the PageElements (see page 1157) property.
V	DeclareStyles (see page 1148)	Returns an HTML Styles (see page 1157) tag that declares the styles specified by the Styles (see page 1157) or StylesFile (see page 1158) property.
V	DeclareWarnings (see page 1148)	Returns the formatted warnings that appear at design time to indicate the status of content generation.
	DoAfterGetContent (see page 1148)	Generates an OnAfterGetContent (see page 1158) event.
	DoBeforeGetContent (see page 1149)	Generates an OnBeforeGetContent (see page 1159) event.
V	DoTagEvent (see page 1149)	Translates HTML-transparent tags in the template.
V	GeneratePageElements (see page 1150)	Fills the PageElements (see page 1157) property with information based on the other properties of the adapter Page Producer.
V	GetContentOptions (see page 1150)	Returns an object that influences how the page producer generates its content.
V	GetDefaultTemplate (see page 1150)	Returns the default template that the page producer can use to generate content.
	GetTemplateFileType (see page 1152)	Returns the type of file that can store the templates this object uses to generate its content.
	GetXMLData (see page 1152)	Returns a stream for reading any XML data associated with the page producer.
	GetXSLData (see page 1152)	Returns a stream for reading an XSL template associated with the page producer.
V	HandleScriptTag (see page 1153)	Translates HTML-transparent tags for an associated server-side script.
	HasHTMLBrowserView (see page 1153)	Indicates whether the IDE should display an HTML browser view for the producer's content.
	HasScriptView (see page 1154)	Indicates whether the IDE should display an associated server-side script.
	HasXMLBrowserView (see page 1154)	Indicates whether the IDE should display an XML tree view for any XML data associated with the page producer.
	HasXSLBrowserView (see page 1154)	Indicates whether the IDE should display an XSL tree view for an XSL template associated with the page producer.
V	ImplCanAddClass (see page 1155)	Provides the underlying implementation for the CanAddClass (see page 1146) method.
	SetWebContentOptions (see page 1156)	Sets the options that limit how the page producer creates its generated HTML.

Public Methods

	Name	Description
V	ContentFromStream (see page 1147)	Returns the content produced using a template read from a stream.
	GetRequiredTags (see page 1151)	Returns the HTML-transparent tags that the adapter page producer requires to have present in its template.
	GetScriptEngines (see page 1151)	Returns a list of script engines that can work with server-side scripts that produce content for the page producer.
	SetStyles (see page 1155)	Assigns a value to the Styles (see page 1157) property.
	SetStylesFile (see page 1156)	Assigns a value to the StylesFile (see page 1158) property.

12.1.2.4.1 TBaseAdapterPageProducer.CanAddClass Method

Specifies whether a Web item of a specified type can be added to the WebPageItems property list.

Pascal

```
function CanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean CanAddClass(TComponent * AParent, TClass AClass);
```

Description

The IDE calls CanAddClass to determine what Web items can be added to supply content for the TBaseAdapterPageProducer (see page 1143) descendant. CanAddClass calls the virtual ImplCanAddClass (see page 1155) method to determine whether a class of Web item is valid.

AParent is the TBaseAdapterPageProducer (see page 1143) descendant to whose WebPageItems property the Web item will be added.

AClass is the class of the proposed child Web item.

CanAddClass returns true if the TBaseAdapterPageProducer (see page 1143) descendant can use content generated by a component of type AClass, false otherwise.

See Also

ImplCanAddClass (see page 1155)

WebPageItems

12.1.2.4.2 TBaseAdapterPageProducer.ContentFromStream Method

Returns the content produced using a template read from a stream.

Pascal

```
function ContentFromStream(InStream: TStream): string; override;
```

C++

```
virtual __fastcall UnicodeString ContentFromStream(TStream InStream);
```

Description

Call ContentFromStream to retrieve the content produced by the adapter page producer based on the template provided by the Stream parameter. ContentFromStream:

1. Generates an OnBeforeGetContent (see page 1159) event.
2. Translates the HTML template that is the value of Stream, using information produced by the items listed in the WebPageItems property.
3. Generates an OnAfterGetContent (see page 1158) event.
4. Returns the HTML produced in step 2.

See Also

Content

OnBeforeGetContent (see page 1159)

WebPageItems

OnAfterGetContent (see page 1158)

12.1.2.4.3 TBaseAdapterPageProducer.CreatePageElements Method

Creates the object that implements the PageElements (see page 1157) property.

Pascal

```
function CreatePageElements: TSitePageElements; virtual;
```

C++

```
virtual __fastcall TSitePageElements CreatePageElements();
```

Description

CreatePageElements creates the object that is used as the value of the PageElements (see page 1157) property. This object holds temporary information that the page producer uses to assemble its content.

See Also

PageElements (see page 1157)

GeneratePageElements (see page 1150)

12.1.2.4.4 TBaseAdapterPageProducer.DeclareStyles Method

Returns an HTML Styles (see page 1157) tag that declares the styles specified by the Styles (see page 1157) or StylesFile (see page 1158) property.

Pascal

```
function DeclareStyles: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareStyles();
```

Description

The GeneratePageElements (see page 1150) method calls DeclareStyles to generate the HTML that declares a stylesheet in the generated HTML page. DeclareStyles uses the StylesFile (see page 1158) property to determine the styles it declares. If StylesFile (see page 1158) is an empty string, DeclareStyles uses the Styles (see page 1157) property instead. If both StylesFile (see page 1158) and Styles (see page 1157) are set to empty strings, DeclareStyles returns an empty string.

See Also

Styles (see page 1157)

StylesFile (see page 1158)

GeneratePageElements (see page 1150)

12.1.2.4.5 TBaseAdapterPageProducer.DeclareWarnings Method

Returns the formatted warnings that appear at design time to indicate the status of content generation.

Pascal

```
function DeclareWarnings(Warnings: TStrings): string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareWarnings(TStrings Warnings);
```

Description

The GeneratePageElements (see page 1150) method calls DeclareWarnings to generate the text that describes any design-time warnings. These warnings indicate possible problems with the hierarchy of web items.

See Also

GeneratePageElements (see page 1150)

WebPageItems

12.1.2.4.6 TBaseAdapterPageProducer.DoAfterGetContent Method

Generates an OnAfterGetContent (see page 1158) event.

Pascal

```
procedure DoAfterGetContent;
```

C++

```
__fastcall DoAfterGetContent();
```

Description

TBaseAdapterPageProducer (see page 1143) calls DoAfterGetContent internally to generate the OnAfterGetContent (see page 1158) event.

See Also

OnAfterGetContent (see page 1158)

12.1.2.4.7 TBaseAdapterPageProducer.DoBeforeGetContent Method

Generates an OnBeforeGetContent (see page 1159) event.

Pascal

```
procedure DoBeforeGetContent;
```

C++

```
__fastcall DoBeforeGetContent();
```

Description

TBaseAdapterPageProducer (see page 1143) calls DoBeforeGetContent internally to generate the OnBeforeGetContent (see page 1159) event.

See Also

OnBeforeGetContent (see page 1159)

12.1.2.4.8 TBaseAdapterPageProducer.DoTagEvent Method

Translates HTML-transparent tags in the template.

Pascal

```
procedure DoTagEvent(Tag: TTag; const TagString: string; TagParams: TStrings; var ReplaceText:
string); override;
```

C++

```
virtual __fastcall DoTagEvent(TTag Tag, const UnicodeString TagString, TStrings TagParams,
UnicodeString ReplaceText);
```

Description

When the page producer encounters an HTML-transparent tag in its template, it calls DoTagEvent to translate that tag into the appropriate value. TBaseAdapterPageProducer (see page 1143) overrides the inherited method to handle the <#STYLES>, <#WARNINGS>, and <#SERVERSCRIPT> tags. For any other tags, DoTagEvent generates an OnHTMLTag event.

Tag is the type of HTML-transparent tag that was encountered in the HTML template.

TagString is tag name of the HTML-transparent tag. This is the first string that follows the pound sign (#).

TagParams gives the parameter portion of the HTML-transparent tag. Each string in the TStrings object has the form ParamName=Value.

ReplaceText returns the translated string that should replace the HTML-transparent tag.

See Also

OnHTMLTag

12.1.2.4.9 TBaseAdapterPageProducer.GeneratePageElements Method

Fills the PageElements (see page 1157) property with information based on the other properties of the adapter Page Producer.

Pascal

```
procedure GeneratePageElements; virtual;
```

C++

```
virtual __fastcall GeneratePageElements();
```

Description

GeneratePageElements assembles information about the styles, warnings, server script, server functions, and server variables that the adapter page producer uses to generate its content. It writes this information into the members of the object that is the value of the PageElements (see page 1157) property.

See Also

PageElements (see page 1157)

12.1.2.4.10 TBaseAdapterPageProducer.GetContentOptions Method

Returns an object that influences how the page producer generates its content.

Pascal

```
function GetContentOptions(var Owned: Boolean): TWebContentOptions; override;
```

C++

```
virtual __fastcall TWebContentOptions GetContentOptions(Boolean Owned);
```

Description

TBaseAdapterPageProducer (see page 1143) calls GetContentOptions internally to look up the options that limit what can be included in the generated HTML.

Owned returns a value that indicates whether the return value should be freed by the caller. If Owned is true, the caller should free the TWebContentOptions (see page 6076) object after it has used it.

See Also

SetWebContentOptions (see page 1156)

12.1.2.4.11 TBaseAdapterPageProducer.GetDefaultTemplate Method

Returns the default template that the page producer can use to generate content.

Pascal

```
function GetDefaultTemplate: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDefaultTemplate();
```

Description

GetDefaultTemplate returns the default template that the page producer can use to generate its content. This template has the form:

```
<HTML>
<HEAD>
```

```
</HEAD>
<BODY>
<#STYLES> <#WARNINGS> <#SERVERSCRIPT>
</BODY>
</HTML>
```

TBaseAdapterPageProducer (see page 1143) automatically handles the conversion of the HTML-transparent tags in the default template as follows:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1157) or StylesFile (see page 1158) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items.

See Also

Styles (see page 1157)

StylesFile (see page 1158)

12.1.2.4.12 TBaseAdapterPageProducer.GetRequiredTags Method

Returns the HTML-transparent tags that the adapter page producer requires to have present in its template.

Pascal

```
class function GetRequiredTags: string;
```

C++

```
__fastcall UnicodeString GetRequiredTags();
```

Description

GetRequiredTags returns a string containing the special tags that the page producer expects to find for generating its content. This method returns the string '<#STYLES> <#WARNINGS> <#SERVERSCRIPT>'.

See Also

ContentFromStream (see page 1147)

12.1.2.4.13 TBaseAdapterPageProducer.GetScriptEngines Method

Returns a list of script engines that can work with server-side scripts that produce content for the page producer.

Pascal

```
class procedure GetScriptEngines(S: TStrings);
```

C++

```
__fastcall GetScriptEngines(TStrings S);
```

Description

GetScriptEngines fills an existing string list with the set of all values that can be assigned to the ScriptEngine property. These determine the script engine that works with associated server-side scripts.

This method adds a single string, 'JSCRIPT', to the string list passed as the S parameter.

See Also

ScriptEngine

12.1.2.4.14 TBaseAdapterPageProducer.GetTemplateFileType Method

Returns the type of file that can store the templates this object uses to generate its content.

Pascal

```
function GetTemplateFileType: string;
```

C++

```
__fastcall UnicodeString GetTemplateFileType();
```

Description

GetTemplateFileType returns the string 'HTML', because Adapter page producers generate their contents based on an HTML template that includes HTML-transparent tags.

See Also

GetDefaultTemplate (see page 1150)

12.1.2.4.15 TBaseAdapterPageProducer.GetXMLData Method

Returns a stream for reading any XML data associated with the page producer.

Pascal

```
function GetXMLData(var Owned: Boolean): TStream;
```

C++

```
__fastcall TStream GetXMLData(Boolean Owned);
```

Description

The IDE calls GetXMLData for producers that indicate that they support an XML browser view (that is, if the HasXMLBrowserView (see page 1154) method returns true). In TBaseAdapterPageProducer (see page 1143), GetXMLData always returns nil (Delphi) or NULL (C++), because adapter page producers do not use associated XML data.

Owned returns an indication of whether the caller needs to free the returned stream. In this case, this parameter is irrelevant, because GetXMLData always returns nil (Delphi) or NULL (C++).

See Also

HasXMLBrowserView (see page 1154)

12.1.2.4.16 TBaseAdapterPageProducer.GetXSLData Method

Returns a stream for reading an XSL template associated with the page producer.

Pascal

```
function GetXSLData(var Owned: Boolean): TStream;
```

C++

```
__fastcall TStream GetXSLData(Boolean Owned);
```

Description

The IDE calls GetXSLData for producers that indicate that they support an XSL browser view (that is, if the HasXSLBrowserView (see page 1154) method returns true). In TBaseAdapterPageProducer (see page 1143), GetXSLData always returns nil (Delphi) or NULL (C++), because adapter page producers do not use an associated XSL template.

Owned returns an indication of whether the caller needs to free the returned stream. In this case, this parameter is irrelevant,

because GetXSLData always returns nil (Delphi) or NULL (C++).

See Also

HasXSLBrowserView (see page 1154)

12.1.2.4.17 TBaseAdapterPageProducer.HandleScriptTag Method

Translates HTML-transparent tags for an associated server-side script.

Pascal

```
function HandleScriptTag(const TagString: string; TagParams: TStrings; var ReplaceString:
string): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandleScriptTag(const UnicodeString TagString, TStrings TagParams,
UnicodeString ReplaceString);
```

Description

When a server-side script encounters an HTML-transparent tag, it calls HandleScriptTag to allow the page producer to translate that tag for it. HandleScriptTag translates the <#SERVERSCRIPT> tag, supplying the content produced by the hierarchy of Web items that is the value of the WebPageItems property.

TagString is tag name of the HTML-transparent tag. This is the first string that follows the pound sign (#).

TagParams gives the parameter portion of the HTML-transparent tag. Each string in the TStrings object has the form ParamName=Value.

ReplaceText returns the translated string that should replace the HTML-transparent tag.

HandleScriptTag returns true if it can translate the tag (that is, if TagString is 'SERVERSCRIPT'). It returns false if TagString identifies any other type of tag.

See Also

WebPageItems

12.1.2.4.18 TBaseAdapterPageProducer.HasHTMLBrowserView Method

Indicates whether the IDE should display an HTML browser view for the producer's content.

Pascal

```
function HasHTMLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasHTMLBrowserView();
```

Description

The IDE calls HasHTMLBrowserView to determine whether it should create an HTML tab page in the code editor for displaying the content of the page producer.

HasHTMLBrowserView returns true. As a result, at design time, the value that the Content method returns appears on the HTML tab page of the code editor when the adapter page producer is selected.

See Also

HasScriptView (see page 1154)

HasXMLBrowserView (see page 1154)

HasXSLBrowserView (see page 1154)

Content

12.1.2.4.19 TBaseAdapterPageProducer.HasScriptView Method

Indicates whether the IDE should display an associated server-side script.

Pascal

```
function HasScriptView: Boolean;
```

C++

```
__fastcall Boolean HasScriptView();
```

Description

The IDE calls HasScriptView to determine whether it should create a script tab page in the code editor for displaying the server-side script associated with the page producer.

HasScriptView returns true. As a result, at design time, the associated server-side script appears on a tab page of the code editor when the adapter page producer is selected.

See Also

HasHTMLBrowserView (see page 1153)

HasXMLBrowserView (see page 1154)

HasXSLBrowserView (see page 1154)

12.1.2.4.20 TBaseAdapterPageProducer.HasXMLBrowserView Method

Indicates whether the IDE should display an XML tree view for any XML data associated with the page producer.

Pascal

```
function HasXMLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasXMLBrowserView();
```

Description

The IDE calls HasXMLBrowserView to determine whether it should create an XML tab page in the code editor for displaying the XML data that the page producer uses.

HasXMLBrowserView returns false because adapter page producers do not use associated XML data.

See Also

HasScriptView (see page 1154)

HasHTMLBrowserView (see page 1153)

HasXSLBrowserView (see page 1154)

GetXMLData (see page 1152)

12.1.2.4.21 TBaseAdapterPageProducer.HasXSLBrowserView Method

Indicates whether the IDE should display an XSL tree view for an XSL template associated with the page producer.

Pascal

```
function HasXSLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasXSLBrowserView();
```

Description

The IDE calls HasXSLBrowserView to determine whether it should create an XSL tab page in the code editor for displaying the XSL template that the page producer uses.

HasXSLBrowserView returns false because adapter page producers do not use associated XSL templates.

See Also

HasScriptView (see page 1154)

HasHTMLBrowserView (see page 1153)

HasXMLBrowserView (see page 1154)

GetXSLData (see page 1152)

12.1.2.4.22 TBaseAdapterPageProducer.ImplCanAddClass Method

Provides the underlying implementation for the CanAddClass (see page 1146) method.

Pascal

```
function ImplCanAddClass(AParent: TComponent; AClass: TClass): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplCanAddClass(TComponent * AParent, TClass AClass);
```

Description

The CanAddClass (see page 1146) method calls ImpleCanAddClass to determine whether the TBaseAdapterPageProducer (see page 1143) descendant can add a component of type AClass to its WebPageItems property list. AParent is the TBaseAdapterPageProducer (see page 1143) instance to which the component will be added.

In TBaseAdapterPageProducer (see page 1143), ImplCanAddClass returns true if AClass descends from TCustomAdapterForm (see page 6490) or TCustomLayoutGroup.

See Also

CanAddClass (see page 1146)

WebPageItems

TCustomAdapterForm (see page 6490)

TCustomLayoutGroup

12.1.2.4.23 TBaseAdapterPageProducer.SetStyles Method

Assigns a value to the Styles (see page 1157) property.

Pascal

```
procedure SetStyles(Value: TStrings);
```

C++

```
__fastcall SetStyles(TStrings Value);
```

Description

SetStyles is the write implementation of the Styles (see page 1157) property.

See Also

Styles (see page 1157)

12.1.2.4.24 TBaseAdapterPageProducer.SetStylesFile Method

Assigns a value to the StylesFile (see page 1158) property.

Pascal

```
procedure SetStylesFile(const Value: TFileName);
```

C++

```
__fastcall SetStylesFile(const TFileName Value);
```

Description

SetStylesFile is the write implementation of the StylesFile (see page 1158) property.

See Also

StylesFile (see page 1158)

12.1.2.4.25 TBaseAdapterPageProducer.SetWebContentOptions Method

Sets the options that limit how the page producer creates its generated HTML.

Pascal

```
procedure SetWebContentOptions(AOptions: TWebContentOptions);
```

C++

```
__fastcall SetWebContentOptions(TWebContentOptions AOptions);
```

Description

SetWebContentOptions assigns a set of flags to the adapter page producer that limit what it can include in generated HTML.

AOptions is the TWebContentOptions (see page 6076) object that represents the set of options for this page producer. TBaseAdapterPageProducer (see page 1143) takes ownership of the object, so the caller should not free it.

See Also

GetContentOptions (see page 1150)

12.1.2.5 TBaseAdapterPageProducer Properties

The properties of the TBaseAdapterPageProducer class are listed here.

Protected Properties

	Name	Description
	PageElements (see page 1157)	Stores information that the Adapter page producer uses when generating its content.

Public Properties

	Name	Description
	Styles (see page 1157)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 1158)	Specifies a file containing the individual styles for the page producer's style sheet.

12.1.2.5.1 TBaseAdapterPageProducer.PageElements Property

Stores information that the Adapter page producer uses when generating its content.

Pascal

```
property PageElements: TSitePageElements;
```

C++

```
__property TSitePageElements PageElements;
```

Description

TBaseAdapterPageProducer (see page 1143) uses PageElements internally to store styles, warnings, server script, server functions, and server variables. It uses the properties of PageElements to assemble its content.

See Also

Content

OnHTMLTag

12.1.2.5.2 TBaseAdapterPageProducer.Styles Property

Defines the styles that can be used by the page producer and its Web items.

Pascal

```
property Styles: TStrings;
```

C++

```
__property TStrings Styles;
```

Description

Use Styles to define a style sheet for the HTML document produced by TBaseAdapterPageProducer (see page 1143). Each string in the TStrings object specifies a specific style by giving a style selector followed by a set of attributes in curly braces. These definitions can define styles for standard HTML elements such as

```
H2 B  {color: red}
```

or they can define styles that you name, such as

```
.MyStyle  {font-family: arial; font-weight: bold; font-size: 18px }
```

Note that user-defined style names must begin with a dot.

Styles for standard elements are applied automatically to HTML that uses the tag or tags that form the style selector. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector.

Note: If you are sharing a set of styles between multiple page producers or multiple applications, you can define the styles in a file. To define the styles in a file, use the StylesFile (see page 1158) property instead. If StylesFile (see page 1158) is defined, it takes precedence over the Styles property.

See Also

StylesFile (see page 1158)

Content

12.1.2.5.3 TBaseAdapterPageProducer.StylesFile Property

Specifies a file containing the individual styles for the page producer's style sheet.

Pascal

```
property StylesFile: TFileName;
```

C++

```
__property TFileName StylesFile;
```

Description

Set StylesFile to the name of a file containing the style definitions used by the page producer. The page producer uses these style definitions to declare a style sheet in the HTML document it generates.

Styles (see page 1157) for standard elements are applied automatically to HTML in the document. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector of a style definition.

Note: If the StylesFile property is not set, you can specify the style definitions using the Styles (see page 1157) property instead.

See Also

Styles (see page 1157)

Content

12.1.2.6 TBaseAdapterPageProducer Events

The events of the TBaseAdapterPageProducer class are listed here.

Public Events

	Name	Description
	OnAfterGetContent (see page 1158)	Occurs after the page producer generates its content.
	OnBeforeGetContent (see page 1159)	Occurs before the page producer generates its content.

12.1.2.6.1 TBaseAdapterPageProducer.OnAfterGetContent Event

Occurs after the page producer generates its content.

Pascal

```
property OnAfterGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAfterGetContent;
```

Description

Write (see page 3707) an OnAfterGetContent event handler to take specific action immediately after the producer generates its content.

See Also

ContentFromStream (see page 1147)

OnBeforeGetContent (see page 1159)

12.1.2.6.2 TBaseAdapterPageProducer.OnBeforeGetContent Event

Occurs before the page producer generates its content.

Pascal

```
property OnBeforeGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBeforeGetContent;
```

Description

Write (see page 3707) an OnBeforeGetContent event handler to take specific action immediately before the producer generates its content.

See Also

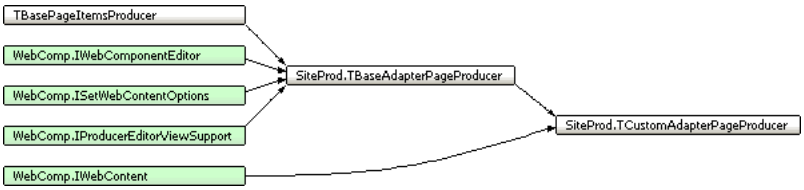
ContentFromStream (see page 1147)

OnAfterGetContent (see page 1158)

12.1.3 TCustomAdapterPageProducer Class

TCustomAdapterPageProducer generates the proper HTML and JavaScript needed to display adapter fields and execute adapter actions.

Class Hierarchy



Pascal

```
TCustomAdapterPageProducer = class(TBaseAdapterPageProducer, IWebContent);
```

C++

```
class TCustomAdapterPageProducer : public TBaseAdapterPageProducer, public IWebContent;
```

File

SiteProd

Description

TCustomAdapterPageProducer creates an HTML page using content it obtains from a hierarchy of components called Web items. The Web items that appear in the TCustomAdapterPageProducer's hierarchy use Adapter components to fetch the information that they display.

Use TCustomAdapterPageProducer as a base class for page producer components that assemble their content from Web items

that use Adapter components.

TCustomAdapterPageProducer introduces two properties, HTMLDoc (see page 1165) and HTMLFile (see page 1166), each of which can specify a template that the page producer uses to generate its content. By default, this template is set to include the following special tags:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1157) or StylesFile (see page 1158) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items. TCustomAdapterPageProducer will not generate any content if this tag is missing.

Applications can alter the template to further embellish the content that the page producer generates.

12.1.3.1 TCustomAdapterPageProducer Members

The following tables list the members exposed by TCustomAdapterPageProducer.

Protected Methods

	Name	Description
	CanAddClass (see page 1146)	Specifies whether a Web item of a specified type can be added to the WebPageItems property list.
V	CreatePageElements (see page 1147)	Creates the object that implements the PageElements (see page 1157) property.
V	DeclareStyles (see page 1148)	Returns an HTML Styles (see page 1157) tag that declares the styles specified by the Styles (see page 1157) or StylesFile (see page 1158) property.
V	DeclareWarnings (see page 1148)	Returns the formatted warnings that appear at design time to indicate the status of content generation.
	DoAfterGetContent (see page 1148)	Generates an OnAfterGetContent (see page 1158) event.
	DoBeforeGetContent (see page 1149)	Generates an OnBeforeGetContent (see page 1159) event.
V	DoTagEvent (see page 1149)	Translates HTML-transparent tags in the template.
V	GeneratePageElements (see page 1150)	Fills the PageElements (see page 1157) property with information based on the other properties of the adapter Page Producer.
V	GetContentOptions (see page 1150)	Returns an object that influences how the page producer generates its content.
V	GetDefaultTemplate (see page 1150)	Returns the default template that the page producer can use to generate content.
V	GetTemplateFileName (see page 1162)	Returns the value of the HTMLFile (see page 1166) property.
	GetTemplateFileType (see page 1152)	Returns the type of file that can store the templates this object uses to generate its content.
V	GetTemplateStream (see page 1163)	Returns a stream from which to read the HTML template that this producer uses.
	GetXMLData (see page 1152)	Returns a stream for reading any XML data associated with the page producer.
	GetXSLData (see page 1152)	Returns a stream for reading an XSL template associated with the page producer.
V	HandleScriptTag (see page 1153)	Translates HTML-transparent tags for an associated server-side script.
	HasHTMLBrowserView (see page 1153)	Indicates whether the IDE should display an HTML browser view for the producer's content.
	HasScriptView (see page 1154)	Indicates whether the IDE should display an associated server-side script.
	HasXMLBrowserView (see page 1154)	Indicates whether the IDE should display an XML tree view for any XML data associated with the page producer.
	HasXSLBrowserView (see page 1154)	Indicates whether the IDE should display an XSL tree view for an XSL template associated with the page producer.
V	ImplCanAddClass (see page 1155)	Provides the underlying implementation for the CanAddClass (see page 1146) method.
	SetHTMLDoc (see page 1163)	Sets the HTMLDoc (see page 1165) property.
	SetHTMLFile (see page 1164)	Sets the HTMLFile (see page 1166) property.
	SetWebContentOptions (see page 1156)	Sets the options that limit how the page producer creates its generated HTML.
	WebContent (see page 1164)	Returns the HTML document assembled by the Adapter page producer.

Protected Properties

	Name	Description
	PageElements (see page 1157)	Stores information that the Adapter page producer uses when generating its content.

Public Events

	Name	Description
	OnAfterGetContent (see page 1158)	Occurs after the page producer generates its content.
	OnBeforeGetContent (see page 1159)	Occurs before the page producer generates its content.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
	Content (see page 6104)	Returns the HTML that the Web item generates.
	ContentFromStream (see page 1147)	Returns the content produced using a template read from a stream.
	Create (see page 1161)	Creates and initializes an instance of TCustomAdapterPageProducer (see page 1159).
	Destroy (see page 1162)	Frees an instance of TCustomAdapterPageProducer (see page 1159).
	GetRequiredTags (see page 1151)	Returns the HTML-transparent tags that the adapter page producer requires to have present in its template.
	GetScriptEngines (see page 1151)	Returns a list of script engines that can work with server-side scripts that produce content for the page producer.
	GetTemplateFileType (see page 6090)	This is GetTemplateFileType, a member of class IProducerEditorViewSupport.
	GetXMLData (see page 6090)	This is GetXMLData, a member of class IProducerEditorViewSupport.
	GetXSLData (see page 6090)	This is GetXSLData, a member of class IProducerEditorViewSupport.
	HasHTMLBrowserView (see page 6091)	This is HasHTMLBrowserView, a member of class IProducerEditorViewSupport.
	HasScriptView (see page 6091)	This is HasScriptView, a member of class IProducerEditorViewSupport.
	HasXMLBrowserView (see page 6091)	This is HasXMLBrowserView, a member of class IProducerEditorViewSupport.
	HasXSLBrowserView (see page 6091)	This is HasXSLBrowserView, a member of class IProducerEditorViewSupport.
	SetStyles (see page 1155)	Assigns a value to the Styles (see page 1157) property.
	SetStylesFile (see page 1156)	Assigns a value to the StylesFile (see page 1158) property.
	SetWebContentOptions (see page 6092)	This is SetWebContentOptions, a member of class ISetWebContentOptions.

Public Properties

	Name	Description
	HTMLDoc (see page 1165)	Specifies the HTML template used to generate the value that the Content method returns.
	HTMLFile (see page 1166)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	Styles (see page 1157)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 1158)	Specifies a file containing the individual styles for the page producer's style sheet.

12.1.3.2 TCustomAdapterPageProducer.Create Constructor

Creates and initializes an instance of TCustomAdapterPageProducer (see page 1159).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomAdapterPageProducer(TComponent * AOwner);
```

Description

Call Create to instantiate an adapter page producer at runtime. Adapter page producers placed in a Web page module at design time (or by the Web page module wizard) are instantiated automatically.

AOwner is a component, typically a Web page module, that becomes the value of the Owner property. The Owner is responsible for freeing the TCustomAdapterPageProducer (see page 1159) instance.

See Also

Owner

12.1.3.3 TCustomAdapterPageProducer.Destroy Destructor

Frees an instance of TCustomAdapterPageProducer (see page 1159).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomAdapterPageProducer();
```

Description

Do not call Destroy directly. Instead, call the Free method, which checks whether the reference to the producer is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

12.1.3.4 TCustomAdapterPageProducer Methods

The methods of the TCustomAdapterPageProducer class are listed here.

Protected Methods

	Name	Description
	GetTemplateFileName (see page 1162)	Returns the value of the HTMLFile (see page 1166) property.
	GetTemplateStream (see page 1163)	Returns a stream from which to read the HTML template that this producer uses.
	SetHTMLDoc (see page 1163)	Sets the HTMLDoc (see page 1165) property.
	SetHTMLFile (see page 1164)	Sets the HTMLFile (see page 1166) property.
	WebContent (see page 1164)	Returns the HTML document assembled by the Adapter page producer.

12.1.3.4.1 TCustomAdapterPageProducer.GetTemplateFileName Method

Returns the value of the HTMLFile (see page 1166) property.

Pascal

```
function GetTemplateFileName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetTemplateFileName();
```

Description

TBasePageProducer introduces the protected GetTemplateFileName method to obtain the name of a file that contains a template from which to produce content. Each page producer component overrides GetTemplateFileName to supply this template in a class-specific way. TCustomAdapterPageProducer (see page 1159) returns the value of the HTMLFile (see page 1166) property.

See Also

GetTemplateStream (see page 1163)

HTMLFile (see page 1166)

12.1.3.4.2 TCustomAdapterPageProducer.GetTemplateStream Method

Returns a stream from which to read the HTML template that this producer uses.

Pascal

```
function GetTemplateStream(out AOwned: Boolean): TStream; override;
```

C++

```
virtual __fastcall TStream GetTemplateStream(Boolean AOwned);
```

Description

TBasePageProducer introduces the protected GetTemplateStream method to obtain a stream from which to read the producer component's HTML template. Each page producer component overrides GetTemplateStream to supply this stream in a class-specific way.

AOwned returns a value that indicates whether the caller should free the returned stream after reading the template. When AOwned is true, the caller should free the stream object.

TCustomAdapterPageProducer (see page 1159) returns a stream from which the template specified by the HTMLFile (see page 1166) or HTMLDoc (see page 1165) property can be read.

See Also

GetTemplateFileName (see page 1162)

HTMLFile (see page 1166)

HTMLDoc (see page 1165)

12.1.3.4.3 TCustomAdapterPageProducer.SetHTMLDoc Method

Sets the HTMLDoc (see page 1165) property.

Pascal

```
procedure SetHTMLDoc(const Value: TStrings);
```

C++

```
__fastcall SetHTMLDoc(const TStrings Value);
```

Description

SetHTMLDoc is the protected write implementation of the HTMLDoc (see page 1165) property.

Value is a TStrings descendant that contains the new HTML template. SetHTMLDoc assigns the strings in this object to the TStrings object that implements the HTMLDoc (see page 1165) property. Note that this method does not take ownership of the specified object.

See Also

HTMLDoc (see page 1165)

Assign

12.1.3.4.4 TCustomAdapterPageProducer.SetHTMLFile Method

Sets the HTMLFile (see page 1166) property.

Pascal

```
procedure SetHTMLFile(const Value: TFileName);
```

C++

```
__fastcall SetHTMLFile(const TFileName Value);
```

Description

SetHTMLFile is the protected write implementation of the HTMLFile (see page 1166) property.

Value is the name of the template that the page producer should use to generate its content.

See Also

HTMLFile (see page 1166)

12.1.3.4.5 TCustomAdapterPageProducer.WebContent Method

Returns the HTML document assembled by the Adapter page producer.

Pascal

```
function WebContent(Options: TWebContentOptions; Layout: TLayout): string;
```

C++

```
__fastcall UnicodeString WebContent(TWebContentOptions Options, TLayout Layout);
```

Description

Call WebContent to get the HTML document produced by TCustomAdapterPageProducer (see page 1159). TCustomAdapterPageProducer (see page 1159) uses WebContent to implement the Content method of its IWebContent (see page 6103) interface.

Options contains a set of flags that limit what can be included in the generated HTML.

Layout is ignored by the WebContent method. It is included as a parameter for compatibility with other content producers that use a helper object to coordinate the layout of content produced by multiple Web items.

The Adapter page producer creates its content by replacing HTML-transparent tags in the template specified by HTMLDoc (see page 1165) or HTMLFile (see page 1166).

By default, this template has the form

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#STYLES> <#WARNINGS> <#SERVERSCRIPT>
</BODY>
</HTML>
```

Although the template can be changed to include any combination of these tags with custom HTML or tags that the application translates in an OnHTMLTag event handler.

The WebContent method translates the tags listed above as follows:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1157) or StylesFile (see page 1158) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items specified by the WebPageItems property.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items. TCustomAdapterPageProducer (see page 1159) will not generate any content if this tag is missing.

The string returned by WebContent can be used as the Content property of the response to an HTTP request message.

WebPageItems

12.1.3.5 TCustomAdapterPageProducer Properties

The properties of the TCustomAdapterPageProducer class are listed here.

Public Properties

	Name	Description
	HTMLDoc (see page 1165)	Specifies the HTML template used to generate the value that the Content method returns.
	HTMLFile (see page 1166)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

12.1.3.5.1 TCustomAdapterPageProducer.HTMLDoc Property

Specifies the HTML template used to generate the value that the Content method returns.

Pascal

```
property HTMLDoc: TStrings;
```

C++

```
__property TStrings HTMLDoc;
```

Description

Set HTMLDoc to a set of strings that make up the HTML template. By default, HTMLDoc is initialized to the following template:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#STYLES> <#WARNINGS> <#SERVERSCRIPT>
</BODY>
</HTML>
```

Each string is a sequence of one or more HTML commands or HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The

pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. TCustomAdapterPageProducer (see page 1159) automatically handles the conversion of the HTML-transparent tags in the default template as follows:

<#STYLES> - This tag is replaced by the stylesheet defined by the Styles (see page 1157) or StylesFile (see page 1158) property.

<#WARNINGS> - This tag is replaced with design time warnings that indicate possible problems with the hierarchy of web items.

<#SERVERSCRIPT> - This tag is replaced with generated HTML/JavaScript based on the hierarchy of Web items. TCustomAdapterPageProducer (see page 1159) will not generate any content if this tag is missing.

If you set HTMLDoc to include other HTML-transparent tags, you must translate these in an OnHTMLTag event handler.

Note: Setting HTMLDoc clears the HTMLFile (see page 1166) property.

HTMLFile (see page 1166)

OnHTMLTag

12.1.3.5.2 TCustomAdapterPageProducer.HTMLFile Property

Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLFile: TFileName;
```

C++

```
__property TFileName HTMLFile;
```

Description

Set HTMLFile to the name of the file that contains an HTML template. The HTML template is a sequence of HTML commands and HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLFile clears the HTMLDoc (see page 1165) property.

Note: When distributing applications that contain page producers which use the HTMLFile property, be sure to distribute the file along with the application. Also, be sure that the value of HTMLFile does not include a hard-coded path name that will not be available on the user's disk.

12.1.4 TSitePageElements Class

TSitePageElements stores part of the content that page producers generate.

Class Hierarchy

Pascal

```
TSitePageElements = class(TObject);
```

C++

```
class TSitePageElements : public TObject;
```

File

SiteProd

Description

TSitePageElements stores styles, warnings, server script, server functions, and server variables. These values are stored as class members of type string (not properties). The adapter page producer combines them to make up its generated content.

12.1.4.1 TSitePageElements Members

The following tables list the members exposed by TSitePageElements.

Public Fields

	Name	Description
	ServerFunctionsContent (see page 1168)	This is ServerFunctionsContent, a member of class TSitePageElements.
	ServerScriptContent (see page 1169)	This is ServerScriptContent, a member of class TSitePageElements.
	ServerVariablesContent (see page 1169)	This is ServerVariablesContent, a member of class TSitePageElements.
	StylesContent (see page 1169)	This is StylesContent, a member of class TSitePageElements.
	WarningsContent (see page 1169)	This is WarningsContent, a member of class TSitePageElements.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

12.1.4.2 TSitePageElements Fields

The fields of the TSitePageElements class are listed here.

Public Fields

	Name	Description
	ServerFunctionsContent (see page 1168)	This is ServerFunctionsContent, a member of class TSitePageElements.
	ServerScriptContent (see page 1169)	This is ServerScriptContent, a member of class TSitePageElements.
	ServerVariablesContent (see page 1169)	This is ServerVariablesContent, a member of class TSitePageElements.
	StylesContent (see page 1169)	This is StylesContent, a member of class TSitePageElements.
	WarningsContent (see page 1169)	This is WarningsContent, a member of class TSitePageElements.

12.1.4.2.1 TSitePageElements.ServerFunctionsContent Field

Pascal

```
ServerFunctionsContent: string;
```

C++

```
UnicodeString ServerFunctionsContent;
```

Description

This is ServerFunctionsContent, a member of class TSitePageElements.

12.1.4.2.2 TSitePageElements.ServerScriptContent Field

Pascal

```
ServerScriptContent: string;
```

C++

```
UnicodeString ServerScriptContent;
```

Description

This is ServerScriptContent, a member of class TSitePageElements.

12.1.4.2.3 TSitePageElements.ServerVariablesContent Field

Pascal

```
ServerVariablesContent: string;
```

C++

```
UnicodeString ServerVariablesContent;
```

Description

This is ServerVariablesContent, a member of class TSitePageElements.

12.1.4.2.4 TSitePageElements.StylesContent Field

Pascal

```
StylesContent: string;
```

C++

```
UnicodeString StylesContent;
```

Description

This is StylesContent, a member of class TSitePageElements.

12.1.4.2.5 TSitePageElements.WarningsContent Field

Pascal

```
WarningsContent: string;
```

C++

```
UnicodeString WarningsContent;
```

Description

This is WarningsContent, a member of class TSitePageElements.

13 SOAPAttachIntf Namespace

This is namespace SOAPAttachIntf.

Topics

Name	Description
Classes (see page 1172)	The following table lists classes in this documentation.
Interfaces (see page 1176)	The following table lists interfaces in this documentation.
Types (see page 1185)	The following table lists types in this documentation.

Classes

	Name	Description
	TSoapDataList (see page 1172)	TSoapDataList maintains a list of SOAP attachments.

Interfaces

	Name	Description
	IMimeAttachmentHandler (see page 1176)	IMimeAttachmentHandler is the interface for interpreting or manipulating the multipart form that represents a Web Service call that includes an attachment.

Types

Name	Description
TOnGetAttachmentEvent (see page 1185)	TOnGetAttachmentEvent is the type of event handlers that respond when a remote interfaced object receives an attachment in a response from a Web Service provider.
TOnSendAttachmentEvent (see page 1185)	TOnSendAttachmentEvent is the type of event handlers that respond when a remote interfaced object sends an attachment in a request to a Web Service provider.

13.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TSoapDataList (see page 1172)	TSoapDataList maintains a list of SOAP attachments.

13.1.1 TSoapDataList Class

TSoapDataList maintains a list of SOAP attachments.

Class Hierarchy

Pascal

```
TSoapDataList = class(TList);
```

C++

```
class TSoapDataList : public TList;
```

File

SOAPAttachIntf

Description

Use TSoapDataList to store and maintain a list of SOAP attachments (TSOAPAttachment objects).

See Also

TList

TSOAPAttachment

13.1.1.1 TSoapDataList Members

The following tables list the members exposed by TSoapDataList.

Public Methods

	Name	Description
	Add (see page 1173)	Adds a new attachment to the end of the list.
	Assign (see page 1173)	Raises an exception.
	Clear (see page 1174)	Empties the list and frees the TSOAPAttachment objects.
	Insert (see page 1174)	Raises an exception.
	Remove (see page 1174)	Raises an exception.

13.1.1.2 TSoapDataList Methods

The methods of the TSoapDataList class are listed here.

Public Methods

	Name	Description
	Add (see page 1173)	Adds a new attachment to the end of the list.
	Assign (see page 1173)	Raises an exception.
V	Clear (see page 1174)	Empties the list and frees the TSOAPAttachment objects.
	Insert (see page 1174)	Raises an exception.
	Remove (see page 1174)	Raises an exception.

13.1.1.2.1 TSoapDataList.Add Method

Adds a new attachment to the end of the list.

Pascal

```
function Add(Item: Pointer): Integer; reintroduce;
```

C++

```
__fastcall int Add(void * Item);
```

Description

Do not call the Add method. This method is used internally to add attachments to the data list when the application first reads an incoming message that includes attachments or when marshaling a message to be sent that includes attachments. Applications should not change the list of attachments, or they will interfere with the marshaling and unmarshaling of attachment data.

Item is a pointer to the TSoapAttachment instance that is added to the list.

Add returns the index of the new attachment.

See Also

Capacity

Count

Insert (see page 1174)

Items

Clear (see page 1174)

13.1.1.2.2 TSoapDataList.Assign Method

Raises an exception.

Pascal

```
procedure Assign(ListA: TList; AOperator: TListAssignOp = laCopy; ListB: TList = Nil);
reintroduce;
```

C++

```
__fastcall Assign(TList ListA, TListAssignOp AOperator = laCopy, TList ListB = Nil);
```

Description

Do not call the Assign method. TSoapDataList (see page 1172) replaces the inherited method to raise an exception if you call

this method because applications should not change the items in a TSoapDataList (see page 1172) object.

See Also

Add (see page 1173)

13.1.1.2.3 TSoapDataList.Clear Method

Empties the list and frees the TSOAPAttachment objects.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Clear removes all of the objects from the list and frees each one. Do not call this method. It is used internally when marshaling and unmarshaling messages that contain attachments. Applications should not change the items in a TSoapDataList (see page 1172) object.

See Also

Delete

Items

Remove

13.1.1.2.4 TSoapDataList.Insert Method

Raises an exception.

Pascal

```
procedure Insert(Index: Integer; aClass: TClass); reintroduce;
```

C++

```
__fastcall Insert(int Index, TClass aClass);
```

Description

Do not call the Insert method. TSoapDataList (see page 1172) replaces the inherited method to raise an exception if you call this method because applications should not change the items in a TSoapDataList (see page 1172) object.

See Also

Add (see page 1173)

13.1.1.2.5 TSoapDataList.Remove Method

Raises an exception.

Pascal

```
function Remove(aClass: TClass): Integer; reintroduce;
```

C++

```
__fastcall int Remove(TClass aClass);
```

Description

Do not call the Remove method. TSoapDataList (see page 1172) replaces the inherited method to raise an exception if you call this method because applications should not change the items in a TSoapDataList (see page 1172) object.

See Also

Clear (see page 1174)

13.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IMimeAttachmentHandler (see page 1176)	IMimeAttachmentHandler is the interface for interpreting or manipulating the multipart form that represents a Web Service call that includes an attachment.

13.2.1 IMimeAttachmentHandler Interface

IMimeAttachmentHandler is the interface for interpreting or manipulating the multipart form that represents a Web Service call that includes an attachment.

Class Hierarchy

SOAPAttachIntf.IMimeAttachmentHandler

Pascal

```
IMimeAttachmentHandler = interface;
```

C++

```
__interface IMimeAttachmentHandler;
```

File

SOAPAttachIntf

Description

IMimeAttachmentHandler defines methods for working with multipart forms that represent SOAP requests which include attachements. It is used internally to process the headers of the SOAP envelope part of multipart forms, to generate events when the application sends or receives a multipart form that represents a Web Service call which includes attachments, and to parse or assemble such a multipart form.

Note: C++ method declarations that use IMimeAttachmentHandler use the _di_IMimeAttachmentHandler type instead. This type is a DelphiInterface (see page 3256) wrapper around the IMimeAttachmentHandler interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IMimeAttachmentHandler >
_di_IMimeAttachmentHandler;
```

See Also

TSOAPAttachment

13.2.1.1 IMimeAttachmentHandler Members

The following tables list the members exposed by IMimeAttachmentHandler.

Public Events

	Name	Description
	OnGetAttachment (see page 1183)	Occurs for each attachment as it is read.
	OnSendAttachment (see page 1183)	Occurs for each attachment that is added to a multipart form to be sent.

Public Methods

	Name	Description
	AddSoapHeader (see page 1177)	Adds a specified header to the SOAP envelope portion of the emerging .
	CreateMimeStream (see page 1178)	Creates and initializes a stream that will eventually contain an assembled multipart form.
	FinalizeStream (see page 1178)	Performs any necessary final steps in creating the emerging multipart form.
	GetMIMEBoundary (see page 1179)	Returns the value of the MIMEBoundary (see page 1182) property.
	GetMIMEStream (see page 1179)	Returns a stream from which to read the assembled multipart form.
	GetOnGetAttachmentEvent (see page 1180)	Returns the OnGetAttachment (see page 1183) event handler.
	GetOnSendAttachmentEvent (see page 1180)	Returns the OnSendAttachment (see page 1183) event handler.
	ProcessMultiPartForm (see page 1180)	Parses a multipart form into the SOAP envelope and a list of attachments.
	SetMIMEBoundary (see page 1181)	Sets the value of the MIMEBoundary (see page 1182) property.
	SetOnGetAttachmentEvent (see page 1181)	Assigns the OnGetAttachment (see page 1183) event handler.
	SetOnSendAttachmentEvent (see page 1182)	Assigns the OnSendAttachment (see page 1183) event handler.

Public Properties

	Name	Description
	MIMEBoundary (see page 1182)	Indicates the MIME boundary string that signals the boundaries between the parts of the multipart form.

13.2.1.2 IMimeAttachmentHandler Methods

The methods of the IMimeAttachmentHandler class are listed here.

Public Methods

	Name	Description
	AddSoapHeader (see page 1177)	Adds a specified header to the SOAP envelope portion of the emerging .
	CreateMimeStream (see page 1178)	Creates and initializes a stream that will eventually contain an assembled multipart form.
	FinalizeStream (see page 1178)	Performs any necessary final steps in creating the emerging multipart form.
	GetMIMEBoundary (see page 1179)	Returns the value of the MIMEBoundary (see page 1182) property.
	GetMIMEStream (see page 1179)	Returns a stream from which to read the assembled multipart form.
	GetOnGetAttachmentEvent (see page 1180)	Returns the OnGetAttachment (see page 1183) event handler.
	GetOnSendAttachmentEvent (see page 1180)	Returns the OnSendAttachment (see page 1183) event handler.
	ProcessMultiPartForm (see page 1180)	Parses a multipart form into the SOAP envelope and a list of attachments.
	SetMIMEBoundary (see page 1181)	Sets the value of the MIMEBoundary (see page 1182) property.
	SetOnGetAttachmentEvent (see page 1181)	Assigns the OnGetAttachment (see page 1183) event handler.
	SetOnSendAttachmentEvent (see page 1182)	Assigns the OnSendAttachment (see page 1183) event handler.

13.2.1.2.1 IMimeAttachmentHandler.AddSoapHeader Method

Adds a specified header to the SOAP envelope portion of the emerging .

Pascal

```
procedure AddSoapHeader(Value: string);
```

C++

```
__fastcall AddSoapHeader(UnicodeString Value);
```

Description

Call AddSoapHeader to add an arbitrary header to the SOAP envelope portion of an emerging multipart form. This method should not be called until after a call to the CreateMimeStream (see page 1178) method initializes the emerging multipart form.

Value is the text of the header to add to the SOAP envelope.

Typically, this method is called to add the ContentType header to the SOAP envelope when its value is not known at the point when the application calls CreateMimeStream (see page 1178).

Note: After all calls to AddSoapHeader have been made to add headers to the SOAP envelope, the application must call the FinalizeStream (see page 1178) method to allow the MIME attachment handler to finish generating the multipart form. Only after the call to FinalizeStream (see page 1178) can the application read the content of the multipart form by calling the GetMIMEStream (see page 1179) method.

See Also

CreateMimeStream (see page 1178)

FinalizeStream (see page 1178)

GetMIMEStream (see page 1179)

13.2.1.1.2.2 IMimeAttachmentHandler.CreateMimeStream Method

Creates and initializes a stream that will eventually contain an assembled multipart form.

Pascal

```
procedure CreateMimeStream(Envelope: TStream; Attachments: TSoapDataList);
```

C++

```
__fastcall CreateMimeStream(TStream Envelope, TSoapDataList Attachments);
```

Description

Call CreateMimeStream as the first step when generating a multipart form to represent a SOAP packet and its associated attachments.

Envelope is a stream from which CreateMimeStream can read the SOAP envelope portion of the multipart form. This must be a complete encoding with the exception of headers, which can be added by subsequent calls to the AddSoapHeader (see page 1177) method.

Attachments is a list of TSoapAttachment objects that represent the attachments that should be included in the multipart form.

CreateMimeStream creates a new stream object and initializes it with the data from Envelope and Attachments. This new stream can then be completed by calling the AddSoapHeader (see page 1177) method to add any headers to the SOAP envelope portion and then calling the FinalizeStream (see page 1178) method. After calling FinalizeStream (see page 1178), the application can access the generated stream by calling the GetMIMEStream (see page 1179) method.

See Also

FinalizeStream (see page 1178)

AddSoapHeader (see page 1177)

GetMIMEStream (see page 1179)

13.2.1.1.2.3 IMimeAttachmentHandler.FinalizeStream Method

Performs any necessary final steps in creating the emerging multipart form.

Pascal

```
procedure FinalizeStream;
```

C++

```
__fastcall FinalizeStream();
```

Description

Call FinalizeStream as a final step when assembling a multipart form to represent a SOAP packet and its associated attachments. When an application assembles a multipart form to represent a SOAP packet and its associated attachments, it takes the following steps:

1. Call CreateMimeStream (see page 1178) to create the stream object that includes data from the SOAP envelope and the content of any attachments.
2. Call AddSoapHeader (see page 1177) to add any headers to the SOAP envelope portion of the stream.
3. Call FinalizeStream to indicate that all changes are complete and allow the MIME attachment handler to make any final changes.

Only after a call to FinalizeStream can the application read the assembled multipart form by calling GetMIMEStream (see page 1179).

See Also

CreateMimeStream (see page 1178)

AddSoapHeader (see page 1177)

GetMIMEStream (see page 1179)

13.2.1.2.4 IMimeAttachmentHandler.GetMIMEBoundary Method

Returns the value of the MIMEBoundary (see page 1182) property.

Pascal

```
function GetMIMEBoundary: String;
```

C++

```
__fastcall UnicodeString GetMIMEBoundary();
```

Description

GetMIMEBoundary is the read implementation for the MIMEBoundary (see page 1182) property.

See Also

MIMEBoundary (see page 1182)

13.2.1.2.5 IMimeAttachmentHandler.GetMIMEStream Method

Returns a stream from which to read the assembled multipart form.

Pascal

```
function GetMIMEStream(Release: Boolean = False): TStream;
```

C++

```
__fastcall TStream GetMIMEStream(Boolean Release = False);
```

Description

Call GetMIMEStream after a call to the FinalizeStream (see page 1178) method to access the stream from which to read a newly-assembled multipart form. This stream should not be used until after the multipart form is fully assembled.

Release (see page 3641) indicates whether the caller is responsible for freeing the stream object. When Release (see page 3641) is true, the caller takes ownership of the stream and is responsible for freeing it. When Release (see page 3641) is false, the caller should not free the stream that is returned, because the object that implements IMimeAttachmentHandler (see page 1176) will free it.

See Also

CreateMimeStream (see page 1178)

AddSoapHeader (see page 1177)

FinalizeStream (see page 1178)

13.2.1.2.6 IMimeAttachmentHandler.GetOnGetAttachmentEvent Method

Returns the OnGetAttachment (see page 1183) event handler.

Pascal

```
function GetOnGetAttachmentEvent: TOnGetAttachmentEvent;
```

C++

```
__fastcall TOnGetAttachmentEvent GetOnGetAttachmentEvent();
```

Description

GetOnGetAttachmentEvent is the read implementation for the OnGetAttachment (see page 1183) event.

See Also

OnGetAttachment (see page 1183)

13.2.1.2.7 IMimeAttachmentHandler.GetOnSendAttachmentEvent Method

Returns the OnSendAttachment (see page 1183) event handler.

Pascal

```
function GetOnSendAttachmentEvent: TOnSendAttachmentEvent;
```

C++

```
__fastcall TOnSendAttachmentEvent GetOnSendAttachmentEvent();
```

Description

GetOnSendAttachmentEvent is the read implementation for the OnSendAttachment (see page 1183) event handler.

See Also

OnSendAttachment (see page 1183)

13.2.1.2.8 IMimeAttachmentHandler.ProcessMultiPartForm Method

Parses a multipart form into the SOAP envelope and a list of attachments.

Pascal

```
procedure ProcessMultiPartForm(const ASourceStream: TStream; const ADestStream: TStream;
```

```
AMimeBoundary: string; SoapHeaders: TStrings; Attachments: TSoapDataList; TempDir: string);
```

C++

```
__fastcall ProcessMultiPartForm(const TStream ASourceStream, const TStream ADestStream,
UnicodeString AMimeBoundary, TStrings SoapHeaders, TSoapDataList Attachments, UnicodeString
TempDir);
```

Description

Call ProcessMultiPartForm to interpret a multipart form that is received by the client or server in a Web Service application. This method separates the SOAP envelope portion of the multipart form from the portions that represent attachments, and parses the headers of the SOAP envelope into a convenient string list.

ASourceStream is a stream from which ProcessMultiPartForm can read the incoming multipart form. This is the content of the incoming message.

ADestStream is a stream to which ProcessMultiPartForm writes the SOAP envelope portion of ASourceStream.

AMimeBoundary is the mime boundary string that identifies the boundaries between the parts of the multipart form. Typically, it is obtained from the headers of the incoming HTTP message whose content is the content of ASourceStream.

SoapHeaders is an existing TStrings descendant to which ProcessMultiPartForm writes the headers of the SOAP envelope portion of the multipart form. Each header is added as a string of the form HeaderName=Value.

Attachments is an empty TSoapDataList (see page 1172) object to which ProcessMultiPartForm adds the TSoapAttachment objects that represent the attachments in the multipart form.

TempDir is the name of the directory where ProcessMultiPartForm writes the temporary files it generates for each of the attachments.

13.2.1.2.9 IMimeAttachmentHandler.SetMIMEBoundary Method

Sets the value of the MIMEBoundary (see page 1182) property.

Pascal

```
procedure SetMIMEBoundary(const MimeBndry: String);
```

C++

```
__fastcall SetMIMEBoundary(const UnicodeString MimeBndry);
```

Description

SetMIMEBoundary is the write implementation for the MIMEBoundary (see page 1182) property.

MimeBndry is the string that should identify the boundary between parts of the multipart form.

See Also

MIMEBoundary (see page 1182)

13.2.1.2.10 IMimeAttachmentHandler.SetOnGetAttachmentEvent Method

Assigns the OnGetAttachment (see page 1183) event handler.

Pascal

```
procedure SetOnGetAttachmentEvent(OnGetAttachment: TOnGetAttachmentEvent);
```

C++

```
__fastcall SetOnGetAttachmentEvent(TOnGetAttachmentEvent OnGetAttachment);
```

Description

SetOnGetAttachmentEvent is the write implementation for the OnGetAttachment (see page 1183) event.

OnGetAttachment (see page 1183) is the event handler that should to respond to the event.

See Also

OnGetAttachment (see page 1183)

13.2.1.2.11 IMimeAttachmentHandler.SetOnSendAttachmentEvent Method

Assigns the OnSendAttachment (see page 1183) event handler.

Pascal

```
procedure SetOnSendAttachmentEvent(OnSendAttachment: TOnSendAttachmentEvent);
```

C++

```
__fastcall SetOnSendAttachmentEvent(TOnSendAttachmentEvent OnSendAttachment);
```

Description

SetOnSendAttachmentEvent is the write implementation for the OnSendAttachment (see page 1183) event.

OnSendAttachment (see page 1183) is the event handler that should to respond to the event.

See Also

OnSendAttachment (see page 1183)

13.2.1.3 IMimeAttachmentHandler Properties

The properties of the IMimeAttachmentHandler class are listed here.

Public Properties

	Name	Description
	MIMEBoundary (see page 1182)	Indicates the MIME boundary string that signals the boundaries between the parts of the multipart form.

13.2.1.3.1 IMimeAttachmentHandler.MIMEBoundary Property

Indicates the MIME boundary string that signals the boundaries between the parts of the multipart form.

Pascal

```
property MIMEBoundary: string;
```

C++

```
__property UnicodeString MIMEBoundary;
```

Description

MIMEBoundary is the string that identifies the boundary between the parts of the multipart form. It is an attribute of the ContentType header for the entire form.

When the MIME attachment handler is processing a received form, this property is not available until after the application has called the ProcessMultiPartForm (see page 1180) method. When the MIME attachment handler is assembling a multipart form in order to send a message that includes attachments, the handler generates this string for the new form, and the CreateMimeStream (see page 1178) method uses it when assembling the form.

See Also

ProcessMultiPartForm (see page 1180)

CreateMimeStream (see page 1178)

13.2.1.4 IMimeAttachmentHandler Events

The events of the IMimeAttachmentHandler class are listed here.

Public Events

	Name	Description
	OnGetAttachment (see page 1183)	Occurs for each attachment as it is read.
	OnSendAttachment (see page 1183)	Occurs for each attachment that is added to a multipart form to be sent.

13.2.1.4.1 IMimeAttachmentHandler.OnGetAttachment Event

Occurs for each attachment as it is read.

Pascal

```
property OnGetAttachment: TOnGetAttachmentEvent;
```

C++

```
__property TOnGetAttachmentEvent OnGetAttachment;
```

Description

The MIME attachment handler generates this event as it reads each incoming attachment. Classes that use the MIME attachment handler, such as TRio or TSoapPascalInvoker, assign their own event handlers as the value of this event.

See Also

OnSendAttachment (see page 1183)

OnGetAttachment

OnGetAttachment (see page 1358)

13.2.1.4.2 IMimeAttachmentHandler.OnSendAttachment Event

Occurs for each attachment that is added to a multipart form to be sent.

Pascal

```
property OnSendAttachment: TOnSendAttachmentEvent;
```

C++

```
__property TOnSendAttachmentEvent OnSendAttachment;
```

Description

The MIME attachment handler generates this event as it adds each outgoing attachment to the multipart form. Classes that use the MIME attachment handler, such as TRio or TSoapPascalInvoker, assign their own event handlers as the value of this event.

See Also

OnGetAttachment (see page 1183)

OnSendAttachment

OnSendAttachment (see page 1358)

13.3 Types

The following table lists types in this documentation.

Types

Name	Description
TOnGetAttachmentEvent (see page 1185)	TOnGetAttachmentEvent is the type of event handlers that respond when a remote interfaced object receives an attachment in a response from a Web Service provider.
TOnSendAttachmentEvent (see page 1185)	TOnSendAttachmentEvent is the type of event handlers that respond when a remote interfaced object sends an attachment in a request to a Web Service provider.

13.3.1 SOAPAttachIntf.TOnGetAttachmentEvent Type

TOnGetAttachmentEvent is the type of event handlers that respond when a remote interfaced object receives an attachment in a response from a Web Service provider.

Pascal

```
TOnGetAttachmentEvent = procedure (AttachmentStream: TStream; Attachment: TSOAPAttachment) of object;
```

C++

```
(AttachmentStream: TStream; Attachment: TSOAPAttachment) ( TOnGetAttachmentEvent)();
```

File

SOAPAttachIntf

Description

TOnGetAttachmentEvent is the type of the OnGetAttachment event handler, which is called for every attachment that a client receives in the encoded results from executing a method on an invokable interface.

AttachmentStream is a stream from which you can read or change the content of the attachment. This is the section of the multipart form received from the server that represents the current attachment.

Attachment is the TSOAPAttachment instance that will represent the current attachment. Because the attachment has not yet been saved to a temporary file, this object can't be used to read the current attachment (use the AttachmentStream parameter instead). However, its ID and Headers properties are initialized when the event handler is called, so Attachment can be used to read the values of any headers in the attachment.

See Also

Procedural types

Creating events

13.3.2 SOAPAttachIntf.TOnSendAttachmentEvent Type

TOnSendAttachmentEvent is the type of event handlers that respond when a remote interfaced object sends an attachment in a

request to a Web Service provider.

Pascal

```
TOnSendAttachmentEvent = procedure (AttachmentStream: TStream; Attachment: TSOAPAttachment) of object;
```

C++

```
(AttachmentStream: TStream; Attachment: TSOAPAttachment) ( TOnSendAttachmentEvent)();
```

File

SOAPAttachIntf

Description

TOnSendAttachmentEvent is the type of the OnSendAttachment event handler, which is called for every attachment that a client sends in the request to execute a method on an invokable interface.

AttachmentStream is a stream from which you can read or change the content of the attachment. This becomes the section of the multipart form sent to the server that represents the current attachment.

Attachment is the TSOAPAttachment instance that represents the current attachment.

14 SOAPConn Namespace

This is namespace SOAPConn.

Topics

Name	Description
Classes (see page 1188)	The following table lists classes in this documentation.

Classes

	Name	Description
	TSoapConnection (see page 1188)	TSoapConnection connects to an application server that is implemented as a Web Service.

14.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TSoapConnection (see page 1188)	TSoapConnection connects to an application server that is implemented as a Web Service.

14.1.1 TSoapConnection Class

TSoapConnection connects to an application server that is implemented as a Web Service.

Class Hierarchy

Pascal

```
TSoapConnection = class(TCustomRemoteServer);
```

C++

```
class TSoapConnection : public TCustomRemoteServer;
```

File

SOAPConn

Description

TSoapConnection is used in the client portion of a multi-tiered database application to establish and maintain the connection between the client and a remote application server that is implemented as a Web Service. The SOAP connection object can

Establish an initial connection to a remote application server.

Obtain an interface for the application server.

Obtain a list of providers on the application server.

Drop the connection to the remote application server.

TSoapConnection establishes the initial connection between the client application and a remote application server using SOAP.

Note: To use TSoapConnection on Windows, you must have wininet.dll installed on the client system. wininet.dll is found in the Windows system directory if you have IE3 or higher installed.

TSoapConnection uses an internal THTTPRio object to obtain an interface from the Web Service application. This interface is either IAppServer or IAppServerSOAP (see page 1340) (or one of their descendants), depending on the value of the UseSOAPAdapter (see page 1200) property. The recommended approach is to use the IAppServerSOAP (see page 1340) interface, which is better adapted to SOAP as a transport protocol. However, some application servers (those created using Delphi 6 or Kylix 2) only support an IAppServer interface. If you are using an application server that does not support IAppServerSOAP (see page 1340), set UseSOAPAdapter (see page 1200) to false.

Regardless of which interface TSoapConnection uses to communicate with the application server, it makes the information available to client datasets in the client application by providing an IAppServer interface. Client datasets use the IAppServer

interface from the SOAP connection component to communicate with providers on the application server, or to otherwise call the application server's data module interface.

Note: Unlike when using other DataSnap connection components, you can't use the AppServer property of TSoapConnection to call methods of the application server's interface that are not IAppServer methods. Instead, to communicate with a SOAP data module on the application interface, use a separate THTTPRIO (see page 1248) object or specify the interface using the SOAPServerIID (see page 1198) property and then call the GetSOAPServer (see page 1194) method

. To connect to remote application servers using DCOM, use the TDCOMConnection component instead. To connect to remote application servers using TCP/IP, use the TSocketConnection component instead. To connect to remote application servers using HTTP (but not SOAP), use TWebConnection.

Extending the Interface of the Application Server

Specifying a Connection Using SOAP

14.1.1.1 TSoapConnection Members

The following tables list the members exposed by TSoapConnection.

Protected Methods

	Name	Description
	DoConnect (see page 1191)	Provides the interface for a method that opens a connection.
	DoDisconnect (see page 1192)	Provides the interface for a method that terminates the connection.
	GetConnected (see page 1192)	Returns the value of the Connected property.
	GetSOAPServerIID (see page 1194)	This is GetSOAPServerIID, a member of class TSoapConnection.
	Notification (see page 1194)	Forwards notification messages to all owned components.
	SetSOAPServerIID (see page 1195)	This is SetSOAPServerIID, a member of class TSoapConnection.
	SetUseSoapAdapter (see page 1195)	This is SetUseSoapAdapter, a member of class TSoapConnection.

Public Methods

	Name	Description
	Create (see page 1190)	Creates and initializes an instance of TSoapConnection (see page 1188).
	Destroy (see page 1191)	Destroys an instance of TSoapConnection (see page 1188).
	GetProviderNames (see page 1192)	Executes a callback for all provider objects on the application server.
	GetServer (see page 1193)	Returns an IAppServer interface for communicating with the application server.
	GetServerList (see page 1193)	Returns a list of application servers (remote data modules) to which the component can connect.

	GetSOAPServer (see page 1194)	Returns the IAppServerSOAP (see page 1340) interface of the application server.

Public Properties

	Name	Description
	RIO (see page 1198)	Provides access to the internal remote interfaced object that communicates with the application server.

Published Events

	Name	Description
	AfterConnect (see page 1201)	Occurs after a connection is established.
	AfterDisconnect (see page 1201)	Occurs after the connection closes.
	BeforeConnect (see page 1202)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 1202)	Occurs immediately before the connection closes.
	OnAfterExecute (see page 1203)	Occurs when TSoapConnection (see page 1188) receives the results from executing a method on the application server.
	OnBeforeExecute (see page 1203)	Occurs before TSoapConnection (see page 1188) sends a method call to the application server for execution.

Published Properties

	Name	Description
	Agent (see page 1196)	Provides the value of the User-Agent header for HTTP messages to the server.
	Connected (see page 1196)	Indicates whether the SOAP connection component is connected to the application server.
	Password (see page 1197)	Specifies the password that allows the client application to log on to a local host or proxy server.
	Proxy (see page 1197)	Lists any proxy servers that are required to make the connection.
	ProxyByPass (see page 1197)	Lists the host names of locally registered servers that do not require a proxy.
	SOAPServerIID (see page 1198)	Identifies the invokable interface that TSoapConnection (see page 1188) uses to communicate with the application server.
	URL (see page 1199)	Specifies the Uniform Resource Locator for the THTTPSoapDispatcher on the application server.
	UserName (see page 1200)	Specifies the user name that allows the client application to log on to a local host or proxy server.
	UseSOAPAdapter (see page 1200)	Specifies how the SOAP connection component communicates with the application server.

14.1.1.2 TSoapConnection.Create Constructor

Creates and initializes an instance of TSoapConnection (see page 1188).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSoapConnection(TComponent * AOwner);
```

Description

Call Create to instantiate a TSoapConnection (see page 1188) object at runtime. SOAP connection components added to forms or data modules at design time are created automatically.

The AOwner parameter specifies the component (usually a form or data module) that is responsible for freeing the SOAP connection component.

See Also

Owner

14.1.1.3 TSoapConnection.Destroy Destructor

Destroys an instance of TSoapConnection (see page 1188).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSoapConnection();
```

Description

Do not call Destroy directly in an application. Instead, use the Free method, which checks that the SOAP connection is not nil before calling Destroy.

14.1.1.4 TSoapConnection Methods

The methods of the TSoapConnection class are listed here.

Protected Methods

	Name	Description
	DoConnect (see page 1191)	Provides the interface for a method that opens a connection.
	DoDisconnect (see page 1192)	Provides the interface for a method that terminates the connection.
	GetConnected (see page 1192)	Returns the value of the Connected property.
	GetSOAPServerIID (see page 1194)	This is GetSOAPServerIID, a member of class TSoapConnection.
	Notification (see page 1194)	Forwards notification messages to all owned components.
	SetSOAPServerIID (see page 1195)	This is SetSOAPServerIID, a member of class TSoapConnection.
	SetUseSoapAdapter (see page 1195)	This is SetUseSoapAdapter, a member of class TSoapConnection.

Public Methods

	Name	Description
	GetProviderNames (see page 1192)	Executes a callback for all provider objects on the application server.
	GetServer (see page 1193)	Returns an IAppServer interface for communicating with the application server.
	GetServerList (see page 1193)	Returns a list of application servers (remote data modules) to which the component can connect.
	GetSOAPServer (see page 1194)	Returns the IAppServerSOAP (see page 1340) interface of the application server.

14.1.1.4.1 TSoapConnection.DoConnect Method

Provides the interface for a method that opens a connection.

Pascal

```
procedure DoConnect; override;
```

C++

```
virtual __fastcall DoConnect();
```

Description

The Connected property uses DoConnect to establish a connection. Descendant classes override the DoConnect method to establish their connection as appropriate. As implemented in TCustomConnection, DoConnect does nothing.

See Also

Connected

DoDisconnect

14.1.1.4.2 TSoapConnection.DoDisconnect Method

Provides the interface for a method that terminates the connection.

Pascal

```
procedure DoDisconnect; override;
```

C++

```
virtual __fastcall DoDisconnect();
```

Description

The Connected property uses DoDisconnect to close a connection. Descendant classes override the DoDisconnect method to drop a connection. As implemented in TCustomConnection, DoDisconnect does nothing.

See Also

Connected

DoConnect

14.1.1.4.3 TSoapConnection.GetConnected Method

Returns the value of the Connected property.

Pascal

```
function GetConnected: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection, GetConnected always returns false.

See Also

Connected

SetConnected

14.1.1.4.4 TSoapConnection.GetProviderNames Method

Executes a callback for all provider objects on the application server.

Pascal

```
procedure GetProviderNames(Proc: TGetStrProc); override;
```

C++

```
virtual __fastcall GetProviderNames(TGetStrProc Proc);
```

Description

Call GetProviderNames to execute the procedure specified by the Proc parameter for every provider exposed by the application server. For every provider listed by the remote data module's AS_GetProviderNames method, Proc is called with the name of the provider.

See Also

AS_GetProviderNames

AppServer

ProviderName

14.1.1.4.5 TSoapConnection.GetServer Method

Returns an IAppServer interface for communicating with the application server.

Pascal

```
function GetServer: IAppServer; override;
```

C++

```
virtual __fastcall IAppServer GetServer();
```

Description

Client datasets call GetServer to set the value of their AppServer property. This allows them to access providers on the remote application server.

GetServer ensures that there is a connection and then returns an IAppServer interface that can be used to communicate with providers on the application server. To use other methods of the application server's interface, use a separate THTTPRIO (see page 1248) object or call the GetSOAPServer (see page 1194) method after setting the SOAPServerIID (see page 1198) property.

See Also

Connected (see page 1196)

AppServer

THTTPRIO (see page 1248)

UseSOAPAdapter (see page 1200)

SOAPServerIID (see page 1198)

14.1.1.4.6 TSoapConnection.GetServerList Method

Returns a list of application servers (remote data modules) to which the component can connect.

Pascal

```
function GetServerList: OleVariant; override;
```

C++

```
virtual __fastcall OleVariant GetServerList();
```

Description

Connection components use GetServerList internally to fill the drop down list in the Object Inspector for the ServerName property.

As implemented in TCustomRemoteServer, GetServerList always returns NULL. Descendant classes override this method to return a list of application servers that are on the local machine and registered in the system registry (TDispatchConnection), or fetched from the server machine (TStreamedConnection).

See Also

ServerName

14.1.1.4.7 TSoapConnection.GetSOAPServer Method

Returns the IAppServerSOAP (see page 1340) interface of the application server.

Pascal

```
function GetSOAPServer: IAppServerSOAP;
```

C++

```
__fastcall IAppServerSOAP GetSOAPServer();
```

Description

Call GetSOAPServer to access the IAppServerSOAP (see page 1340) interface that the SOAP connection component uses when UseSOAPAdapter (see page 1200) is true. The internal adapter uses this interface to implement the IAppServer interface that the GetServer (see page 1193) method returns.

Tip: If you have set the SOAPServerIID (see page 1198) property, you can use the as operator (Delphi) or the Supports (see page 4294) method (C++) to convert this interface into the application server's interface.

See Also

Connected (see page 1196)

GetServer (see page 1193)

UseSOAPAdapter (see page 1200)

THTTPRIO (see page 1248)

SOAPServerIID (see page 1198)

14.1.1.4.8 TSoapConnection.GetSOAPServerIID Method

Pascal

```
function GetSOAPServerIID: TGUID;
```

C++

```
__fastcall TGUID GetSOAPServerIID();
```

Description

This is GetSOAPServerIID, a member of class TSoapConnection.

14.1.1.4.9 TSoapConnection.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

14.1.1.4.10 TSoapConnection.SetSOAPServerIID Method

Pascal

```
procedure SetSOAPServerIID(const IID: String);
```

C++

```
__fastcall SetSOAPServerIID(const UnicodeString IID);
```

Description

This is SetSOAPServerIID, a member of class TSoapConnection.

14.1.1.4.11 TSoapConnection.SetUseSoapAdapter Method

Pascal

```
procedure SetUseSoapAdapter(Value: Boolean);
```

C++

```
__fastcall SetUseSoapAdapter(Boolean Value);
```

Description

This is SetUseSoapAdapter, a member of class TSoapConnection.

14.1.1.5 TSoapConnection Properties

The properties of the TSoapConnection class are listed here.

Public Properties

	Name	Description
	RIO (see page 1198)	Provides access to the internal remote interfaced object that communicates with the application server.

Published Properties

	Name	Description
	Agent (see page 1196)	Provides the value of the User-Agent header for HTTP messages to the server.
	Connected (see page 1196)	Indicates whether the SOAP connection component is connected to the application server.
	Password (see page 1197)	Specifies the password that allows the client application to log on to a local host or proxy server.
	Proxy (see page 1197)	Lists any proxy servers that are required to make the connection.
	ProxyByPass (see page 1197)	Lists the host names of locally registered servers that do not require a proxy.
	SOAPServerIID (see page 1198)	Identifies the invokable interface that TSoapConnection (see page 1188) uses to communicate with the application server.
	URL (see page 1199)	Specifies the Uniform Resource Locator for the THTTPSoapDispatcher on the application server.
	UserName (see page 1200)	Specifies the user name that allows the client application to log on to a local host or proxy server.
	UseSOAPAdapter (see page 1200)	Specifies how the SOAP connection component communicates with the application server.

14.1.1.5.1 TSoapConnection.Agent Property

Provides the value of the User-Agent header for HTTP messages to the server.

Pascal

```
property Agent: string;
```

C++

```
__property UnicodeString Agent;
```

Description

Use Agent to supply HTTP messages generated by the SOAP connection component with the name of your application. This name is included as a User-Agent header. The User-Agent header is an optional string that describes the application generating the HTTP message.

See Also

Title

14.1.1.5.2 TSoapConnection.Connected Property

Indicates whether the SOAP connection component is connected to the application server.

Pascal

```
property Connected;
```

C++

```
__property Connected;
```

Description

Set Connected to true to establish a connection to the application server. Set Connected to false to terminate the connection.

When changing the value of Connected, TSoapConnection (see page 1188) generates a BeforeConnect (see page 1202) and an AfterConnect (see page 1201) event, or a BeforeDisconnect (see page 1202) and an AfterDisconnect (see page 1201) event.

See Also

BeforeConnect

AfterConnect

BeforeDisconnect

AfterDisconnect

14.1.1.5.3 TSoapConnection.Password Property

Specifies the password that allows the client application to log on to a local host or proxy server.

Pascal

```
property Password: string;
```

C++

```
__property UnicodeString Password;
```

Description

When the SOAP connection component connects to the application server, it supplies the values of the UserName (see page 1200) and Password properties so that it can log on to the local host or proxy. The value of Password can be an empty string if neither the local host nor proxy requires authentication.

Note: On Linux, if the proxy does not require authentication, you can use the UserName (see page 1200) and Password properties to log on to the Web Server.

See Also

UserName (see page 1200)

Specifying a Connection Using SOAP

14.1.1.5.4 TSoapConnection.Proxy Property

Lists any proxy servers that are required to make the connection.

Pascal

```
property Proxy: string;
```

C++

```
__property UnicodeString Proxy;
```

Description

Use Proxy if the SOAP connection component can't resolve the host portion of URL (see page 1199) locally. If the server is registered locally, Proxy can be a null string. Otherwise, Proxy lists the host names of any proxy servers that can forward request messages on to the intended server machine.

See Also

ProxyByPass (see page 1197)

Specifying a Connection Using SOAP

14.1.1.5.5 TSoapConnection.ProxyByPass Property

Lists the host names of locally registered servers that do not require a proxy.

Pascal

```
property ProxyByPass: string;
```

C++

```
__property UnicodeString ProxyByPass;
```

Description

Use ProxyByPass to indicate any server systems to which the SOAP connection component can make a direct connection. When the URL (see page 1199) property identifies a server in this list, the Web connection component makes a direct connection even if the Proxy (see page 1197) property is specified.

When ProxyByPass is an empty string, the Web connection component checks the registry for any locally known servers and bypasses the proxy server if the host portion of URL (see page 1199) refers to a registered local server.

See Also

Proxy (see page 1197)

URL (see page 1199)

14.1.1.5.6 TSoapConnection.RIO Property

Provides access to the internal remote interfaced object that communicates with the application server.

Pascal

```
property RIO: THTTPRIO;
```

C++

```
__property THTTPRIO RIO;
```

Description

TSoapConnection (see page 1188) uses an internal remote interfaced object (THTTPRIO (see page 1248)) to communicate with the application server. This internal object obtains a reference to an invokable interface that is specified by the SOAPServerIID (see page 1198) property.

Use RIO to access the internal THTTPRIO (see page 1248) instance.

See Also

SOAPServerIID (see page 1198)

14.1.1.5.7 TSoapConnection.SOAPServerIID Property

Identifies the invokable interface that TSoapConnection (see page 1188) uses to communicate with the application server.

Pascal

```
property SOAPServerIID: String;
```

C++

```
__property UnicodeString SOAPServerIID;
```

Description

Set SOAPServerIID to identify the interface of the application server. SOAPServerIID is the GUID of the application server's interface. This interface is a descendant of IAppServerSOAP (see page 1340). Once you have formed a connection, you can access this interface by first calling the GetSOAPServer (see page 1194) method and then using the global Supports (see page 4294) function or as operator (Delphi) or the Supports (see page 4294) method of the interface (C++).

Warning: Use the GUID for the interface that is generated by the WSDL importer when you import the application server's definitions. This may differ from the GUID that the server uses in its implementation.

Note: In Delphi, at runtime, you can use the interface name in code and the compiler automatically converts that to the GUID. At design time (in the Object Inspector) or in C++ code, you must specify the GUID itself, not the interface name.

Note: SOAPServerIID is only used if the UseSOAPAdapter (see page 1200) property is true. In addition, if you set SOAPServerIID to anything other than IAppServerSOAP (see page 1340), you must import the definition of the application server's interface so that it is registered with the invocation registry.

Specifying a Connection Using SOAP

14.1.1.5.8 TSoapConnection.URL Property

Specifies the Uniform Resource Locator for the THTTPSoapDispatcher on the application server.

Pascal

```
property URL: string;
```

C++

```
__property UnicodeString URL;
```

Description

Use URL to specify the Uniform Resource Locator that the SOAP connection component uses to locate the application server.

URL includes the protocol (http or https), host name, and scriptname for the application server, as well as a path portion that identifies the THTTPSoapDispatcher on the application server. Typically, it has the form

```
http://DataHost.org/scripts/AppServer.dll/SOAP/
http://DataHost.org/scripts/AppServer.so/SOAP/
```

Note: By default, URL does not include the interface name. The name of the interface is assumed to be IAppServerSOAP (see page 1340) (or IAppServer). If the server is written in the Delphi language and the target remote data module supports an IAppServerSOAP (see page 1340) descendant, Delphi clients can optionally include the target interface name at the end of the URL. This allows clients to identify a SOAP data module when the server contains multiple SOAP data modules, or allows you to access the server's interface by calling the GetSOAPServer (see page 1194) method. If the client or server is not written using Delphi, you can accomplish this same effect using the SOAPServerIID (see page 1198) property.

Note: URL is a standard Uniform Resource Locator. As such, you can also use it to override the port associated with http (80) or https (443) if the Web server is configured differently. The port number follows the host name, preceded by a colon.

Specifying a Connection Using SOAP

14.1.1.5.9 TSoapConnection.UserName Property

Specifies the user name that allows the client application to log on to a local host or proxy server.

Pascal

```
property UserName: string;
```

C++

```
__property UnicodeString UserName;
```

Description

When the SOAP connection component connects to the application server on a local host or to a proxy server, it supplies the values of the UserName and Password (see page 1197) properties so that it can log in. If neither the host nor the proxy server requires authentication, UserName can be an empty string.

Note: On Linux, if the proxy does not require authentication, you can use the UserName and Password (see page 1197) properties to log on to the Web Server.

See Also

Password (see page 1197)

Proxy (see page 1197)

Specifying a Connection Using SOAP

14.1.1.5.10 TSoapConnection.UseSOAPAdapter Property

Specifies how the SOAP connection component communicates with the application server.

Pascal

```
property UseSOAPAdapter: Boolean;
```

C++

```
__property Boolean UseSOAPAdapter;
```

Description

When UseSOAPAdapter is true, TSoapConnection (see page 1188) communicates with the application server using an IAppServerSOAP (see page 1340) interface. It then uses an internal adapter which implements the IAppServer interface for client datasets. In this case, the GetServer (see page 1193) method returns the IAppServer interface that the internal adapter implements.

When UseSOAPAdpater is false, TSoapConnection (see page 1188) uses an IAppServer interface to communicate with the application server and exposes that interface with the GetServer (see page 1193) method. In this case, the GetSOAPServer (see page 1194) method returns nil (Delphi) or NULL (C++).

The recommended setting for UseSOAPAdapter is true. Unlike IAppServer, the IAppServerSOAP (see page 1340) interface does not use the safecall calling convention. This makes it easier to marshal interface calls when the client or server is written in C++. IAppServerSOAP (see page 1340) is not supported, however, when the application server is built using Delphi 6 (before update patch 2) or Kylix 2. If you are connecting to a server that does not support IAppServerSOAP (see page 1340), set UseSOAPAdapter to false.

14.1.1.6 TSoapConnection Events

The events of the TSoapConnection class are listed here.

Published Events

	Name	Description
	AfterConnect (see page 1201)	Occurs after a connection is established.
	AfterDisconnect (see page 1201)	Occurs after the connection closes.
	BeforeConnect (see page 1202)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 1202)	Occurs immediately before the connection closes.
	OnAfterExecute (see page 1203)	Occurs when TSoapConnection (see page 1188) receives the results from executing a method on the application server.
	OnBeforeExecute (see page 1203)	Occurs before TSoapConnection (see page 1188) sends a method call to the application server for execution.

14.1.1.6.1 TSoapConnection.AfterConnect Event

Occurs after a connection is established.

Pascal

```
property AfterConnect;
```

C++

```
__property AfterConnect;
```

Description

Write an AfterConnect event handler to take application-specific actions immediately after the connection component opens a connection to the remote source of database information.

See Also

BeforeConnect

Connected

Connecting to a Database Server

14.1.1.6.2 TSoapConnection.AfterDisconnect Event

Occurs after the connection closes.

Pascal

```
property AfterDisconnect;
```

C++

```
__property AfterDisconnect;
```

Description

Write an AfterDisconnect event handler to take application-specific actions after the connection component drops a connection.

See Also

BeforeDisconnect

Connected

Disconnecting from a Database Server

14.1.1.6.3 TSoapConnection.BeforeConnect Event

Occurs immediately before establishing a connection.

Pascal

```
property BeforeConnect;
```

C++

```
__property BeforeConnect;
```

Description

Write a BeforeConnect event handler to take application-specific actions before the connection component opens a connection to the remote source of database information.

See Also

AfterConnect

Connected

Connecting to a Database Server

14.1.1.6.4 TSoapConnection.BeforeDisconnect Event

Occurs immediately before the connection closes.

Pascal

```
property BeforeDisconnect;
```

C++

```
__property BeforeDisconnect;
```

Description

Write a BeforeDisconnect event handler to take application-specific actions before dropping a connection.

Delphi Examples:

```
{
This BeforeDisconnect event handler makes sure that the
client dataset has applied all its pending updates before
terminating the connection to the server.
}
procedure TForm1.RemoteServer1BeforeDisconnect(Sender: TObject);
begin
  if (ClientDataSet1.ChangeCount > 0) then
```

```
    ClientDataSet1.ApplyUpdates(-1);
end;
```

See Also

AfterDisconnect

Connected

Disconnecting from a Database Server

14.1.1.6.5 TSoapConnection.OnAfterExecute Event

Occurs when TSoapConnection (see page 1188) receives the results from executing a method on the application server.

Pascal

```
property OnAfterExecute: TAfterExecuteEvent;
```

C++

```
__property TAfterExecuteEvent OnAfterExecute;
```

Description

Write (see page 3707) an OnAfterExecute event handler to examine or alter the encoded results from executing a method on the application server. OnAfterExecute is assigned as the OnAfterExecute event handler of an internal remote interfaced object that the SOAP connection uses to communicate with the application server.

See Also

OnBeforeExecute (see page 1203)

OnAfterExecute

GetServer (see page 1193)

14.1.1.6.6 TSoapConnection.OnBeforeExecute Event

Occurs before TSoapConnection (see page 1188) sends a method call to the application server for execution.

Pascal

```
property OnBeforeExecute: TBeforeExecuteEvent;
```

C++

```
__property TBeforeExecuteEvent OnBeforeExecute;
```

Description

Write (see page 3707) an OnBeforeExecute event handler to examine or alter an encoded method call before it is sent to the server. OnBeforeExecute occurs after the call has been marshaled into a SOAP request packet, but before that SOAP request packet has been sent to the application server.

OnBeforeExecute is assigned as the OnBeforeExecute event handler of an internal remote interfaced object that the SOAP connection uses to communicate with the application server.

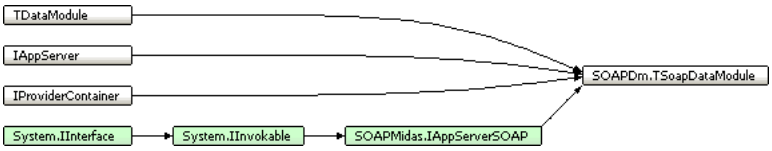
15.1.1 TSoapDataModule Class

TSoapDataModule encapsulates the objects and interfaces of an application server in a SOAP-based multi-tiered database application.

Class Hierarchy



Pascal

```
TSoapDataModule = class(TDataModule, IAppServer, IAppServerSOAP, IProviderContainer);
```

C++

```
class TSoapDataModule : public TDataModule, public IAppServer, public IAppServerSOAP, public
IProviderContainer;
```

File

SOAPDm

Description

Use a TSoapDataModule object as the central repository for all objects in a SOAP-based application server. SOAP data modules can contain any nonvisual components. Typically these are data access components, such as datasets and the provider components that handle communication between these datasets and client applications. They can also contain other nonvisual components, such as TTimer, or TImageList.

At design time a TSoapDataModule object provides a visual container into which a developer can place nonvisual components, set their properties, and write event handlers for them. In the unit file for the SOAP data module a developer can also code any business rules that are to be centralized in the middle tier of a multi-tiered application.

TSoapDataModule implements the IAppServer and IAppServerSOAP (see page 1340) interfaces. These are both invokable interfaces, so if you add TSoapDataModule to a Web Service application, the invoker automatically forwards all IAppServer or IAppServerSOAP (see page 1340) calls to the SOAP data module. The client application uses a TSoapConnection component to generate these calls.

To create a SOAP data module at design time,

1. Choose File|New (see page 3619)|Other, and select Web Services application from the WebServices page of the new items dialog. This generates a Web module that contains a dispatcher and an invoker component. These components work together to interpret and execute incoming SOAP requests.
2. Choose File|New (see page 3619)|Other, and select SOAP DataModule from the Web Services page of the new items dialog. This adds a TSoapDataModule descendant to your application. The TSoapDataModule descendant supports an invokable interface that descends from IAppServerSOAP (see page 1340) as well as an IAppServer interface.

   Note: Web Service applications should not include more than one TSoapDataModule descendant. When the invoker component that appears in the primary Web module receives a request for the IAppServer or IAppServerSOAP (see page 1340) interface, it can't distinguish between multiple implementation classes.

15.1.1.1 TSoapDataModule Members

The following tables list the members exposed by TSoapDataModule.

Protected Methods

	Name	Description
	ApplyUpdates (see page 1211)	Applies updates received from a client using a specified provider.
	AS_ApplyUpdates (see page 1211)	Applies updates received from a client using a specified provider.
	AS_DataRequest (see page 1212)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 1213)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 1214)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 1215)	Returns a list of all the available providers on the SOAP data module.
	AS_GetRecords (see page 1215)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 1216)	Returns information from a specified record of the provider's dataset.
	DataRequest (see page 1217)	Generates an OnDataRequest event on the specified provider component.
	Execute (see page 1218)	Executes the query or stored procedure bound to a specified provider.
	GetParams (see page 1219)	Fetches current parameter values from the dataset bound to a specified provider.
V	GetProvider (see page 1219)	Returns a registered provider component given its name.
	GetProviderNames (see page 1220)	Returns a list of all the available providers on the SOAP data module.
	GetRecords (see page 1220)	Returns a data packet that contains the specified data.
	RowRequest (see page 1222)	Returns information from a specified record of the provider's dataset.
V	SAS_ApplyUpdates (see page 1223)	Applies updates received from a client using a specified provider.
V	SAS_DataRequest (see page 1224)	Generates an OnSAS_DataRequest event on the specified provider component.
V	SAS_Execute (see page 1225)	SAS_Executes the query or stored procedure bound to a specified provider.
V	SAS_GetParams (see page 1226)	Fetches current parameter values from the dataset bound to a specified provider.
V	SAS_GetProviderNames (see page 1226)	Returns a list of all the available providers on the SOAP data module.
V	SAS_GetRecords (see page 1227)	Returns a data packet that contains the specified data.
V	SAS_RowRequest (see page 1228)	Returns information from a specified record of the provider's dataset.

Public Methods

	Name	Description
	_AddRef (see page 1210)	Increments the reference count for this data module's interface.
	_Release (see page 1210)	Decrements the reference count for this data module's interface.
V	AfterConstruction (see page 1210)	Generates an OnCreate event.
V	BeforeDestruction (see page 1217)	Generates an OnDestroy event.
V	Create (see page 1208)	Creates a SOAP data module instance.

	Destroy (see page 1208)	Frees a SOAP data module instance.
	Lock (see page 1221)	Locks the SOAP data module so that it can't be locked by other threads.
	NewInstance (see page 1221)	Allocates memory for each instance of TSoapDataModule (see page 1206).
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	RegisterProvider (see page 1222)	Adds a provider to the list returned by AS_GetProviderNames (see page 1215).
	SafeCallException (see page 1223)	Handles exceptions in methods declared using the safecall calling convention.
	Unlock (see page 1229)	Unlocks the SOAP data module after it was locked by a call to the Lock (see page 1221) method.
	UnRegisterProvider (see page 1229)	Removes a provider from the list returned by AS_GetProviderNames (see page 1215).

Public Properties

	Name	Description
	ProviderCount (see page 1230)	Indicates the number of providers registered with the SOAP data module.
	Providers (see page 1230)	Lists the registered provider components that are contained in the SOAP data module.
	RefCount (see page 1231)	Reference counts the data module's interface.

15.1.1.2 TSoapDataModule.Create Constructor

Creates a SOAP data module instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSoapDataModule(TComponent * AOwner);
```

Description

Most applications do not need to call the constructor for TSoapDataModule (see page 1206). Instead, add a SOAP data module to a Web service application using the SOAP data module wizard on the SOAP page of the new items dialog.

AOwner specifies the component that is responsible for freeing the SOAP data module (typically the application). If you supply an owner, the SOAP data module acts as a component, and is freed by that owner. If you pass nil for the AOwner parameter, the SOAP data module acts like an interfaced object, and maintains a reference count for every use of its interface. When that reference count goes to zero, the SOAP data module automatically frees itself. Note that is you set AOwner to nil but never obtain a reference to this object's interface, you must explicitly free the data module.

See Also

Create

15.1.1.3 TSoapDataModule.Destroy Destructor

Frees a SOAP data module instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSoapDataModule();
```

Description

Most applications do not need to call the destructor for TSoapDataModule (see page 1206). The SOAP data module is freed

by its owner when the application shuts down.

If you must destroy a SOAP data module at runtime, call the Free method instead.

See Also

System::TObject::Free (see page 3372)

15.1.1.4 TSoapDataModule Methods

The methods of the TSoapDataModule class are listed here.

Protected Methods

	Name	Description
	ApplyUpdates (see page 1211)	Applies updates received from a client using a specified provider.
	AS_ApplyUpdates (see page 1211)	Applies updates received from a client using a specified provider.
	AS_DataRequest (see page 1212)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 1213)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 1214)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 1215)	Returns a list of all the available providers on the SOAP data module.
	AS_GetRecords (see page 1215)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 1216)	Returns information from a specified record of the provider's dataset.
	DataRequest (see page 1217)	Generates an OnDataRequest event on the specified provider component.
	Execute (see page 1218)	Executes the query or stored procedure bound to a specified provider.
	GetParams (see page 1219)	Fetches current parameter values from the dataset bound to a specified provider.
V	GetProvider (see page 1219)	Returns a registered provider component given its name.
	GetProviderNames (see page 1220)	Returns a list of all the available providers on the SOAP data module.
	GetRecords (see page 1220)	Returns a data packet that contains the specified data.
	RowRequest (see page 1222)	Returns information from a specified record of the provider's dataset.
V	SAS_ApplyUpdates (see page 1223)	Applies updates received from a client using a specified provider.
V	SAS_DataRequest (see page 1224)	Generates an OnSAS_DataRequest event on the specified provider component.
V	SAS_Execute (see page 1225)	SAS_Executes the query or stored procedure bound to a specified provider.
V	SAS_GetParams (see page 1226)	Fetches current parameter values from the dataset bound to a specified provider.
V	SAS_GetProviderNames (see page 1226)	Returns a list of all the available providers on the SOAP data module.
V	SAS_GetRecords (see page 1227)	Returns a data packet that contains the specified data.
V	SAS_RowRequest (see page 1228)	Returns information from a specified record of the provider's dataset.

Public Methods

	Name	Description
	_AddRef (see page 1210)	Increments the reference count for this data module's interface.
	_Release (see page 1210)	Decrements the reference count for this data module's interface.
V	AfterConstruction (see page 1210)	Generates an OnCreate event.
V	BeforeDestruction (see page 1217)	Generates an OnDestroy event.
V	Lock (see page 1221)	Locks the SOAP data module so that it can't be locked by other threads.
V	NewInstance (see page 1221)	Allocates memory for each instance of TSoapDataModule (see page 1206).
	RegisterProvider (see page 1222)	Adds a provider to the list returned by AS_GetProviderNames (see page 1215).
V	SafeCallException (see page 1223)	Handles exceptions in methods declared using the safecall calling convention.
V	Unlock (see page 1229)	Unlocks the SOAP data module after it was locked by a call to the Lock (see page 1221) method.
	UnRegisterProvider (see page 1229)	Removes a provider from the list returned by AS_GetProviderNames (see page 1215).

15.1.1.4.1 TSoapDataModule._AddRef Method

Increments the reference count for this data module's interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

Do not call the __AddRef method directly. This method is called when an application obtains a reference to the SOAP data module's interface pointer. __AddRef increments the RefCount (see page 1231) property.

When the caller is through with the interface, it calls _Release (see page 1210). This allows the data module to free itself when it is no longer used (when the reference count goes to zero).

See Also

_Release (see page 1210)

RefCount (see page 1231)

IAppServer

15.1.1.4.2 TSoapDataModule._Release Method

Decrements the reference count for this data module's interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

Do not call the __Release method directly. This method is called when an application releases a reference to the SOAP data module's interface pointer. __Release decrements the RefCount (see page 1231) property.

If the SOAP data module does not have an Owner, that is, if the value of the Owner property is nil (Delphi) or NULL (C++), then if the call to __Release changes the value of RefCount (see page 1231) to zero, the SOAP data module automatically frees itself.

See Also

_AddRef (see page 1210)

RefCount (see page 1231)

IAppServer

Owner

15.1.1.4.3 TSoapDataModule.AfterConstruction Method

Generates an OnCreate event.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called after the SOAP data module's constructor has finished. Do not call it explicitly in applications.

AfterConstruction generates an OnCreate event when OldCreateOrder is false. Then, after the OnCreate event handler exits, it decrements the reference count, which is artificially incremented when the data module is first allocated to prevent the data module from accidentally freeing itself from within the constructor because of a zero reference count.

See Also

BeforeDestruction (see page 1217)

OnCreate

OldCreateOrder

RefCount (see page 1231)

15.1.1.4.4 TSoapDataModule.ApplyUpdates Method

Applies updates received from a client using a specified provider.

Pascal

```
function ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors: Integer;
out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int MaxErrors,
int ErrorCount, OleVariant OwnerData);
```

Description

ApplyUpdates provides the underlying implementation for the AS_ApplyUpates method (on the IAppServer interface) and the SAS_ApplyUpdates (see page 1223) method (on the IAppServerSoap interface). It writes client updates to a dataset or database server.

ProviderName specifies the name of the provider component that manages the update operation.

Delta is a Variant (see page 3421) containing the updated, inserted, and deleted records to write to the database.

MaxErrors indicates the maximum number of errors to permit before rolling back the update operation

ErrorCount returns the actual number of errors encountered during the update operation.

OwnerData is information supplied by the client application in a BeforeApplyUpdates event handler and returned to the client application in an AfterApplyUpdates event handler. It is passed to the provider's BeforeApplyUpdates event handler and returned from the provider's AfterApplyUpdates event handler.

ApplyUpdates returns a Variant (see page 3421) that is a data packet containing all records that could not be applied.

See Also

AS_ApplyUpdates (see page 1211)

SAS_ApplyUpdates (see page 1223)

15.1.1.4.5 TSoapDataModule.AS_ApplyUpdates Method

Applies updates received from a client using a specified provider.

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

AS_AS_ApplyUpdates writes client updates to a dataset or database server. ProviderName specifies the name of the provider component that manages the update operation. Delta is a Variant (see page 3421) containing the updated, inserted, and deleted records to write to the database. MaxErrors indicates the maximum number of errors to permit before rolling back the update operation; ErrorCount returns the actual number of errors encountered during the update operation. OwnerData is information supplied by the client application in a BeforeAS_ApplyUpdates event handler and returned to the client application in an AfterAS_ApplyUpdates event handler. It is passed to the provider's BeforeAS_ApplyUpdates event handler and returned from the provider's AfterAS_ApplyUpdates event handler.

Note: In Delphi, AS_AS_ApplyUpdates returns a Variant (see page 3421) that is a data packet containing all records that could not be applied.

Note: In C++, the AS_ApplyUpdates_result parameter returns the Variant (see page 3421) containing the data packet.

Note: Applications can only call the protected AS_AS_ApplyUpdates method using the IAppServer interface. To apply updates directly in code from the application server, use the provider component's AS_ApplyUpdates method.

AfterApplyUpdates

Providers (see page 1230)

IAppServer

15.1.1.4.6 TSoapDataModule.AS_DataRequest Method

Generates an OnAS_DataRequest event on the specified provider component.

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use AS_AS_DataRequest to invoke an OnAS_DataRequest event handler of the provider named by ProviderName. This

method is provided to allow application developers to customize the communication between a client application and a provider component. There is no predefined meaning for the Data parameter or the return value (Delphi) or AS_DataRequest_result parameter (C++).

Note: Applications can only call the protected AS_AS_DataRequest method using the IAppServer interface.

See Also

OnDataRequest

Providers (see page 1230)

DataRequest

IAppServer

15.1.1.4.7 TSoapDataModule.AS_Execute Method

AS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Use AS_AS_Execute to pass an execute command to a remote provider, using a specified set of parameters. AS_AS_Execute calls the AS_Execute method of the specified provider after assigning any parameters. Output (see page 3833) parameters that result from executing a query or stored procedure are returned in the Params parameter.

Note: AS_AS_Execute should only be called for a provider whose dataset represents a query or stored procedure that does not return a cursor.

The ProviderName parameter specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a stored procedure that replaces the provider's underlying stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

The Params parameter encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams method.

The OwnerData parameter contains custom information that appears as an argument to the provider's BeforeAS_Execute and AfterAS_Execute event handlers. This information originates in a client dataset's BeforeAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterAS_Execute event handler.

Note: Applications can only call the protected AS_AS_Execute method using the IAppServer interface. To execute a dataset in code from the application server, use the dataset component directly.

Options

15.1.1.4.8 TSoapDataModule.AS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use AS_AS_GetParams to retrieve the current parameter values from the dataset associated with a provider. The ProviderName parameter specifies the name of the provider component whose dataset has the parameters. The OwnerData represents custom information that originates in a client dataset's BeforeAS_GetParams event handler and returns information that is passed to the client dataset's AfterAS_GetParams event handler.

Note: In Delphi, AS_AS_GetParams returns the parameters, encoded as a Variant (see page 3421) array, or, if the provider does not support parameter fetching, a Null (see page 5056) Variant (see page 3421).

Note: In C++, the AS_GetParams_result parameter the Variant (see page 3421) array containing the parameters (or the Null (see page 5056) Variant (see page 3421)).

Use the UnpackParams procedure to convert parameter values returned by AS_AS_GetParams to a TParams object.

Warning: It is not a good idea to call AS_AS_GetParams on a SOAP data module. SOAP data modules are stateless, and any parameter values you fetch may be changed by other applications. The recommended way to obtain output parameter values is to call the AS_Execute (see page 1213) method instead.

Note: Applications can only call the protected AS_AS_GetParams method using the IAppServer interface.

15.1.1.4.9 TSoapDataModule.AS_GetProviderNames Method

Returns a list of all the available providers on the SOAP data module.

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

Call AS_AS_GetProviderNames for a list of all registered providers available from a SOAP data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the SOAP data module. When calling any of the SOAP data modules through the IAppServer interface, pass one of these names to indicate the provider that is the target of the method call.

AS_AS_GetProviderNames returns the names of the providers in a Variant (see page 3421) array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

Note: Applications can only call the protected AS_AS_GetProviderNames method using the IAppServer interface.

See Also

ProviderName

Providers (see page 1230)

Exported

15.1.1.4.10 TSoapDataModule.AS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call AS_AS_GetRecords to retrieve a specified number of records. AS_AS_GetRecords returns the requested records, starting with the current record of the provider's dataset. Because SOAP data modules are stateless, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeAS_GetRecords event handler.

ProviderName gives the name of the provider component that provides the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params is a Variant (see page 3421) containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_GetRecords event handler. This information is passed to the provider's BeforeAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterAS_GetRecords event handler.

Records are returned as a data packet in a Variant (see page 3421) (as the return value in Delphi or the AS_GetRecords_result parameter in C++).

Note: Applications can only call the protected AS_AS_GetRecords method using the IAppServer interface. To fetch records directly in code from the application server, use the provider component's AS_GetRecords method.

Providers (see page 1230)

IAppServer

15.1.1.4.11 TSoapDataModule.AS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

Client datasets call AS_AS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

The ProviderName parameter indicates the provider associated with the dataset from which information should be fetched.

The Row parameter is an OleVariant (see page 3274) that describes the current record on the client dataset.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_RowRequest event handler. This information is passed to the provider's BeforeAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterAS_RowRequest event handler.

The requested data is returned as a delta packet.

Note: Applications can only call the protected AS_AS_RowRequest method using the IAppServer interface.

15.1.1.4.12 TSoapDataModule.BeforeDestruction Method

Generates an OnDestroy event.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

BeforeDestruction is called immediately before the data module's destructor. Do not call it explicitly in applications.

BeforeDestruction generates an OnDestroy event when OldCreateOrder is false.

See Also

AfterConstruction (see page 1210)

OnDestroy

OldCreateOrder

15.1.1.4.13 TSoapDataModule.DataRequest Method

Generates an OnDataRequest event on the specified provider component.

Pascal

```
function DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

DataRequest provides the underlying implementation for the AS_DataRequest (see page 1212) method (on the IAppServer interface) and the SAS_DataRequest (see page 1224) method (on the IAppServerSOAP (see page 1340) interface). This method calls any OnDataRequest event handler of the specified provider.

There is no predefined meaning for the Data parameter. It represents custom information supplied by the client and passed to the OnDataRequest event handler.

DataRequest returns the value that is assigned to the OwnerData parameter of the event handler on exit.

See Also

AS_DataRequest (see page 1212)

SAS_DataRequest (see page 1224)

OnDataRequest

15.1.1.4.14 TSoapDataModule.Execute Method

Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure Execute(const ProviderName: WideString; const CommandText: WideString; var Params:
OleVariant; var OwnerData: OleVariant);
```

C++

```
__fastcall Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Execute provides the underlying implementation for the AS_Execute (see page 1213) method (on the IAppServer interface) and the SAS_Execute (see page 1225) method (on the IAppServerSOAP (see page 1340) interface). It calls the Execute method of the specified provider after assigning any parameters. Output (see page 3833) parameters that result from executing a query or stored procedure are returned in Params.

ProviderName specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a stored procedure that replaces the provider's underlying stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

Params encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams method.

OwnerData contains custom information that appears as an argument to the provider's BeforeExecute and AfterExecute event handlers. This information originates in a client dataset's BeforeExecute event handler. The value returned in OwnerData is passed to the client dataset's AfterExecute event handler.

See Also

AS_Execute (see page 1213)

SAS_Execute (see page 1225)

15.1.1.4.15 TSoapDataModule.GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

GetParams provides the underlying implementation of the AS_GetParams (see page 1214) method (on the IAppServer interface) and the SAS_GetParams (see page 1226) method (on the IAppServerSOAP (see page 1340) interface).

ProviderName specifies the name of the provider component whose dataset has the parameters to fetch.

OwnerData represents custom information that originates in a client dataset's BeforeGetParams event handler and returns information that is passed to the client dataset's AfterGetParams event handler.

GetParams returns the parameters, encoded as a Variant (see page 3421) array, or, if the provider does not support parameter fetching, GetParams returns a Null (see page 5056) Variant (see page 3421). Use the UnpackParams procedure to convert parameter values returned by GetParams to a TParams object.

See Also

SAS_GetParams (see page 1226)

AS_GetParams (see page 1214)

15.1.1.4.16 TSoapDataModule.GetProvider Method

Returns a registered provider component given its name.

Pascal

```
function GetProvider(const ProviderName: string): TCustomProvider; virtual;
```

C++

```
virtual __fastcall TCustomProvider GetProvider(const UnicodeString ProviderName);
```

Description

GetProvider is the protected read implementation of the Providers (see page 1230) property.

ProviderName specifies the name of a provider that is returned. If ProviderName is not one of the names returned by AS_GetProviderNames (see page 1215) (for example, if the provider's Exported property is false), GetProvider raises an exception.

See Also

Providers (see page 1230)

Exported

AS_GetProviderNames (see page 1215)

15.1.1.4.17 TSoapDataModule.GetProviderNames Method

Returns a list of all the available providers on the SOAP data module.

Pascal

```
function GetProviderNames: OleVariant;
```

C++

```
__fastcall OleVariant GetProviderNames();
```

Description

GetProviderNames provides the underlying implementation for the AS_GetProviderNames (see page 1215) method (on the IAppServer interface) and the SAS_GetProviderNames (see page 1226) method (on the IAppServerSOAP (see page 1340) interface). It returns a list of all registered providers available from a SOAP data module.

GetProviderNames returns the names of the providers in a Variant (see page 3421) array.

See Also

AS_GetProviderNames (see page 1215)

SAS_GetProviderNames (see page 1226)

15.1.1.4.18 TSoapDataModule.GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant GetRecords(const BSTR ProviderName, int Count, int RecsOut, int Options,
const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

GetRecords provides the underlying implementation for the AS_GetRecords (see page 1215) method (on the IAppServer interface) and the SAS_GetRecords (see page 1227) method (on the IAppServerSOAP (see page 1340) interface). GetRecords returns the requested records, starting with the current record of the provider's dataset.

- ProviderName gives the name of the provider component that supplies the records.
- Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.
- RecsOut returns the actual number of records retrieved.
- Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants.:
- CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.
- Params is a Variant (see page 3421) containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.
- OwnerData contains custom information that is supplied by a client dataset's BeforeGetRecords event handler. This information is passed to the provider's BeforeGetRecords event handler. OwnerData returns information supplied by the provider's AfterGetRecords event handler.

- Records are returned as a data packet in a Variant (see page 3421).

See Also

AS_GetRecords (see page 1215)

SAS_GetRecords (see page 1227)

15.1.1.4.19 TSoapDataModule.Lock Method

Locks the SOAP data module so that it can't be locked by other threads.

Pascal

```
procedure Lock; virtual;
```

C++

```
virtual __fastcall Lock();
```

Description

SOAP data modules use Lock internally to ensure that all IAppServer calls are thread-safe. When implementing a SOAP data module descendant, call Lock before accessing any instance data, including the providers contained in the data module. When finished with the block of code that must be protected from thread conflicts, call the Unlock (see page 1229) method to release the lock.

Lock uses a critical section to guard against thread conflicts. This means that any code that accesses the SOAP data module's properties or contained objects must call Lock or it will introduce thread conflicts.

See Also

Providers (see page 1230)

Unlock (see page 1229)

IAppServer

TCriticalSection (see page 3125)

15.1.1.4.20 TSoapDataModule.NewInstance Method

Allocates memory for each instance of TSoapDataModule (see page 1206).

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
virtual __fastcall TObject * NewInstance();
```

Description

All constructors call NewInstance automatically. NewInstance calls InstanceSize to determine how much memory to allocate from the heap to contain a particular instance. Do not call NewInstance directly.

TSoapDataModule (see page 1206) overrides NewInstance to increment the reference count when a new instance is created. This prevents any constructor from accidentally deleting the instance due to a reference count of zero. The AfterConstruction (see page 1210) method decrements the reference count after all constructors have executed.

See Also

System::TObject::NewInstance (see page 3379)

System::TObject::InstanceSize (see page 3377)

AfterConstruction (see page 1210)

15.1.1.4.21 TSoapDataModule.RegisterProvider Method

Adds a provider to the list returned by AS_GetProviderNames (see page 1215).

Pascal

```
procedure RegisterProvider(Value: TCustomProvider);
```

C++

```
__fastcall RegisterProvider(TCustomProvider Value);
```

Description

Call RegisterProvider to make a provider available through the SOAP data module's IAppServer interface. Pass a reference to the provider as the Value parameter. Once a provider is registered, its availability to client applications can be turned on or off using its Exported property.

There is no need to call RegisterProvider for providers that are added at design time or when the SOAP data module is assigned as an Owner in the provider's constructor. These are registered automatically.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider (see page 1229) method. Providers (see page 1230) that have the SOAP data module as an Owner are unregistered automatically from their destructors.

See Also

UnRegisterProvider (see page 1229)

AS_GetProviderNames (see page 1215)

IAppServer

Create

Exported

15.1.1.4.22 TSoapDataModule.RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer; var
OwnerData: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

RowRequest provides the underlying implementation for the AS_RowRequest (see page 1216) method (on the IAppServer interface) and the SAS_RowRequest (see page 1228) method (on the IAppServerSOAP (see page 1340) interface).

ProviderName indicates the provider associated with the dataset from which information should be fetched.

Row is an OleVariant (see page 3274) that describes the current record on the client dataset.

RequestType indicates the type of information required. It is an integer version of the TFetchOptions type.

OwnerData contains custom information that is supplied by a client dataset's BeforeRowRequest event handler. This information

is passed to the provider's BeforeRowRequest event handler. OwnerData returns custom information supplied by the provider's AfterRowRequest event handler.

The requested data is returned as a delta packet.

See Also

AS_RowRequest (see page 1216)

SAS_RowRequest (see page 1228)

15.1.1.4.23 TSoapDataModule.SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException is used for handling exceptions that are raised by methods such as the AS... methods, which use the safecall calling convention. This method ensures that the SOAP fault packet includes all the necessary error information so that clients can respond appropriately to exceptions in safecall methods.

ExceptObject (see page 3562) is the exception that was raised.

ExceptAddr (see page 3562) is the address where the exception occurred.

SafeCallException returns an error code that indicates what error occurred.

See Also

SafeCallException

15.1.1.4.24 TSoapDataModule.SAS_ApplyUpdates Method

Applies updates received from a client using a specified provider.

Pascal

```
function SAS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall OleVariant SAS_ApplyUpdates(const BSTR ProviderName, OleVariant
Delta, int MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

SAS_SAS_ApplyUpdates writes client updates to a dataset or database server.

ProviderName specifies the name of the provider component that manages the update operation.

Delta is a Variant (see page 3421) containing the updated, inserted, and deleted records to write to the database.

MaxErrors indicates the maximum number of errors to permit before rolling back the update operation.

ErrorCount returns the actual number of errors encountered during the update operation.

OwnerData is information supplied by the client application in a BeforeSAS_ApplyUpdates event handler and returned to the

client application in an AfterSAS_ApplyUpdates event handler. It is passed to the provider's BeforeSAS_ApplyUpdates event handler and returned from the provider's AfterSAS_ApplyUpdates event handler.

SAS_SAS_ApplyUpdates returns a Variant (see page 3421) that is a data packet containing all records that could not be applied.

Note: Applications can only call the protected SAS_SAS_ApplyUpdates method using the IAppServerSOAP (see page 1340) interface. To apply updates directly in code from the application server, use the provider component's SAS_ApplyUpdates method.

See Also

ApplyUpdates

ApplyUpdates

AfterApplyUpdates

BeforeApplyUpdates

AfterApplyUpdates

Providers (see page 1230)

IAppServerSOAP (see page 1340)

15.1.1.4.25 TSoapDataModule.SAS_DataRequest Method

Generates an OnSAS_DataRequest event on the specified provider component.

Pascal

```
function SAS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall OleVariant SAS_DataRequest(const BSTR ProviderName, OleVariant
Data);
```

Description

Use SAS_SAS_DataRequest to invoke an OnSAS_DataRequest event handler of the provider named by ProviderName. This method is provided to allow application developers to customize the communication between a client application and a provider component.

ProviderName is the provider on which the data module generates an OnSAS_DataRequest event.

There is no predefined meaning for the Data parameter or the return value.

Note: Applications can only call the protected SAS_SAS_DataRequest method using the IAppServerSOAP (see page 1340) interface.

See Also

OnDataRequest

Providers (see page 1230)

DataRequest

IAppServerSOAP (see page 1340)

15.1.1.4.26 TSoapDataModule.SAS_Execute Method

SAS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure SAS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall SAS_Execute(const BSTR ProviderName, const BSTR CommandText,
OleVariant Params, OleVariant OwnerData);
```

Description

Use SAS_SAS_Execute to pass an execute command to a remote provider, using a specified set of parameters. SAS_SAS_Execute calls SAS_Execute, which calls the SAS_Execute method of the specified provider after assigning any parameters. Output (see page 3833) parameters that result from executing a query or stored procedure are returned in the Params parameter.

Note: SAS_SAS_Execute should only be called for a provider whose dataset represents a query or stored procedure that does not return a cursor.

ProviderName specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a stored procedure that replaces the provider's underlying stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

Params encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams method.

OwnerData contains custom information that appears as an argument to the provider's BeforeSAS_Execute and AfterSAS_Execute event handlers. This information originates in a client dataset's BeforeSAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterSAS_Execute event handler.

Note: Applications can only call the protected SAS_SAS_Execute method using the IAppServerSOAP (see page 1340) interface. To execute a dataset in code from the application server, use the dataset component directly.

15.1.1.4.27 TSoapDataModule.SAS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function SAS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall OleVariant SAS_GetParams(const BSTR ProviderName, OleVariant
OwnerData);
```

Description

Use SAS_SAS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

ProviderName specifies the name of the provider component whose dataset has the parameters.

OwnerData represents custom information that originates in a client dataset's BeforeSAS_GetParams event handler and returns information that is passed to the client dataset's AfterSAS_GetParams event handler.

SAS_SAS_GetParams returns the parameters, encoded as a Variant (see page 3421) array, or, if the provider does not support parameter fetching, SAS_SAS_GetParams returns a Null (see page 5056) Variant (see page 3421). Use the UnpackParams procedure to convert parameter values returned by SAS_SAS_GetParams to a TParams object.

Warning: It is not a good idea to call SAS_SAS_GetParams on a SOAP data module. SOAP data modules are stateless, and any parameter values you fetch may be changed by other applications. The recommended way to obtain output parameter values is to call the SAS_Execute (see page 1225) method instead.

Note: Applications can only call the protected SAS_SAS_GetParams method using the IAppServerSOAP (see page 1340) interface.

15.1.1.4.28 TSoapDataModule.SAS_GetProviderNames Method

Returns a list of all the available providers on the SOAP data module.

Pascal

```
function SAS_GetProviderNames: TWideStringDynArray; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall TWideStringDynArray SAS_GetProviderNames();
```

Description

Call SAS_SAS_GetProviderNames for a list of all registered providers available from a SOAP data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the SOAP data module. When calling any of the SOAP data modules through the IAppServerSOAP (see page 1340) interface, pass one of these names to indicate the provider that is the target of the method call.

SAS_SAS_GetProviderNames returns the names of the providers in a dynamic array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

Note: Applications can only call the protected SAS_SAS_GetProviderNames method using the IAppServerSOAP (see page 1340) interface.

See Also

ProviderName

Providers (see page 1230)

IAppServerSOAP (see page 1340)

Exported

15.1.1.4.29 TSoapDataModule.SAS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function SAS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall OleVariant SAS_GetRecords(const BSTR ProviderName, int Count, int
RecsOut, int Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call SAS_SAS_GetRecords to retrieve a specified number of records. SAS_SAS_GetRecords returns the requested records, starting with the current record of the provider's dataset. Because SOAP data modules are stateless, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeSAS_GetRecords event handler.

ProviderName gives the name of the provider component that supplies the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or

stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params is a Variant (see page 3421) containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.

OwnerData contains custom information that is supplied by a client dataset's BeforeSAS_GetRecords event handler. This information is passed to the provider's BeforeSAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterSAS_GetRecords event handler.

Records are returned as a data packet in a Variant (see page 3421).

Note: Applications can only call the protected SAS_SAS_GetRecords method using the IAppServerSOAP (see page 1340) interface. To fetch records directly in code from the application server, use the provider component's SAS_GetRecords method.

15.1.1.4.30 TSoapDataModule.SAS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function SAS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall OleVariant SAS_RowRequest(const BSTR ProviderName, OleVariant
Row, int RequestType, OleVariant OwnerData);
```

Description

Client datasets call SAS_SAS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

ProviderName indicates the provider associated with the dataset from which information should be fetched.

Row is an OleVariant (see page 3274) that describes the current record on the client dataset.

RequestType indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeSAS_RowRequest event handler. This information is passed to the provider's BeforeSAS_RowRequest event handler. OwnerData returns custom information supplied

by the provider's AfterSAS_RowRequest event handler.

The requested data is returned as a delta packet.

Note: Applications can only call the protected SAS_SAS_RowRequest method using the IAppServerSOAP (see page 1340) interface.

15.1.1.4.31 TSoapDataModule.Unlock Method

Unlocks the SOAP data module after it was locked by a call to the Lock (see page 1221) method.

Pascal

```
procedure Unlock; virtual;
```

C++

```
virtual __fastcall Unlock();
```

Description

Use Unlock to release the critical section that was entered by a call to the Lock (see page 1221) method. Every call to the Lock (see page 1221) method must be paired with a corresponding call to Unlock.

See Also

Lock (see page 1221)

15.1.1.4.32 TSoapDataModule.UnRegisterProvider Method

Removes a provider from the list returned by AS_GetProviderNames (see page 1215).

Pascal

```
procedure UnRegisterProvider(Value: TCustomProvider);
```

C++

```
__fastcall UnRegisterProvider(TCustomProvider Value);
```

Description

Call UnRegisterProvider to remove a provider from the SOAP data module's list of available providers. Pass a reference to the provider that should be removed as the Value parameter. When a provider is not registered, it is not returned by the AS_GetProviderNames (see page 1215) method, which can be accessed through the IAppServer interface.

To temporarily disable a provider, use the provider's Exported property. Unexported providers can't be accessed through any IAppServer method calls.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider method. Providers (see page 1230) that have the SOAP data module as an Owner are unregistered automatically from their destructors.

See Also

RegisterProvider (see page 1222)

Exported

15.1.1.5 TSoapDataModule Properties

The properties of the TSoapDataModule class are listed here.

Public Properties

	Name	Description
	ProviderCount (see page 1230)	Indicates the number of providers registered with the SOAP data module.
	Providers (see page 1230)	Lists the registered provider components that are contained in the SOAP data module.
	RefCount (see page 1231)	Reference counts the data module's interface.

15.1.1.5.1 TSoapDataModule.ProviderCount Property

Indicates the number of providers registered with the SOAP data module.

Pascal

```
property ProviderCount: integer;
```

C++

```
__property int ProviderCount;
```

Description

ProviderCount is the number of providers that can be accessed using the Providers (see page 1230) property.

See Also

Providers (see page 1230)

RegisterProvider (see page 1222)

15.1.1.5.2 TSoapDataModule.Providers Property

Lists the registered provider components that are contained in the SOAP data module.

Pascal

```
property Providers [const ProviderName: string]: TCustomProvider;
```

C++

```
__property TCustomProvider Providers[UnicodeString const ProviderName];
```

Description

Use Providers to access a provider component from the SOAP data module given its name. The SOAP data module uses

Providers to locate the target of method calls made using the IAppServer interface.

If the value passed as is not one of the names returned by AS_GetProviderNames (see page 1215) (for example, if the provider's Exported property is false) reading Providers raises an exception.

See Also

AS_GetProviderNames (see page 1215)

Exported

RegisterProvider (see page 1222)

ProviderCount (see page 1230)

15.1.1.5.3 TSoapDataModule.RefCount Property

Reference counts the data module's interface.

Pascal

```
property RefCount: Integer;
```

C++

```
__property int RefCount;
```

Description

RefCount keeps track of the number of times the application takes a reference to the SOAP data module's interface. When application code obtains this data module's interface, a call is generated to the _AddRef (see page 1210) method, which increments RefCount. When application code releases the interface, a call is generated to the _Release (see page 1210) method, which decrements RefCount. When RefCount drops to zero, the SOAP data module frees itself if its Owner property is not nil (Delphi) or NULL (C++).

See Also

_AddRef (see page 1210)

_Release (see page 1210)

Classes

	Name	Description
	TSOAPDOMProcessor (see page 1234)	TSOAPDOMProcessor is the base class for components that process the SOAP headers from SOAP requests.

16.1.1 TSOAPDOMProcessor Class

TSOAPDOMProcessor is the base class for components that process the SOAP headers from SOAP requests.

Class Hierarchy

Pascal

```
TSOAPDOMProcessor = class(TComponent, IInterface);
```

C++

```
class TSOAPDOMProcessor : public TComponent, public IInterface;
```

File

SOAPDomConv

Description

TSOAPDOMProcessor is the base class for DOM-based components that interpret and create SOAP method calls. It manages a list of interfaces that it uses to create or interpret specialized headers in the SOAP message. Such headers can include application-specific information such as authentication, compression/decompression, encryption/decryption, and so on.

Do not create instances of TSOAPDOMProcessor. It is intended only as a base class for components that use the information in SOAP headers when interpreting or creating SOAP method calls.

See Also

TOPToSoapDomConvert

16.1.1.1 TSOAPDOMProcessor Members

The following tables list the members exposed by TSOAPDOMProcessor.

Protected Fields

	Name	Description
	FHeaderProcessors (see page 1235)	This is FHeaderProcessors, a member of class TSOAPDOMProcessor.

Protected Methods

	Name	Description
	_AddRef (see page 1236)	Implements the IInterface (see page 3502) __AddRef method.
	_Release (see page 1236)	Implements the IInterface (see page 3502) __Release method.
	FindHeaderProcessor (see page 1238)	Locates a processor to interpret or generate a specified SOAP header.
	MakeHeaderNodes (see page 1239)	Generates all the SOAP headers that this object knows how to create.

Public Methods

	Name	Description
	AddHeaderProcessor (see page 1237)	Adds a processor to the internal list of interfaces to use for interpreting and creating SOAP headers.
	AfterConstruction (see page 1237)	Responds after the last constructor executes.
	DefaultProcessHeader (see page 1238)	Handles the interpretation of a SOAP header when no processor can be found.
	Destroy (see page 1235)	Frees the memory associated with the TSOAPDOMProcessor (see page 1234) object.
	NewInstance (see page 1239)	Allocates memory for each instance of TSOAPDOMProcessor (see page 1234).
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

16.1.1.2 TSOAPDOMProcessor.Destroy Destructor

Frees the memory associated with the TSOAPDOMProcessor (see page 1234) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSOAPDOMProcessor();
```

Description

Do not call Destroy to free an instance of TSOAPDOMProcessor (see page 1234). Instead, use the Free method, which first checks for a nil reference before calling Destroy.

See Also

System::TObject::Free (see page 3372)

16.1.1.3 TSOAPDOMProcessor Fields

The fields of the TSOAPDOMProcessor class are listed here.

Protected Fields

	Name	Description
	FHeaderProcessors (see page 1235)	This is FHeaderProcessors, a member of class TSOAPDOMProcessor.

16.1.1.3.1 TSOAPDOMProcessor.FHeaderProcessors Field

Pascal

```
FHeaderProcessors: TDOMHeaderProcessorArray;
```

C++

```
TDOMHeaderProcessorArray FHeaderProcessors;
```

Description

This is FHeaderProcessors, a member of class TSOAPDOMProcessor.

16.1.1.4 TSOAPDOMProcessor Methods

The methods of the TSOAPDOMProcessor class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 1236)	Implements the IInterface (see page 3502) __AddRef method.
	_Release (see page 1236)	Implements the IInterface (see page 3502) __Release method.
	FindHeaderProcessor (see page 1238)	Locates a processor to interpret or generate a specified SOAP header.
	MakeHeaderNodes (see page 1239)	Generates all the SOAP headers that this object knows how to create.

Public Methods

	Name	Description
	AddHeaderProcessor (see page 1237)	Adds a processor to the internal list of interfaces to use for interpreting and creating SOAP headers.
	AfterConstruction (see page 1237)	Responds after the last constructor executes.
	DefaultProcessHeader (see page 1238)	Handles the interpretation of a SOAP header when no processor can be found.
	NewInstance (see page 1239)	Allocates memory for each instance of TSOAPDOMProcessor (see page 1234).

16.1.1.4.1 TSOAPDOMProcessor._AddRef Method

Implements the IInterface (see page 3502) __AddRef method.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

Do not call the protected __AddRef method directly. __AddRef is called through the IInterface (see page 3502) interface to indicate that another object is using the TSOAPDOMProcessor (see page 1234) object's interface pointer. When the other object is through with the interface, it calls _Release (see page 1236) through the same interface. This allows the TSOAPDOMProcessor (see page 1234) object to free itself when it is no longer used (when the reference count goes to zero).

See Also

_Release (see page 1236)

16.1.1.4.2 TSOAPDOMProcessor._Release Method

Implements the IInterface (see page 3502) __Release method.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

Do not call the protected __Release method directly. __Release is called through the IInterface (see page 3502) interface to indicate that another object is through with the TSOAPDOMProcessor (see page 1234) object's interface pointer. This allows the TSOAPDOMProcessor (see page 1234) object to free itself when it is no longer used (when the reference count goes to zero).

See Also

_AddRef (see page 1236)

16.1.1.4.3 TSOAPDOMProcessor.AddHeaderProcessor Method

Adds a processor to the internal list of interfaces to use for interpreting and creating SOAP headers.

Pascal

```
procedure AddHeaderProcessor(Namespace: WideString; HeaderName: WideString; TypeName:
WideString; Processor: IDOMHeaderProcessor); virtual;
```

C++

```
virtual __fastcall AddHeaderProcessor(BSTR Namespace, BSTR HeaderName, BSTR TypeName,
IDOMHeaderProcessor Processor);
```

Description

AddHeaderProcessor stores a specified processor interface and the information necessary to identify the SOAP headers that it handles.

Namespace is the namespace URI in which the SOAP header identified by HeaderName is defined.

HeaderName is the name of the SOAP header that the processor handles.

TypeName is the name of the type that is used for the value of the header.

Processor is the interface for a helper object that creates or interprets SOAP headers that match Namespace, HeaderName, and TypeName.

Note: AddHeaderProcessor is supplied for backward compatibility. Headers are handled differently, using lists of TSOAPHeader descendants that are supplied as parameters to methods in descendant classes.

See Also

FindHeaderProcessor (see page 1238)

16.1.1.4.4 TSOAPDOMProcessor.AfterConstruction Method

Responds after the last constructor executes.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

When an instance of TSOAPDOMProcessor (see page 1234) is allocated, its reference count is incremented to prevent its destruction while processing the constructor. AfterConstruction decrements that reference count to re-establish the correct count after all constructors have executed.

See Also

System::TObject::BeforeDestruction (see page 3358)

NewInstance (see page 1239)

16.1.1.4.5 TSOAPDOMProcessor.DefaultProcessHeader Method

Handles the interpretation of a SOAP header when no processor can be found.

Pascal

```
procedure DefaultProcessHeader(HeaderNode: IXMLNode; var Handled: Boolean; var AbortRequest:
Boolean); virtual;
```

C++

```
virtual __fastcall DefaultProcessHeader(IXMLNode HeaderNode, Boolean Handled, Boolean
AbortRequest);
```

Description

DefaultProcessHeader is called to provide a default interpretation of a SOAP header when it is not processed by one of the processors that FindHeaderProcessor (see page 1238) returns.

HeaderNode is the interface of the DOM representation of the SOAP header to be processed.

Handled returns true if DefaultProcessHeader handles the header node.

AbortRequest returns true if DefaultProcessHeader determines that the SOAP header can't be handled and that this results in an inability to interpret the entire SOAP request.

Note: DefaultProcessHeader is supplied for backward compatibility. Headers are handled differently, using lists of TSOAPHeader descendants that are supplied as parameters to methods in descendant classes.

See Also

FindHeaderProcessor (see page 1238)

16.1.1.4.6 TSOAPDOMProcessor.FindHeaderProcessor Method

Locates a processor to interpret or generate a specified SOAP header.

Pascal

```
function FindHeaderProcessor(Namespace: WideString; HeaderName: WideString; TypeName:
WideString): IDOMHeaderProcessor; virtual;
```

C++

```
virtual __fastcall IDOMHeaderProcessor FindHeaderProcessor(BSTR Namespace, BSTR HeaderName,
BSTR TypeName);
```

Description

FindHeaderProcessor returns the interface of the helper object that can generate or interpret a specified SOAP header. This processor must be previously added to the TSOAPDOMProcessor (see page 1234) object's internal list of processors by a call to the AddHeaderProcessor (see page 1237) method.

Namespace is the namespace URI in which the SOAP header identified by HeaderName is defined.

HeaderName is the name of the SOAP header that the processor handles.

TypeName is the name of the type that is used for the value of the header.

Note: FindHeaderProcessor is supplied for backward compatibility. Headers are handled differently, using lists of TSOAPHeader descendants that are supplied as parameters to methods in descendant classes.

See Also

AddHeaderProcessor (see page 1237)

16.1.1.4.7 TSOAPDOMProcessor.MakeHeaderNodes Method

Generates all the SOAP headers that this object knows how to create.

Pascal

```
function MakeHeaderNodes(HeaderNode: IXMLNode): IXMLNode;
```

C++

```
__fastcall IXMLNode MakeHeaderNodes(IXMLNode HeaderNode);
```

Description

MakeHeaderNodes uses the processors that have been added by the AddHeaderProcessor (see page 1237) method to generate a set of SOAP header nodes. These generated nodes are added as child nodes to the node specified by HeaderNode.

Note: MakeHeaderNodes is supplied for backward compatibility. Headers are handled differently, using lists of TSOAPHeader descendants that are supplied as parameters to methods in descendant classes.

See Also

AddHeaderProcessor (see page 1237)

16.1.1.4.8 TSOAPDOMProcessor.NewInstance Method

Allocates memory for each instance of TSOAPDOMProcessor (see page 1234).

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
virtual __fastcall TObject * NewInstance();
```

Description

All constructors call NewInstance automatically. NewInstance calls InstanceSize to determine how much memory to allocate from the heap to contain a particular instance. Do not call NewInstance directly.

TSOAPDOMProcessor (see page 1234) overrides NewInstance to increment the reference count when a new instance is created. This prevents any constructor from accidentally deleting the instance due to a reference count of zero. The AfterConstruction (see page 1237) method decrements the reference count after all constructors have executed.

See Also

System::TObject::NewInstance (see page 3379)

System::TObject::InstanceSize (see page 3377)

AfterConstruction (see page 1237)

16.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDOMHeaderProcessor (see page 1241)	IDOMHeaderProcessor is the interface for objects that interpret and create SOAP headers.

16.2.1 IDOMHeaderProcessor Interface

IDOMHeaderProcessor is the interface for objects that interpret and create SOAP headers.

Class Hierarchy

Pascal

```
IDOMHeaderProcessor = interface;
```

C++

```
__interface IDOMHeaderProcessor;
```

File

SOAPDomConv

Description

IDOMHeaderProcessor provides an interface for working with specialized SOAP headers. Each object that implements IDOMHeaderProcessor handles a specific type of soap header. The TSOAPDOMProcessor (see page 1234) class calls on this interface when it needs to create or interpret the headers of a SOAP packet.

IDOMHeaderProcessor declares two methods, CreateHeader (see page 1242) and ProcessHeader (see page 1242), which create or respond to a given SOAP header, respectively.

Note: C++ method declarations that use IDOMHeaderProcessor use the _di_IDOMHeaderProcessor type instead. This type is a DelphiInterface (see page 3256) wrapper around the IDOMHeaderProcessor interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IDOMHeaderProcessor >
_di_IDOMHeaderProcessor;
```

Note: IDOMHeaderProcessor is supplied for backward compatibility. Headers are handled differently, using the ISOAPHeaders interface.

See Also

TSOAPDOMProcessor (see page 1234)

ISOAPHeaders

16.2.1.1 IDOMHeaderProcessor Members

The following tables list the members exposed by IDOMHeaderProcessor.

Public Methods

	Name	Description
	CreateHeader (see page 1242)	Creates a new SOAP header node.
	ProcessHeader (see page 1242)	Interprets and responds to a SOAP header.

16.2.1.2 IDOMHeaderProcessor Methods

The methods of the IDOMHeaderProcessor class are listed here.

Public Methods

	Name	Description
	CreateHeader (see page 1242)	Creates a new SOAP header node.
	ProcessHeader (see page 1242)	Interprets and responds to a SOAP header.

16.2.1.2.1 IDOMHeaderProcessor.CreateHeader Method

Creates a new SOAP header node.

Pascal

```
function CreateHeader(HeaderNode: IXMLNode): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateHeader(IXMLNode HeaderNode);
```

Description

CreateHeader creates a new header node.

HeaderNode is the node in the emerging SOAP packet that acts as a parent to the new header.

CreateHeader returns the new header node.

See Also

MakeHeaderNodes (see page 1239)

16.2.1.2.2 IDOMHeaderProcessor.ProcessHeader Method

Interprets and responds to a SOAP header.

Pascal

```
procedure ProcessHeader(HeaderNode: IXMLNode; var Handled: Boolean; var AbortRequest: Boolean);
```

C++

```
__fastcall ProcessHeader(IXMLNode HeaderNode, Boolean Handled, Boolean AbortRequest);
```

Description

ProcessHeader provides a response to a given SOAP header node.

HeaderNode is the interface of the DOM representation of the SOAP header to be processed.

Handled returns true if ProcessHeader handles the header node.

AbortRequest returns true if ProcessHeader determines that the SOAP header can't be handled and that this results in an inability to interpret the entire SOAP request. For example, if the header node represents authentication information, ProcessHeader could set AbortRequest to true if the header supplied an invalid password.

16.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TDOMHeaderProcessorEntry (see page 1244)	This is record SOAPDomConv.TDOMHeaderProcessorEntry.

16.3.1 SOAPDomConv.TDOMHeaderProcessorEntry Record

Pascal

```
TDOMHeaderProcessorEntry = record
  Processor: IDOMHeaderProcessor;
  NameSpace: WideString;
  HeaderName: WideString;
  TypeName: WideString;
end;
```

C++

```
struct TDOMHeaderProcessorEntry {
  IDOMHeaderProcessor Processor;
  BSTR NameSpace;
  BSTR HeaderName;
  BSTR TypeName;
};
```

File

SOAPDomConv

Description

This is record SOAPDomConv.TDOMHeaderProcessorEntry.

16.4 Types

The following table lists types in this documentation.

Types

Name	Description
TDOMHeaderProcessorArray (see page 1245)	This is type SOAPDomConv.TDOMHeaderProcessorArray.

16.4.1 SOAPDomConv.TDOMHeaderProcessorArray Type

Pascal

```
TDOMHeaderProcessorArray = array of TDOMHeaderProcessorEntry;
```

C++

```
array of TDOMHeaderProcessorEntry TDOMHeaderProcessorArray;
```

File

SOAPDomConv

Description

This is type SOAPDomConv.TDOMHeaderProcessorArray.

17 SOAPHTTPClient Namespace

This is namespace SOAPHTTPClient.

Topics

Name	Description
Classes (see page 1248)	The following table lists classes in this documentation.

Classes

	Name	Description
	THTTPRIO (see page 1248)	THTTPRIO uses HTTP messages to call remote interfaced objects using SOAP.

17.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	THTTPRIO (see page 1248)	THTTPRIO uses HTTP messages to call remote interfaced objects using SOAP.

17.1.1 THTTPRIO Class

THTTPRIO uses HTTP messages to call remote interfaced objects using SOAP.

Class Hierarchy

Pascal

```
THTTPRIO = class(TRIO);
```

C++

```
class THTTPRIO : public TRIO;
```

File

SOAPHTTPClient

Description

Use THTTPRIO to generate statically-linked calls to invokable interfaces on a remote Web Service (see page 1253) application. When an application casts THTTPRIO to a registered invokable interface, it dynamically generates an in-memory method table, providing an implementation to that invokable interface. THTTPRIO executes the methods in this method table by encoding the method call as a SOAP request and sending an HTTP request message to the Web Service (see page 1253) application. It unpacks the resulting HTTP response message to obtain the return value and any output parameters, or to raise an exception if the request generated an exception on the server.

Use the published properties of THTTPRIO to indicate how connect to the Web Service (see page 1253) application. There are two ways to identify where the server application is located:

You can use the URL (see page 1254) property to specify the URL (see page 1254) where the server application is located,.

If you want to look up connection information dynamically at runtime from a WSDL document, you can set the WSDLLocation (see page 1255) property. After setting WSDLLocation (see page 1255), select values for the Service (see page 1253) and Port (see page 1253) properties from drop-down lists in the object inspector to fully specify the binding you want to use.

If you need to use a proxy server, or if the server requires authentication, use the properties of the THTTPReqResp (see page 1276) object that is the value of the HTTPWebNode (see page 1252) property to provide the necessary information.

Before THTTPRIO can generate a method table for an invokable interface, the interface must be registered with the invocation registry. To register an invokable interface, use the global InvRegistry function to access the registry, and use its RegisterInterface method.

InvRegistry

TInvokableClassRegistry

Calling Invokable Interfaces

Understanding Invokable Interfaces

17.1.1.1 THTTPRIO Members

The following tables list the members exposed by THTTPRIO.

Protected Methods

	Name	Description
	Notification (see page 1250)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	Create (see page 1249)	Creates an instance of THTTPRIO (see page 1248).
	Destroy (see page 1250)	Destroys the instance of a THTTPRIO (see page 1248) object.
	QueryInterface (see page 1251)	Implements the IInterface (see page 3502) QueryInterface method.

Public Properties

	Name	Description
	WSDLItems (see page 1255)	Provides access to the definitions in the WSDL file specified by WSDLLocation (see page 1255).

Published Properties

	Name	Description
	Converter (see page 1252)	Handles the marshaling and unmarshaling of calls to an invokable interface.
	HTTPWebNode (see page 1252)	Handles the execution of method calls on the invokable interface.
	Port (see page 1253)	Specifies the port to use when sending the SOAP message to execute a method call.
	Service (see page 1253)	Specifies the Service to use when sending the SOAP message to execute a method call.
	URL (see page 1254)	Specifies the URL that identifies the target Web Service (see page 1253) application.
	WSDLLocation (see page 1255)	Specifies the location of the WSDL document that describes the target Web Service (see page 1253).

17.1.1.2 THTTPRIO.Create Constructor

Creates an instance of THTTPRIO (see page 1248).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall THTTPRIO(TComponent * AOwner);
```

Description

Call Create to instantiate a THTTPRIO (see page 1248) object at runtime. THTTPRIO (see page 1248) components added to forms or data modules at design time are created automatically.

The AOwner parameter specifies another component (usually a form or data module) that is responsible for freeing the THTTPRIO (see page 1248) instance. It becomes the value of the Owner property. If the THTTPRIO (see page 1248) instance is created with AOwner set to nil (Delphi) or NULL (C++), then it is automatically freed when its reference count drops to zero.

See Also

RefCount

Owner

17.1.1.3 THTTPRIO.Destroy Destructor

Destroys the instance of a THTTPRIO (see page 1248) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THTTPRIO();
```

Description

There is no need to explicitly free a THTTPRIO (see page 1248) instance.

If the THTTPRIO (see page 1248) object is created with an Owner, then that Owner handles the freeing of the THTTPRIO (see page 1248) instance. If the THTTPRIO (see page 1248) object is created without an Owner, then it is automatically freed when the reference count on its interface drops to zero.

See Also

Create (see page 1249)

Owner

RefCount

17.1.1.4 THTTPRIO Methods

The methods of the THTTPRIO class are listed here.

Protected Methods

	Name	Description
	Notification (see page 1250)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	QueryInterface (see page 1251)	Implements the IInterface (see page 3502) QueryInterface method.

17.1.1.4.1 THTTPRIO.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

17.1.1.4.2 THTTPRIO.QueryInterface Method

Implements the IInterface (see page 3502) QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface is called through the IInterface (see page 3502) interface to obtain an interface pointer for the interface identified by the IID parameter. In Delphi, this call is generated when an application casts THTTPRIO (see page 1248) to an invokable interface using the as operator.

THTTPRIO (see page 1248) can only return a single type of interface pointer. The first time an application calls QueryInterface, THTTPRIO (see page 1248) generates an in-memory method table to support calls to the methods on the requested interface.

IID specifies the invokable interface that the application wants to call using this THTTPRIO (see page 1248) instance. If the THTTPRIO (see page 1248) object has already been typecast to an interface, then IID must identify that interface. If the THTTPRIO (see page 1248) instance has not yet been typecast to an interface, then IID must be a registered invokable interface.

Obj returns an interface pointer for the specified interface, unless THTTPRIO (see page 1248) was already implementing a different interface or IID identified an interface that was not registered.

QueryInterface returns 0 (S_OK (see page 3860)) if Obj successfully returns an interface pointer. It returns E_NOINTERFACE (see page 3845) otherwise.

Note: In C++, a second, templatized syntax takes a variable that is a DelphiInterface (see page 3256) wrapper for the desired interface type.

If QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

17.1.1.5 THTTPRIO Properties

The properties of the THTTPRIO class are listed here.

Public Properties

	Name	Description
	WSDLItems (see page 1255)	Provides access to the definitions in the WSDL file specified by WSDLLocation (see page 1255).

Published Properties

	Name	Description
	Converter (see page 1252)	Handles the marshaling and unmarshaling of calls to an invokable interface.
	HTTPWebNode (see page 1252)	Handles the execution of method calls on the invokable interface.
	Port (see page 1253)	Specifies the port to use when sending the SOAP message to execute a method call.
	Service (see page 1253)	Specifies the Service to use when sending the SOAP message to execute a method call.
	URL (see page 1254)	Specifies the URL that identifies the target Web Service (see page 1253) application.
	WSDLLocation (see page 1255)	Specifies the location of the WSDL document that describes the target Web Service (see page 1253).

17.1.1.5.1 THTTPRIO.Converter Property

Handles the marshaling and unmarshaling of calls to an invokable interface.

Pascal

```
property Converter: TOPToSoapDomConvert;
```

C++

```
__property TOPToSoapDomConvert Converter;
```

Description

THTTPRIO (see page 1248) uses Converter internally to marshal and unmarshal calls to an invokable interface. That is, when the THTTPRIO (see page 1248) object has been typecast to an invokable interface, it implements each method call by using Converter to marshal the call from an internal format into an encoding protocol, and to unmarshal any return values after that call is executed.

See Also

HTTPWebNode (see page 1252)

17.1.1.5.2 THTTPRIO.HTTPWebNode Property

Handles the execution of method calls on the invokable interface.

Pascal

```
property HTTPWebNode: THTTPReqResp;
```

C++

```
__property THTTPReqResp HTTPWebNode;
```

Description

THTTPRIO (see page 1248) uses HTTPWebNode internally to execute method calls. It is the implementation of the WebNode (see page 6615) property.

THTTPRio executes a method call by sending a SOAP request as an HTTP message to the Web Service (see page 1253) identified by either the URL (see page 1254) property or the WSDLLocation (see page 1255), Service (see page 1253), and Port (see page 1253) properties. If you need to use a proxy server to access the Web Service (see page 1253) application, or if the server requires authentication, use the properties of the THTTPReqResp (see page 1276) object to provide the necessary information.

See Also

WebNode

URL (see page 1254)

WSDLLocation (see page 1255)

Service (see page 1253)

Port (see page 1253)

17.1.1.5.3 THTTPRIO.Port Property

Specifies the port to use when sending the SOAP message to execute a method call.

Pascal

```
property Port: string;
```

C++

```
__property UnicodeString Port;
```

Description

Set Port to indicate the desired port within the service specified by the Service (see page 1253) property. Port is the name of a port defined in the WSDL document specified by the WSDLLocation (see page 1255) property. Once you have set the WSDLLocation (see page 1255) property, you can select a value for Port from a drop-down list in the Object Inspector.

A port defines a binding (which indicates the interface to call and the encoding and transport protocols to use) and the address of the server machine.

See Also

WSDLLocation (see page 1255)

Service (see page 1253)

HTTPWebNode (see page 1252)

17.1.1.5.4 THTTPRIO.Service Property

Specifies the Service to use when sending the SOAP message to execute a method call.

Pascal

```
property Service: string;
```

C++

```
__property UnicodeString Service;
```

Description

Set Service to indicate the Service that you want to use by making a remote method call. Service is the name of a Service defined in the WSDL document specified by the WSDLLocation (see page 1255) property. Once you have set the WSDLLocation (see page 1255) property, you can select a value for Service from a drop-down list in the Object Inspector.

A Service is a set of related interfaces provided by a Web Service application. The interface that THTTPRIO (see page 1248) represents must be on one of the interfaces that make up the specified service.

Note: When defining the target Web Service application by referring to a WSDL document, you must set the Port (see page 1253) property as well as the Service and WSDLLocation (see page 1255) properties.

See Also

WSDLLocation (see page 1255)

Port (see page 1253)

HTTPWebNode (see page 1252)

17.1.1.5.5 THTTPRIO.URL Property

Specifies the URL that identifies the target Web Service (see page 1253) application.

Pascal

```
property URL: string;
```

C++

```
__property UnicodeString URL;
```

Description

Use URL to identify the target application that implements the invokable interface when there is no need to look up connection information from a WSDL document dynamically at runtime. If the server was written using the VCL, the path portion of this URL must match the target path name of the THTTPSoapDispatcher component on the Web Service (see page 1253) application. The protocol portion must specify http or https. Thus, for servers written in the VCL, URL has the form

`http://MyHost.com/scripts/MyWebService.dllso/SOAP/IMyInterface`

When you use URL to identify the server, THTTPRIO (see page 1248) obtains a namespace for the target interface from the invocation registry. It is necessary, therefore, that the target interface be registered with the same namespace in both client and server applications

Note: In Delphi, this happens automatically if you

Use the same unit to declare and register the target interface in both client and server applications.

Use the same value for the AppNamespacePrefix global variable.

Use the automatically-generated namespace.

If you are using C++, or if one of the above criteria is not met, you can ensure that the target interface is registered with the same namespace by explicitly specifying a namespace in the code that registers the interface.

Note: If you want your application to look up connection information from a WSDL document dynamically at runtime, you must use the WSDLLocation (see page 1255), Service (see page 1253), and Port (see page 1253) properties instead. Using the URL property is mutually exclusive with the use of WSDLLocation (see page 1255), Service (see page 1253) and Port (see page 1253).

See Also

WSDLLocation (see page 1255)

WebDispatch (see page 5950)

HTTPWebNode (see page 1252)

AppNameSpacePrefix

17.1.1.5.6 THTTPRIO.WSDLItems Property

Provides access to the definitions in the WSDL file specified by WSDLLocation (see page 1255).

Pascal

```
property WSDLItems: TWSDLItems;
```

C++

```
__property TWSDLItems WSDLItems;
```

Description

WSDLItems is a helper object whose methods return the definitions included in the WSDL file specified by WSDLLocation (see page 1255). Applications should not need to use this object. Rather, THTTPRIO (see page 1248) uses this property to obtain information about how to connect to the Web Service (see page 1253) application and how to encode request messages.

See Also

WSDLLocation (see page 1255)

17.1.1.5.7 THTTPRIO.WSDLLocation Property

Specifies the location of the WSDL document that describes the target Web Service (see page 1253).

Pascal

```
property WSDLLocation: string;
```

C++

```
__property UnicodeString WSDLLocation;
```

Description

Use WSDLLocation to specify a WSDL document that defines the target interface (port type). WSDLLocation can be either a fully qualified path name, or a URL (see page 1254) that indicates where the WSDL document can be found.

When using a WSDL document to indicate the target Web Service (see page 1253), you must also specify values for the Service (see page 1253) and Port (see page 1253) properties. Once WSDLLocation is set, you can use a drop-down list in the Object Inspector to select values for Port (see page 1253) and Service (see page 1253).

Note: If you do not need to look up connection information from the WSDL document at runtime, you can use the URL (see page 1254) property instead. Using the WSDLLocation property is mutually exclusive with the use of the URL (see page 1254) property.

Interfaces

	Name	Description
	IHTTPSoapDispatch (see page 1262)	IHTTPSoapDispatch is the interface for objects that interpret SOAP request messages and execute the corresponding invokable interface.

18.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	THTTPSoapDispatchNode (see page 1258)	THTTPSoapDispatchNode forwards SOAP messages to an invoker for interpretation.

18.1.1 THTTPSoapDispatchNode Class

THTTPSoapDispatchNode forwards SOAP messages to an invoker for interpretation.

Class Hierarchy

Pascal

```
THTTPSoapDispatchNode = class(TComponent);
```

C++

```
class THTTPSoapDispatchNode : public TComponent;
```

File

SOAPHTTPDisp

Description

Use THTTPSoapDispatchNode as a base class for objects that use an invoker component to interpret and execute SOAP message calls. THTTPSoapDispatchNode maintains a reference to the interface of a component that can interpret and execute SOAP method calls. These calls are requests to execute a method on an invokable interface that is registered in the application. You can register an invokable interface by calling the RegisterInterface method of the TInvokableClassRegistry object that the global InvRegistry function returns.

18.1.1.1 THTTPSoapDispatchNode Members

The following tables list the members exposed by THTTPSoapDispatchNode.

Protected Fields

	Name	Description
	FSoapDispatcher (see page 1259)	This is FSoapDispatcher, a member of class THTTPSoapDispatchNode.

Protected Methods

	Name	Description
	Notification (see page 1260)	Responds when objects are added or removed from the Web module.

Public Methods

	Name	Description
	DispatchSOAP (see page 1259)	Forwards the SOAP message on to the invoker for interpretation and execution.

Published Properties

	Name	Description
	Dispatcher (see page 1261)	Specifies the interface of the component that interprets SOAP messages.

18.1.1.2 THTTPSoapDispatchNode Fields

The fields of the THTTPSoapDispatchNode class are listed here.

Protected Fields

	Name	Description
	FSoapDispatcher (see page 1259)	This is FSoapDispatcher, a member of class THTTPSoapDispatchNode.

18.1.1.2.1 THTTPSoapDispatchNode.FSoapDispatcher Field

Pascal

```
FSoapDispatcher: IHTTPSoapDispatch;
```

C++

```
IHTTPSoapDispatch FSoapDispatcher;
```

Description

This is FSoapDispatcher, a member of class THTTPSoapDispatchNode.

18.1.1.3 THTTPSoapDispatchNode Methods

The methods of the THTTPSoapDispatchNode class are listed here.

Protected Methods

	Name	Description
	Notification (see page 1260)	Responds when objects are added or removed from the Web module.

Public Methods

	Name	Description
	DispatchSOAP (see page 1259)	Forwards the SOAP message on to the invoker for interpretation and execution.

18.1.1.3.1 THTTPSoapDispatchNode.DispatchSOAP Method

Forwards the SOAP message on to the invoker for interpretation and execution.

Pascal

```
procedure DispatchSOAP(const Path: WideString; const SoapAction: WideString; const Request:
TStream; Response: TStream); virtual;
```

C++

```
virtual __fastcall DispatchSOAP(const BSTR Path, const BSTR SoapAction, const TStream Request,
TStream Response);
```

Description

DispatchSOAP calls the DispatchSOAP method of the interface specified by the Dispatcher (see page 1261) property. The invoker that implements that interface interprets the message, executes it, and returns the results as a SOAP string.

Path is the path portion of the URL to which the incoming request message was addressed.

SoapAction is the content of the SOAP Action header of the incoming HTTP request message.

Request is a stream from which DispatchSOAP can read the content of the incoming request message. It contains the SOAP encoding of an interface call.

Response is a stream to which DispatchSOAP writes the content for the outgoing response message. DispatchSoap fills it out with the SOAP encoding of any return values.

See Also

DispatchSOAP (see page 1263)

Dispatcher (see page 1261)

18.1.1.3.2 THTTPSoapDispatchNode.Notification Method

Responds when objects are added or removed from the Web module.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. When Operation is opRemove, Notification checks whether AComponent is the implementer of the Dispatcher (see page 1261) property. If so, it sets Dispatcher (see page 1261) to nil (Delphi) or NULL (C++).

See Also

Dispatcher (see page 1261)

18.1.1.4 THTTPSoapDispatchNode Properties

The properties of the THTTPSoapDispatchNode class are listed here.

Published Properties

	Name	Description
	Dispatcher (see page 1261)	Specifies the interface of the component that interprets SOAP messages.

18.1.1.4.1 THTTPSoapDispatchNode.Dispatcher Property

Specifies the interface of the component that interprets SOAP messages.

Pascal

```
property Dispatcher: IHTTPSoapDispatch;
```

C++

```
__property IHTTPSoapDispatch Dispatcher;
```

Description

Set Dispatcher to the interface of a component that interprets SOAP messages and passes them on to the target invokable interface. Dispatcher is the interface of an invoker component, such as THTTPSoapPascalInvoker (Delphi) or THTTPSoapCppInvoker (C++). Invoker components interpret incoming SOAP calls, identify the invokable interface to which they are directed, execute the call, and assemble a response message.

See Also

THTTPSoapPascalInvoker (see page 1267)

THTTPSoapCppInvoker (see page 1266)

18.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IHTTPSoapDispatch (see page 1262)	IHTTPSoapDispatch is the interface for objects that interpret SOAP request messages and execute the corresponding invokable interface.

18.2.1 IHTTPSoapDispatch Interface

IHTTPSoapDispatch is the interface for objects that interpret SOAP request messages and execute the corresponding invokable interface.

Class Hierarchy

SOAPHTTPDisp.IHTTPSoapDispatch

Pascal

```
IHTTPSoapDispatch = interface;
```

C++

```
__interface IHTTPSoapDispatch;
```

File

SOAPHTTPDisp

Description

The THTTPSoapDispatcher component uses this interface to call the object that interprets and responds to the incoming SOAP messages that it receives. By using an interface, THTTPSoapDispatcher can work with any component that interprets and executes SOAP messages.

This interface is implemented by THTTPSoapPascalInvoker and THTTPSoapCppInvoker.

Note: C++ method declarations that use IHTTPSoapDispatch use the _di_IHTTPSoapDispatch type instead. This type is a DelphiInterface (see page 3256) wrapper around the IHTTPSoapDispatch interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IHTTPSoapDispatch >
_di_IHTTPSoapDispatch;
```

See Also

THTTPSoapPascalInvoker (see page 1267)

THTTPSoapDispatchNode (see page 1258)

18.2.1.1 IHTTPSoapDispatch Members

The following tables list the members exposed by IHTTPSoapDispatch.

Public Methods

	Name	Description
	DispatchSOAP (see page 1263)	Interprets an incoming SOAP message, calls the target interface, and encodes any return values.

18.2.1.2 IHTTPSoapDispatch Methods

The methods of the IHTTPSoapDispatch class are listed here.

Public Methods

	Name	Description
	DispatchSOAP (see page 1263)	Interprets an incoming SOAP message, calls the target interface, and encodes any return values.

18.2.1.2.1 IHTTPSoapDispatch.DispatchSOAP Method

Interprets an incoming SOAP message, calls the target interface, and encodes any return values.

Pascal

```
procedure DispatchSOAP(const Path: WideString; const SoapAction: WideString; const Request:
TStream; Response: TStream; var BindingType: TWebServiceBindingType);
```

C++

```
__fastcall DispatchSOAP(const BSTR Path, const BSTR SoapAction, const TStream Request, TStream
Response, TWebServiceBindingType BindingType);
```

Description

DispatchSOAP interprets a SOAP message, executes the interface call it represents, and encodes any return values as a SOAP string.

Path is the path portion of the URL to which the incoming request message was addressed.

SoapAction is the content of the SOAP Action header of the incoming HTTP request message.

Request is a stream from which DispatchSOAP can read the content of the incoming request message. It contains the SOAP encoding of an interface call.

Response is a stream to which DispatchSOAP writes the content for the outgoing response message. DispatchSoap fills it out with the SOAP encoding of any return values.

BindingType indicates the format of the Request and Response. It is either btSOAP (to indicate a SOAP packet) or btMime (for a multipart form when the request or response includes attachments). On entry, BindingType indicates the format of the encoded request message. DispatchSOAP changes BindingType to the format of the response message.

19 SOAPHTTPPasInv Namespace

This is namespace SOAPHTTPPasInv.

Topics

Name	Description
Classes (see page 1266)	The following table lists classes in this documentation.

Classes

	Name	Description
	THTTPSoapCppInvoker (see page 1266)	THTTPSoapCppInvoker interprets a SOAP request message and executes the corresponding invokable interface.
	THTTPSoapPascalInvoker (see page 1267)	THTTPSoapPascalInvoker interprets a SOAP request message and executes the corresponding invokable interface.

19.1 Classes

The following table lists classes in this documentation.

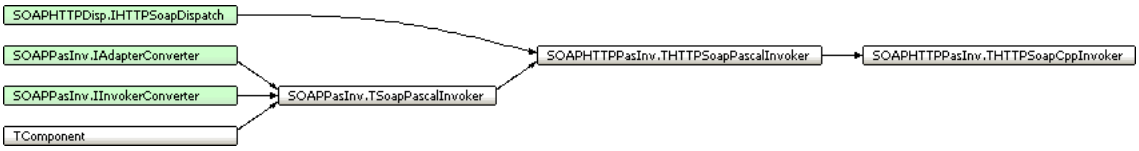
Classes

	Name	Description
	THTTPSoapCppInvoker (see page 1266)	THTTPSoapCppInvoker interprets a SOAP request message and executes the corresponding invokable interface.
	THTTPSoapPascalInvoker (see page 1267)	THTTPSoapPascalInvoker interprets a SOAP request message and executes the corresponding invokable interface.

19.1.1 THTTPSoapCppInvoker Class

THTTPSoapCppInvoker interprets a SOAP request message and executes the corresponding invokable interface.

Class Hierarchy



Pascal

```
THTTPSoapCppInvoker = class(THTTPSoapPascalInvoker);
```

C++

```
class THTTPSoapCppInvoker : public THTTPSoapPascalInvoker;
```

File

SOAPHTTPPasInv

Description

Use THTTPSoapCppInvoker in a C++ application that publishes a Web Service using SOAP. THTTPSoapCppInvoker receives an incoming SOAP request from a THTTPSoapDispatcher component, parses it and generates the appropriate call to a registered invokable interface, and encodes the results of that interface call.

THTTPSoapCppInvoker implements the IHTTPSoapDispatch (see page 1262) interface, which the dispatcher uses to pass it incoming SOAP requests and to receive the content of the response message. To enable the dispatcher to use this interface, assign it as the value of the THTTPSoapDispatcher component's Dispatcher property.

THTTPSoapCppInvoker uses the invocation registry (InvRegistry) to determine whether the interface call encoded in the incoming SOAP request matches a method on a registered invokable interface. Thus, before the invoker can handle a call, the target interface must be registered using the RegisterInterface method of the invocation registry. In addition, the implementation class for that interface must be registered with the invocation registry.

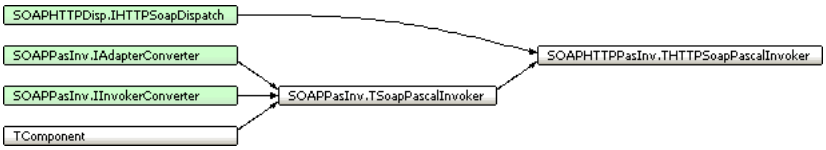
19.1.2 THTTPSoapPascalInvoker Class

THTTPSoapPascalInvoker interprets a SOAP request message and executes the corresponding invokable interface.

Class Hierarchy



Pascal

```
THTTPSoapPascalInvoker = class(TSoapPascalInvoker, IHTTPSoapDispatch);
```

C++

```
class THTTPSoapPascalInvoker : public TSoapPascalInvoker, public IHTTPSoapDispatch;
```

File

SOAPHTTPPasInv

Description

Use THTTPSoapPascalInvoker in an application that publishes a Web Service using SOAP. THTTPSoapPascalInvoker receives an incoming SOAP request from a THTTPSoapDispatcher component, parses it and generates the appropriate call to a registered invokable interface, and encodes the results of that interface call.

In Delphi, you use THTTPSoapPascalInvoker directly as the invoker in your Web Service application. In C++, you use THTTPSoapCppInvoker (see page 1266), a descendant class, instead.

THTTPSoapPascalInvoker implements the IHTTPSoapDispatch (see page 1262) interface, which the dispatcher uses to pass it incoming SOAP requests and to receive the content of the response message. To enable the dispatcher to use this interface, assign it as the value of the THTTPSoapDispatcher component's Dispatcher property.

THTTPSoapPascalInvoker uses the invocation registry (InvRegistry) to determine whether the interface call encoded in the incoming SOAP request matches a method on a registered invokable interface. Thus, before the invoker can handle a call, the target interface must be registered using the RegisterInterface method of the invocation registry. In addition, the implementation class for that interface must be registered with the invocation registry.

19.1.2.1 THTTPSoapPascalInvoker Members

The following tables list the members exposed by THTTPSoapPascalInvoker.

Protected Fields

	Name	Description
	FConverter (see page 1352)	This is FConverter, a member of class TSoapPascalInvoker.
	FDomConverter (see page 1352)	This is FDomConverter, a member of class TSoapPascalInvoker.
	FHeadersIn (see page 1353)	This is FHeadersIn, a member of class TSoapPascalInvoker.
	FHeadersOut (see page 1353)	This is FHeadersOut, a member of class TSoapPascalInvoker.
	FSOAPHeaders (see page 1353)	This is FSOAPHeaders, a member of class TSoapPascalInvoker.

Protected Methods

	Name	Description
	GetDomConverter (see page 1354)	This is GetDomConverter, a member of class TSoapPascalInvoker.
	GetInvoker (see page 1354)	This is GetInvoker, a member of class TSoapPascalInvoker.
	Notification (see page 1355)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	Create (see page 1351)	Creates a new TSoapPascalInvoker (see page 1350) object.
	Destroy (see page 1352)	Frees the memory associated with the TSoapPascalInvoker (see page 1350) object.
	DispatchSOAP (see page 1269)	Interprets an incoming SOAP message, calls the target interface, and encodes any return values.
	GetDomConverter (see page 1360)	This is GetDomConverter, a member of class IAdapterConverter.
	GetInvoker (see page 1361)	This is GetInvoker, a member of class IInvokerConverter.
	Invoke (see page 1354)	Interprets a SOAP request message, calls the target interface, and encodes any return values.

Published Events

	Name	Description
	AfterDispatchEvent (see page 1356)	Occurs after the invoker successfully calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent2 (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	OnExceptionEvent (see page 1357)	Occurs when the invoker encounters an exception while executing a SOAP request.
	OnGetAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) reads each attachment included in an incoming request.
	OnSendAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) sends each attachment included in the response to the current request.

Published Properties

	Name	Description
	Converter (see page 1355)	Specifies the interface of the component that handles the marshaling of SOAP messages.

19.1.2.2 THTTPSoapPascalInvoker Methods

The methods of the THTTPSoapPascalInvoker class are listed here.

Public Methods

	Name	Description
	DispatchSOAP (see page 1269)	Interprets an incoming SOAP message, calls the target interface, and encodes any return values.

19.1.2.2.1 THTTPSoapPascalInvoker.DispatchSOAP Method

Interprets an incoming SOAP message, calls the target interface, and encodes any return values.

Pascal

```
procedure DispatchSOAP(const Path: WideString; const SoapAction: WideString; const Request:
TStream; Response: TStream; var BindingType: TWebServiceBindingType); virtual;
```

C++

```
virtual __fastcall DispatchSOAP(const BSTR Path, const BSTR SoapAction, const TStream Request,
TStream Response, TWebServiceBindingType BindingType);
```

Description

The SOAP dispatcher component (THTTPSoapDispatcher) calls DispatchSOAP when it receives an incoming SOAP message. DispatchSOAP interprets the message, looks up the target interface in the invocation registry, and calls the Invoke method to execute the call and encode any return values as a SOAP string.

Path is the path portion of the URL to which the incoming request message was addressed.

SoapAction is the content of the SOAP Action header of the incoming HTTP request message.

Request is a stream from which DispatchSOAP can read the content of the incoming request message. It contains the SOAP encoding of an interface call.

Response is a stream to which DispatchSOAP writes the SOAP encoding of any return values. THTTPSoapPascalInvoker (see page 1267) uses this as the content for the outgoing response message.

BindingType indicates the format of the Request and Response. It is either btSOAP (to indicate a SOAP packet) or btMime (for a multipart form when the request or response includes attachments). On entry, BindingType indicates the format of the encoded request message. DispatchSOAP changes BindingType to the format of the response message.

20 SOAPHTTPTrans Namespace

This is namespace SOAPHTTPTrans.

Topics

Name	Description
Classes (see page 1272)	The following table lists classes in this documentation.
Interfaces (see page 1296)	The following table lists interfaces in this documentation.
Structs, Records, Enums (see page 1298)	The following table lists structs, records, enums in this documentation.
Types (see page 1299)	The following table lists types in this documentation.

Classes

	Name	Description
	ESOAPHTTPException (see page 1272)	ESOAPHTTPException is the class for exceptions that occur when sending or receiving an HTTP message that contains a SOAP packet.
	THTTPReqResp (see page 1276)	THTTPReqResp executes a method call on an invokable interface by sending a SOAP message to the server.

Interfaces

	Name	Description
	IHTTPReqResp (see page 1296)	This is class SOAPHTTPTrans.IHTTPReqResp.

Structs, Records, Enums

	Name	Description
	SOAPInvokeOptions (see page 1298)	SOAPInvokeOptions and TSOAPInvokeOptions (see page 1300) represent flags that customize how to handle a SOAP message.

Types

Name	Description
TBeforePostEvent (see page 1299)	TBeforePostEvent is the type of the OnBeforePost event of THTTPReqResp (see page 1276).
TPostingDataEvent (see page 1299)	TPostingDataEvent is the type of the OnPostingData event of THTTPReqResp (see page 1276).
TReceivingDataEvent (see page 1300)	TReceivingDataEvent is the type of the OnReceivingData event of THTTPReqResp (see page 1276).
TSOAPInvokeOptions (see page 1300)	This is type SOAPHTTPTrans.TSOAPInvokeOptions.
TWinInetErrorEvent (see page 1301)	This is type SOAPHTTPTrans.TWinInetErrorEvent.

20.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ESOAPHTTPException (see page 1272)	ESOAPHTTPException is the class for exceptions that occur when sending or receiving an HTTP message that contains a SOAP packet.
	THTTPReqResp (see page 1276)	THTTPReqResp executes a method call on an invokable interface by sending a SOAP message to the server.

20.1.1 ESOAPHTTPException Class

ESOAPHTTPException is the class for exceptions that occur when sending or receiving an HTTP message that contains a SOAP packet.

Class Hierarchy

Pascal

```
ESOAPHTTPException = class(Exception);
```

C++

```
class ESOAPHTTPException : public Exception;
```

File

SOAPHTTPTrans

Description

ESOAPHTTPException is raised when there is a problem with the HTTP messages that communicate a SOAP request or response in a Web Services application. Such problems include

The application can't send or receive the HTTP message.

The URL that describes the server is missing or badly formed.

The Content-type header of an HTTP message is not consistent with SOAP.

See Also

THTTPReqResp (see page 1276)

20.1.1.1 ESOAPHTTPException Members

The following tables list the members exposed by ESOAPHTTPException.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.

	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 1274)	Instantiates an instance of an ESOAPHTTPException (see page 1272) with a simple message string.
	CreateFmt (see page 1274)	Instantiates an instance of an ESOAPHTTPException (see page 1272) with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.

	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
V	ToString (see page 3380)	Returns a string containing the class name.
V	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
R	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
R	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.
	StatusCode (see page 1275)	Indicates the HTTP status code of the message that gave rise to this exception.

20.1.1.2 ESOAPHTTPException.Create Constructor

Instantiates an instance of an ESOAPHTTPException (see page 1272) with a simple message string.

Pascal

```
constructor Create(const Msg: string; SCode: Integer = 0; Dummy: Integer = 0);
```

C++

```
__fastcall ESOAPHTTPException(const UnicodeString Msg, int SCode = 0, int Dummy = 0);
```

Description

Call Create to construct an ESOAPHTTPException (see page 1272) object with a simple message string.

Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

SCode is the HTTP status code, if any, that triggered this exception. It becomes the value of the StatusCode (see page 1275) property.

See Also

CreateFmt (see page 1274)

StatusCode (see page 1275)

Message (see page 3965)

20.1.1.3 ESOAPHTTPException.CreateFmt Constructor

Instantiates an instance of an ESOAPHTTPException (see page 1272) with a formatted message string.

Pascal

```
constructor CreateFmt(const Msg: string; const Args: array of const; SCode: Integer = 0;
Dummy: Integer = 0);
```

C++

```
__fastcall ESOAPHTTPException(const UnicodeString Msg, const array of const Args, int SCode =
```

```
0, int Dummy = 0);
```

Description

Call CreateFmt to construct an ESOAPHTTPException (see page 1272) with a formatted message string.

Msg is a string constant containing format specifiers to be replaced with values from Args.

Args is an array of constants containing values to format according to format specifiers in Msg. CreateFmt calls the Format (see page 4188) function to transform Msg with the values in Args.

SCode is the HTTP status code, if any, that triggered this exception. It becomes the value of the StatusCode (see page 1275) property.

See Also

Create (see page 1274)

StatusCode (see page 1275)

Message (see page 3965)

20.1.1.4 ESOAPHTTPException Properties

The properties of the ESOAPHTTPException class are listed here.

Public Properties

	Name	Description
	StatusCode (see page 1275)	Indicates the HTTP status code of the message that gave rise to this exception.

20.1.1.4.1 ESOAPHTTPException.StatusCode Property

Indicates the HTTP status code of the message that gave rise to this exception.

Pascal

```
property StatusCode: Integer;
```

C++

```
__property int StatusCode;
```

Description

StatusCode indicates the HTTP status code of the message that caused the application to raise an ESOAPHTTPException (see page 1272) exception. If the exception does not represent an HTTP response with a status code that indicates an error, StatusCode is 0.

The value of StatusCode is set by the ESOAPHTTPException (see page 1272) constructor.

Note: In Delphi code, this is set by the CreateFmt (see page 1274) or Create (see page 1274) constructor.

Note: In C++ code, this is set using one of the two constructor syntaxes that take a status code parameter.

See Also

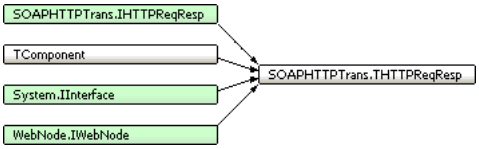
Create (see page 1274)

CreateFmt (see page 1274)

20.1.2 THTTPReqResp Class

THTTPReqResp executes a method call on an invokable interface by sending a SOAP message to the server.

Class Hierarchy



Pascal

```
THTTPReqResp = class(TComponent, IInterface, IWebNode, IHTTPReqResp);
```

C++

```
class THTTPReqResp : public TComponent, public IInterface, public IWebNode, public
IHTTPReqResp;
```

File

SOAPHTTPTrans

Description

THTTPReqResp handles HTTP-based communication with a Web Service provider on behalf of a THTTPRio instance. THTTPRio uses this component to establish a connection to the Web Service provider and perform two tasks:

It can issue a "Get (see page 1283)" request to obtain information from a WSDL document.

It can issue a "Post" request to pass a method call to the server for execution and retrieve the results.

The Web Service that is the target of these HTTP messages can be specified directly, using the SoapAction (see page 1291) and URL (see page 1292) properties, or it can be taken from the SoapAction (see page 1291) in a WSDL document, as specified by the WSDLView (see page 1293) property. Additional properties provide details that are included in the HTTP request message header.

Note: On Windows, THTTPReqResp uses WinInet to establish a connection to the server. Wininet.dll must be installed on the client system. wininet.dll is found in the Windows system directory if you have IE3 or higher installed. WinInet has the advantage that it provides support for secure connections (https). To use WinInet, compile your project without the USE_INDY symbol defined.

Note: On Linux, THTTPReqResp uses an internal instance of the Indy HTTP component (TIdHTTP) to communicate with the server. The Indy component has the advantage that it can be used from an application that acts as both client and server, whereas WinInet only works for pure client code. To use an internal TIdHTTP, compile your project with the USE_INDY symbol defined.

IWebNode (see page 6616)

THTTPRIO (see page 1248)

TRIO

20.1.2.1 THTTPReqResp Members

The following tables list the members exposed by THTTPReqResp.

Protected Methods

	Name	Description
	_AddRef (see page 1279)	Called when an application uses a component interface.
	_Release (see page 1280)	Called when an application releases a component interface.
	GetMimeBoundary (see page 1284)	Returns the value of the MimeBoundary property.
	SetMimeBoundary (see page 1287)	Sets the value of the MimeBoundary property.

Public Methods

	Name	Description
	AfterConstruction (see page 1280)	Responds after the last constructor executes.
	BeforeExecute (see page 1280)	Performs transport-specific setup before executing an encoded method call.
	Check (see page 1281)	Raises an exception when an error is detected.
	CheckContentType (see page 1282)	Raises an exception if the response to a SOAP method call has a common invalid content-type header.
	Connect (see page 1282)	Establishes or terminates a connection to the Web Service application.
	Create (see page 1278)	Creates a new THTTPReqResp (see page 1276) object.
	Destroy (see page 1278)	Frees the memory associated with the THTTPReqResp (see page 1276) object.
	Execute (see page 1282)	This is the overview for the Execute method overload.
	Execute (see page 6618)	This is the overview for the Execute method overload.
	Get (see page 1283)	Sends a "Get" request to the server and retrieves the results.
	GetHTTPReqResp (see page 1284)	Returns a reference to this component.
	HandleWinInetError (see page 1285)	This is HandleWinInetError, a member of class THTTPReqResp.
	NewInstance (see page 1285)	Allocates memory for each instance of THTTPReqResp (see page 1276).
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	Receive (see page 1285)	Receives the contents of an HTTP response to the message sent by the Send (see page 1286) message.
	Send (see page 1286)	Sends the encoded method call as an HTTP-based SOAP message.
	SendGet (see page 1286)	SendGets sends a "GET" request to the server.

Public Properties

	Name	Description
	ConnectTimeout (see page 1288)	Indicates the number of milliseconds that can elapse before aborting an attempt to connect to the server.
	MaxSinglePostSize (see page 1289)	This is MaxSinglePostSize, a member of class THTTPReqResp.
	MimeBoundary (see page 6619)	Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.
	ReceiveTimeout (see page 1290)	Indicates the number of milliseconds that can elapse before canceling a request when no response is received from the server.
	SendTimeout (see page 1291)	Indicates the number of milliseconds that can elapse before timing out the sending of a request.
	SoapAction (see page 1291)	Specifies the SoapAction header to include in the HTTP message that executes the method call.
	URL (see page 1292)	Specifies the URL that identifies the target interface on the target Web Service application.

Published Events

	Name	Description
	OnBeforePost (see page 1294)	Occurs before THTTPReqResp (see page 1276) sends its message.
	OnPostingData (see page 1294)	Occurs before THTTPReqResp (see page 1276) sends each chunk of data when the content is large.

	OnReceivingData (see page 1295)	Occurs after THTTPReqResp (see page 1276) receives each chunk of data when the content is large.
	OnWinInetError (see page 1295)	This is OnWinInetError, a member of class THTTPReqResp.

Published Properties

	Name	Description
	Agent (see page 1288)	Provides the value of the User-Agent header for HTTP messages to the Web Service provider.
	InvokeOptions (see page 1288)	Customizes the way THTTPReqResp (see page 1276) generates or handles headers in the messages it sends to the server.
	Password (see page 1289)	Specifies the password that allows the client application to log on when the Web Service provider requires authentication.
	Proxy (see page 1289)	Lists any proxy servers that are required to make the connection.
	ProxyByPass (see page 1290)	Lists the host names of locally registered servers that do not require a proxy.
	UDDIBindingKey (see page 1291)	Indicates the binding key of a UDDI entry to use for fail-over support.
	UDDIOperator (see page 1292)	Indicates the URL (see page 1292) of the UDDI registry to use for fail-over support.
	UserName (see page 1293)	Specifies the user name that allows the client application to log on to the server.
	UseUTF8InHeader (see page 1293)	Specifies whether the Content-Type header should specify UTF-8 as a character set.
	WSDLView (see page 1293)	Indicates the target interface method using a WSDL document.

20.1.2.2 THTTPReqResp.Create Constructor

Creates a new THTTPReqResp (see page 1276) object.

Pascal

```
constructor Create(Owner: TComponent); override;
```

C++

```
virtual __fastcall THTTPReqResp(TComponent * Owner);
```

Description

Most applications do not create instances of THTTPReqResp (see page 1276). It is created and used by the THTTPRio class.

The Owner parameter specifies the component that is responsible for freeing the THTTPReqResp (see page 1276) instance.

See Also

Owner

THTTPRIO (see page 1248)

20.1.2.3 THTTPReqResp.Destroy Destructor

Frees the memory associated with the THTTPReqResp (see page 1276) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THTTPReqResp();
```

Description

Do not call the Destroy method directly. Instead, use the Free method, which checks for a nil reference before calling Destroy.

The THTTPReqResp (see page 1276) destructor ensures that the connection to the server is closed before the component is

freed.

See Also

System::TObject::Free (see page 3372)

20.1.2.4 THTTPReqResp Methods

The methods of the THTTPReqResp class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 1279)	Called when an application uses a component interface.
	_Release (see page 1280)	Called when an application releases a component interface.
	GetMimeBoundary (see page 1284)	Returns the value of the MimeBoundary property.
	SetMimeBoundary (see page 1287)	Sets the value of the MimeBoundary property.

Public Methods

	Name	Description
	AfterConstruction (see page 1280)	Responds after the last constructor executes.
	BeforeExecute (see page 1280)	Performs transport-specific setup before executing an encoded method call.
	Check (see page 1281)	Raises an exception when an error is detected.
	CheckContentType (see page 1282)	Raises an exception if the response to a SOAP method call has a common invalid content-type header.
	Connect (see page 1282)	Establishes or terminates a connection to the Web Service application.
	Execute (see page 1282)	This is the overview for the Execute method overload.
	Get (see page 1283)	Sends a "Get" request to the server and retrieves the results.
	GetHTTPReqResp (see page 1284)	Returns a reference to this component.
	HandleWinInetError (see page 1285)	This is HandleWinInetError, a member of class THTTPReqResp.
	NewInstance (see page 1285)	Allocates memory for each instance of THTTPReqResp (see page 1276).
	Receive (see page 1285)	Receives the contents of an HTTP response to the message sent by the Send (see page 1286) message.
	Send (see page 1286)	Sends the encoded method call as an HTTP-based SOAP message.
	SendGet (see page 1286)	SendGets sends a "GET" request to the server.

20.1.2.4.1 THTTPReqResp._AddRef Method

Called when an application uses a component interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef is a basic implementation of the IInterface method, _AddRef.

Note: If the component is a wrapper for a COM object, __AddRef calls the _AddRef method of that COM object, and returns the resulting reference count.

In all other cases, __AddRef simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __AddRef to implement reference counting.

See Also

QueryInterface

_Release

_AddRef (see page 3503)

20.1.2.4.2 THTTPReqResp._Release Method

Called when an application releases a component interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release is a basic implementation of the IInterface method, _Release.

__Release returns the resulting value of the reference count for the component's interface.

Note:

In all other cases, __Release simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __Release to implement reference counting.

See Also

QueryInterface

_AddRef

20.1.2.4.3 THTTPReqResp.AfterConstruction Method

Responds after the last constructor executes.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

When an instance of THTTPReqResp (see page 1276) is allocated, its reference count is incremented to prevent its destruction while processing the constructor. AfterConstruction decrements that reference count to re-establish the correct count after all constructors have executed.

See Also

System::TObject::BeforeDestruction (see page 3358)

NewInstance (see page 1285)

20.1.2.4.4 THTTPReqResp.BeforeExecute Method

Performs transport-specific setup before executing an encoded method call.

Pascal

```
procedure BeforeExecute(const IntfMD: TIntfMetaData; const MethMD: TIntfMethEntry;
MethodIndex: Integer; AttachHandler: IMimeAttachmentHandler);
```

C++

```
__fastcall BeforeExecute(const TIntfMetaData IntfMD, const TIntfMethEntry MethMD, int
MethodIndex, IMimeAttachmentHandler AttachHandler);
```

Description

BeforeExecute implements the IWebNode (see page 6616) method of the same name. The remote interface object (TRio) calls this method after its OnBeforeExecute event, but before calling the Execute (see page 1283) method to send a request to the server. BeforeExecute looks up the information needed to call the server from the invocation registry, based on either the URL (see page 1292) that was supplied to the remote interfaced object or on the WSDLLocation, Service, and Port that were supplied to the remote interfaced object. If the method call requires an attachment, BeforeExecute looks up the MIME boundary for the attachment and adds headers to indicate the MIME boundary and content type of the attachment.

IntfMD is the runtime type information (RTTI) of the invokable interface that includes the method to execute.

MethMD is describes the method that is about to be executed.

MethodIndex indicates which overload to use when methMD describes an overloaded method. 0 indicates the first overload, 1 indicates the second overload, and so on.

AttachHandler is an interface to use for handling any attachments that are used as parameters of the method. If AttachHandler is nil (Delphi) or NULL (C++), the method call does not require passing any attachments.

See Also

Execute (see page 1283)

OnBeforeExecute

BeforeExecute (see page 6617)

URL (see page 1254)

WSDLLocation (see page 1255)

Service (see page 1253)

Port (see page 1253)

20.1.2.4.5 THTTPReqResp.Check Method

Raises an exception when an error is detected.

Pascal

```
procedure Check(Error: Boolean; ShowSOAPAction: Boolean = False);
```

C++

```
__fastcall Check(Boolean Error, Boolean ShowSOAPAction = False);
```

Description

Note: On Windows (when using WinInet), THTTPReqResp (see page 1276) calls Check internally to raise an exception when it encounters an error.

Note: Check is not available on Linux.

Error (see page 3560) indicates whether an error condition was detected.

ShowSOAPAction indicates whether the error message should include information about the SOAP Action header.

See Also

Exception (see page 3949)

20.1.2.4.6 THTTPReqResp.CheckContentType Method

Raises an exception if the response to a SOAP method call has a common invalid content-type header.

Pascal

```
procedure CheckContentType;
```

C++

```
__fastcall CheckContentType();
```

Description

CheckContentType checks the Content-type header of the response that THTTPReqResp (see page 1276) receives after sending a request to the Web Service application. If it recognizes the content-type as invalid, CheckContentType raises an ESOAPHTTPException (see page 1272).

CheckContentType does not rule out all invalid content types, only the most common.

See Also

ESOAPHTTPException (see page 1272)

20.1.2.4.7 THTTPReqResp.Connect Method

Establishes or terminates a connection to the Web Service application.

Pascal

```
procedure Connect(Value: Boolean);
```

C++

```
__fastcall Connect(Boolean Value);
```

Description

Note: On Windows, call Connect to open or close a connection to the Web Service application identified by the URL (see page 1292) property. Connect opens a connection using WinInet.

Note: Connect is not available on Linux.

Value indicates whether to open or close the connection. When Value is true, Connect establishes a connection. When Value is false, Connect terminates the connection.

See Also

URL (see page 1292)

20.1.2.4.8 Execute Method

This is the overview for the Execute method overload.

Overload List

	Name	Description
	THTTPReqResp.Execute (String, TStream) (see page 1283)	Executes a SOAP method call and returns the encoded results.
	THTTPReqResp.Execute (TStream) (see page 1283)	Executes a SOAP method call and returns the encoded results.
	THTTPReqResp.Execute (TStream, TStream) (see page 1283)	Executes a SOAP method call and returns the encoded results.

20.1.2.4.8.1 THTTPReqResp.Execute Method (String, TStream)

Executes a SOAP method call and returns the encoded results.

Pascal

```
procedure Execute(const DataMsg: String; Resp: TStream); virtual; overload;
procedure Execute(const Request: TStream; Response: TStream); virtual; overload;
function Execute(const Request: TStream): TStream; virtual; overload;
```

C++

```
virtual __fastcall Execute(const UnicodeString DataMsg, TStream Resp);
virtual __fastcall Execute(const TStream Request, TStream Response);
virtual __fastcall TStream Execute(const TStream Request);
```

Description

Execute implements the IWebNode (see page 6616) method of the same name. THTTPRio uses this method to execute a method on an invokable interface that has been encoded as a SOAP method call.

Execute

1. Connects to the Web Service application identified by the URL (see page 1292) property.
2. Creates an HTTP message with DataMsg or Request as its content and SoapAction (see page 1291) as its SoapAction (see page 1291) header.
3. Sends it to the Web Service application and retrieves the results.
4. Writes the results to the stream specified by Resp or returns a stream from which you can read the results. If using the third syntax, which returns a stream, the caller is responsible for freeing the stream object.

See Also

Execute (see page 6618)

THTTPRIO (see page 1248)

URL (see page 1292)

Send (see page 1286)

Receive (see page 1285)

SoapAction (see page 1291)

20.1.2.4.9 THTTPReqResp.Get Method

Sends a "Get" request to the server and retrieves the results.

Pascal

```
procedure Get(Resp: TStream); virtual;
```

C++

```
virtual __fastcall Get(TStream Resp);
```

Description

Get sends an HTTP request message to the server with a method type of GET. THTTPRio uses this method to fetch the WSDL document that underlies the WSDLView (see page 1293) property.

Resp is a stream that receives the contents of the response to the "Get" request message.

See Also

THTTPRIO (see page 1248)

URL (see page 1292)

Send (see page 1286)

Receive (see page 1285)

Execute (see page 1283)

WSDLView (see page 1293)

20.1.2.4.10 THTTPReqResp.GetHTTPReqResp Method

Returns a reference to this component.

Pascal

```
function GetHTTPReqResp: THTTPReqResp;
```

C++

```
__fastcall THTTPReqResp GetHTTPReqResp();
```

Description

GetHTTPReqResp returns this THTTPReqResp (see page 1276) instance (Delphi) or a pointer to this instance (C++).

20.1.2.4.11 THTTPReqResp.GetMimeBoundary Method

Returns the value of the MimeBoundary property.

Pascal

```
function GetMimeBoundary: string;
```

C++

```
__fastcall UnicodeString GetMimeBoundary();
```

Description

GetMimeBoundary is the read access method for the MimeBoundary property.

See Also

MimeBoundary (see page 6619)

20.1.2.4.12 THTTPReqResp.HandleWinInetError Method

Pascal

```
function HandleWinInetError(LastError: DWord; Request: HINTERNET): DWord;
```

C++

```
__fastcall DWord HandleWinInetError(DWord LastError, HINTERNET Request);
```

Description

This is HandleWinInetError, a member of class THTTPReqResp.

20.1.2.4.13 THTTPReqResp.NewInstance Method

Allocates memory for each instance of THTTPReqResp (see page 1276).

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
virtual __fastcall TObject * NewInstance();
```

Description

All constructors call NewInstance automatically. NewInstance calls InstanceSize to determine how much memory to allocate from the heap to contain a particular instance. Do not call NewInstance directly.

THTTPReqResp (see page 1276) overrides NewInstance to increment the reference count when a new instance is created. This prevents any constructor from accidentally deleting the instance due to a reference count of zero. The AfterConstruction (see page 1280) method decrements the reference count after all constructors have executed.

See Also

System::TObject::NewInstance (see page 3379)

System::TObject::InstanceSize (see page 3377)

AfterConstruction (see page 1280)

20.1.2.4.14 THTTPReqResp.Receive Method

Receives the contents of an HTTP response to the message sent by the Send (see page 1286) message.

Pascal

```
procedure Receive(Context: Integer; Resp: TStream; IsGet: Boolean = False); virtual;
```

C++

```
virtual __fastcall Receive(int Context, TStream Resp, Boolean IsGet = False);
```

Description

Note: On Windows (when using WinInet), Receive fetches the HTTP response to the message sent by the SendMessage method, and writes its contents to the specified stream.

Note: Receive is not available on Linux.

Context is the context ID that identifies the original request message that the Send (see page 1286) message sent. It is the

return value from a previous call to the Send (see page 1286) method.

Resp is a stream to which Receive can write the contents of the response message.

IsGet indicates whether the response stream contains the results from a "Get (see page 1283)" request message.

See Also

Send (see page 1286)

Execute (see page 1283)

20.1.2.4.15 THTTPReqResp.Send Method

Sends the encoded method call as an HTTP-based SOAP message.

Pascal

```
function Send(const ASrc: TStream): Integer; virtual;
```

C++

```
virtual __fastcall int Send(const TStream ASrc);
```

Description

Note: On Windows (when using WinInet), Send sends an HTTP request message with the SoapAction (see page 1291) header specified by SoapAction (see page 1291) to the URL (see page 1292) specified by URL (see page 1292).

Note: Send is not available on Linux.

ASrc is a stream from which to read the contents of a SOAP message for the method call.

Send returns a context ID that identifies this request message. This context ID is passed to the Receive (see page 1285) method to retrieve the corresponding response message from the server.

See Also

Receive (see page 1285)

Execute (see page 1283)

SoapAction (see page 1291)

URL (see page 1292)

20.1.2.4.16 THTTPReqResp.SendGet Method

SendGets sends a "GET" request to the server.

Pascal

```
function SendGet: Integer; virtual;
```

C++

```
virtual __fastcall int SendGet();
```

Description

Note: On Windows (when using WinInet), the Get (see page 1283) method calls SendGet to send the GET request to the URL (see page 1292) specified by URL (see page 1292).

Note: SendGet is not available on Linux.

SendGet returns a context ID that identifies the GET request message. The Get (see page 1283) method uses this context ID to retrieve the corresponding response message from the server.

See Also

Get (see page 1283)

URL (see page 1292)

20.1.2.4.17 THTTPReqResp.SetMimeBoundary Method

Sets the value of the MimeBoundary property.

Pascal

```
procedure SetMimeBoundary(Value: string);
```

C++

```
__fastcall SetMimeBoundary(UnicodeString Value);
```

Description

SetMimeBoundary is the write implementation for the MimeBoundary property.

Value is the new value for MimeBoundary.

See Also

MimeBoundary (see page 6619)

20.1.2.5 THTTPReqResp Properties

The properties of the THTTPReqResp class are listed here.

Public Properties

	Name	Description
	ConnectTimeout (see page 1288)	Indicates the number of milliseconds that can elapse before aborting an attempt to connect to the server.
	MaxSinglePostSize (see page 1289)	This is MaxSinglePostSize, a member of class THTTPReqResp.
	ReceiveTimeout (see page 1290)	Indicates the number of milliseconds that can elapse before canceling a request when no response is received from the server.
	SendTimeout (see page 1291)	Indicates the number of milliseconds that can elapse before timing out the sending of a request.
	SoapAction (see page 1291)	Specifies the SoapAction header to include in the HTTP message that executes the method call.
	URL (see page 1292)	Specifies the URL that identifies the target interface on the target Web Service application.

Published Properties

	Name	Description
	Agent (see page 1288)	Provides the value of the User-Agent header for HTTP messages to the Web Service provider.
	InvokeOptions (see page 1288)	Customizes the way THTTPReqResp (see page 1276) generates or handles headers in the messages it sends to the server.
	Password (see page 1289)	Specifies the password that allows the client application to log on when the Web Service provider requires authentication.
	Proxy (see page 1289)	Lists any proxy servers that are required to make the connection.
	ProxyByPass (see page 1290)	Lists the host names of locally registered servers that do not require a proxy.

	UDDIBindingKey (see page 1291)	Indicates the binding key of a UDDI entry to use for fail-over support.
	UDDIOperator (see page 1292)	Indicates the URL (see page 1292) of the UDDI registry to use for fail-over support.
	UserName (see page 1293)	Specifies the user name that allows the client application to log on to the server.
	UseUTF8InHeader (see page 1293)	Specifies whether the Content-Type header should specify UTF-8 as a character set.
	WSDLView (see page 1293)	Indicates the target interface method using a WSDL document.

20.1.2.5.1 THTTPReqResp.Agent Property

Provides the value of the User-Agent header for HTTP messages to the Web Service provider.

Pascal

```
property Agent: string;
```

C++

```
__property UnicodeString Agent;
```

Description

Use Agent to supply the SOAP request message with the name of your application. This name is included as a User-Agent header. The User-Agent header is an optional string that describes the application generating the request.

See Also

Title

20.1.2.5.2 THTTPReqResp.ConnectTimeout Property

Indicates the number of milliseconds that can elapse before aborting an attempt to connect to the server.

Pascal

```
property ConnectTimeout: Integer;
```

C++

```
__property int ConnectTimeout;
```

Description

Use ConnectTimeout to indicate the number of milliseconds that can elapse before THTTPReqResp (see page 1276) abandons the attempt to form a connection.

See Also

SendTimeout (see page 1291)

ReceiveTimeout (see page 1290)

20.1.2.5.3 THTTPReqResp.InvokeOptions Property

Customizes the way THTTPReqResp (see page 1276) generates or handles headers in the messages it sends to the server.

Pascal

```
property InvokeOptions: TSOAPInvokeOptions;
```

C++

```
__property TSOAPInvokeOptions InvokeOptions;
```

Description

Use InvokeOptions to customize the way THTTPReqResp (see page 1276) generates SOAP messages to the invokable interface on the server. InvokeOptions is a set, allowing you to specify that THTTPReqResp (see page 1276) include none of the options.

See Also

SoapAction (see page 1291)

20.1.2.5.4 THTTPReqResp.MaxSinglePostSize Property

Pascal

```
property MaxSinglePostSize: Integer;
```

C++

```
__property int MaxSinglePostSize;
```

Description

This is MaxSinglePostSize, a member of class THTTPReqResp.

20.1.2.5.5 THTTPReqResp.Password Property

Specifies the password that allows the client application to log on when the Web Service provider requires authentication.

Pascal

```
property Password: string;
```

C++

```
__property UnicodeString Password;
```

Description

When THTTPReqResp (see page 1276) establishes a connection, it supplies the values of the UserName (see page 1293) and Password properties so that it can log on to the host or proxy. The value of Password can be an empty string if neither the host nor proxy requires authentication.

See Also

UserName (see page 1293)

Connect (see page 1282)

20.1.2.5.6 THTTPReqResp.Proxy Property

Lists any proxy servers that are required to make the connection.

Pascal

```
property Proxy: string;
```

C++

```
__property UnicodeString Proxy;
```

Description

Use Proxy if the client application can't resolve the value of host portion of URL (see page 1292) locally. If the server is registered locally, Proxy can be a null string. Otherwise, Proxy lists the host names of any proxy servers that can forward request messages on to the intended server machine.

See Also

ProxyByPass (see page 1290)

URL (see page 1292)

20.1.2.5.7 THTTPReqResp.ProxyByPass Property

Lists the host names of locally registered servers that do not require a proxy.

Pascal

```
property ProxyByPass: string;
```

C++

```
__property UnicodeString ProxyByPass;
```

Description

Use ProxyByPass to indicate any server systems to which the client application can make a direct connection. When the URL (see page 1292) property addresses a server in this list, THTTPReqResp (see page 1276) makes a direct connection even if the Proxy (see page 1289) property is specified.

Note: ProxyByPass is only used on Windows, when the connection is formed using WinInet. On Linux, where the connection is formed using Indy, this property has no effect.

Note: When using WinInet, if ProxyByPass is an empty string, THTTPReqResp (see page 1276) checks the registry for any locally known servers and bypasses the proxy server if URL (see page 1292) refers to a registered local server.

See Also

Proxy (see page 1289)

URL (see page 1292)

20.1.2.5.8 THTTPReqResp.ReceiveTimeout Property

Indicates the number of milliseconds that can elapse before canceling a request when no response is received from the server.

Pascal

```
property ReceiveTimeout: Integer;
```

C++

```
__property int ReceiveTimeout;
```

Description

Use ReceiveTimeout to indicate the number of milliseconds that can elapse after sending a request before THTTPReqResp (see page 1276) cancels a request on the assumption that there will be no response forthcoming.

See Also

SendTimeout (see page 1291)

ConnectTimeout (see page 1288)

20.1.2.5.9 THTTPReqResp.SendTimeout Property

Indicates the number of milliseconds that can elapse before timing out the sending of a request.

Pascal

```
property SendTimeout: Integer;
```

C++

```
__property int SendTimeout;
```

Description

Use SendTimeout to indicate the number of milliseconds that can elapse when sending a request before THTTPReqResp (see page 1276) cancels the request.

See Also

ReceiveTimeout (see page 1290)

ConnectTimeout (see page 1288)

20.1.2.5.10 THTTPReqResp.SoapAction Property

Specifies the SoapAction header to include in the HTTP message that executes the method call.

Pascal

```
property SoapAction: string;
```

C++

```
__property UnicodeString SoapAction;
```

Description

SoapAction specifies the SoapAction header that appears in the HTTP message that is sent by the Send (see page 1286) method.The value of this header is deduced from information in a WSDL document, as indicated by the WSDLView (see page 1293) property.

See Also

URL (see page 1292)

WSDLView (see page 1293)

Send (see page 1286)

RegisterInterface

20.1.2.5.11 THTTPReqResp.UDDIBindingKey Property

Indicates the binding key of a UDDI entry to use for fail-over support.

Pascal

```
property UDDIBindingKey: WideString;
```

C++

```
__property BSTR UDDIBindingKey;
```

Description

UDDIBindingKey identifies the binding key for the Web Service TModel the defines the target interface. This key is used to look

up the Web Service definition in the UDDI registry that the UDDIOperator (see page 1292) property identifies. UDDIBindingKey and UDDIOperator (see page 1292) are used to implement fail-over support for Web Services that are imported using the UDDI browser.

See Also

UDDIOperator (see page 1292)

20.1.2.5.12 THTTPReqResp.UDDIOperator Property

Indicates the URL (see page 1292) of the UDDI registry to use for fail-over support.

Pascal

```
property UDDIOperator: String;
```

C++

```
__property UnicodeString UDDIOperator;
```

Description

UDDIOperator identifies the UDDI registry that was used to import the Web Service definition for the target interface. THTTPReqResp (see page 1276) uses this registry to look up the Web Service definition that the UDDIBindingKey (see page 1291) property identifies. UDDIOperator and UDDIBindingKey (see page 1291) are used to implement fail-over support for Web Services that are imported using the UDDI browser.

See Also

UDDIBindingKey (see page 1291)

20.1.2.5.13 THTTPReqResp.URL Property

Specifies the URL that identifies the target interface on the target Web Service application.

Pascal

```
property URL: string;
```

C++

```
__property UnicodeString URL;
```

Description

URL specifies the URL to which to send the message containing the SOAP request.

When communicating with a Web Service based on an imported WSDL document, the value of URL is deduced from information in a WSDL document, as indicated by the WSDLView (see page 1293) property.

Note: In Delphi, you can construct this URL as follows: The path portion must match the target path name of the THTTPSoapDispatcher component on the Web Service application and the protocol portion must specify http or https.

See Also

WSDLView (see page 1293)

WebDispatch (see page 5950)

SoapAction (see page 1291)

Send (see page 1286)

20.1.2.5.14 THTTPReqResp.UserName Property

Specifies the user name that allows the client application to log on to the server.

Pascal

```
property UserName: string;
```

C++

```
__property UnicodeString UserName;
```

Description

When THTTPReqResp (see page 1276) establishes a connection, it supplies the values of the UserName and Password (see page 1289) properties so that it can log on to the host or proxy. The value of Password (see page 1289) can be an empty string if neither the host nor proxy requires authentication.

See Also

Password (see page 1289)

Connect (see page 1282)

20.1.2.5.15 THTTPReqResp.UseUTF8InHeader Property

Specifies whether the Content-Type header should specify UTF-8 as a character set.

Pascal

```
property UseUTF8InHeader: Boolean;
```

C++

```
__property Boolean UseUTF8InHeader;
```

Description

Set UseUTF8InHeader to indicate how THTTPReqResp (see page 1276) should generate the Content-Type header of the HTTP request message it sends to the server. When UseUTF8InHeader is true, the Content-Type header indicates that the content of the request is encoded in XML using the UTF-8 character set. Otherwise, the Content-Type header simply indicates that the content is encoded in XML.

See Also

SoapAction (see page 1291)

20.1.2.5.16 THTTPReqResp.WSDLView Property

Indicates the target interface method using a WSDL document.

Pascal

```
property WSDLView: TWSDLView;
```

C++

```
__property TWSDLView WSDLView;
```

Description

WSDLView is a helper object that represents the WSDL file used to define the interfaces and protocols in the target Web Service application, as well as properties that indicate which is the target method call. It is used to generate the URL (see page 1292) and SoapAction (see page 1291) properties when importing definitions from a WSDL document.

See Also

URL (see page 1292)

SoapAction (see page 1291)

20.1.2.6 THTTPReqResp Events

The events of the THTTPReqResp class are listed here.

Published Events

	Name	Description
	OnBeforePost (see page 1294)	Occurs before THTTPReqResp (see page 1276) sends its message.
	OnPostingData (see page 1294)	Occurs before THTTPReqResp (see page 1276) sends each chunk of data when the content is large.
	OnReceivingData (see page 1295)	Occurs after THTTPReqResp (see page 1276) receives each chunk of data when the content is large.
	OnWinInetError (see page 1295)	This is OnWinInetError, a member of class THTTPReqResp.

20.1.2.6.1 THTTPReqResp.OnBeforePost Event

Occurs before THTTPReqResp (see page 1276) sends its message.

Pascal

```
property OnBeforePost: TBeforePostEvent;
```

C++

```
__property TBeforePostEvent OnBeforePost;
```

Description

Write (see page 3707) an OnBeforePost event handler to make final changes to the HTTP request before it is sent. The Send (see page 1286) method generates OnBeforePost after setting up the content and headers of a request message but before sending it.

See Also

OnPostingData (see page 1294)

Send (see page 1286)

20.1.2.6.2 THTTPReqResp.OnPostingData Event

Occurs before THTTPReqResp (see page 1276) sends each chunk of data when the content is large.

Pascal

```
property OnPostingData: TPostingDataEvent;
```

C++

```
__property TPostingDataEvent OnPostingData;
```

Description

Write (see page 3707) an OnPostingData event handler to provide the end-user with feedback of the progress when sending a request that contains a large amount of data. When the content of a request is very large (for example, when it contains large attachments), the Send (see page 1286) method breaks the message into blocks, which it sends separately. After sending each of these blocks, it generates an OnPostingData event. You can use the event handler to update a progress bar or similar

control to indicate how much of the message has been sent.

See Also

OnBeforePost (see page 1294)

Send (see page 1286)

OnReceivingData (see page 1295)

20.1.2.6.3 THTTPReqResp.OnReceivingData Event

Occurs after THTTPReqResp (see page 1276) receives each chunk of data when the content is large.

Pascal

```
property OnReceivingData: TReceivingDataEvent;
```

C++

```
__property TReceivingDataEvent OnReceivingData;
```

Description

Write (see page 3707) an OnReceivingData event handler to provide the end-user with feedback of the progress when receiving a request that contains a large amount of data. When the content of a response is very large (for example, when it contains large attachments), it is broken into blocks, which are sent separately. After receiving each of these blocks, the Receive (see page 1285) method generates an OnReceivingData event. You can use the event handler to update a progress bar or similar control to indicate how much of the response has been received.

See Also

OnPostingData (see page 1294)

Receive (see page 1285)

20.1.2.6.4 THTTPReqResp.OnWinInetError Event

Pascal

```
property OnWinInetError: TWinInetErrorEvent;
```

C++

```
__property TWinInetErrorEvent OnWinInetError;
```

Description

This is OnWinInetError, a member of class THTTPReqResp.

20.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IHTTPReqResp (see page 1296)	This is class SOAPHTTPTrans.IHTTPReqResp.

20.2.1 IHTTPReqResp Interface

Class Hierarchy

SOAPHTTPTrans.IHTTPReqResp

Pascal

```
IHTTPReqResp = interface;
```

C++

```
__interface IHTTPReqResp;
```

File

SOAPHTTPTrans

Description

This is class SOAPHTTPTrans.IHTTPReqResp.

20.2.1.1 IHTTPReqResp Members

The following tables list the members exposed by IHTTPReqResp.

Public Methods

	Name	Description
	GetHTTPReqResp (see page 1297)	This is GetHTTPReqResp, a member of class IHTTPReqResp.

20.2.1.2 IHTTPReqResp Methods

The methods of the IHTTPReqResp class are listed here.

Public Methods

	Name	Description
	GetHTTPReqResp (see page 1297)	This is GetHTTPReqResp, a member of class IHTTPReqResp.

20.2.1.2.1 IHTTPReqResp.GetHTTPReqResp Method

Pascal

```
function GetHTTPReqResp: THTTPReqResp;
```

C++

```
__fastcall THTTPReqResp GetHTTPReqResp();
```

Description

This is GetHTTPReqResp, a member of class IHTTPReqResp.

20.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	SOAPInvokeOptions (see page 1298)	SOAPInvokeOptions and TSOAPInvokeOptions (see page 1300) represent flags that customize how to handle a SOAP message.

20.3.1 SOAPHTTPTrans.SOAPInvokeOptions Enumeration

SOAPInvokeOptions and TSOAPInvokeOptions (see page 1300) represent flags that customize how to handle a SOAP message.

Pascal

```
SOAPInvokeOptions = (
  soNoValueForEmptySOAPAction,
  soIgnoreInvalidCerts,
  soNoSOAPActionHeader,
  soAutoCheckAccessPointViaUDDI
);
```

C++

```
enum SOAPInvokeOptions {
  soNoValueForEmptySOAPAction,
  soIgnoreInvalidCerts,
  soNoSOAPActionHeader,
  soAutoCheckAccessPointViaUDDI
};
```

File

SOAPHTTPTrans

Description

TSOAPInvokeOptions (see page 1300) is a set of TSoapInvokeOption values. TSoapInvokeOption values are flags that specify how THTTPReqResp (see page 1276) manages the sending and receiving of SOAP messages. The following table lists the possible values:

Value	Meaning
soNoValueForEmptySOAPAction	When calling Web services that specify empty SOAP actions, omit the SOAPAction header rather then generating a SOAPAction header whose value is an empty string.
soIgnoreInvalidCerts	When the server uses SSL but has an invalid certificate, treat it as if the certificate had been valid. This is useful when debugging applications that use a secure server.
soNoSOAPActionHeader	Always omit the SOAP action header when calling Web services. It is advised that you only use this option with extreme caution.
soAutoCheckAccessPointViaUDDI	Provide fail-over support for messages that result in a status code of 404, 405, or 410. This option causes THTTPReqResp (see page 1276) to look up the UDDI entry that was used to import the Web Service description and attempt to locate a new binding.

20.4 Types

The following table lists types in this documentation.

Types

Name	Description
TBeforePostEvent (see page 1299)	TBeforePostEvent is the type of the OnBeforePost event of THTTPReqResp (see page 1276).
TPostingDataEvent (see page 1299)	TPostingDataEvent is the type of the OnPostingData event of THTTPReqResp (see page 1276).
TReceivingDataEvent (see page 1300)	TReceivingDataEvent is the type of the OnReceivingData event of THTTPReqResp (see page 1276).
TSOAPInvokeOptions (see page 1300)	This is type SOAPHTTPTrans.TSOAPInvokeOptions.
TWinInetErrorEvent (see page 1301)	This is type SOAPHTTPTrans.TWinInetErrorEvent.

20.4.1 SOAPHTTPTrans.TBeforePostEvent Type

TBeforePostEvent is the type of the OnBeforePost event of THTTPReqResp (see page 1276).

Pascal

```
TBeforePostEvent = procedure (const HTTPReqResp: THTTPReqResp; Data: Pointer) of object;
```

C++

```
(const HTTPReqResp: THTTPReqResp; Data: Pointer) ( TBeforePostEvent)();
```

File

SOAPHTTPTrans

Description

TBeforePostEvent is the type of the OnBeforePost event handler, which is called before an HTTP request message containing SOAP content is sent to a Web Service provider.

HTTPReqResp is the component that generates and sends the HTTP request message.

Data is a handle to the wininet request object.

Procedural types

Creating events

20.4.2 SOAPHTTPTrans.TPostingDataEvent Type

TPostingDataEvent is the type of the OnPostingData event of THTTPReqResp (see page 1276).

Pascal

```
TPostingDataEvent = procedure (Sent: Integer; Total: Integer) of object;
```

C++

```
(Sent: Integer; Total: Integer) ( TPostingDataEvent)();
```

File

SOAPHTTPTrans

Description

TPostingDataEvent is the type of the OnPostingData event handler, which is called after each chunk of data that is sent when a request is very large.

Sent indicates the (cumulative) number of bytes that have already been sent.

Total indicates the total number of bytes that need to be sent.

See Also

Procedural types

Creating events

20.4.3 SOAPHTTPTrans.TReceivingDataEvent Type

TReceivingDataEvent is the type of the OnReceivingData event of THTTPReqResp (see page 1276).

Pascal

```
TReceivingDataEvent = procedure (Read: Integer; Total: Integer) of object;
```

C++

```
(Read: Integer; Total: Integer) ( TReceivingDataEvent)();
```

File

SOAPHTTPTrans

Description

TReceivingDataEvent is the type of the OnReceivingData event handler, which is called after each chunk of data that is received when a large response has been broken into smaller chunks.

Read (see page 3634) indicates the (cumulative) number of bytes that have been received.

Total indicates the total number of bytes that are expected.

See Also

Procedural types

Creating events

20.4.4 SOAPHTTPTrans.TSOAPInvokeOptions Type

Pascal

```
TSOAPInvokeOptions = set of SOAPInvokeOptions;
```

C++

```
SOAPInvokeOptions TSOAPInvokeOptions;
```

File

SOAPHTTPTrans

Description

This is type SOAPHTTPTrans.TSOAPInvokeOptions.

20.4.5 SOAPHTTPTrans.TWinInetErrorEvent Type

Pascal

```
TWinInetErrorEvent = function (LastError: DWord; Request: Pointer): DWord of object;
```

C++

```
(LastError: DWord; Request: Pointer): DWord ( TWinInetErrorEvent)();
```

File

SOAPHTTPTrans

Description

This is type SOAPHTTPTrans.TWinInetErrorEvent.

21 SOAPLinked Namespace

This is namespace SOAPLinked.

Topics

Name	Description
Classes (see page 1305)	The following table lists classes in this documentation.
Interfaces (see page 1332)	The following table lists interfaces in this documentation.
Structs, Records, Enums (see page 1336)	The following table lists structs, records, enums in this documentation.
Types (see page 1337)	The following table lists types in this documentation.

Classes

	Name	Description
	ECustomException (see page 1305)	This is class SOAPLinked.ECustomException.
	TFTCompT (see page 1311)	This is class SOAPLinked.TFTCompT.
	TFTCompTI (see page 1313)	This is class SOAPLinked.TFTCompTI.
	TLinkedRIO (see page 1316)	TLinkedRIO makes calls to a registered invokable interface that is implemented in the same application.
	TLinkedWebNode (see page 1321)	TLinkedWebNode executes a method call on an invokable interface that is implemented in the same application.
	TLogLinkedWebNode (see page 1326)	This is class SOAPLinked.TLogLinkedWebNode.
	TWinHandleUser (see page 1329)	This is class SOAPLinked.TWinHandleUser.

Interfaces

	Name	Description
	IIntegerTest (see page 1332)	This is class SOAPLinked.IIntegerTest.
	IObjectGetter (see page 1333)	This is class SOAPLinked.IObjectGetter.
	IStringTest (see page 1334)	This is class SOAPLinked.IStringTest.

Structs, Records, Enums

	Name	Description
	EventKind (see page 1336)	This is record SOAPLinked.EventKind.

Types

Name	Description
TCStringEvent (see page 1337)	This is type SOAPLinked.TCStringEvent.
TCustExCallback (see page 1337)	This is type SOAPLinked.TCustExCallback.
TStringEvent (see page 1338)	This is type SOAPLinked.TStringEvent.

TVStringEvent (see page 1338)	This is type SOAPLinked.TVStringEvent.

21.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ECustomException (see page 1305)	This is class SOAPLinked.ECustomException.
	TFTCompT (see page 1311)	This is class SOAPLinked.TFTCompT.
	TFTCompTI (see page 1313)	This is class SOAPLinked.TFTCompTI.
	TLinkedRIO (see page 1316)	TLinkedRIO makes calls to a registered invokable interface that is implemented in the same application.
	TLinkedWebNode (see page 1321)	TLinkedWebNode executes a method call on an invokable interface that is implemented in the same application.
	TLogLinkedWebNode (see page 1326)	This is class SOAPLinked.TLogLinkedWebNode.
	TWinHandleUser (see page 1329)	This is class SOAPLinked.TWinHandleUser.

21.1.1 ECustomException Class

Class Hierarchy

Pascal

```
ECustomException = class(Exception);
```

C++

```
class ECustomException : public Exception;
```

File

SOAPLinked

Description

This is class SOAPLinked.ECustomException.

21.1.1.1 ECustomException Members

The following tables list the members exposed by ECustomException.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
V	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.

	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	CatchException (see page 1310)	This is CatchException, a member of class ECustomException.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 1307)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 1309)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceCount (see page 1310)	This is InstanceCount, a member of class ECustomException.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowExcept (see page 1310)	This is ThrowExcept, a member of class ECustomException.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3380)	Returns a string containing the class name.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

21.1.1.2 ECustomException.Create Constructor

Instantiates an instance of an exception with a simple message string.

Pascal

```
constructor Create(const msg: string);
```

C++

```
__fastcall ECustomException(const UnicodeString msg);
```

Description

Call Create to construct an exception object with a simple message string.

Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("Cannot create C:\\temp again!");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
```

```
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
          FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
          GetMem(Buffer, StringLen); { allocate the buffer }
          cellString := StringGrid1.Cells[X,Y];
          for I := 1 to StringLen do
             Buffer[I - 1] := cellString[I];
          FileWrite(FileHandle, Buffer^, StringLen);
        finally
          FreeMem(Buffer, StringLen);
        end;
      end;
    end;
    FileClose(FileHandle);
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
```

```
      Cells[1,1] := 'Object';
      Cells[2,1] := 'Pascal';
      Cells[3,1] := 'is';
      Cells[4,1] := 'excellent';
      Cells[0,2] := 'Row 2';
      Cells[1,2] := 'Delphi';
      Cells[2,2] := 'is';
      Cells[4,2] := 'RAD';
    end;
  end;
  {
  In addition to displaying the exception message, which
  happens by default, the following code shuts down the
  application when an exception is not caught and handled.
  AppException should be declared a method of TForm1.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnException := AppException;
  end;

  procedure TForm1.AppException(Sender: TObject; E: Exception);
  begin
    Application.ShowException(E);
    Application.Terminate;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    raise EPasswordInvalid.Create('Incorrect password entered');
  end;
```

21.1.1.3 ECustomException.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~ECustomException();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

21.1.1.4 ECustomException Methods

The methods of the ECustomException class are listed here.

Public Methods

	Name	Description
	CatchException (see page 1310)	This is CatchException, a member of class ECustomException.
	InstanceCount (see page 1310)	This is InstanceCount, a member of class ECustomException.
	ThrowExcept (see page 1310)	This is ThrowExcept, a member of class ECustomException.

21.1.1.4.1 ECustomException.CatchException Method

Pascal

```
class function CatchException(var ExceptTypeName: string; var Address: Pointer; TypedHandler:
boolean; Callback: TCustExCallback): boolean; static;
```

C++

```
static __fastcall boolean CatchException(UnicodeString ExceptTypeName, void * Address, boolean
TypedHandler, TCustExCallback Callback);
```

Description

This is CatchException, a member of class ECustomException.

21.1.1.4.2 ECustomException.InstanceCount Method

Pascal

```
class function InstanceCount: Integer; static;
```

C++

```
static __fastcall int InstanceCount();
```

Description

This is InstanceCount, a member of class ECustomException.

21.1.1.4.3 ECustomException.ThrowExcept Method

Pascal

```
class procedure ThrowExcept(const msg: string); static;
```

C++

```
static __fastcall ThrowExcept(const UnicodeString msg);
```

Description

This is ThrowExcept, a member of class ECustomException.

21.1.2 TFTCompT Class

Class Hierarchy

Pascal

```
TFTCompT = class(TComponent);
```

C++

```
class TFTCompT : public TComponent;
```

File

SOAPLinked

Description

This is class SOAPLinked.TFTCompT.

21.1.2.1 TFTCompT Members

The following tables list the members exposed by TFTCompT.

Public Methods

	Name	Description
	fireEvent (see page 1312)	This is fireEvent, a member of class TFTCompT.
	fireEventEx (see page 1312)	This is fireEventEx, a member of class TFTCompT.

Published Events

	Name	Description
	CStringEvent (see page 1312)	This is CStringEvent, a member of class TFTCompT.
	StringEvent (see page 1312)	This is StringEvent, a member of class TFTCompT.
	VStringEvent (see page 1313)	This is VStringEvent, a member of class TFTCompT.

21.1.2.2 TFTCompT Methods

The methods of the TFTCompT class are listed here.

Public Methods

	Name	Description
	fireEvent (see page 1312)	This is fireEvent, a member of class TFTCompT.
	fireEventEx (see page 1312)	This is fireEventEx, a member of class TFTCompT.

21.1.2.2.1 TFTCompT.fireEvent Method

Pascal

```
function fireEvent(S: string; ek: EventKind): string;
```

C++

```
__fastcall UnicodeString fireEvent(UnicodeString S, EventKind ek);
```

Description

This is fireEvent, a member of class TFTCompT.

21.1.2.2.2 TFTCompT.fireEventEx Method

Pascal

```
procedure fireEventEx(var S: string; ek: EventKind);
```

C++

```
__fastcall fireEventEx(UnicodeString S, EventKind ek);
```

Description

This is fireEventEx, a member of class TFTCompT.

21.1.2.3 TFTCompT Events

The events of the TFTCompT class are listed here.

Published Events

	Name	Description
	CStringEvent (see page 1312)	This is CStringEvent, a member of class TFTCompT.
	StringEvent (see page 1312)	This is StringEvent, a member of class TFTCompT.
	VStringEvent (see page 1313)	This is VStringEvent, a member of class TFTCompT.

21.1.2.3.1 TFTCompT.CStringEvent Event

Pascal

```
property CStringEvent: TCStringEvent;
```

C++

```
__property TCStringEvent CStringEvent;
```

Description

This is CStringEvent, a member of class TFTCompT.

21.1.2.3.2 TFTCompT.StringEvent Event

Pascal

```
property StringEvent: TStringEvent;
```

C++

```
__property TStringEvent StringEvent;
```

Description

This is StringEvent, a member of class TFTCompT.

21.1.2.3.3 TFTCompT.VStringEvent Event

Pascal

```
property VStringEvent: TVStringEvent;
```

C++

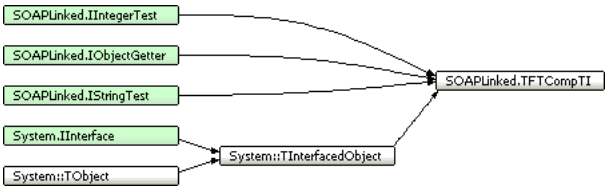
```
__property TVStringEvent VStringEvent;
```

Description

This is VStringEvent, a member of class TFTCompT.

21.1.3 TFTCompTI Class

Class Hierarchy



Pascal

```
TFTCompTI = class(TInterfacedObject, IStringTest, IIntegerTest, IObjectGetter);
```

C++

```
class TFTCompTI : public TInterfacedObject, public IStringTest, public IIntegerTest, public
IObjectGetter;
```

File

SOAPLinked

Description

This is class SOAPLinked.TFTCompTI.

21.1.3.1 TFTCompTI Members

The following tables list the members exposed by TFTCompTI.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.

	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	Add (see page 1315)	This is Add, a member of class TFTCompTI.
	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	Append (see page 1315)	This is Append, a member of class TFTCompTI.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Doubler (see page 1315)	This is Doubler, a member of class TFTCompTI.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetAsObject (see page 1316)	This is GetAsObject, a member of class TFTCompTI.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	UpCase (see page 1316)	This is UpCase, a member of class TFTCompTI.

Public Properties

	Name	Description
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

21.1.3.2 TFTCompTI Methods

The methods of the TFTCompTI class are listed here.

Public Methods

	Name	Description
	Add (see page 1315)	This is Add, a member of class TFTCompTI.
	Append (see page 1315)	This is Append, a member of class TFTCompTI.
	Doubler (see page 1315)	This is Doubler, a member of class TFTCompTI.
	GetAsObject (see page 1316)	This is GetAsObject, a member of class TFTCompTI.
	UpCase (see page 1316)	This is UpCase, a member of class TFTCompTI.

21.1.3.2.1 TFTCompTI.Add Method

Pascal

```
function Add(const I1: Integer; const I2: Integer): Integer; stdcall;
```

C++

```
__fastcall __stdcall int Add(const int I1, const int I2);
```

Description

This is Add, a member of class TFTCompTI.

21.1.3.2.2 TFTCompTI.Append Method

Pascal

```
function Append(const Str1: string; const Str2: string): string; cdecl;
```

C++

```
__cdecl __fastcall UnicodeString Append(const UnicodeString Str1, const UnicodeString Str2);
```

Description

This is Append, a member of class TFTCompTI.

21.1.3.2.3 TFTCompTI.Doubler Method

Pascal

```
procedure Doubler(var I: Integer); cdecl;
```

C++

```
__cdecl __fastcall Doubler(int I);
```

Description

This is Doubler, a member of class TFTCompTI.

21.1.3.2.4 TFTCompTI.GetAsObject Method

Pascal

```
function GetAsObject: TObject;
```

C++

```
__fastcall TObject * GetAsObject();
```

Description

This is GetAsObject, a member of class TFTCompTI.

21.1.3.2.5 TFTCompTI.UpCase Method

Pascal

```
procedure UpCase(var Str1: string); stdcall;
```

C++

```
__fastcall __stdcall UpCase(UnicodeString Str1);
```

Description

This is UpCase, a member of class TFTCompTI.

21.1.4 TLinkedRIO Class

TLinkedRIO makes calls to a registered invokable interface that is implemented in the same application.

Class Hierarchy

Pascal

```
TLinkedRIO = class(TRIO);
```

C++

```
class TLinkedRIO : public TRIO;
```

File

SOAPLinked

Description

Use TLinkedRIO to generate calls to registered invokable interfaces within a Web Service application. Unlike other remote interfaced objects (TRIO descendants), TLinkedRIO provides no mechanism for connecting to a remote server. Rather, it passes calls directly to a TLinkedWebNode (see page 1321) object, which uses an internal invoker component to look up the target interface and forward calls to the implementation object.

TLinkedRIO is intended primarily for debugging Web Service applications during development. Instead of directly calling the implementation objects in the application, TLinkedRIO marshals the call into its SOAP representation and uses the invocation registry to locate the implementation object and forward the encoded request. If you use the CreateFile (see page 1318) constructor (Delphi) or supply a pair of file names to the constructor (C++), TLinkedRIO saves the encoded value of every method call and the encoded results so that you can track the "messages" that your application receives and sends.

Before TLinkedRIO can call a method table on an invokable interface, the interface must be registered with the invocation

registry. To register an invokable interface, use the global InvRegistry function to access the registry, and use its RegisterInterface method.

InvRegistry

TInvokableClassRegistry

TSoapPascalInvoker (see page 1350)

TLinkedWebNode (see page 1321)

21.1.4.1 TLinkedRIO Members

The following tables list the members exposed by TLinkedRIO.

Protected Methods

	Name	Description
	GetResponseStream (see page 1319)	Returns a newly created stream that receives the results of executing a method call.

Public Methods

	Name	Description
	Create (see page 1317)	Creates an instance of TLinkedRIO (see page 1316).
	CreateFile (see page 1318)	Creates an instance of TLinkedRIO (see page 1316).
	Destroy (see page 1318)	Destroys the instance of a TLinkedRIO (see page 1316) object.
	QueryInterface (see page 1319)	Implements the IInterface (see page 3502) QueryInterface method.

Public Properties

	Name	Description
	WebNode (see page 1320)	Handles the execution of method calls on the invokable interface.

21.1.4.2 TLinkedRIO.Create Constructor

Creates an instance of TLinkedRIO (see page 1316).

Pascal

```
constructor Create(AOwner: TComponent); override; overload;
```

C++

```
virtual __fastcall TLinkedRIO(TComponent * AOwner);
```

Description

Call Create to instantiate a TLinkedRIO (see page 1316) object at runtime.

The AOwner parameter specifies another component (usually a form or data module) that is responsible for freeing the TLinkedRIO (see page 1316) instance. It becomes the value of the Owner property. If the TLinkedRIO (see page 1316) instance is created with AOwner set to nil, then it is automatically freed when its reference count drops to zero.

Tip: To save the encoded method calls that TLinkedRIO (see page 1316) generates and the encoded results that it receives, use the CreateFile (see page 1318) constructor instead.

See Also

RefCount

Owner

CreateFile (see page 1318)

21.1.4.3 TLinkedRIO.CreateFile Constructor

Creates an instance of TLinkedRIO (see page 1316).

Pascal

```
constructor CreateFile(AOwner: TComponent; ReqFile: string; RespFile: string); overload;
```

C++

```
__fastcall TLinkedRIO(TComponent * AOwner, UnicodeString ReqFile, UnicodeString RespFile);
```

Description

Call Create (see page 1317) to instantiate a TLinkedRIO (see page 1316) object when you want to save all of the encoded requests that it generates and the encoded results it receives to a file.

The AOwner parameter specifies another component (usually a form or data module) that is responsible for freeing the TLinkedRIO (see page 1316) instance. It becomes the value of the Owner property. If the TLinkedRIO (see page 1316) instance is created with AOwner set to nil, then it is automatically freed when its reference count drops to zero.

ReqFile is a file to which TLinkedRIO (see page 1316) writes every encoded request before passing it on to WebNode (see page 1320) for execution. If ReqFile is an empty string, TLinkedRIO (see page 1316) automatically generates a file with the same name as the invoked method. This lets you generate separate log files for each method of the interface.

RespFile is a file to which TLinkedRIO (see page 1316) writes every encoded response it receives from WebNode (see page 1320) after executing a method call. If RespFile is an empty string, TLinkedRIO (see page 1316) automatically generates a file with the name of the method and the string _resp appended. This lets you generate separate log files for responses to each method of the interface.

See Also

RefCount

Owner

Create (see page 1317)

WebNode (see page 1320)

21.1.4.4 TLinkedRIO.Destroy Destructor

Destroys the instance of a TLinkedRIO (see page 1316) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLinkedRIO();
```

Description

There is no need to explicitly free a TLinkedRIO (see page 1316) instance.

If the TLinkedRIO (see page 1316) object is created with an Owner, then that Owner handles the freeing of the TLinkedRIO (see page 1316) instance. If the TLinkedRIO (see page 1316) object is created without an Owner, then it is automatically freed

when the reference count on its interface drops to zero.

See Also

Create (see page 1317)

Owner

RefCount

21.1.4.5 TLinkedRIO Methods

The methods of the TLinkedRIO class are listed here.

Protected Methods

	Name	Description
	GetResponseStream (see page 1319)	Returns a newly created stream that receives the results of executing a method call.

Public Methods

	Name	Description
	QueryInterface (see page 1319)	Implements the IInterface (see page 3502) QueryInterface method.

21.1.4.5.1 TLinkedRIO.GetResponseStream Method

Returns a newly created stream that receives the results of executing a method call.

Pascal

```
function GetResponseStream(BindingType: TWebServiceBindingType): TStream; override;
```

C++

```
virtual __fastcall TStream GetResponseStream(TWebServiceBindingType BindingType);
```

Description

TRIO calls GetResponseStream internally when it executes a method call. It passes the returned stream as the Response parameter of the Execute method on the interface that the WebNode property specifies. After this stream receives the encoded response of a method call, the RIO component decodes the response and frees the stream.

BindingType indicates the expected coding of the response that the stream will hold. GetResponseStream can use this information to determine what type of stream to create.

See Also

Execute (see page 6618)

WebNode

21.1.4.5.2 TLinkedRIO.QueryInterface Method

Implements the IInterface (see page 3502) QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface is called through the IInterface (see page 3502) interface to obtain an interface pointer for the interface identified by the IID parameter. In Delphi, this call is generated when an application casts TLinkedRIO (see page 1316) to an invokable interface using the as operator.

TLinkedRIO (see page 1316) can only return a single type of interface pointer. The first time an application calls QueryInterface, TLinkedRIO (see page 1316) generates an in-memory method table to support calls to the methods on the requested interface.

IID specifies the invokable interface that the application wants to call using this TLinkedRIO (see page 1316) instance. If the TLinkedRIO (see page 1316) object has already been typecast to an interface, then IID must identify that interface. If the TLinkedRIO (see page 1316) instance has not yet been typecast to an interface, then IID must be a registered invokable interface.

Obj returns an interface pointer for the specified interface, unless TLinkedRIO (see page 1316) was already implementing a different interface or IID identified an interface that was not registered.

QueryInterface returns 0 (S_OK (see page 3860)) if Obj successfully returns an interface pointer. It returns E_NOINTERFACE (see page 3845) otherwise.

Note: In C++, a second, templatized syntax takes a variable that is a DelphiInterface (see page 3256) wrapper for the desired interface type.

If QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

21.1.4.6 TLinkedRIO Properties

The properties of the TLinkedRIO class are listed here.

Public Properties

	Name	Description
R	WebNode (see page 1320)	Handles the execution of method calls on the invokable interface.

21.1.4.6.1 TLinkedRIO.WebNode Property

Handles the execution of method calls on the invokable interface.

Pascal

```
property WebNode: TLinkedWebNode;
```

C++

```
__property TLinkedWebNode WebNode;
```

Description

TLinkedRIO (see page 1316) uses WebNode internally to execute method calls. It is the implementation of the IWebNode (see page 6616) interface that all TRIO descendants use to send method calls to the Web Service application. In the case of TLinkedRIO (see page 1316), this object can only execute calls on invokable interfaces that are implemented in the same application.

See Also

WebNode

IWebNode (see page 6616)

21.1.5 TLinkedWebNode Class

TLinkedWebNode executes a method call on an invokable interface that is implemented in the same application.

Class Hierarchy

Pascal

```
TLinkedWebNode = class(TComponent, IWebNode);
```

C++

```
class TLinkedWebNode : public TComponent, public IWebNode;
```

File

SOAPLinked

Description

TLinkedWebNode handles the communication between a TLinkedRIO (see page 1316) component and the implementation classes of registered invokable interfaces in the same application. To this end, it implements the IWebNode (see page 6616) interface that all TRIO descendants use for executing encoded method calls.

TLinkedRIO (see page 1316) uses an internal invoker (TSoapPascalInvoker (see page 1350)) to look up the invokable interface in the invocation registry and forward encoded requests for execution.

See Also

IWebNode (see page 6616)

TLinkedRIO (see page 1316)

TSoapPascalInvoker (see page 1350)

21.1.5.1 TLinkedWebNode Members

The following tables list the members exposed by TLinkedWebNode.

Protected Methods

	Name	Description
	GetMimeBoundary (see page 1324)	Returns the value of the MimeBoundary (see page 1326) property.
V	GetResponseStream (see page 1325)	Returns a stream to which the application can write the response to the method call.
	SetMimeBoundary (see page 1325)	Sets the value of the MimeBoundary (see page 1326) property.

Public Methods

	Name	Description
V	BeforeExecute (see page 1323)	Caches the RTTI for the method that is about to be executed.

	Create (see page 1322)	Creates a new TLinkedWebNode (see page 1321) object.
	Destroy (see page 1322)	Frees the memory associated with the TLinkedWebNode (see page 1321) object.
	Execute (see page 1323)	This is the overview for the Execute method overload.
	Execute (see page 6618)	This is the overview for the Execute method overload.

Public Properties

	Name	Description
	Invoker (see page 1326)	Executes encoded method calls received from the associated TLinkedRIO (see page 1316) object.
	MimeBoundary (see page 1326)	Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.

21.1.5.2 TLinkedWebNode.Create Constructor

Creates a new TLinkedWebNode (see page 1321) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TLinkedWebNode(TComponent * AOwner);
```

Description

Most applications do not create instances of TLinkedWebNode (see page 1321). It is created and used by the TLinkedRIO (see page 1316) class.

The Owner parameter specifies the component that is responsible for freeing the TLinkedWebNode (see page 1321) instance.

See Also

Owner

TLinkedRIO (see page 1316)

21.1.5.3 TLinkedWebNode.Destroy Destructor

Frees the memory associated with the TLinkedWebNode (see page 1321) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLinkedWebNode();
```

Description

Do not call the Destroy method directly. Instead, use the Free method, which checks for a nil reference before calling Destroy.

See Also

System::TObject::Free (see page 3372)

21.1.5.4 TLinkedWebNode Methods

The methods of the TLinkedWebNode class are listed here.

Protected Methods

	Name	Description
	GetMimeBoundary (see page 1324)	Returns the value of the MimeBoundary (see page 1326) property.
	GetResponseStream (see page 1325)	Returns a stream to which the application can write the response to the method call.
	SetMimeBoundary (see page 1325)	Sets the value of the MimeBoundary (see page 1326) property.

Public Methods

	Name	Description
	BeforeExecute (see page 1323)	Caches the RTTI for the method that is about to be executed.
	Execute (see page 1323)	This is the overview for the Execute method overload.

21.1.5.4.1 TLinkedWebNode.BeforeExecute Method

Caches the RTTI for the method that is about to be executed.

Pascal

```
procedure BeforeExecute(const IntfMetaData: TIntfMetaData; const MethodMetaData:
TIntfMethEntry; MethodIndex: Integer; AttachHandler: IMimeAttachmentHandler); virtual;
```

C++

```
virtual __fastcall BeforeExecute(const TIntfMetaData IntfMetaData, const TIntfMethEntry
MethodMetaData, int MethodIndex, IMimeAttachmentHandler AttachHandler);
```

Description

BeforeExecute implements the IWebNode (see page 6616) method of the same name. The remote interface object (TRio) calls this method after its OnBeforeExecute event, but before calling the Execute (see page 1324) method to send a request to the Web Service application. BeforeExecute allows an IWebNode (see page 6616) implementation class to perform any transport-specific tasks prior to establishing a connection. Because TLinkedWebNode (see page 1321) only works with interfaces implemented in the same executable, there is no transport protocol at all, and no transport-specific tasks to perform. BeforeExecute merely caches the RTTI for the method that is about to be executed.

IntfMD is the runtime type information (RTTI) of the invokable interface that includes the method to execute.

MethMD is describes the method that is about to be executed.

MethodIndex indicates which overload to use when methMD describes an overloaded method. 0 indicates the first overload, 1 indicates the second overload, and so on.

AttachHandler is an interface to use for handling any attachments that are used as parameters of the method. If AttachHandler is nil (Delphi) or NULL (C++), the method call does not require passing any attachments.

See Also

Execute (see page 1324)

OnBeforeExecute

BeforeExecute (see page 6617)

21.1.5.4.2 Execute Method

This is the overview for the Execute method overload.

Overload List

	Name	Description
	TLinkedWebNode.Execute (String, TStream) (see page 1324)	Executes a SOAP method call and returns the encoded results.
	TLinkedWebNode.Execute (TStream) (see page 1324)	Executes a SOAP method call and returns the encoded results.
	TLinkedWebNode.Execute (TStream, TStream) (see page 1324)	Executes a SOAP method call and returns the encoded results.

21.1.5.4.2.1 TLinkedWebNode.Execute Method (String, TStream)

Executes a SOAP method call and returns the encoded results.

Pascal

```
procedure Execute(const DataMsg: String; Resp: TStream); virtual; overload;
procedure Execute(const Request: TStream; Response: TStream); virtual; overload;
function Execute(const Request: TStream): TStream; overload;
```

C++

```
virtual __fastcall Execute(const UnicodeString DataMsg, TStream Resp);
virtual __fastcall Execute(const TStream Request, TStream Response);
__fastcall TStream Execute(const TStream Request);
```

Description

Execute implements the IWebNode (see page 6616) method of the same name. TLinkedRio uses this method to execute a method on an invokable interface that has been encoded as a SOAP method call.

Execute

1. Uses the invocation registry to look up the implementation class for the invokable interface.
2. Uses its internal invoker (the Invoker (see page 1326) property) to unmarshal the request specified by Request or DataMsg and pass it to the implementation class for execution.
3. Returns the encoded results from the invoker in the stream specified by Response or, using the third syntax, in a stream that is the return value of the method. When using the third syntax, the caller is responsible for freeing the returned stream.

See Also

Execute (see page 6618)

TLinkedRIO (see page 1316)

Invoker (see page 1326)

21.1.5.4.3 TLinkedWebNode.GetMimeBoundary Method

Returns the value of the MimeBoundary (see page 1326) property.

Pascal

```
function GetMimeBoundary: string;
```

C++

```
__fastcall UnicodeString GetMimeBoundary();
```

Description

GetMimeBoundary is the read implementation of the MimeBoundary (see page 1326) property.

See Also

MimeBoundary (see page 1326)

21.1.5.4.4 TLinkedWebNode.GetResponseStream Method

Returns a stream to which the application can write the response to the method call.

Pascal

```
function GetResponseStream: TStream; virtual;
```

C++

```
virtual __fastcall TStream GetResponseStream();
```

Description

GetResponseStream creates and returns a memory stream. The linked RIO object uses this stream as its response stream, which receives the response that results from the method call.

See Also

GetResponseStream

21.1.5.4.5 TLinkedWebNode.SetMimeBoundary Method

Sets the value of the MimeBoundary (see page 1326) property.

Pascal

```
procedure SetMimeBoundary(Value: string);
```

C++

```
__fastcall SetMimeBoundary(UnicodeString Value);
```

Description

SetMimeBoundary is the write implementation for the MimeBoundary (see page 1326) property.

Value is the new MIME boundary string.

See Also

MimeBoundary (see page 1326)

21.1.5.5 TLinkedWebNode Properties

The properties of the TLinkedWebNode class are listed here.

Public Properties

	Name	Description
	Invoker (see page 1326)	Executes encoded method calls received from the associated TLinkedRIO (see page 1316) object.
	MimeBoundary (see page 1326)	Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.

21.1.5.5.1 TLinkedWebNode.Invoker Property

Executes encoded method calls received from the associated TLinkedRIO (see page 1316) object.

Pascal

```
property Invoker: TSoapPascalInvoker;
```

C++

```
__property TSoapPascalInvoker Invoker;
```

Description

Invoker is the internal invoker component that looks up method calls in the invocation registry, forwards encoded requests to the registered implementation class, and returns the encoded results for the associated TLinkedRIO (see page 1316) object.

See Also

TLinkedRIO (see page 1316)

21.1.5.5.2 TLinkedWebNode.MimeBoundary Property

Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.

Pascal

```
property MimeBoundary: string;
```

C++

```
__property UnicodeString MimeBoundary;
```

Description

When the encoded method call is included in a multipart form, MimeBoundary is the value of the MIME boundary header that uniquely identifies the part of the form that contains the method call. If the method call is not included in a multipart form, MimeBoundary is an empty string.

See Also

MimeBoundary (see page 6619)

21.1.6 TLogLinkedWebNode Class

Class Hierarchy

Pascal

```
TLogLinkedWebNode = class(TLinkedWebNode);
```

C++

```
class TLogLinkedWebNode : public TLinkedWebNode;
```

File

SOAPLinked

Description

This is class SOAPLinked.TLogLinkedWebNode.

21.1.6.1 TLogLinkedWebNode Members

The following tables list the members exposed by TLogLinkedWebNode.

Protected Methods

	Name	Description
	GetMimeBoundary (see page 1324)	Returns the value of the MimeBoundary (see page 1326) property.
V	GetResponseStream (see page 1328)	Returns a stream to which the application can write the response to the method call.
	SetMimeBoundary (see page 1325)	Sets the value of the MimeBoundary (see page 1326) property.

Public Methods

	Name	Description
V	BeforeExecute (see page 1323)	Caches the RTTI for the method that is about to be executed.
	BeforeExecute (see page 6617)	Performs any transport-specific setup before executing an encoded method call.
V	Create (see page 1327)	Creates a new TLinkedWebNode object.
V	Destroy (see page 1328)	Frees the memory associated with the TLinkedWebNode object.
V	Execute (see page 1328)	This is Execute, a member of class TLogLinkedWebNode.
V	Execute (see page 1323)	This is the overview for the Execute method overload.
	Execute (see page 6618)	This is the overview for the Execute method overload.
	GetMimeBoundary (see page 6619)	Returns the value of the MimeBoundary (see page 6619) property.
	SetMimeBoundary (see page 6619)	Sets the value of the MimeBoundary (see page 6619) property.

Public Properties

	Name	Description
R	Invoker (see page 1326)	Executes encoded method calls received from the associated TLinkedRIO (see page 1316) object.
	MimeBoundary (see page 1326)	Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.
	MimeBoundary (see page 6619)	Specifies the value of the MIME boundary header, if any, for the section of the document that contains the method call.

Published Properties

	Name	Description
	ReqFile (see page 1329)	This is ReqFile, a member of class TLogLinkedWebNode.
	RespFile (see page 1329)	This is RespFile, a member of class TLogLinkedWebNode.

21.1.6.2 TLogLinkedWebNode.Create Constructor

Creates a new TLinkedWebNode object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TLogLinkedWebNode(TComponent * AOwner);
```

Description

Most applications do not create instances of TLinkedWebNode. It is created and used by the TLinkedRIO class.

The Owner parameter specifies the component that is responsible for freeing the TLinkedWebNode instance.

See Also

Owner

TLinkedRIO (see page 1316)

21.1.6.3 TLogLinkedWebNode.Destroy Destructor

Frees the memory associated with the TLinkedWebNode object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLogLinkedWebNode();
```

Description

Do not call the Destroy method directly. Instead, use the Free method, which checks for a nil reference before calling Destroy.

See Also

System::TObject::Free (see page 3372)

21.1.6.4 TLogLinkedWebNode Methods

The methods of the TLogLinkedWebNode class are listed here.

Protected Methods

	Name	Description
	GetResponseStream (see page 1328)	Returns a stream to which the application can write the response to the method call.

Public Methods

	Name	Description
	Execute (see page 1328)	This is Execute, a member of class TLogLinkedWebNode.

21.1.6.4.1 TLogLinkedWebNode.Execute Method

Pascal

```
procedure Execute(const Request: TStream; Response: TStream); override;
```

C++

```
virtual __fastcall Execute(const TStream Request, TStream Response);
```

Description

This is Execute, a member of class TLogLinkedWebNode.

21.1.6.4.2 TLogLinkedWebNode.GetResponseStream Method

Returns a stream to which the application can write the response to the method call.

Pascal

```
function GetResponseStream: TStream; override;
```

C++

```
virtual __fastcall TStream GetResponseStream();
```

Description

GetResponseStream creates and returns a memory stream. The linked RIO object uses this stream as its response stream, which receives the response that results from the method call.

GetResponseStream

21.1.6.5 TLogLinkedWebNode Properties

The properties of the TLogLinkedWebNode class are listed here.

Published Properties

	Name	Description
	ReqFile (see page 1329)	This is ReqFile, a member of class TLogLinkedWebNode.
	RespFile (see page 1329)	This is RespFile, a member of class TLogLinkedWebNode.

21.1.6.5.1 TLogLinkedWebNode.ReqFile Property

Pascal

```
property ReqFile: string;
```

C++

```
__property UnicodeString ReqFile;
```

Description

This is ReqFile, a member of class TLogLinkedWebNode.

21.1.6.5.2 TLogLinkedWebNode.RespFile Property

Pascal

```
property RespFile: string;
```

C++

```
__property UnicodeString RespFile;
```

Description

This is RespFile, a member of class TLogLinkedWebNode.

21.1.7 TWinHandleUser Class

Class Hierarchy

Pascal

```
TWinHandleUser = class(TObject);
```

C++

```
class TWinHandleUser : public TObject;
```

File

SOAPLinked

Description

This is class SOAPLinked.TWinHandleUser.

21.1.7.1 TWinHandleUser Members

The following tables list the members exposed by TWinHandleUser.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	UseHandle1 (see page 1331)	This is UseHandle1, a member of class TWinHandleUser.
	UseHandle2 (see page 1331)	This is UseHandle2, a member of class TWinHandleUser.

21.1.7.2 TWinHandleUser Methods

The methods of the TWinHandleUser class are listed here.

Public Methods

	Name	Description
	UseHandle1 (see page 1331)	This is UseHandle1, a member of class TWinHandleUser.
	UseHandle2 (see page 1331)	This is UseHandle2, a member of class TWinHandleUser.

21.1.7.2.1 TWinHandleUser.UseHandle1 Method

Pascal

```
procedure UseHandle1(ahdesk: HDESK; aenhMf: HENHMETAFILE; amf: HMETAFILE; apalette: HPALETTE;
apen: HPEN; adc: HDC; abmp: HBITMAP; awnd: HWND; ahkl: HKL; aicon: HICON; afont: HFONT);
virtual;
```

C++

```
virtual __fastcall UseHandle1(HDESK ahdesk, HENHMETAFILE aenhMf, HMETAFILE amf, HPALETTE
apalette, HPEN apen, HDC adc, HBITMAP abmp, HWND awnd, HKL ahkl, HICON aicon, HFONT afont);
```

Description

This is UseHandle1, a member of class TWinHandleUser.

21.1.7.2.2 TWinHandleUser.UseHandle2 Method

Pascal

```
procedure UseHandle2(abrush: HBRUSH; amenu: HMENU; akey: HKEY; atask: HTASK; ainst: HINST;
ahook: HHOOK; agdiobj: HGDIOBJ; aAccel: HACCEL; aClrSpc: HCOLORSPACE; aglrc: HGLRC; acrsr:
HCURSOR; ahstr: HSTR; ahwinsta: HWINSTA); virtual;
```

C++

```
virtual __fastcall UseHandle2(HBRUSH abrush, HMENU amenu, HKEY akey, HTASK atask, HINST ainst,
HHOOK ahook, HGDIOBJ agdiobj, HACCEL aAccel, HCOLORSPACE aClrSpc, HGLRC aglrc, HCURSOR acrsr,
HSTR ahstr, HWINSTA ahwinsta);
```

Description

This is UseHandle2, a member of class TWinHandleUser.

21.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IIntegerTest (see page 1332)	This is class SOAPLinked.IIntegerTest.
	IObjectGetter (see page 1333)	This is class SOAPLinked.IObjectGetter.
	IStringTest (see page 1334)	This is class SOAPLinked.IStringTest.

21.2.1 IIntegerTest Interface

Class Hierarchy

Pascal

```
IIntegerTest = interface;
```

C++

```
__interface IIntegerTest;
```

File

SOAPLinked

Description

This is class SOAPLinked.IIntegerTest.

21.2.1.1 IIntegerTest Members

The following tables list the members exposed by IIntegerTest.

Public Methods

	Name	Description
	Add (see page 1333)	This is Add, a member of class IIntegerTest.
	Doubler (see page 1333)	This is Doubler, a member of class IIntegerTest.

21.2.1.2 IIntegerTest Methods

The methods of the IIntegerTest class are listed here.

Public Methods

	Name	Description
	Add (see page 1333)	This is Add, a member of class IIntegerTest.
	Doubler (see page 1333)	This is Doubler, a member of class IIntegerTest.

21.2.1.2.1 IIntegerTest.Add Method

Pascal

```
function Add(const I1: Integer; const I2: Integer): Integer; stdcall;
```

C++

```
__fastcall __stdcall int Add(const int I1, const int I2);
```

Description

This is Add, a member of class IIntegerTest.

21.2.1.2.2 IIntegerTest.Doubler Method

Pascal

```
procedure Doubler(var I: Integer); cdecl;
```

C++

```
__cdecl __fastcall Doubler(int I);
```

Description

This is Doubler, a member of class IIntegerTest.

21.2.2 IObjectGetter Interface

Class Hierarchy

SOAPLinked.IObjectGetter

Pascal

```
IObjectGetter = interface;
```

C++

```
__interface IObjectGetter;
```

File

SOAPLinked

Description

This is class SOAPLinked.IObjectGetter.

21.2.2.1 IObjectGetter Members

The following tables list the members exposed by IObjectGetter.

Public Methods

	Name	Description
	GetAsObject (see page 1334)	This is GetAsObject, a member of class IObjectGetter.

21.2.2.2 IObjectGetter Methods

The methods of the IObjectGetter class are listed here.

Public Methods

	Name	Description
	GetAsObject (see page 1334)	This is GetAsObject, a member of class IObjectGetter.

21.2.2.2.1 IObjectGetter.GetAsObject Method

Pascal

```
function GetAsObject: TObject;
```

C++

```
__fastcall TObject * GetAsObject();
```

Description

This is GetAsObject, a member of class IObjectGetter.

21.2.3 IStringTest Interface

Class Hierarchy

Pascal

```
IStringTest = interface;
```

C++

```
__interface IStringTest;
```

File

SOAPLinked

Description

This is class SOAPLinked.IStringTest.

21.2.3.1 IStringTest Members

The following tables list the members exposed by IStringTest.

Public Methods

	Name	Description
	Append (see page 1335)	This is Append, a member of class IStringTest.
	UpCase (see page 1335)	This is UpCase, a member of class IStringTest.

21.2.3.2 IStringTest Methods

The methods of the IStringTest class are listed here.

Public Methods

	Name	Description
	Append (see page 1335)	This is Append, a member of class IStringTest.
	UpCase (see page 1335)	This is UpCase, a member of class IStringTest.

21.2.3.2.1 IStringTest.Append Method

Pascal

```
function Append(const Str1: string; const Str2: string): string; cdecl;
```

C++

```
__cdecl __fastcall UnicodeString Append(const UnicodeString Str1, const UnicodeString Str2);
```

Description

This is Append, a member of class IStringTest.

21.2.3.2.2 IStringTest.UpCase Method

Pascal

```
procedure UpCase(var Str1: string); stdcall;
```

C++

```
__fastcall __stdcall UpCase(UnicodeString Str1);
```

Description

This is UpCase, a member of class IStringTest.

21.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	EventKind (see page 1336)	This is record SOAPLinked.EventKind.

21.3.1 SOAPLinked.EventKind Enumeration

Pascal

```
EventKind = (
  evNormal,
  evConst,
  evVar
);
```

C++

```
enum EventKind {
  evNormal,
  evConst,
  evVar
};
```

File

SOAPLinked

Description

This is record SOAPLinked.EventKind.

21.4 Types

The following table lists types in this documentation.

Types

Name	Description
TCStringEvent (see page 1337)	This is type SOAPLinked.TCStringEvent.
TCustExCallback (see page 1337)	This is type SOAPLinked.TCustExCallback.
TStringEvent (see page 1338)	This is type SOAPLinked.TStringEvent.
TVStringEvent (see page 1338)	This is type SOAPLinked.TVStringEvent.

21.4.1 SOAPLinked.TCStringEvent Type

Pascal

```
TCStringEvent = procedure (Sender: TObject; const S: string) of object;
```

C++

```
(Sender: TObject; const S: string) ( TCStringEvent)();
```

File

SOAPLinked

Description

This is type SOAPLinked.TCStringEvent.

21.4.2 SOAPLinked.TCustExCallback Type

Pascal

```
TCustExCallback = procedure;
```

C++

```
( TCustExCallback)();
```

File

SOAPLinked

Description

This is type SOAPLinked.TCustExCallback.

21.4.3 SOAPLinked.TStringEvent Type

Pascal

```
TStringEvent = procedure (Sender: TObject; S: string) of object;
```

C++

```
(Sender: TObject; S: string) ( TStringEvent)();
```

File

SOAPLinked

Description

This is type SOAPLinked.TStringEvent.

21.4.4 SOAPLinked.TVStringEvent Type

Pascal

```
TVStringEvent = procedure (Sender: TObject; var S: string) of object;
```

C++

```
(Sender: TObject; var S: string) ( TVStringEvent)();
```

File

SOAPLinked

Description

This is type SOAPLinked.TVStringEvent.

22 SOAPMidas Namespace

This is namespace SOAPMidas.

Topics

Name	Description
Interfaces (see page 1340)	The following table lists interfaces in this documentation.
Functions (see page 1347)	The following table lists functions in this documentation.

Functions

	Name	Description
	RegDefIAppServerInvClass (see page 1347)	Registers a SOAP data module for use by clients built using Kylix 2 or Delphi 5 prior to update patch 2.

Interfaces

	Name	Description
	IAppServerSOAP (see page 1340)	IAppServerSOAP is the interface for communication with a SOAP data module.

22.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IAppServerSOAP (see page 1340)	IAppServerSOAP is the interface for communication with a SOAP data module.

22.1.1 IAppServerSOAP Interface

IAppServerSOAP is the interface for communication with a SOAP data module.

Class Hierarchy

Pascal

```
IAppServerSOAP = interface(IInvokable);
```

C++

```
__interface IAppServerSOAP : public IInvokable;
```

File

SOAPMidas

Description

TSoapConnection and TSoapDataModule use the IAppServerSOAP interface to communicate information in a SOAP-based multi-tiered database application. This is different from other DataSnap components, which use the IAppServer interface. IAppServerSOAP differs from IAppServer primarily in that it uses the stdcall calling convention rather than safecall. This makes it easier for marshalling interface calls when the client or server is written in C++.

Note: C++ method declarations that use IAppServerSOAP use the _di_IAppServerSOAP type instead. This type is a DelphiInterface (see page 3256) wrapper around the IAppServerSOAP interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IAppServerSOAP >  _di_IAppServerSOAP;
```

See Also

TSoapConnection (see page 1188)

TSoapDataModule (see page 1206)

IAppServer

22.1.1.1 IAppServerSOAP Members

The following tables list the members exposed by IAppServerSOAP.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	SAS_ApplyUpdates (see page 1341)	Applies updates received from a client dataset using a specified provider.
	SAS_DataRequest (see page 1342)	Generates an OnSAS_DataRequest event on the specified provider component.
	SAS_Execute (see page 1342)	SAS_Executes the query or stored procedure bound to a specified provider.
	SAS_GetParams (see page 1343)	Fetches current parameter values from the dataset bound to a specified provider.
	SAS_GetProviderNames (see page 1344)	Returns a list of all the available providers on a remote data module.
	SAS_GetRecords (see page 1344)	Returns a data packet that contains the specified data.
	SAS_RowRequest (see page 1345)	Returns information from a specified record of the provider's dataset.

22.1.1.2 IAppServerSOAP Methods

The methods of the IAppServerSOAP class are listed here.

Public Methods

	Name	Description
	SAS_ApplyUpdates (see page 1341)	Applies updates received from a client dataset using a specified provider.
	SAS_DataRequest (see page 1342)	Generates an OnSAS_DataRequest event on the specified provider component.
	SAS_Execute (see page 1342)	SAS_Executes the query or stored procedure bound to a specified provider.
	SAS_GetParams (see page 1343)	Fetches current parameter values from the dataset bound to a specified provider.
	SAS_GetProviderNames (see page 1344)	Returns a list of all the available providers on a remote data module.
	SAS_GetRecords (see page 1344)	Returns a data packet that contains the specified data.
	SAS_RowRequest (see page 1345)	Returns information from a specified record of the provider's dataset.

22.1.1.2.1 IAppServerSOAP.SAS_ApplyUpdates Method

Applies updates received from a client dataset using a specified provider.

Pascal

```
function SAS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; stdcall;
```

C++

```
__fastcall __stdcall OleVariant SAS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta,
int MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

SAS_SAS_ApplyUpdates writes client updates to a dataset or database server.

ProviderName specifies the name of the provider component that manages the update operation.

Delta is a Variant (see page 3421) containing the updated, inserted, and deleted records to write to the database.

MaxErrors indicates the maximum number of errors to permit before rolling back the update operation.

ErrorCount returns the actual number of errors encountered during the update operation.

OwnerData is information supplied by the client application in a BeforeSAS_ApplyUpdates event handler and returned to the client application in an AfterSAS_ApplyUpdates event handler. It is passed to the provider's BeforeSAS_ApplyUpdates event handler and returned from the provider's AfterSAS_ApplyUpdates event handler.

SAS_SAS_ApplyUpdates returns a Variant (see page 3421) that is a data packet containing all records that could not be

applied.

ApplyUpdates

ApplyUpdates

BeforeApplyUpdates

AfterApplyUpdates

BeforeApplyUpdates

AfterApplyUpdates

SAS_ApplyUpdates (see page 1223)

22.1.1.2.2 IAppServerSOAP.SAS_DataRequest Method

Generates an OnSAS_DataRequest event on the specified provider component.

Pascal

```
function SAS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
stdcall;
```

C++

```
__fastcall __stdcall OleVariant SAS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use SAS_SAS_DataRequest to invoke an OnSAS_DataRequest event handler of the provider named by ProviderName. This method is provided to allow application developers to customize the communication between a client application and a provider component.

ProviderName is the provider on which the data module generates an OnSAS_DataRequest event.

There is no predefined meaning for the Data parameter or the return value.

See Also

OnDataRequest

DataRequest

22.1.1.2.3 IAppServerSOAP.SAS_Execute Method

SAS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure SAS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); stdcall;
```

C++

```
__fastcall __stdcall SAS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant
Params, OleVariant OwnerData);
```

Description

Use SAS_SAS_Execute to pass an execute command to a remote provider, using a specified set of parameters. SAS_SAS_Execute calls the SAS_Execute method of the specified provider after assigning any parameters. Output (see page 3833) parameters that result from executing a query or stored procedure are returned in the Params parameter.

The provider's SAS_Execute method generates a BeforeSAS_Execute event, passes the command on to its associated dataset, and generates an AfterSAS_Execute event. The dataset must represent a query or stored procedure that does not return a cursor.

ProviderName specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the query, or the name of a stored procedure that replaces the dataset's stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams method. To decode Params into a TParams object, use the Unpackparams routine.

OwnerData contains custom information that appears as an argument to the provider's BeforeSAS_Execute and AfterSAS_Execute event handlers. This information originates in a client dataset's BeforeSAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterSAS_Execute event handler.

PackageParams

UnpackParams

22.1.1.2.4 IAppServerSOAP.SAS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function SAS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
stdcall;
```

C++

```
__fastcall __stdcall OleVariant SAS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use SAS_SAS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

ProviderName specifies the name of the provider component whose dataset has the parameters.

OwnerData represents custom information that originates in a client dataset's BeforeSAS_GetParams event handler and returns information that is passed to the client dataset's AfterSAS_GetParams event handler.

SAS_SAS_GetParams returns the parameters, encoded as a Variant (see page 3421) array, or, if the provider does not

support parameter fetching, SAS_SAS_GetParams returns a Null Variant (see page 3421). Use the UnpackParams procedure to convert parameter values returned by SAS_SAS_GetParams to a TParams object.

Warning: Calling SAS_SAS_GetParams is not recommended because SOAP data modules are stateless, and any parameter values you fetch may be changed by other applications. The recommended way to obtain output parameter values is to call the SAS_Execute (see page 1342) method instead.

AfterGetParams

SAS_Execute (see page 1342)

UnpackParams

22.1.1.2.5 IAppServerSOAP.SAS_GetProviderNames Method

Returns a list of all the available providers on a remote data module.

Pascal

```
function SAS_GetProviderNames: TWideStringDynArray; stdcall;
```

C++

```
__fastcall __stdcall TWideStringDynArray SAS_GetProviderNames();
```

Description

Call SAS_SAS_GetProviderNames for a list of all registered providers available from a SOAP data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the SOAP data module. When calling any of the SOAP data modules through the IAppServerSOAP (see page 1340) interface, pass one of these names to indicate the provider that is the target of the method call.

SAS_SAS_GetProviderNames returns the names of the providers in a dynamic array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

See Also

ProviderName

Providers (see page 1230)

22.1.1.2.6 IAppServerSOAP.SAS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function SAS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; stdcall;
```

C++

```
__fastcall __stdcall OleVariant SAS_GetRecords(const BSTR ProviderName, int Count, int
RecsOut, int Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call SAS_SAS_GetRecords to retrieve a specified number of records. SAS_SAS_GetRecords returns the requested records, starting with the current record of the provider's dataset. Because SOAP data modules are stateless, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeSAS_GetRecords event handler.

ProviderName gives the name of the provider component that supplies the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params is a Variant (see page 3421) containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.

OwnerData contains custom information that is supplied by a client dataset's BeforeSAS_GetRecords event handler. This information is passed to the provider's BeforeSAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterSAS_GetRecords event handler.

Records are returned as a data packet in a Variant (see page 3421).

22.1.1.2.7 IAppServerSOAP.SAS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function SAS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; stdcall;
```

C++

```
__fastcall __stdcall OleVariant SAS_RowRequest(const BSTR ProviderName, OleVariant Row, int
RequestType, OleVariant OwnerData);
```

Description

SAS_SAS_RowRequest provides the implementation for a client dataset's FetchBlobs, FetchDetails , or RefreshRecord method.

ProviderName indicates the provider associated with the dataset from which information should be fetched.

Row is an OleVariant (see page 3274) that describes the current record on the client dataset.

RequestType indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeSAS_RowRequest event handler. This information is passed to the provider's BeforeSAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterSAS_RowRequest event handler.

The requested data is returned as a delta packet.

22.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	RegDefIAppServerInvClass (see page 1347)	Registers a SOAP data module for use by clients built using Kylix 2 or Delphi 5 prior to update patch 2.

22.2.1 SOAPMidas.RegDefIAppServerInvClass Function

Registers a SOAP data module for use by clients built using Kylix 2 or Delphi 5 prior to update patch 2.

Pascal

```
procedure RegDefIAppServerInvClass;
```

C++

```
RegDefIAppServerInvClass();
```

File

SOAPMidas

Description

RegDefIAppServerInvClass registers TSoapDataModule as an invokable class that implements IAppServer as a Web Service. C++ applications must add a call to this procedure after the registration of IAppServerSOAP (see page 1340) in the program startup code if they are to be used by clients written using Kylix 2 or Delphi 5 prior to update patch 2. This call is not necessary for other clients of a Web Service-based application server, because they look for the IAppServerSOAP (see page 1340) interface.

Note: Delphi applications do not need to call this procedure.

The following example shows where to place the call to RegDefIAppServerInvClass:

```
void static RegTypes()
{
  InvRegistry()->RegisterInterface(__interfaceTypeinfo(IMyAppServerService));
  InvRegistry()->RegisterInvokableClass(__classid(TMyAppServerService),
MyAppServerServiceFactory);
  RegDefIAppServerInvClass();
}
#pragma statrtup RegTypes 32
```

23 SOAPPasInv Namespace

This is namespace SOAPPasInv.

Topics

Name	Description
Classes (see page 1350)	The following table lists classes in this documentation.
Interfaces (see page 1359)	The following table lists interfaces in this documentation.
Functions (see page 1362)	The following table lists functions in this documentation.
Types (see page 1363)	The following table lists types in this documentation.

Classes

	Name	Description
	TSoapPascalInvoker (see page 1350)	TSoapPascalInvoker is the base class for components that interpret SOAP requests and execute the corresponding invokable interface.

Functions

	Name	Description
	GetSOAPHeaders (see page 1362)	Returns the interface for accessing the SOAP headers that were received with a SOAP request and supplying the headers for the outgoing response.

Interfaces

	Name	Description
	IAdapterConverter (see page 1359)	This is class SOAPPasInv.IAdapterConverter.
	IInvokerConverter (see page 1360)	This is class SOAPPasInv.IInvokerConverter.

Types

Name	Description
TAfterDispatchEvent (see page 1363)	TAfterDispatchEvent is the type of the AfterDispatchEvent event on an invoker component.
TBeforeDispatchEvent (see page 1363)	TBeforeDispatchEvent is the type of the BeforeDispatchEvent event on an invoker component.
TBeforeDispatchEvent2 (see page 1364)	TBeforeDispatchEvent2 is the type of the BeforeDispatchEvent2 event on an invoker component.
TOnExceptionEvent (see page 1364)	TOnExceptionEvent is the type of the OnExceptionEvent event on an invoker component.

23.1 Classes

The following table lists classes in this documentation.

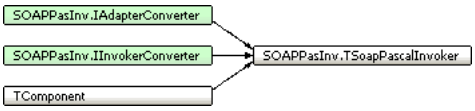
Classes

	Name	Description
	TSoapPascalInvoker (see page 1350)	TSoapPascalInvoker is the base class for components that interpret SOAP requests and execute the corresponding invokable interface.

23.1.1 TSoapPascalInvoker Class

TSoapPascalInvoker is the base class for components that interpret SOAP requests and execute the corresponding invokable interface.

Class Hierarchy



Pascal

```
TSoapPascalInvoker = class(TComponent, IAdapterConverter, IInvokerConverter);
```

C++

```
class TSoapPascalInvoker : public TComponent, public IAdapterConverter, public
IInvokerConverter;
```

File

SOAPPasInv

Description

Use TSoapPascalInvoker as a base class for components that interpret SOAP requests. TSoapPascalInvoker implements the logic that parses a SOAP request, given its target invokable interface, executes the interface call, and encodes the results of that code.

Each TSoapPascalInvoker descendant receives SOAP requests that arrive via a specific transport protocol. The TSoapPascalInvoker descendant must implement the logic to take the incoming SOAP request, identify the target invokable interface, and look up its implementation class and runtime type information (RTTI).

IInvokable (see page 3504)

THTTPSoapPascalInvoker (see page 1267)

23.1.1.1 TSoapPascalInvoker Members

The following tables list the members exposed by TSoapPascalInvoker.

Protected Fields

	Name	Description
	FConverter (see page 1352)	This is FConverter, a member of class TSoapPascalInvoker.
	FDomConverter (see page 1352)	This is FDomConverter, a member of class TSoapPascalInvoker.
	FHeadersIn (see page 1353)	This is FHeadersIn, a member of class TSoapPascalInvoker.
	FHeadersOut (see page 1353)	This is FHeadersOut, a member of class TSoapPascalInvoker.
	FSOAPHeaders (see page 1353)	This is FSOAPHeaders, a member of class TSoapPascalInvoker.

Protected Methods

	Name	Description
	GetDomConverter (see page 1354)	This is GetDomConverter, a member of class TSoapPascalInvoker.
	GetInvoker (see page 1354)	This is GetInvoker, a member of class TSoapPascalInvoker.
V	Notification (see page 1355)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
V	Create (see page 1351)	Creates a new TSoapPascalInvoker (see page 1350) object.
V	Destroy (see page 1352)	Frees the memory associated with the TSoapPascalInvoker (see page 1350) object.
V	Invoke (see page 1354)	Interprets a SOAP request message, calls the target interface, and encodes any return values.

Published Events

	Name	Description
	AfterDispatchEvent (see page 1356)	Occurs after the invoker successfully calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent2 (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	OnExceptionEvent (see page 1357)	Occurs when the invoker encounters an exception while executing a SOAP request.
	OnGetAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) reads each attachment included in an incoming request.
	OnSendAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) sends each attachment included in the response to the current request.

Published Properties

	Name	Description
	Converter (see page 1355)	Specifies the interface of the component that handles the marshaling of SOAP messages.

23.1.1.2 TSoapPascalInvoker.Create Constructor

Creates a new TSoapPascalInvoker (see page 1350) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSoapPascalInvoker(TComponent * AOwner);
```

Description

Call Create to instantiate an invoker at runtime. Invoker components added to Web modules at design time (including the one that the Soap Server wizard adds automatically) are created automatically.

The AOwner parameter specifies the component that is responsible for freeing the TSoapPascalInvoker (see page 1350) instance.

See Also

Owner

23.1.1.3 TSoapPascalInvoker.Destroy Destructor

Frees the memory associated with the TSoapPascalInvoker (see page 1350) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSoapPascalInvoker();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the invoker component is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

23.1.1.4 TSoapPascalInvoker Fields

The fields of the TSoapPascalInvoker class are listed here.

Protected Fields

	Name	Description
	FConverter (see page 1352)	This is FConverter, a member of class TSoapPascalInvoker.
	FDomConverter (see page 1352)	This is FDomConverter, a member of class TSoapPascalInvoker.
	FHeadersIn (see page 1353)	This is FHeadersIn, a member of class TSoapPascalInvoker.
	FHeadersOut (see page 1353)	This is FHeadersOut, a member of class TSoapPascalInvoker.
	FSOAPHeaders (see page 1353)	This is FSOAPHeaders, a member of class TSoapPascalInvoker.

23.1.1.4.1 TSoapPascalInvoker.FConverter Field

Pascal

```
FConverter: IOPConvert;
```

C++

```
IOPConvert FConverter;
```

Description

This is FConverter, a member of class TSoapPascalInvoker.

23.1.1.4.2 TSoapPascalInvoker.FDomConverter Field

Pascal

```
FDomConverter: TOPToSoapDomConvert;
```

C++

```
TOPToSoapDomConvert FDomConverter;
```

Description

This is FDomConverter, a member of class TSoapPascalInvoker.

23.1.1.4.3 TSoapPascalInvoker.FHeadersIn Field

Pascal

```
FHeadersIn: THeaderList;
```

C++

```
THeaderList FHeadersIn;
```

Description

This is FHeadersIn, a member of class TSoapPascalInvoker.

23.1.1.4.4 TSoapPascalInvoker.FHeadersOut Field

Pascal

```
FHeadersOut: THeaderList;
```

C++

```
THeaderList FHeadersOut;
```

Description

This is FHeadersOut, a member of class TSoapPascalInvoker.

23.1.1.4.5 TSoapPascalInvoker.FSOAPHeaders Field

Pascal

```
FSOAPHeaders: TSOAPHeaders;
```

C++

```
TSOAPHeaders FSOAPHeaders;
```

Description

This is FSOAPHeaders, a member of class TSoapPascalInvoker.

23.1.1.5 TSoapPascalInvoker Methods

The methods of the TSoapPascalInvoker class are listed here.

Protected Methods

	Name	Description
	GetDomConverter (see page 1354)	This is GetDomConverter, a member of class TSoapPascalInvoker.
	GetInvoker (see page 1354)	This is GetInvoker, a member of class TSoapPascalInvoker.
V	Notification (see page 1355)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	Invoke (see page 1354)	Interprets a SOAP request message, calls the target interface, and encodes any return values.

23.1.1.5.1 TSoapPascalInvoker.GetDomConverter Method

Pascal

```
function GetDomConverter: TOPToSoapDomConvert;
```

C++

```
__fastcall TOPToSoapDomConvert GetDomConverter();
```

Description

This is GetDomConverter, a member of class TSoapPascalInvoker.

23.1.1.5.2 TSoapPascalInvoker.GetInvoker Method

Pascal

```
function GetInvoker: TSoapPascalInvoker;
```

C++

```
__fastcall TSoapPascalInvoker GetInvoker();
```

Description

This is GetInvoker, a member of class TSoapPascalInvoker.

23.1.1.5.3 TSoapPascalInvoker.Invoke Method

Interprets a SOAP request message, calls the target interface, and encodes any return values.

Pascal

```
procedure Invoke(AClass: TClass; IntfInfo: PTypeInfo; MethName: string; const Request:
TStream; Response: TStream; var BindingType: TWebServiceBindingType); virtual;
```

C++

```
virtual __fastcall Invoke(TClass AClass, PTypeInfo IntfInfo, UnicodeString MethName, const
TStream Request, TStream Response, TWebServiceBindingType BindingType);
```

Description

Call Invoke to convert a SOAP request to an interface call on an invokable interface.

AClass is the class that implements the invokable interface. The invoker passes this to the invocation registry so that it can obtain an instance of the implementation class, which it uses to execute the SOAP request.

IntfInfo is the runtime type information (RTTI) from the invokable interface that is the target of the SOAP request. The invoker uses this to interpret the SOAP request.

MethName is the name of the method to call on the invokable interface.

Request is a stream from which Invoke can read the SOAP request. It contains the SOAP encoding of an interface call.

Response is a stream to which Invoke writes the SOAP encoding of any return values.

BindingType indicates the format of the Request and Response. It is either btSOAP (to indicate a SOAP packet) or btMime (for a

multipart form when the request or response includes attachments). On entry, BindingType indicates the format of the encoded request message. Invoke changes BindingType to the format of the response message.

See Also

IInvokable (see page 3504)

InvRegistry

GetInvokableObjectFromClass

23.1.1.5.4 TSoapPascalInvoker.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

23.1.1.6 TSoapPascalInvoker Properties

The properties of the TSoapPascalInvoker class are listed here.

Published Properties

	Name	Description
	Converter (see page 1355)	Specifies the interface of the component that handles the marshaling of SOAP messages.

23.1.1.6.1 TSoapPascalInvoker.Converter Property

Specifies the interface of the component that handles the marshaling of SOAP messages.

Pascal

```
property Converter: TOPToSoapDomConvert;
```

C++

```
__property TOPToSoapDomConvert Converter;
```

Description

Converter is the component that marshals and unmarshals method calls for the invoker. The invoker uses this object to interpret incoming method calls and to generate the results it returns.

See Also

TOPToSoapDomConvert

23.1.1.7 TSoapPascalInvoker Events

The events of the TSoapPascalInvoker class are listed here.

Published Events

	Name	Description
	AfterDispatchEvent (see page 1356)	Occurs after the invoker successfully calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	BeforeDispatchEvent2 (see page 1357)	Occurs before the invoker calls an invokable interface to execute a SOAP request.
	OnExceptionEvent (see page 1357)	Occurs when the invoker encounters an exception while executing a SOAP request.
	OnGetAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) reads each attachment included in an incoming request.
	OnSendAttachment (see page 1358)	Occurs when TSoapPascalInvoker (see page 1350) sends each attachment included in the response to the current request.

23.1.1.7.1 TSoapPascalInvoker.AfterDispatchEvent Event

Occurs after the invoker successfully calls an invokable interface to execute a SOAP request.

Pascal

```
property AfterDispatchEvent: TAfterDispatchEvent;
```

C++

```
__property TAfterDispatchEvent AfterDispatchEvent;
```

Description

Write (see page 3707) a AfterDispatchEvent event handler to examine a SOAP response after the invoker executes a request by calling the target invokable interface. The Invoke (see page 1354) method generates this event after it has executed a requested method and generated a response packet.

Note: AfterDispatchEvent only occurs if the method call is successful. If the invoker encounters an exception when trying to execute the specified method, it generates an OnExceptionEvent (see page 1357) instead.

See Also

BeforeDispatchEvent (see page 1357)

Invoke (see page 1354)

OnExceptionEvent (see page 1357)

23.1.1.7.2 TSoapPascalInvoker.BeforeDispatchEvent Event

Occurs before the invoker calls an invokable interface to execute a SOAP request.

Pascal

```
property BeforeDispatchEvent: TBeforeDispatchEvent;
```

C++

```
__property TBeforeDispatchEvent BeforeDispatchEvent;
```

Description

Write (see page 3707) a BeforeDispatchEvent event handler to examine a SOAP request before the invoker calls on the target invokable interface to execute it. The Invoke (see page 1354) method generates this event after it has obtained an interface pointer for the target invokable interface, but before it calls the specified method on that interface.

See Also

AfterDispatchEvent (see page 1356)

Invoke (see page 1354)

BeforeDispatchEvent2 (see page 1357)

23.1.1.7.3 TSoapPascalInvoker.BeforeDispatchEvent2 Event

Occurs before the invoker calls an invokable interface to execute a SOAP request.

Pascal

```
property BeforeDispatchEvent2: TBeforeDispatchEvent2;
```

C++

```
__property TBeforeDispatchEvent2 BeforeDispatchEvent2;
```

Description

Write (see page 3707) a BeforeDispatchEvent2 event handler to override the default handling of an incoming request. The Invoke (see page 1354) method generates this event after it has obtained an interface pointer for the target invokable interface, but before it calls the specified method on that interface.

See Also

AfterDispatchEvent (see page 1356)

Invoke (see page 1354)

BeforeDispatchEvent (see page 1357)

23.1.1.7.4 TSoapPascalInvoker.OnExceptionEvent Event

Occurs when the invoker encounters an exception while executing a SOAP request.

Pascal

```
property OnExceptionEvent: TOnExceptionEvent;
```

C++

```
__property TOnExceptionEvent OnExceptionEvent;
```

Description

Write (see page 3707) a OnExceptionEvent event handler to examine a SOAP fault packet after the invoker encounters an exception when executing a SOAP request. The Invoke (see page 1354) method generates this event if it encounters an exception, after it generates the SOAP fault packet that describes the problem.

See Also

AfterDispatchEvent (see page 1356)

23.1.1.7.5 TSoapPascalInvoker.OnGetAttachment Event

Occurs when TSoapPascalInvoker (see page 1350) reads each attachment included in an incoming request.

Pascal

```
property OnGetAttachment: TOnGetAttachmentEvent;
```

C++

```
__property TOnGetAttachmentEvent OnGetAttachment;
```

Description

Write (see page 3707) an OnGetAttachment event handler to examine the encoded attachments included with an incoming request or to redirect them so that they are saved to a specific file. OnGetAttachment occurs once for each attachment received.

Tip: Use the FileName property of the attachment object to redirect the attachment to a different file.

See Also

OnSendAttachment (see page 1358)

BeforeDispatchEvent (see page 1357)

23.1.1.7.6 TSoapPascalInvoker.OnSendAttachment Event

Occurs when TSoapPascalInvoker (see page 1350) sends each attachment included in the response to the current request.

Pascal

```
property OnSendAttachment: TOnSendAttachmentEvent;
```

C++

```
__property TOnSendAttachmentEvent OnSendAttachment;
```

Description

Write (see page 3707) an OnSendAttachment event handler to examine or alter the attachments that are to be included in a message that represents the results of a method call. OnSendAttachment occurs once for each attachment sent with the response message.

See Also

AfterDispatchEvent (see page 1356)

OnGetAttachment (see page 1358)

23.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IAdapterConverter (see page 1359)	This is class SOAPPasInv.IAdapterConverter.
	IInvokerConverter (see page 1360)	This is class SOAPPasInv.IInvokerConverter.

23.2.1 IAdapterConverter Interface

Class Hierarchy

SOAPPasInv.IAdapterConverter

Pascal

```
IAdapterConverter = interface;
```

C++

```
__interface IAdapterConverter;
```

File

SOAPPasInv

Description

This is class SOAPPasInv.IAdapterConverter.

23.2.1.1 IAdapterConverter Members

The following tables list the members exposed by IAdapterConverter.

Public Methods

	Name	Description
	GetDomConverter (see page 1360)	This is GetDomConverter, a member of class IAdapterConverter.

23.2.1.2 IAdapterConverter Methods

The methods of the IAdapterConverter class are listed here.

Public Methods

	Name	Description
	GetDomConverter (see page 1360)	This is GetDomConverter, a member of class IAdapterConverter.

23.2.1.2.1 IAdapterConverter.GetDomConverter Method

Pascal

```
function GetDomConverter: TOPToSoapDomConvert;
```

C++

```
__fastcall TOPToSoapDomConvert GetDomConverter();
```

Description

This is GetDomConverter, a member of class IAdapterConverter.

23.2.2 IInvokerConverter Interface

Class Hierarchy

SOAPPasInv.IInvokerConverter

Pascal

```
IInvokerConverter = interface;
```

C++

```
__interface IInvokerConverter;
```

File

SOAPPasInv

Description

This is class SOAPPasInv.IInvokerConverter.

23.2.2.1 IInvokerConverter Members

The following tables list the members exposed by IInvokerConverter.

Public Methods

	Name	Description
	GetInvoker (see page 1361)	This is GetInvoker, a member of class IInvokerConverter.

23.2.2.2 IInvokerConverter Methods

The methods of the IInvokerConverter class are listed here.

Public Methods

	Name	Description
	GetInvoker (see page 1361)	This is GetInvoker, a member of class IInvokerConverter.

23.2.2.2.1 IInvokerConverter.GetInvoker Method

Pascal

```
function GetInvoker: TSoapPascalInvoker;
```

C++

```
__fastcall TSoapPascalInvoker GetInvoker();
```

Description

This is GetInvoker, a member of class IInvokerConverter.

23.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	GetSOAPHeaders (see page 1362)	Returns the interface for accessing the SOAP headers that were received with a SOAP request and supplying the headers for the outgoing response.

23.3.1 SOAPPasInv.GetSOAPHeaders Function

Returns the interface for accessing the SOAP headers that were received with a SOAP request and supplying the headers for the outgoing response.

Pascal

```
function GetSOAPHeaders: ISOAPHeaders;
```

C++

```
ISOAPHeaders GetSOAPHeaders();
```

File

SOAPPasInv

Description

Call GetSOAPHeaders from an application that implements a Web Service when you do not use TInvokableClass as a base class for the implementation of an invokable interface. GetSOAPHeaders returns an ISOAPHeaders interface, which lets your application examine the SOAP headers in an incoming request message and to add SOAP headers to be sent with the outgoing response.

See Also

TInvokableClass

Defining and Using SOAP Headers

23.4 Types

The following table lists types in this documentation.

Types

Name	Description
TAfterDispatchEvent (see page 1363)	TAfterDispatchEvent is the type of the AfterDispatchEvent event on an invoker component.
TBeforeDispatchEvent (see page 1363)	TBeforeDispatchEvent is the type of the BeforeDispatchEvent event on an invoker component.
TBeforeDispatchEvent2 (see page 1364)	TBeforeDispatchEvent2 is the type of the BeforeDispatchEvent2 event on an invoker component.
TOnExceptionEvent (see page 1364)	TOnExceptionEvent is the type of the OnExceptionEvent event on an invoker component.

23.4.1 SOAPPasInv.TAfterDispatchEvent Type

TAfterDispatchEvent is the type of the AfterDispatchEvent event on an invoker component.

Pascal

```
TAfterDispatchEvent = procedure (const MethodName: string; SOAPResponse: TStream) of object;
```

C++

```
(const MethodName: string; SOAPResponse: TStream) ( TAfterDispatchEvent)();
```

File

SOAPPasInv

Description

TAfterDispatchEvent is the type of the AfterDispatchEvent event handler, which is called after an invoker executes a request by calling the target invokable interface.

MethodName is the name of the method that was just called.

SOAPResponse is a stream from which the event handler can read or alter the response packet that represents the results of the method call.

See Also

Procedural types

Creating events

23.4.2 SOAPPasInv.TBeforeDispatchEvent Type

TBeforeDispatchEvent is the type of the BeforeDispatchEvent event on an invoker component.

Pascal

```
TBeforeDispatchEvent = procedure (const MethodName: string; const Request: TStream) of object;
```

C++

```
(const MethodName: string; const Request: TStream) ( TBeforeDispatchEvent)();
```

File

SOAPPasInv

Description

TBeforeDispatchEvent is the type of the BeforeDispatchEvent event handler, which is called before an invoker executes a request by calling the target invokable interface.

MethodName is the name of the method that is about to be called.

Request is a stream from which the event handler can read the SOAP request that is about to be executed.

See Also

Procedural types

Creating events

23.4.3 SOAPPasInv.TBeforeDispatchEvent2 Type

TBeforeDispatchEvent2 is the type of the BeforeDispatchEvent2 event on an invoker component.

Pascal

```
TBeforeDispatchEvent2 = procedure (const MethodName: string; const Request: TStream; Response:
TStream; var BindingType: TWebServiceBindingType; var Handled: Boolean) of object;
```

C++

```
(const MethodName: string; const Request: TStream; Response: TStream; var BindingType:
TWebServiceBindingType; var Handled: Boolean) ( TBeforeDispatchEvent2)();
```

File

SOAPPasInv

Description

TBeforeDispatchEvent2 is the type of the BeforeDispatchEvent2 event handler, which is called before an invoker executes a request by calling the target invokable interface.

MethodName is the name of the method that is about to be called.

Request is a stream from which the event handler can read the SOAP request that is about to be executed.

Response is a stream to which the event handler can write a response for the request.

BindingType indicates the encoding that is used by the request.

Handled returns true if the event handler supplies a response using the Response parameter. It returns false if the invoker should forward the request to a registered implementation class after the event handler exits.

23.4.4 SOAPPasInv.TOnExceptionEvent Type

TOnExceptionEvent is the type of the OnExceptionEvent event on an invoker component.

Pascal

```
TOnExceptionEvent = procedure (const MethodName: string; const Request: TStream; const
Response: TStream) of object;
```

C++

```
(const MethodName: string; const Request: TStream; const Response: TStream) (
TOnExceptionEvent)();
```

File

SOAPPasInv

Description

TOnExceptionEvent is the type of the OnExceptionEventEvent event handler, which is called when an invoker encounters an exception while executing a request by calling a target invokable interface.

MethodName is the name of the method that was just called.

Request is a stream from which the event handler can read the SOAP request that contained the method call.

Response is a stream from which the event handler can read the SOAP fault packet that was created to describe the exception.

See Also

Procedural types

Creating events

24 Sockets Namespace

This is namespace Sockets.

Topics

Name	Description
Classes (see page 1369)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 1499)	The following table lists structs, records, enums in this documentation.
Types (see page 1504)	The following table lists types in this documentation.
Constants (see page 1508)	The following table lists constants in this documentation.

Classes

	Name	Description
	ESocketError (see page 1369)	Exception (see page 3949) class for failures that occur when trying to create, use, or shut down Windows socket objects.
	TBaseSocket (see page 1370)	TBaseSocket encapsulates local operations on file descriptors.
	TClientSocketThread (see page 1396)	Enables creation of separate threads of execution for the client socket in an application.
	TCustomIpClient (see page 1400)	Encapsulates the client network functions.
	TCustomTcpServer (see page 1406)	Ancestor object of all the server socket descendants.
	TIpSocket (see page 1416)	Encapsulates the network support functions.
	TRawSocket (see page 1431)	Encapsulates a raw socket.
	TServerSocketThread (see page 1433)	Enables creation of separate threads of execution for the server socket in an application.
	TTcpClient (see page 1439)	TCP client component.
	TTcpServer (see page 1459)	TTcpServer is the TCP server component.
	TUdpSocket (see page 1477)	UDP component.

Constants

Name	Description
CRLF (see page 1508)	This is constant Sockets.CRLF.

Structs, Records, Enums

	Name	Description
	TIPHeader (see page 1499)	This is record Sockets.TIPHeader.
	TServerSocketBlockMode (see page 1500)	Defines the set of possible socket flags for block mode.
	TSocketDomain (see page 1500)	Set of possible protocol family types used by a socket.
	TSocketType (see page 1502)	The TSocketType type defines the set of possible socket types.

Types

Name	Description
TGetThreadEvent (see page 1504)	This is type Sockets.TGetThreadEvent.
TSocketAcceptEvent (see page 1504)	This is type Sockets.TSocketAcceptEvent.
TSocketBlockMode (see page 1505)	Defines the set of possible flags for blocking mode of the socket.
TSocketDataEvent (see page 1505)	This is type Sockets.TSocketDataEvent.
TSocketErrorEvent (see page 1505)	This is type Sockets.TSocketErrorEvent.
TSocketHost (see page 1506)	This is type Sockets.TSocketHost.
TSocketNotifyEvent (see page 1506)	This is type Sockets.TSocketNotifyEvent.
TSocketPort (see page 1506)	This is type Sockets.TSocketPort.
TSocketProtocol (see page 1507)	TSocketProtocol is the code for a socket protocol.

24.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ESocketError (see page 1369)	Exception (see page 3949) class for failures that occur when trying to create, use, or shut down Windows socket objects.
	TBaseSocket (see page 1370)	TBaseSocket encapsulates local operations on file descriptors.
	TClientSocketThread (see page 1396)	Enables creation of separate threads of execution for the client socket in an application.
	TCustomIpClient (see page 1400)	Encapsulates the client network functions.
	TCustomTcpServer (see page 1406)	Ancestor object of all the server socket descendants.
	TIpSocket (see page 1416)	Encapsulates the network support functions.
	TRawSocket (see page 1431)	Encapsulates a raw socket.
	TServerSocketThread (see page 1433)	Enables creation of separate threads of execution for the server socket in an application.
	TTcpClient (see page 1439)	TCP client component.
	TTcpServer (see page 1459)	TTcpServer is the TCP server component.
	TUdpSocket (see page 1477)	UDP component.

24.1.1 ESocketError Class

Exception (see page 3949) class for failures that occur when trying to create, use, or shut down Windows socket objects.

Class Hierarchy

Pascal

```
ESocketError = class(Exception);
```

C++

```
class ESocketError : public Exception;
```

File

Sockets

Description

ESocketError is the exception class for failures that occur when trying to create, use, or shut down Windows socket objects.

ESocketError is thrown if:

A socket cannot be created.

A socket cannot be initialized.

A socket cannot be opened.

An application tries to change the properties of an already open socket.

A failure occurs when reading from or writing to a socket.

A socket cannot be properly closed.

There are two ESocketError classes defined, one in the ScktComp (see page 11) unit and one in the Sockets (see page 1367) unit. The two exception classes are identically defined and serve the same function for different categories of socket objects. The two definitions occur simply to ensure that ESocketError is defined for all socket objects.

See Also

TCustomWinSocket (see page 64)

24.1.2 TBaseSocket Class

TBaseSocket encapsulates local operations on file descriptors.

Class Hierarchy

Pascal

```
TBaseSocket = class(TComponent);
```

C++

```
class TBaseSocket : public TComponent;
```

File

Sockets

Description

The TBaseSocket component encapsulates local operations on files descriptors, which are objects that a program uses to read from or write to an open file, or open a network socket or a variety of other devices.

Do not create instances of TBaseSocket. Use TBaseSocket as a base class when declaring non-visual components that can appear on the component palette and be used in the form designer. Properties and methods of TBaseSocket provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TIpSocket (see page 1416)

24.1.2.1 TBaseSocket Members

The following tables list the members exposed by TBaseSocket.

Protected Methods

	Name	Description
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
V	Close (see page 1373)	Shuts down the socket connection.
V	Create (see page 1371)	Creates an instance of TBaseSocket (see page 1370).
V	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
V	Open (see page 1375)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1385)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	SockType (see page 1387)	Sets or returns the socket type.

24.1.2.2 TBaseSocket.Create Constructor

Creates an instance of TBaseSocket (see page 1370).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBaseSocket(TComponent * AOwner);
```

Description

For C++, call Create indirectly, using the **new** keyword, to instantiate a TBaseSocket (see page 1370) object.

See Also

TBaseSocket (see page 1370)

24.1.2.3 TBaseSocket.Destroy Destructor

Frees the memory associated with the TBaseSocket (see page 1370) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBaseSocket();
```

Description

For C++, do not call ~TBaseSocket (see page 1370) directly. Instead, use the **delete** keyword on the object, which causes ~TBaseSocket (see page 1370) to be invoked automatically.

See Also

delete

TBaseSocket (see page 1370)

24.1.2.4 TBaseSocket Methods

The methods of the TBaseSocket class are listed here.

Protected Methods

	Name	Description
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Methods

	Name	Description
	Close (see page 1373)	Shuts down the socket connection.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
	Open (see page 1375)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

24.1.2.4.1 TBaseSocket.Close Method

Shuts down the socket connection.

Pascal

```
procedure Close; virtual;
```

C++

```
virtual __fastcall Close();
```

Description

Call Close to shut down the socket connection. Close sets the Active (see page 1383) property to **false**.

For client sockets, Close terminates the connection to the server. For server sockets, Close shuts down the connection so that the server socket is no longer listening for client requests.

See Also

Active (see page 1383)

Open (see page 1375)

24.1.2.4.2 TBaseSocket.DoCreateHandle Method

Pascal

```
procedure DoCreateHandle; dynamic;
```

C++

```
__fastcall DoCreateHandle();
```

Description

This is DoCreateHandle, a member of class TBaseSocket.

24.1.2.4.3 TBaseSocket.DoDestroyHandle Method

Pascal

```
procedure DoDestroyHandle; dynamic;
```

C++

```
__fastcall DoDestroyHandle();
```

Description

This is DoDestroyHandle, a member of class TBaseSocket.

24.1.2.4.4 TBaseSocket.DoHandleError Method

Pascal

```
procedure DoHandleError; dynamic;
```

C++

```
__fastcall DoHandleError();
```

Description

This is DoHandleError, a member of class TBaseSocket.

24.1.2.4.5 TBaseSocket.DoReceive Method

Pascal

```
procedure DoReceive(Buf: pchar; var DataLen: Integer); virtual;
```

C++

```
virtual __fastcall DoReceive(const char * Buf, int DataLen);
```

Description

This is DoReceive, a member of class TBaseSocket.

24.1.2.4.6 TBaseSocket.DoSend Method

Pascal

```
procedure DoSend(Buf: pchar; var DataLen: Integer); virtual;
```

C++

```
virtual __fastcall DoSend(const char * Buf, int DataLen);
```

Description

This is DoSend, a member of class TBaseSocket.

24.1.2.4.7 TBaseSocket.ErrorCheck Method

Pascal

```
function ErrorCheck(rc: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int ErrorCheck(int rc);
```

Description

This is ErrorCheck, a member of class TBaseSocket.

24.1.2.4.8 TBaseSocket.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling

pointers can be used after being streamed in.

As implemented in TComponent, Loaded clears the csLoading flag in the ComponentState property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

See Also

ComponentState

Create

TReader

24.1.2.4.9 TBaseSocket.MapDomain Method

Maps the domain.

Pascal

```
function MapDomain(sd: TSocketDomain): Integer;
```

C++

```
__fastcall int MapDomain(TSocketDomain sd);
```

Description

MapDomain maps the socket domain to an integer based on the value supplied by the Domain (see page 1386) property.

See Also

Domain (see page 1386)

MapSockType (see page 1375)

24.1.2.4.10 TBaseSocket.MapSockType Method

Maps the socket type.

Pascal

```
function MapSockType(st: TSocketType): Integer;
```

C++

```
__fastcall int MapSockType(TSocketType st);
```

Description

MapSockType maps the socket type to an integer based on the value supplied by the SockType (see page 1387) property.

See Also

SockType (see page 1387)

24.1.2.4.11 TBaseSocket.Open Method

Creates the socket connection.

Pascal

```
procedure Open; virtual;
```

C++

```
virtual __fastcall Open();
```

Description

Call Open to create the socket connection. Descendants of TBaseSocket (see page 1370) use Open to initiate the socket connection.

For client sockets, Open locates and connects to a server. For server sockets, Open opens the socket connection in a listening mode, but does not complete the connection to a client socket.

See Also

TBaseSocket (see page 1370)

Active (see page 1383)

Close (see page 1373)

24.1.2.4.12 TBaseSocket.PeekBuf Method

Reads the buffer.

Pascal

```
function PeekBuf(var Buf; BufSize: Integer): Integer;
```

C++

```
__fastcall int PeekBuf( Buf, int BufSize);
```

Description

Use PeekBuf to make a copy of data waiting in the socket buffer. Use the **Buf** parameter to assign a variable to the buffer, and use **Bufsize** to set the size of the buffer to be copied. PeekBuf only copies, but does not otherwise affect the contents of the buffer.

See Also

ReceiveBuf (see page 1376)

SendBuf (see page 1380)

24.1.2.4.13 TBaseSocket.ReceiveBuf Method

Reads data buffers to the socket.

Pascal

```
function ReceiveBuf(var Buf; BufSize: Integer; Flags: Integer = 0): Integer;
```

C++

```
__fastcall int ReceiveBuf( Buf, int BufSize, int Flags = 0);
```

Description

ReceiveBuf reads data buffers of size **bufsize** to the socket. Use **buf** to assign a variable to the buffer, and use **bufsize** to set the size of the buffer to be read. The **flags** argument can be any of the flags used by the Linux **recv** function. Refer to recv(2) in the Linux manual pages for more information.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
```

```
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;
```

```
procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

See Also

PeekBuf (see page 1376)

SendBuf (see page 1380)

24.1.2.4.14 TBaseSocket.ReceiveIn Method

Reads delimited lines of data from the socket.

Pascal

```
function Receiveln(const eol: string = CRLF): string;
```

C++

```
__fastcall UnicodeString Receiveln(const UnicodeString eol = CRLF);
```

Description

Receiveln reads a delimited chunk of data from the socket. The **delimeter** cannot be part of the character set. Receiveln fills the buffer until it reaches the **delimeter**.

See Also

Sendln (see page 1380)

OnReceive (see page 1393)

24.1.2.4.15 TBaseSocket.Select Method

Tests for socket activity.

Pascal

```
function Select(ReadReady: PBoolean; WriteReady: PBoolean; ExceptFlag: PBoolean; TimeOut:
Integer = 0): Boolean;
```

C++

```
__fastcall Boolean Select(PBoolean ReadReady, PBoolean WriteReady, PBoolean ExceptFlag, int
TimeOut = 0);
```

Description

Use Select to test for socket activity. Select indicates whether there is any data on the socket waiting to be sent or whether an error condition exists.

The parameter **TimeOut** is the time-out value. The socket waits for activity up to **TimeOut** milliseconds before returning. If **TimeOut** is not explicitly specified, the default value is zero. If **TimeOut** is any negative number, the socket is blocked. It waits for activity indefinitely, which can be useful for servers.

See Also

WaitForData (see page 1383)

24.1.2.4.16 TBaseSocket.SendBuf Method

Writes data buffers of size bufsize from the socket.

Pascal

```
function SendBuf(var Buf; BufSize: Integer; Flags: Integer = 0): Integer;
```

C++

```
__fastcall int SendBuf( Buf, int BufSize, int Flags = 0);
```

Description

SendBuf sends data buffers of size **bufsize** to the socket. Use **buf** to assign a variable to the buffer, and use **bufsize** to set the size of the buffer to be sent. The flags argument can be any of the flags used by the Linux **send** function. Refer to the send Linux manual page for more information.

See Also

PeekBuf (see page 1376)

ReceiveBuf (see page 1376)

24.1.2.4.17 TBaseSocket.SendIn Method

Writes delimited lines of data to the socket.

Pascal

```
function Sendln(s: string; const eol: string = CRLF): Integer;
```

C++

```
__fastcall int Sendln(UnicodeString s, const UnicodeString eol = CRLF);
```

Description

Sendln sends a delimited chunk of data to the socket. The **delimeter** cannot be part of the character set. Sendln fills the buffer until it reaches the **delimeter**.

See Also

Receiveln (see page 1379)

OnReceive (see page 1393)

24.1.2.4.18 TBaseSocket.SendStream Method

Writes a stream of data to the socket.

Pascal

```
function SendStream(AStream: TStream): Integer;
```

C++

```
__fastcall int SendStream(TStream AStream);
```

Description

SendStream sends a stream of data to the socket.

C++ Examples:

```
/*
```

```
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
```

```
    myStream := TMemoryStream.Create();
    for I := 0 to 8 do
    begin
      myStream.WriteBuffer(I,1);
    end;
    userValue := StrToIntDef(Edit1.Text, 0);
    myStream.WriteBuffer(userValue,1);

    //resetting the stream position
    myStream.Seek(0,0);

    //sending the stream
    TcpClient1.Active := true;
    TcpClient1.SendStream(myStream);
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

See Also

OnReceive (see page 1393)

24.1.2.4.19 TBaseSocket.SetBytesReceived Method

Pascal

```
procedure SetBytesReceived(Value: Cardinal);
```

C++

```
__fastcall SetBytesReceived(unsigned Value);
```

Description

This is SetBytesReceived, a member of class TBaseSocket.

24.1.2.4.20 TBaseSocket.SetBytesSent Method

Pascal

```
procedure SetBytesSent(Value: Cardinal);
```

C++

```
__fastcall SetBytesSent(unsigned Value);
```

Description

This is SetBytesSent, a member of class TBaseSocket.

24.1.2.4.21 TBaseSocket.WaitForData Method

Waits for the socket connection to be ready to transfer data.

Pascal

```
function WaitForData(TimeOut: Integer = 0): Boolean;
```

C++

```
__fastcall Boolean WaitForData(int TimeOut = 0);
```

Description

Call WaitForData to ensure that the socket connection is ready to read or write information. WaitForData returns **true** if the socket connection is ready. WaitForData returns **false** if the socket connection is not ready after **TimeOut** milliseconds elapse.

Call WaitForData before reading or writing information over the socket connection. Otherwise, ReceiveBuf (see page 1376), ReceiveIn (see page 1379), SendBuf (see page 1380), and SendIn (see page 1380) method calls may time out before any data is transferred.

See Also

ReceiveBuf (see page 1376)

ReceiveIn (see page 1379)

SendBuf (see page 1380)

SendIn (see page 1380)

24.1.2.5 TBaseSocket Properties

The properties of the TBaseSocket class are listed here.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1385)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	SockType (see page 1387)	Sets or returns the socket type.

24.1.2.5.1 TBaseSocket.Active Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before attempting to use or change the socket connection, read Active to determine whether the connection is open and ready. For client sockets, setting Active opens or shuts down a socket connection to another machine. For server sockets, setting Active opens or shuts down a listening connection that makes the socket available for client requests.

At design time, set Active to **true** to make the socket open a connection when the application starts running (the default value is false). At runtime, use the Open (see page 1375) or Close (see page 1373) method to open or close the connection.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
```

```
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

See Also

Close (see page 1373)

Open (see page 1375)

24.1.2.5.2 TBaseSocket.BlockMode Property

Sets or returns the blocking mode of the socket.

Pascal

```
property BlockMode: TSocketBlockMode;
```

C++

```
__property TSocketBlockMode BlockMode;
```

Description

Use BlockMode to set or return the blocking mode for the socket. By default, the socket is set to bmBlocking.

The TSocketBlockMode (see page 1505) type defines the set of possible socket flags for the BlockMode property.

See Also

TSocketBlockMode (see page 1505)

OnReceive (see page 1393)

OnSend (see page 1394)

24.1.2.5.3 TBaseSocket.BytesReceived Property

Returns the number of bytes received by the socket.

Pascal

```
property BytesReceived: Cardinal;
```

C++

```
__property unsigned BytesReceived;
```

Description

BytesReceived returns the number of bytes received by the socket.

See Also

BytesSent (see page 1386)

24.1.2.5.4 TBaseSocket.BytesSent Property

Returns the number of bytes sent from the socket.

Pascal

```
property BytesSent: Cardinal;
```

C++

```
__property unsigned BytesSent;
```

Description

BytesSent returns the number of bytes sent from the socket.

See Also

BytesReceived (see page 1386)

24.1.2.5.5 TBaseSocket.Domain Property

Sets or returns the protocol family used by the socket.

Pascal

```
property Domain: TSocketDomain;
```

C++

```
__property TSocketDomain Domain;
```

Description

Use Domain to set or return the protocol family used by the socket. The TSocketDomain (see page 1500) type defines the set of possible protocol family types for the Domain property. The default value of this property is pfUnspec.

See Also

MapDomain (see page 1375)

TSocketDomain (see page 1500)

24.1.2.5.6 TBaseSocket.Handle Property

Provides access to the unique-4 byte identifier that represents the instance of the socket object.

Pascal

```
property Handle: TSocket;
```

C++

```
__property TSocket Handle;
```

Description

Use Handle to return a typed pointer to the instance of the socket class. This Handle can be used when making low level function calls into the QT shared libraries, where the function call requires an instance pointer to the object.

24.1.2.5.7 TBaseSocket.Protocol Property

Sets or returns the protocol used by the socket.

Pascal

```
property Protocol: TSocketProtocol;
```

C++

```
__property TSocketProtocol Protocol;
```

Description

Protocol sets or returns the protocol used by the socket. The socket protocol can be IP, TCP, UDP, or other network protocols.

See Also

TTcpServer (see page 1459)

24.1.2.5.8 TBaseSocket.SockType Property

Sets or returns the socket type.

Pascal

```
property SockType: TSocketType;
```

C++

```
__property TSocketType SockType;
```

Description

SockType sets or returns the type of socket connection.

The TSocketType (see page 1502) type defines the set of possible socket types for the SockType property.

See Also

TSocketType (see page 1502)

24.1.2.6 TBaseSocket Events

The events of the TBaseSocket class are listed here.

Public Events

	Name	Description
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

24.1.2.6.1 TBaseSocket.OnCreateHandle Event

Occurs when the handle to a socket becomes active.

Pascal

```
property OnCreateHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnCreateHandle;
```

Description

Write (see page 3707) an OnCreateHandle event handler to take specific action when the handle to a socket becomes active.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
```

```
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;
```

```
procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

See Also

Active (see page 1383)

Handle (see page 1387)

24.1.2.6.2 TBaseSocket.OnDestroyHandle Event

Occurs when a socket is deactivated.

Pascal

```
property OnDestroyHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDestroyHandle;
```

Description

Write (see page 3707) an OnDestroyHandle event handler to take specific action when the socket is deactivated.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
```

```
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
```

```
    begin
      Memo1.Lines.Add(IntToStr(a[I] + a[9]));
    end;
    Memo1.Lines.Add('--------------------');

  end;

  procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
  end;

  procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
  begin
    if Self.Memo1 <> nil then
      Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
  end;
```

24.1.2.6.3 TBaseSocket.OnError Event

Occurs when the socket fails in making, using, or shutting down a connection.

Pascal

```
property OnError: TSocketErrorEvent;
```

C++

```
__property TSocketErrorEvent OnError;
```

Description

Write (see page 3707) an OnError event handler to respond to errors that arise with the socket connection. Set the **ErrorCode** parameter to 0 if the OnError event handler successfully deals with the error condition, to prevent an ESocketError (see page 1369) exception from being raised.

See Also

ESocketError (see page 1369)

24.1.2.6.4 TBaseSocket.OnReceive Event

Occurs after a socket receives data, but before it passes the data to the application.

Pascal

```
property OnReceive: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnReceive;
```

Description

Write (see page 3707) an OnReceive event handler to read from the socket connection. Use the OnReceive event to filter data before passing it back to the client application. If the socket is a blocking socket, use a TWinSocketStream object to read from the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual reading.

See Also

TWinSocketStream (see page 138)

BytesReceived (see page 1386)

ReceiveBuf (see page 1376)

ReceiveIn (see page 1379)

24.1.2.6.5 TBaseSocket.OnSend Event

Occurs just before a client socket writes information to the socket connection.

Pascal

```
property OnSend: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnSend;
```

Description

Write (see page 3707) an OnSend event handler to perform actions just prior to sending data. Use OnSend to monitor the data stream and change it (for example, by removing linefeeds). If the socket is a blocking socket, use a TWinSocketStream object to write to the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual writing.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------
```

```
void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

See Also

TWinSocketStream (see page 138)

SendBuf (see page 1380)

SendIn (see page 1380)

24.1.3 TClientSocketThread Class

Enables creation of separate threads of execution for the client socket in an application.

Class Hierarchy

Pascal

```
TClientSocketThread = class(TThread);
```

C++

```
class TClientSocketThread : public TThread;
```

File

Sockets

Description

Create (see page 1397) a TClientSocketThread (or a descendant of the class) to represent an execution thread for the client socket in a multi-threaded application. Each new instance of TClientSocketThread, a TThread descendant, is a new thread of execution. Using a separate TClientSocketThread allows the client socket to block without blocking the whole application.

See Also

Writing Multi-threaded Applications

TServerSocketThread (see page 1433)

TThread

24.1.3.1 TClientSocketThread Members

The following tables list the members exposed by TClientSocketThread.

Protected Methods

	Name	Description
	SyncProc (see page 1398)	Method where data synchronization is actually performed.

Public Methods

	Name	Description
	Create (see page 1397)	Creates an instance of a TClientSocketThread (see page 1396) object.
	Destroy (see page 1397)	Destroys the thread object and releases the memory allocated to it.
	Execute (see page 1398)	Executes when the thread is run.
	ExecuteSyncProc (see page 1398)	Synchronizes data between threads.

Public Properties

	Name	Description
	ClientSocket (see page 1399)	Refers to the client socket handling the connection in that thread.
	ServerSocketThread (see page 1399)	Specifies the server socket's thread.

24.1.3.2 TClientSocketThread.Create Constructor

Creates an instance of a TClientSocketThread (see page 1396) object.

Pascal

```
constructor Create(ServerSocketThread: TServerSocketThread);
```

C++

```
__fastcall TClientSocketThread(TServerSocketThread ServerSocketThread);
```

Description

For C++, call Create indirectly, using the **new** keyword, to create a thread in an application. If the **CreateSuspended** parameter is false, Execute (see page 1398) is called immediately. If **CreateSuspended** is true, Execute (see page 1398) is not called until after Resume is called.

See Also

TClientSocketThread (see page 1396)

Destroy (see page 1397)

Execute (see page 1398)

Resume

24.1.3.3 TClientSocketThread.Destroy Destructor

Destroys the thread object and releases the memory allocated to it.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TClientSocketThread();
```

Description

For C++, do not call Destroy in an application. Instead, use the **delete** keyword to destroy a thread when FreeOnTerminate is false.

See Also

delete

Create

FreeOnTerminate

24.1.3.4 TClientSocketThread Methods

The methods of the TClientSocketThread class are listed here.

Protected Methods

	Name	Description
	SyncProc (see page 1398)	Method where data synchronization is actually performed.

Public Methods

	Name	Description
	Execute (see page 1398)	Executes when the thread is run.
	ExecuteSyncProc (see page 1398)	Synchronizes data between threads.

24.1.3.4.1 TClientSocketThread.Execute Method

Executes when the thread is run.

Pascal

```
procedure Execute; override;
```

C++

```
virtual __fastcall Execute();
```

Description

Use Execute to execute the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated property to determine if the thread needs to exit.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize method.

See Also

Terminated

Synchronize

24.1.3.4.2 TClientSocketThread.ExecuteSyncProc Method

Synchronizes data between threads.

Pascal

```
procedure ExecuteSyncProc;
```

C++

```
__fastcall ExecuteSyncProc();
```

Description

Objects in the client socket thread should not directly manipulate data in the main thread. Attempting to do so will cause synchronization problems and, most likely, the application will crash. To avoid synchronization errors, override the SyncProc (see page 1398) method to include instructions that must be executed by the main thread.

See Also

Synchronize

SyncProc (see page 1398)

24.1.3.4.3 TClientSocketThread.SyncProc Method

Method where data synchronization is actually performed.

Pascal

```
procedure SyncProc; virtual;
```

C++

```
virtual __fastcall SyncProc();
```

Description

In subclasses of TClientSocketThread (see page 1396), override SyncProc to perform synchronization between threads. Put code in it to be executed by the main thread.

Warning: Do not call this protected method directly; instead, call ExecuteSyncProc (see page 1398).

See Also

TClientSocketThread (see page 1396)

ExecuteSyncProc (see page 1398)

Synchronize

24.1.3.5 TClientSocketThread Properties

The properties of the TClientSocketThread class are listed here.

Public Properties

	Name	Description
R	ClientSocket (see page 1399)	Refers to the client socket handling the connection in that thread.
R	ServerSocketThread (see page 1399)	Specifies the server socket's thread.

24.1.3.5.1 TClientSocketThread.ClientSocket Property

Refers to the client socket handling the connection in that thread.

Pascal

```
property ClientSocket: TCustomIpClient;
```

C++

```
__property TCustomIpClient ClientSocket;
```

Description

Use ClientSocket to obtain access to the client socket object handling the connection in the current thread of execution.

See Also

TCustomIpClient (see page 1400)

24.1.3.5.2 TClientSocketThread.ServerSocketThread Property

Specifies the server socket's thread.

Pascal

```
property ServerSocketThread: TServerSocketThread;
```

C++

```
__property TServerSocketThread ServerSocketThread;
```

Description

Use ServerSocketThread get access to the thread object of the server socket.

See Also

TServerSocketThread (see page 1433)

24.1.4 TCustomIpClient Class

Encapsulates the client network functions.

Class Hierarchy

Pascal

```
TCustomIpClient = class(TIpSocket);
```

C++

```
class TCustomIpClient : public TIpSocket;
```

File

Sockets

Description

TCustomIpClient encapsulates the client network functions, linking sockets to network protocols such as TCP/IP and UDP, as well as raw sockets and custom protocols. Do not create instances of TCustomIpClient. Use TCustomIpClient as a base class when declaring non-visual components that can appear on the component palette and be used in the form designer. Properties and methods of TCustomIpClient provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TBaseSocket (see page 1370)

24.1.4.1 TCustomIpClient Members

The following tables list the members exposed by TCustomIpClient.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
V	DoConnect (see page 1403)	This is DoConnect, a member of class TCustomIpClient.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
V	DoDisconnect (see page 1404)	This is DoDisconnect, a member of class TCustomIpClient.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
V	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
V	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
V	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
V	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnConnect (see page 1405)	Occurs on client sockets just after the connection to the server is opened.
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnDisconnect (see page 1406)	Occurs on client sockets just after the connection to the server is closed.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
V	Close (see page 1402)	Shuts down the socket connection.
	Connect (see page 1403)	Connects the local socket to the remote socket.
V	Create (see page 1402)	Creates an instance of TCustomIpClient (see page 1400).
V	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	Disconnect (see page 1403)	Disconnects the local socket from the remote socket.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	GetThreadObject (see page 1404)	Returns a reference to the TThread object for the currently executing thread.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
V	Open (see page 1404)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1385)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
R	Connected (see page 1405)	Indicates whether the socket connection is open and available for communication with other machines.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	LocalHost (see page 1423)	Specifies the name of the local system.

	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.
	SockType (see page 1387)	Sets or returns the socket type.

24.1.4.2 TCustomIpClient.Create Constructor

Creates an instance of TCustomIpClient (see page 1400).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomIpClient(TComponent * AOwner);
```

Description

For C++, call Create indirectly, using the **new** keyword, to instantiate a TCustomIpClient (see page 1400) object.

See Also

Destroy (see page 1372)

24.1.4.3 TCustomIpClient Methods

The methods of the TCustomIpClient class are listed here.

Protected Methods

	Name	Description
	DoConnect (see page 1403)	This is DoConnect, a member of class TCustomIpClient.
	DoDisconnect (see page 1404)	This is DoDisconnect, a member of class TCustomIpClient.

Public Methods

	Name	Description
	Close (see page 1402)	Shuts down the socket connection.
	Connect (see page 1403)	Connects the local socket to the remote socket.
	Disconnect (see page 1403)	Disconnects the local socket from the remote socket.
	GetThreadObject (see page 1404)	Returns a reference to the TThread object for the currently executing thread.
	Open (see page 1404)	Creates the socket connection.

24.1.4.3.1 TCustomIpClient.Close Method

Shuts down the socket connection.

Pascal

```
procedure Close; override;
```

C++

```
virtual __fastcall Close();
```

Description

Call Close to shut down the socket connection. This method performs the same functions as Disconnect (see page 1403).

See Also

Disconnect (see page 1403)

Open (see page 1404)

Active (see page 1383)

24.1.4.3.2 TCustomIpClient.Connect Method

Connects the local socket to the remote socket.

Pascal

```
function Connect: Boolean;
```

C++

```
__fastcall Boolean Connect();
```

Description

Call Connect to connect the local socket to the remote socket.

See Also

Connected (see page 1405)

Close (see page 1402)

Disconnect (see page 1403)

24.1.4.3.3 TCustomIpClient.Disconnect Method

Disconnects the local socket from the remote socket.

Pascal

```
procedure Disconnect;
```

C++

```
__fastcall Disconnect();
```

Description

Call Disconnect to break the connection between the local and remote sockets. This method performs the same function as Close (see page 1402).

See Also

Connected (see page 1405)

Close (see page 1402)

Connect (see page 1403)

24.1.4.3.4 TCustomIpClient.DoConnect Method

Pascal

```
procedure DoConnect; virtual;
```

C++

```
virtual __fastcall DoConnect();
```

Description

This is DoConnect, a member of class TCustomIpClient.

24.1.4.3.5 TCustomIpClient.DoDisconnect Method

Pascal

```
procedure DoDisconnect; virtual;
```

C++

```
virtual __fastcall DoDisconnect();
```

Description

This is DoDisconnect, a member of class TCustomIpClient.

24.1.4.3.6 TCustomIpClient.GetThreadObject Method

Returns a reference to the TThread object for the currently executing thread.

Pascal

```
function GetThreadObject: TClientSocketThread;
```

C++

```
__fastcall TClientSocketThread GetThreadObject();
```

Description

Call GetThreadObject to obtain a reference to the currently executing thread. GetThreadObject is only useful when BlockMode (see page 1385) is set to **bmBlockingMode**, which means that the client is executing in its own thread. If this method is called from the main application thread, the value NULL is returned.

See Also

TThread

BlockMode (see page 1385)

24.1.4.3.7 TCustomIpClient.Open Method

Creates the socket connection.

Pascal

```
procedure Open; override;
```

C++

```
virtual __fastcall Open();
```

Description

Call Open to create and initiate the socket connection.

For client sockets, Open locates and connects to a server. For server sockets, Open opens the socket connection in a listening mode, but does not complete the connection to a client socket.

See Also

Active (see page 1383)

Close (see page 1402)

24.1.4.4 TCustomIpClient Properties

The properties of the TCustomIpClient class are listed here.

Public Properties

	Name	Description
	Connected (see page 1405)	Indicates whether the socket connection is open and available for communication with other machines.

24.1.4.4.1 TCustomIpClient.Connected Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Connected: Boolean;
```

C++

```
__property Boolean Connected;
```

Description

Read (see page 3634) Connected before trying to use or change the socket connection. Connected indicates whether the socket connection has been established. When Connected is **true**, the socket is open and available for use. When Connected is **false**, the socket is closed and can be changed.

To open a socket, use the Open (see page 1404) method. To close a socket, use the Closemethod.

See Also

Close (see page 1402)

Open (see page 1404)

OnConnect (see page 1405)

24.1.4.5 TCustomIpClient Events

The events of the TCustomIpClient class are listed here.

Public Events

	Name	Description
	OnConnect (see page 1405)	Occurs on client sockets just after the connection to the server is opened.
	OnDisconnect (see page 1406)	Occurs on client sockets just after the connection to the server is closed.

24.1.4.5.1 TCustomIpClient.OnConnect Event

Occurs on client sockets just after the connection to the server is opened.

Pascal

```
property OnConnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnConnect;
```

Description

Write (see page 3707) an OnConnect event handler for a client socket to take specific action after the connection to a server socket has been established. Depending on the service, this may be the point when the socket should start reading or writing over the connection.

See Also

Connected (see page 1405)

OnDisconnect (see page 1406)

24.1.4.5.2 TCustomIpClient.OnDisconnect Event

Occurs on client sockets just after the connection to the server is closed.

Pascal

```
property OnDisconnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDisconnect;
```

Description

Write (see page 3707) an OnDisconnect event handler for a client socket to take specific action just after the connection to a server socket is terminated.

See Also

Connected (see page 1405)

OnConnect (see page 1405)

24.1.5 TCustomTcpServer Class

Ancestor object of all the server socket descendants.

Class Hierarchy

Pascal

```
TCustomTcpServer = class(TIpSocket);
```

C++

```
class TCustomTcpServer : public TIpSocket;
```

File

Sockets

Description

Do not create instances of TCustomTcpServer. Use TCustomTcpServer as a base class when declaring non-visual components that can appear on the component palette and be used in the form designer. Properties and methods of TCustomTcpServer provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

24.1.5.1 TCustomTcpServer Members

The following tables list the members exposed by TCustomTcpServer.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
V	DoAccept (see page 1410)	This is DoAccept, a member of class TCustomTcpServer.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
V	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
V	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
V	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
	Listen (see page 1410)	This is Listen, a member of class TCustomTcpServer.
V	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnAccept (see page 1413)	Occurs on server sockets just after the connection to a client socket is accepted.
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnGetThread (see page 1415)	A wrapper for the TServerSocketThread (see page 1433) event of the same name.
	OnListening (see page 1416)	Occurs when a server socket begins listening for connections.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
	Accept (see page 1409)	This is the overview for the Accept method overload.
V	Close (see page 1410)	Shuts down the socket connection.
V	Create (see page 1408)	Creates an instance of TCustomTcpServer (see page 1406).
V	Destroy (see page 1408)	Frees the memory associated with the TCustomTcpServer (see page 1406) object.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
V	Open (see page 1411)	Opens the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.

	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendLn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForConnection (see page 1411)	Listens for TCP connections.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1411)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
R	Listening (see page 1412)	Sets the server application to listen for client requests.
	LocalHost (see page 1423)	Specifies the name of the local system.
	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.
	ServerSocketThread (see page 1412)	Specifies the TServerSocketThread (see page 1433) in use.
	SockType (see page 1387)	Sets or returns the socket type.

24.1.5.2 TCustomTcpServer.Create Constructor

Creates an instance of TCustomTcpServer (see page 1406).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomTcpServer(TComponent * AOwner);
```

Description

For C++, call Create indirectly, using the **new** keyword, to instantiate a TCustomTcpServer (see page 1406) object.

See Also

TCustomTcpServer (see page 1406)

Destroy (see page 1408)

24.1.5.3 TCustomTcpServer.Destroy Destructor

Frees the memory associated with the TCustomTcpServer (see page 1406) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomTcpServer();
```

Description

For C++, do not call Destroy directly. Instead, use the **delete** keyword on the object, which causes Destroy to be invoked automatically.

See Also

delete

24.1.5.4 TCustomTcpServer Methods

The methods of the TCustomTcpServer class are listed here.

Protected Methods

	Name	Description
	DoAccept (see page 1410)	This is DoAccept, a member of class TCustomTcpServer.
	Listen (see page 1410)	This is Listen, a member of class TCustomTcpServer.

Public Methods

	Name	Description
	Accept (see page 1409)	This is the overview for the Accept method overload.
	Close (see page 1410)	Shuts down the socket connection.
	Open (see page 1411)	Opens the socket connection.
	WaitForConnection (see page 1411)	Listens for TCP connections.

24.1.5.4.1 Accept Method

This is the overview for the Accept method overload.

Overload List

	Name	Description
	TCustomTcpServer.Accept () (see page 1409)	Accepts a connection to a client socket.
	TCustomTcpServer.Accept (TCustomIpClient) (see page 1409)	Accepts a connection to a client socket.

24.1.5.4.1.1 TCustomTcpServer.Accept Method ()

Accepts a connection to a client socket.

Pascal

```
function Accept: Boolean; overload;
function Accept(var ClientSocket: TCustomIpClient): Boolean; overload;
```

C++

```
__fastcall Boolean Accept();
__fastcall Boolean Accept(TCustomIpClient ClientSocket);
```

Description

Accept is called automatically in response to notifications that a client socket is requesting a connection.

The Accept method for TCustomTcpServerdoes nothing with the notification. Descendants of TCustomTcpServer (see page

1406) that represent listening server sockets override this method to accept the connection to the client socket. In the second declaration of the method, a TCustomIpClient (see page 1400) object is created (as the **ClientSocket** parameter) to handle the connection.

See Also

TCustomIpClient (see page 1400)

TCustomTcpServer (see page 1406)

OnAccept (see page 1413)

24.1.5.4.2 TCustomTcpServer.Close Method

Shuts down the socket connection.

Pascal

```
procedure Close; override;
```

C++

```
virtual __fastcall Close();
```

Description

Call Close to shut down the socket connection. Close sets the Active (see page 1383) property to false.

For client sockets, Close terminates the connection to the server. For server sockets, Close shuts down the connection so that the server socket is no longer listening for client requests.

See Also

Active (see page 1383)

Open (see page 1411)

24.1.5.4.3 TCustomTcpServer.DoAccept Method

Pascal

```
procedure DoAccept(ClientSocket: TCustomIpClient); virtual;
```

C++

```
virtual __fastcall DoAccept(TCustomIpClient ClientSocket);
```

Description

This is DoAccept, a member of class TCustomTcpServer.

24.1.5.4.4 TCustomTcpServer.Listen Method

Pascal

```
function Listen(backlog: Integer = SOMAXCONN): Boolean;
```

C++

```
__fastcall Boolean Listen(int backlog = SOMAXCONN);
```

Description

This is Listen, a member of class TCustomTcpServer.

24.1.5.4.5 TCustomTcpServer.Open Method

Opens the socket connection.

Pascal

```
procedure Open; override;
```

C++

```
virtual __fastcall Open();
```

Description

Call Open to initiate the socket connection. Open sets the Active (see page 1383) property to true.

For client sockets, Open locates and connects to a server. For server sockets, Open opens the socket connection in a listening mode, but does not complete the connection to a client socket.

See Also

Active (see page 1383)

Close (see page 1410)

24.1.5.4.6 TCustomTcpServer.WaitForConnection Method

Listens for TCP connections.

Pascal

```
function WaitForConnection: Boolean;
```

C++

```
__fastcall Boolean WaitForConnection();
```

Description

Call WaitForConnection to listen for TCP connections on the port specified by the LocalPort (see page 1424) property. The thread will block until a connection request is received.

See Also

LocalPort (see page 1424)

Accept (see page 1409)

24.1.5.5 TCustomTcpServer Properties

The properties of the TCustomTcpServer class are listed here.

Public Properties

	Name	Description
	BlockMode (see page 1411)	Sets or returns the blocking mode of the socket.
R	Listening (see page 1412)	Sets the server application to listen for client requests.
	ServerSocketThread (see page 1412)	Specifies the TServerSocketThread (see page 1433) in use.

24.1.5.5.1 TCustomTcpServer.BlockMode Property

Sets or returns the blocking mode of the socket.

Pascal

```
property BlockMode: TServerSocketBlockMode;
```

C++

```
__property TServerSocketBlockMode BlockMode;
```

Description

Use BlockMode to set or return the blocking mode for the socket. By default, the socket is set to bmThreadBlocking.

The TServerSocketBlockMode (see page 1500) type defines the set of possible socket flags for the BlockMode property.

See Also

OnReceive (see page 1393)

OnSend (see page 1394)

TServerSocketBlockMode (see page 1500)

24.1.5.5.2 TCustomTcpServer.Listening Property

Sets the server application to listen for client requests.

Pascal

```
property Listening: Boolean;
```

C++

```
__property Boolean Listening;
```

Description

Listening sets the server application to listen for client requests.

24.1.5.5.3 TCustomTcpServer.ServerSocketThread Property

Specifies the TServerSocketThread (see page 1433) in use.

Pascal

```
property ServerSocketThread: TServerSocketThread;
```

C++

```
__property TServerSocketThread ServerSocketThread;
```

Description

ServerSocketThread is a reference to the server socket thread object.

See Also

TServerSocketThread (see page 1433)

Listening (see page 1412)

24.1.5.6 TCustomTcpServer Events

The events of the TCustomTcpServer class are listed here.

Public Events

	Name	Description
	OnAccept (see page 1413)	Occurs on server sockets just after the connection to a client socket is accepted.
	OnGetThread (see page 1415)	A wrapper for the TServerSocketThread (see page 1433) event of the same name.
	OnListening (see page 1416)	Occurs when a server socket begins listening for connections.

24.1.5.6.1 TCustomTcpServer.OnAccept Event

Occurs on server sockets just after the connection to a client socket is accepted.

Pascal

```
property OnAccept: TSocketAcceptEvent;
```

C++

```
__property TSocketAcceptEvent OnAccept;
```

Description

Write (see page 3707) an OnAccept event handler for a server socket to take specific action after the connection to a client socket has been accepted. This is the first point when information is available about the local port and IP address that is used in the server endpoint of the connection. The port number, and possibly the IP address, differs from those of the listening socket.

Server sockets open a socket connection for listening to establish a queue to hold client requests. After a request from the queue is accepted by the server socket, an OnAccept event occurs. After the server socket accepts the connection, the client socket completes the connection, and an OnConnect event occurs for the client socket.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");
```

```
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;
```

```
procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

See Also

Active (see page 1383)

OnConnect (see page 1405)

OnListening (see page 1416)

24.1.5.6.2 TCustomTcpServer.OnGetThread Event

A wrapper for the TServerSocketThread (see page 1433) event of the same name.

Pascal

```
property OnGetThread: TGetThreadEvent;
```

C++

```
__property TGetThreadEvent OnGetThread;
```

Description

This event is exactly the same as the OnGetThread event of the TServerSocketThread (see page 1433) object referenced in ServerSocketThread (see page 1412).

See Also

TServerSocketThread (see page 1433)

ServerSocketThread (see page 1399)

OnGetThread (see page 1439)

24.1.5.6.3 TCustomTcpServer.OnListening Event

Occurs when a server socket begins listening for connections.

Pascal

```
property OnListening: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnListening;
```

Description

Write (see page 3707) an OnListening event to take specific action when a server begins listening for a connection.

See Also

Listening (see page 1412)

TNotifyEvent

24.1.6 TIpSocket Class

Encapsulates the network support functions.

Class Hierarchy

Pascal

```
TIpSocket = class(TBaseSocket);
```

C++

```
class TIpSocket : public TBaseSocket;
```

File

Sockets

Description

TIpSocket encapsulates the network support functions, linking sockets to network protocols such as TCP/IP and UDP, as well as raw sockets and custom protocols.

Do not create instances of TIpSocket. Use TIpSocket as a base class when declaring non-visual components that can appear on the component palette and be used in the form designer. Properties and methods of TIpSocket provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TBaseSocket (see page 1370)

24.1.6.1 TIpSocket Members

The following tables list the members exposed by TIpSocket.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
	Close (see page 1373)	Shuts down the socket connection.
	Create (see page 1418)	Creates an instance of TIpSocket (see page 1416).
	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
	Open (see page 1375)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveLn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendLn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1385)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	LocalHost (see page 1423)	Specifies the name of the local system.
	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.
	SockType (see page 1387)	Sets or returns the socket type.

24.1.6.2 TIpSocket.Create Constructor

Creates an instance of TIpSocket (see page 1416).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TIpSocket(TComponent * AOwner);
```

Description

For C++, call Create indirectly, using the **new** keyword, to instantiate a TIpSocket (see page 1416) object.

See Also

Destroy (see page 1372)

24.1.6.3 TIpSocket Methods

The methods of the TIpSocket class are listed here.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.

Public Methods

	Name	Description
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	ReceiveFrom (see page 1422)	Receives a packet of information.

	SendTo (see page 1422)	Sends a packet of information.

24.1.6.3.1 TIpSocket.Bind Method

Pascal

```
function Bind: Boolean;
```

C++

```
__fastcall Boolean Bind();
```

Description

This is Bind, a member of class TIpSocket.

24.1.6.3.2 TIpSocket.GetSocketAddr Method

Builds a valid network socket address.

Pascal

```
function GetSocketAddr(h: TSocketHost; p: TSocketPort): TSockAddr;
```

C++

```
__fastcall TSockAddr GetSocketAddr(TSocketHost h, TSocketPort p);
```

Description

Use GetSocketAddr to build a valid socket address based on the host name and port number. The **TSocketHost (see page 1506)** and **TSocketPort (see page 1506)** arguments are used to return a TSockAddr structure, which can then be passed to Connect or Bind (see page 1419).

See Also

Bind (see page 1419)

Connect (see page 1403)

LocalHostAddr (see page 1420)

LookupHostAddr (see page 1420)

RemoteHost (see page 1426)

RemotePort (see page 1428)

24.1.6.3.3 TIpSocket.LocalDomainName Method

Returns the domain name for the local host.

Pascal

```
function LocalDomainName: string;
```

C++

```
__fastcall UnicodeString LocalDomainName();
```

Description

Use LocalDomainName name to return the domain name for the local host.

See Also

LocalHostAddr (see page 1420)

LocalHostName (see page 1420)

24.1.6.3.4 TIpSocket.LocalHostAddr Method

Returns the local IP address for the host machine.

Pascal

```
function LocalHostAddr: TSocketHost;
```

C++

```
__fastcall TSocketHost LocalHostAddr();
```

Description

Use LocalHostAddr to return the local IP address in string format.

See Also

LocalHost (see page 1423)

LocalDomainName (see page 1419)

LocalHostName (see page 1420)

24.1.6.3.5 TIpSocket.LocalHostName Method

Returns the local host name.

Pascal

```
function LocalHostName: TSocketHost;
```

C++

```
__fastcall TSocketHost LocalHostName();
```

Description

Use LocalHostName to return the host name for the local host. For example:

```
ShowMessage(TcpClient1.LocalHostName);
```

See Also

LocalHost (see page 1423)

LocalDomainName (see page 1419)

LocalHostAddr (see page 1420)

24.1.6.3.6 TIpSocket.LookupHostAddr Method

Looks up the host address based on the host name.

Pascal

```
function LookupHostAddr(const hn: AnsiString): TSocketHost;
```

C++

```
__fastcall TSocketHost LookupHostAddr(const AnsiString hn);
```

Description

Use LookupHostAddr to look up the host address based on the machine's host name. For example:

```
StrToInt(TcpClient1.LookupHostAddr("borland.com"));
```

See Also

RemoteHost (see page 1426)

LookupHostName (see page 1421)

LookupPort (see page 1421)

24.1.6.3.7 TIpSocket.LookupHostName Method

Looks up the host name based on the IP address.

Pascal

```
function LookupHostName(const ipaddr: AnsiString): TSocketHost;
```

C++

```
__fastcall TSocketHost LookupHostName(const AnsiString ipaddr);
```

Description

Use LookupHostName to look up the host name based on the machine's IP address. For example:

```
TcpClient1.LookupHostName("123.60.192.10");
```

See Also

RemoteHost (see page 1426)

LookupHostAddr (see page 1420)

LookupPort (see page 1421)

24.1.6.3.8 TIpSocket.LookupPort Method

Returns the port number.

Pascal

```
function LookupPort(const sn: AnsiString; pn: PAnsiChar = nil): word;
```

C++

```
__fastcall word LookupPort(const AnsiString sn, PAnsiChar pn = nil);
```

Description

Use LookupPort to return the port number of the IP socket. The port number is related to the service name and protocol number.

For more information, refer to the home page of the Internet Assigned (see page 3524) Numbers Authority (www.iana.org), which maintains lists of port numbers and their associated protocols. Also, refer to the documentation for the application's target operating system for information on how port numbers are stored and changed in that OS.

See Also

RemotePort (see page 1428)

LookupProtocol (see page 1421)

24.1.6.3.9 TIpSocket.LookupProtocol Method

Returns the protocol number.

Pascal

```
function LookupProtocol(const pn: AnsiString): TSocketProtocol;
```

C++

```
__fastcall TSocketProtocol LookupProtocol(const AnsiString pn);
```

Description

Use LookupProtocol to return the protocol number being used by the IP socket. The protocol number is based on the protocol name.

For more information, refer to the home page of the Internet Assigned (see page 3524) Numbers Authority (www.iana.org), which maintains lists of protocol numbers and their associated protocols.

See Also

RemotePort (see page 1428)

LookupPort (see page 1421)

24.1.6.3.10 TIpSocket.ReceiveFrom Method

Receives a packet of information.

Pascal

```
function ReceiveFrom(var buf; bufsize: Integer; ToAddr: TSockAddr; var len: Integer; flags:
Integer = 0): Integer;
```

C++

```
__fastcall int ReceiveFrom( buf, int bufsize, TSockAddr ToAddr, int len, int flags = 0);
```

Description

Use ReceiveFrom to receive a single packet of information. Note that information in the packet is not checked for length, completeness, and such, which occurs at a higher level.

See Also

SendTo (see page 1422)

OnReceive (see page 1393)

24.1.6.3.11 TIpSocket.SendTo Method

Sends a packet of information.

Pascal

```
function SendTo(var buf; bufsize: Integer; ToAddr: TSockAddr; flags: Integer = 0): Integer;
```

C++

```
__fastcall int SendTo( buf, int bufsize, TSockAddr ToAddr, int flags = 0);
```

Description

Use SendTo to send a single packet of information over the network. Note that information in the packet is not checked for length, completeness, and such, which occurs at a higher level.

See Also

ReceiveFrom (see page 1422)

OnSend (see page 1394)

24.1.6.4 TIpSocket Properties

The properties of the TIpSocket class are listed here.

Public Properties

	Name	Description
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
	LocalHost (see page 1423)	Specifies the name of the local system.
	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.

24.1.6.4.1 TIpSocket.Domain Property

Sets or returns the protocol family used by the socket.

Pascal

```
property Domain: TSocketDomain;
```

C++

```
__property TSocketDomain Domain;
```

Description

Use Domain to set or return the protocol family used by the socket. The TSocketDomain type defines the set of possible protocol family types for the Domain property. The default value of this property is pfUnspec.

See Also

MapDomain (see page 1375)

TSocketDomain (see page 1500)

24.1.6.4.2 TIpSocket.LocalHost Property

Specifies the name of the local system.

Pascal

```
property LocalHost: TSocketHost;
```

C++

```
__property TSocketHost LocalHost;
```

Description

Use LocalHost to get the name of the system that is running the application that uses the socket. LocalHost is a string containing the domain name and service of the local socket endpoint, such as http://www.wSite.Com.

Port numbers allow a single system, identified by the LocalHostAddr (see page 1420) function, to host multiple connections simultaneously. Each combination of LocalPort (see page 1424) and LocalHostAddr (see page 1420) can only be bound to a single socket connection.

LocalHost provides an alias for the local IP address given in the LocalHostAddr (see page 1420) function. Most Intranets provide host names for the IP addresses of systems on the net. For more information on defining a host name for a given

system, contact your network administrator.

See Also

LocalPort (see page 1424)

RemoteHost (see page 1426)

LocalHostAddr (see page 1420)

LookupHostName (see page 1421)

LookupPort (see page 1421)

24.1.6.4.3 TIpSocket.LocalPort Property

Specifies the ID number of the port used by the socket connection.

Pascal

```
property LocalPort: TSocketPort;
```

C++

```
__property TSocketPort LocalPort;
```

Description

Use LocalPort to determine the port number that is bound to the socket connection. For server endpoints of listening connections, LocalPort is the ID associated with the service the server socket provides. For client or server endpoints of connections to another socket, LocalPort is usually an arbitrary value picked when the connection was made.

Many values of LocalPort are associated by convention with a particular service such as FTP or HTTP.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
```

```
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
```

```
    Memo1.Lines.Clear;
  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Memo1.Lines.Clear;

    //server initialization
    TcpServer1 := TTcpServer.Create(Self);
    TcpServer1.OnAccept := TCpServer1Accept;
    TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
    TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
    TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
  end;

  procedure TForm3.TcpServer1Accept(Sender: TObject;
    ClientSocket: TCustomIpClient);
  var
    a : array[0..9] of byte;
    I : Cardinal;
  begin

    ClientSocket.ReceiveBuf(a,10,0);
    Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                    IntToStr(a[9]));
    for I := 0 to 8 do
    begin
      Memo1.Lines.Add(IntToStr(a[I] + a[9]));
    end;
    Memo1.Lines.Add('--------------------');

  end;

  procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
  end;

  procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
  begin
    if Self.Memo1 <> nil then
      Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
  end;
```

See Also

LocalHost (see page 1423)

RemotePort (see page 1428)

LookupPort (see page 1421)

24.1.6.4.4 TIpSocket.RemoteHost Property

Specifies the name of the remote system.

Pascal

```
property RemoteHost: TSocketHost;
```

C++

```
__property TSocketHost RemoteHost;
```

Description

Use RemoteHost to get the name of the system on the other end of the socket connection. RemoteHost is a string containing the

domain name and service of the remote endpoint of the socket connection, such as http://www.wSite.Com.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
```

```
    myStream : TMemoryStream;
    I : Cardinal;
    userValue : Integer;
  begin
    //creating a stream
    myStream := TMemoryStream.Create();
    for I := 0 to 8 do
    begin
      myStream.WriteBuffer(I,1);
    end;
    userValue := StrToIntDef(Edit1.Text, 0);
    myStream.WriteBuffer(userValue,1);

    //resetting the stream position
    myStream.Seek(0,0);

    //sending the stream
    TcpClient1.Active := true;
    TcpClient1.SendStream(myStream);
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

LocalHostName (see page 1420)

LookupHostAddr (see page 1420)

LookupHostName (see page 1421)

24.1.6.4.5 TIpSocket.RemotePort Property

Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.

Pascal

```
property RemotePort: TSocketPort;
```

C++

```
__property TSocketPort RemotePort;
```

Description

Use RemotePort to determine the port number used by the socket on the other end of the socket connection.

Port numbers allow a single system, identified by the RemoteHost (see page 1426) property, to host multiple connections simultaneously. Each combination of RemotePort and RemoteHost (see page 1426) can only be bound to a single socket connection.

Many port numbers are associated by convention with a particular service such as ftp or http. To determine whether the value of RemotePort is associated with a specific service, use the LookupProtocol (see page 1421) method.

Note: If a client socket requests a specific port to indicate a desired service, the value of RemotePort for the actual connection may differ from the requested port number. Most server sockets listen on the port associated with a service, but switch to an arbitrary available port number for forming connections.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)
```

```
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

24.1.7 TRawSocket Class

Encapsulates a raw socket.

Class Hierarchy

Pascal

```
TRawSocket = class(TIpSocket);
```

C++

```
class TRawSocket : public TIpSocket;
```

File

Sockets

Description

TRawSocket encapsulates a raw socket.

See Also

TBaseSocket (see page 1370)

24.1.7.1 TRawSocket Members

The following tables list the members exposed by TRawSocket.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
V	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
V	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
V	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
V	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnCreateHandle (see page 1388)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1390)	Occurs when a socket is deactivated.
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
	Close (see page 1373)	Shuts down the socket connection.
	Create (see page 1432)	Creates an instance of a TRawSocket (see page 1431) object.
	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
	Open (see page 1375)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
	Active (see page 1383)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1385)	Sets or returns the blocking mode of the socket.
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	LocalHost (see page 1423)	Specifies the name of the local system.
	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.
	SockType (see page 1433)	Sets or returns the socket type.

24.1.7.2 TRawSocket.Create Constructor

Creates an instance of a TRawSocket (see page 1431) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRawSocket(TComponent * AOwner);
```

Description

Call Create indirectly, using the **new** keyword, to instantiate a TRawSocket (see page 1431) object.

See Also

TRawSocket (see page 1431)

Destroy (see page 1372)

24.1.7.3 TRawSocket Properties

The properties of the TRawSocket class are listed here.

Public Properties

	Name	Description
	SockType (see page 1433)	Sets or returns the socket type.

24.1.7.3.1 TRawSocket.SockType Property

Sets or returns the socket type.

Pascal

```
property SockType: TSocketType;
```

C++

```
__property TSocketType SockType;
```

Description

SockType sets or returns the type of socket connection.

The TSocketType (see page 1502) type defines the set of possible socket types for the SockType property.

See Also

TSocketType (see page 1502)

24.1.8 TServerSocketThread Class

Enables creation of separate threads of execution for the server socket in an application.

Class Hierarchy

Pascal

```
TServerSocketThread = class(TThread);
```

C++

```
class TServerSocketThread : public TThread;
```

File

Sockets

Description

Create (see page 1434) TServerSocketThread (or a descendant of the class) to represent an execution thread for the server socket in a multi-threaded application. Each new instance of a TServerSocketThread, a TThread descendant, is a new thread of execution. Using a separate TServerSocketThread allows the server socket to block without blocking the whole application.

See Also

Writing Multi-threaded Applications

TClientSocketThread (see page 1396)

TThread

24.1.8.1 TServerSocketThread Members

The following tables list the members exposed by TServerSocketThread.

Protected Methods

	Name	Description
	AddClientSocketThread (see page 1436)	This is AddClientSocketThread, a member of class TServerSocketThread.
V	CreateThread (see page 1436)	This is CreateThread, a member of class TServerSocketThread.
	FetchClientSocketThread (see page 1437)	This is FetchClientSocketThread, a member of class TServerSocketThread.
	RemoveClientSocketThread (see page 1437)	This is RemoveClientSocketThread, a member of class TServerSocketThread.

Public Events

	Name	Description
	OnGetThread (see page 1439)	Creates and initializes a client socket thread when a connection is requested.

Public Methods

	Name	Description
	ClearThreadPool (see page 1436)	Terminates all of the threads in the thread pool.
	Create (see page 1434)	Creates an instance of a TServerSocketThread (see page 1433) object.
V	Destroy (see page 1435)	Destroys the thread object and releases the memory allocated to it.
V	Execute (see page 1436)	Provides the code which executes when the thread is run.

Public Properties

	Name	Description
R	ServerSocket (see page 1438)	Specifies the TCustomTcpServer (see page 1406) object that manages all the TClientSocketThread (see page 1396) objects for its client connections.
	ThreadCacheSize (see page 1438)	Indicates the number of TServerSocketThread (see page 1433) objects cached for reuse by new connections to client sockets.
R	ThreadPool (see page 1438)	A list of all the client socket threads created by the TServerSocketThread (see page 1433) object.

24.1.8.2 TServerSocketThread.Create Constructor

Creates an instance of a TServerSocketThread (see page 1433) object.

Pascal

```
constructor Create(AServerSocket: TCustomTcpServer);
```

C++

```
__fastcall TServerSocketThread(TCustomTcpServer AServerSocket);
```

Description

For C++, call Create indirectly, using the **new** keyword, to create a thread in an application.

See Also

Destroy (see page 1435)

Execute (see page 1436)

24.1.8.3 TServerSocketThread.Destroy Destructor

Destroys the thread object and releases the memory allocated to it.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TServerSocketThread();
```

Description

For C++, do not call Destroy in an application. Instead, use the **delete** keyword to destroy a thread when FreeOnTerminate is false.

Destroy signals the thread to terminate and then waits for the thread to return before calling the parent class's destructor.

See Also

delete

FreeOnTerminate

Create (see page 1434)

24.1.8.4 TServerSocketThread Methods

The methods of the TServerSocketThread class are listed here.

Protected Methods

	Name	Description
	AddClientSocketThread (see page 1436)	This is AddClientSocketThread, a member of class TServerSocketThread.
V	CreateThread (see page 1436)	This is CreateThread, a member of class TServerSocketThread.
	FetchClientSocketThread (see page 1437)	This is FetchClientSocketThread, a member of class TServerSocketThread.
	RemoveClientSocketThread (see page 1437)	This is RemoveClientSocketThread, a member of class TServerSocketThread.

Public Methods

	Name	Description
	ClearThreadPool (see page 1436)	Terminates all of the threads in the thread pool.
V	Execute (see page 1436)	Provides the code which executes when the thread is run.

24.1.8.4.1 TServerSocketThread.AddClientSocketThread Method

Pascal

```
function AddClientSocketThread: TClientSocketThread;
```

C++

```
__fastcall TClientSocketThread AddClientSocketThread();
```

Description

This is AddClientSocketThread, a member of class TServerSocketThread.

24.1.8.4.2 TServerSocketThread.ClearThreadPool Method

Terminates all of the threads in the thread pool.

Pascal

```
procedure ClearThreadPool;
```

C++

```
__fastcall ClearThreadPool();
```

Description

The thread pool is a list of client socket threads that are available to handle connection requests. This list is kept to allow reuse of old threads and improve performance. It is sometimes useful to destroy all of the thread object instances in this list.

Use ClearThreadPool to terminate all of the threads in the thread pool list. Any suspended thread in the pool is resumed so that termination can proceed.

See Also

ThreadPool (see page 1438)

Terminate

24.1.8.4.3 TServerSocketThread.CreateThread Method

Pascal

```
function CreateThread: TClientSocketThread; virtual;
```

C++

```
virtual __fastcall TClientSocketThread CreateThread();
```

Description

This is CreateThread, a member of class TServerSocketThread.

24.1.8.4.4 TServerSocketThread.Execute Method

Provides the code which executes when the thread is run.

Pascal

```
procedure Execute; override;
```

C++

```
virtual __fastcall Execute();
```

Description

Use Execute to execute the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated property to determine if the thread needs to exit.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize method.

See Also

Terminated

Synchronize

Create (see page 1434)

24.1.8.4.5 TServerSocketThread.FetchClientSocketThread Method

Pascal

```
function FetchClientSocketThread: TClientSocketThread;
```

C++

```
__fastcall TClientSocketThread FetchClientSocketThread();
```

Description

This is FetchClientSocketThread, a member of class TServerSocketThread.

24.1.8.4.6 TServerSocketThread.RemoveClientSocketThread Method

Pascal

```
procedure RemoveClientSocketThread(ClientSocketThread: TClientSocketThread);
```

C++

```
__fastcall RemoveClientSocketThread(TClientSocketThread ClientSocketThread);
```

Description

This is RemoveClientSocketThread, a member of class TServerSocketThread.

24.1.8.5 TServerSocketThread Properties

The properties of the TServerSocketThread class are listed here.

Public Properties

	Name	Description
	ServerSocket (see page 1438)	Specifies the TCustomTcpServer (see page 1406) object that manages all the TClientSocketThread (see page 1396) objects for its client connections.
	ThreadCacheSize (see page 1438)	Indicates the number of TServerSocketThread (see page 1433) objects cached for reuse by new connections to client sockets.
	ThreadPool (see page 1438)	A list of all the client socket threads created by the TServerSocketThread (see page 1433) object.

24.1.8.5.1 TServerSocketThread.ServerSocket Property

Specifies the TCustomTcpServer (see page 1406) object that manages all the TClientSocketThread (see page 1396) objects for its client connections.

Pascal

```
property ServerSocket: TCustomTcpServer;
```

C++

```
__property TCustomTcpServer ServerSocket;
```

Description

Use ServerSocket to get direct access to the listening socket object that spawned the thread for a client connection it accepted. TServerSocketThread (see page 1433) passes events and errors to the appropriate event handlers assigned to ServerSocket. TServerSocketThread (see page 1433) adds itself to the cache of threads maintained by ServerSocket from its constructor, and removes itself when the thread terminates.

See Also

TClientSocketThread (see page 1396)

TServerSocketThread (see page 1433)

24.1.8.5.2 TServerSocketThread.ThreadCacheSize Property

Indicates the number of TServerSocketThread (see page 1433) objects cached for reuse by new connections to client sockets.

Pascal

```
property ThreadCacheSize: Integer;
```

C++

```
__property int ThreadCacheSize;
```

Description

Set ThreadCacheSize to specify the number of threads that are cached for reuse. The ideal value for ThreadCacheSize depends on the number and frequency of client socket requests received by the server socket. If ThreadCacheSize is too low, the server socket will spend more time freeing and creating threads when client connections are accepted. If ThreadCacheSize is too high, the server socket may unnecessarily lock up the memory for threads that are never reused.

24.1.8.5.3 TServerSocketThread.ThreadPool Property

A list of all the client socket threads created by the TServerSocketThread (see page 1433) object.

Pascal

```
property ThreadPool: TList;
```

C++

```
__property TList ThreadPool;
```

Description

TServerSocketThread (see page 1433) objects listen for requests on the network and delegate them to client socket threads. Each client socket thread is added to the list ThreadPool after it is created. Creating and destroying client socket threads can be quite time consuming, so whenever one completes its work on a given connection it becomes dormant. When a new connection request is received, the ThreadPool is checked for dormant client socket threads. If one is available, it is assigned the

connection. If not, a new client socket thread created. By reusing previously-created threads, the application's performance is improved.

TClientSocketThread (see page 1396)

ClearThreadPool (see page 1436)

24.1.8.6 TServerSocketThread Events

The events of the TServerSocketThread class are listed here.

Public Events

	Name	Description
	OnGetThread (see page 1439)	Creates and initializes a client socket thread when a connection is requested.

24.1.8.6.1 TServerSocketThread.OnGetThread Event

Creates and initializes a client socket thread when a connection is requested.

Pascal

```
property OnGetThread: TGetThreadEvent;
```

C++

```
__property TGetThreadEvent OnGetThread;
```

Description

An OnGetThread event occurs when a connection is requested. The event handler creates an instance of TClientSocketThread (see page 1396) and initializes it. Write (see page 3707) an event handler on TCustomTcpServer (see page 1406) to create and initialize instances of your own client socket thread class.

TClientSocketThread (see page 1396)

TCustomTcpServer (see page 1406)

24.1.9 TTcpClient Class

TCP client component.

Class Hierarchy

Pascal

```
TTcpClient = class(TCustomIpClient);
```

C++

```
class TTcpClient : public TCustomIpClient;
```

File

Sockets

Description

Use TTcpClient to create TCP client applications.

TTcpClient publishes properties and events from its ancestor socket components.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
```

```
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

TCustomIpClient (see page 1400)

TTcpServer (see page 1459)

24.1.9.1 TTcpClient Members

The following tables list the members exposed by TTcpClient.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
V	DoConnect (see page 1403)	This is DoConnect, a member of class TCustomIpClient.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
V	DoDisconnect (see page 1404)	This is DoDisconnect, a member of class TCustomIpClient.

	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
V	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
V	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
V	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
V	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Methods

	Name	Description
V	Close (see page 1373)	Shuts down the socket connection.
V	Close (see page 1402)	Shuts down the socket connection.
	Connect (see page 1403)	Connects the local socket to the remote socket.
V	Create (see page 1371)	Creates an instance of TBaseSocket (see page 1370).
V	Create (see page 1402)	Creates an instance of TCustomIpClient (see page 1400).
V	Create (see page 1418)	Creates an instance of TIpSocket (see page 1416).
V	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	Disconnect (see page 1403)	Disconnects the local socket from the remote socket.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	GetThreadObject (see page 1404)	Returns a reference to the TThread object for the currently executing thread.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
V	Open (see page 1375)	Creates the socket connection.
V	Open (see page 1404)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	Receiveln (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	Sendln (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	LocalHost (see page 1423)	Specifies the name of the local system.
	LocalPort (see page 1424)	Specifies the ID number of the port used by the socket connection.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	SockType (see page 1387)	Sets or returns the socket type.

Published Events

	Name	Description
	OnConnect (see page 1450)	Occurs on client sockets just after the connection to the server is opened.
	OnCreateHandle (see page 1451)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1453)	Occurs when a socket is deactivated.
	OnDisconnect (see page 1456)	Occurs on client sockets just after the connection to the server is closed.
	OnError (see page 1456)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1456)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1457)	Occurs just before a client socket writes information to the socket connection.

Published Properties

	Name	Description
	Active (see page 1443)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1445)	Sets or returns the blocking mode of the socket.
	Connected (see page 1446)	Indicates whether the socket connection is open and available for communication with other machines.
	RemoteHost (see page 1446)	Specifies the name of the remote system.
	RemotePort (see page 1448)	Specifies the ID number of the port used by the RemoteHost to form the socket connection.

24.1.9.2 TTcpClient Properties

The properties of the TTcpClient class are listed here.

Published Properties

	Name	Description
	Active (see page 1443)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1445)	Sets or returns the blocking mode of the socket.
	Connected (see page 1446)	Indicates whether the socket connection is open and available for communication with other machines.
	RemoteHost (see page 1446)	Specifies the name of the remote system.
	RemotePort (see page 1448)	Specifies the ID number of the port used by the RemoteHost to form the socket connection.

24.1.9.2.1 TTcpClient.Active Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before attempting to use or change the socket connection, read Active to determine whether the connection is open and ready. For client sockets, setting Active opens or shuts down a socket connection to another machine. For server sockets, setting Active opens or shuts down a listening connection that makes the socket available for client requests.

At design time, set Active to **true** to make the socket open a connection when the application starts running (the default value is false). At runtime, use the Open or Close method to open or close the connection.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
```

```
    userValue : Integer;
  begin
    //creating a stream
    myStream := TMemoryStream.Create();
    for I := 0 to 8 do
    begin
      myStream.WriteBuffer(I,1);
    end;
    userValue := StrToIntDef(Edit1.Text, 0);
    myStream.WriteBuffer(userValue,1);

    //resetting the stream position
    myStream.Seek(0,0);

    //sending the stream
    TcpClient1.Active := true;
    TcpClient1.SendStream(myStream);
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

See Also

Close (see page 1373)

Open (see page 1375)

24.1.9.2.2 TTcpClient.BlockMode Property

Sets or returns the blocking mode of the socket.

Pascal

```
property BlockMode: TSocketBlockMode;
```

C++

```
__property TSocketBlockMode BlockMode;
```

Description

Use BlockMode to set or return the blocking mode for the socket. By default, the socket is set to bmBlocking.

The TSocketBlockMode type defines the set of possible socket flags for the BlockMode property.

See Also

TSocketBlockMode (see page 1505)

OnReceive (see page 1393)

OnSend (see page 1394)

24.1.9.2.3 TTcpClient.Connected Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Connected: Boolean;
```

C++

```
__property Boolean Connected;
```

Description

Read Connected before trying to use or change the socket connection. Connected indicates whether the socket connection has been established. When Connected is **true**, the socket is open and available for use. When Connected is **false**, the socket is closed and can be changed.

To open a socket, use the Open method. To close a socket, use the Closemethod.

See Also

Close (see page 1402)

Open (see page 1404)

OnConnect (see page 1405)

24.1.9.2.4 TTcpClient.RemoteHost Property

Specifies the name of the remote system.

Pascal

```
property RemoteHost: TSocketHost;
```

C++

```
__property TSocketHost RemoteHost;
```

Description

Use RemoteHost to get the name of the system on the other end of the socket connection. RemoteHost is a string containing the domain name and service of the remote endpoint of the socket connection, such as http://www.wSite.Com.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
```

```
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
```

```
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

See Also

RemotePort (see page 1428)

LocalHostAddr (see page 1420)

LocalHostName (see page 1420)

LookupHostAddr (see page 1420)

LookupHostName (see page 1421)

24.1.9.2.5 TTcpClient.RemotePort Property

Specifies the ID number of the port used by the RemoteHost to form the socket connection.

Pascal

```
property RemotePort: TSocketPort;
```

C++

```
__property TSocketPort RemotePort;
```

Description

Use RemotePort to determine the port number used by the socket on the other end of the socket connection.

Port numbers allow a single system, identified by the RemoteHost property, to host multiple connections simultaneously. Each combination of RemotePort and RemoteHost can only be bound to a single socket connection.

Many port numbers are associated by convention with a particular service such as ftp or http. To determine whether the value of RemotePort is associated with a specific service, use the LookupProtocol method.

Note: If a client socket requests a specific port to indicate a desired service, the value of RemotePort for the actual connection may differ from the requested port number. Most server sockets listen on the port associated with a service, but switch to an arbitrary available port number for forming connections.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
```

```
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
```

```
    begin
      myStream.WriteBuffer(I,1);
    end;
    userValue := StrToIntDef(Edit1.Text, 0);
    myStream.WriteBuffer(userValue,1);

    //resetting the stream position
    myStream.Seek(0,0);

    //sending the stream
    TcpClient1.Active := true;
    TcpClient1.SendStream(myStream);
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

24.1.9.3 TTcpClient Events

The events of the TTcpClient class are listed here.

Published Events

	Name	Description
	OnConnect (see page 1450)	Occurs on client sockets just after the connection to the server is opened.
	OnCreateHandle (see page 1451)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1453)	Occurs when a socket is deactivated.
	OnDisconnect (see page 1456)	Occurs on client sockets just after the connection to the server is closed.
	OnError (see page 1456)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1456)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1457)	Occurs just before a client socket writes information to the socket connection.

24.1.9.3.1 TTcpClient.OnConnect Event

Occurs on client sockets just after the connection to the server is opened.

Pascal

```
property OnConnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnConnect;
```

Description

Write an OnConnect event handler for a client socket to take specific action after the connection to a server socket has been established. Depending on the service, this may be the point when the socket should start reading or writing over the connection.

See Also

Connected (see page 1405)

OnDisconnect (see page 1406)

24.1.9.3.2 TTcpClient.OnCreateHandle Event

Occurs when the handle to a socket becomes active.

Pascal

```
property OnCreateHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnCreateHandle;
```

Description

Write an OnCreateHandle event handler to take specific action when the handle to a socket becomes active.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
```

```
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
```

```
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

24.1.9.3.3 TTcpClient.OnDestroyHandle Event

Occurs when a socket is deactivated.

Pascal

```
property OnDestroyHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDestroyHandle;
```

Description

Write an OnDestroyHandle event handler to take specific action when the socket is deactivated.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------

  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
```

```
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

24.1.9.3.4 TTcpClient.OnDisconnect Event

Occurs on client sockets just after the connection to the server is closed.

Pascal

```
property OnDisconnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDisconnect;
```

Description

Write an OnDisconnect event handler for a client socket to take specific action just after the connection to a server socket is terminated.

See Also

Connected (see page 1405)

OnConnect (see page 1405)

24.1.9.3.5 TTcpClient.OnError Event

Occurs when the socket fails in making, using, or shutting down a connection.

Pascal

```
property OnError: TSocketErrorEvent;
```

C++

```
__property TSocketErrorEvent OnError;
```

Description

Write an OnError event handler to respond to errors that arise with the socket connection. Set the **ErrorCode** parameter to 0 if the OnError event handler successfully deals with the error condition, to prevent an ESocketError exception from being raised.

See Also

ESocketError (see page 1369)

24.1.9.3.6 TTcpClient.OnReceive Event

Occurs after a socket receives data, but before it passes the data to the application.

Pascal

```
property OnReceive: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnReceive;
```

Description

Write an OnReceive event handler to read from the socket connection. Use the OnReceive event to filter data before passing it back to the client application. If the socket is a blocking socket, use a TWinSocketStream object to read from the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual reading.

See Also

TWinSocketStream (see page 138)

BytesReceived (see page 1386)

ReceiveBuf (see page 1376)

ReceiveIn (see page 1379)

24.1.9.3.7 TTcpClient.OnSend Event

Occurs just before a client socket writes information to the socket connection.

Pascal

```
property OnSend: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnSend;
```

Description

Write an OnSend event handler to perform actions just prior to sending data. Use OnSend to monitor the data stream and change it (for example, by removing linefeeds). If the socket is a blocking socket, use a TWinSocketStream object to write to the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual writing.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
```

```
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
```

```
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

See Also

SendBuf (see page 1380)

SendIn (see page 1380)

24.1.10 TTcpServer Class

TTcpServer is the TCP server component.

Class Hierarchy

Pascal

```
TTcpServer = class(TCustomTcpServer);
```

C++

```
class TTcpServer : public TCustomTcpServer;
```

File

Sockets

Description

Use TTcpServer to create TCP server applications.

TTcpServer publishes properties and events from its ancestor socket components.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
```

```
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
```

```
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

24.1.10.1 TTcpServer Members

The following tables list the members exposed by TTcpServer.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
	DoAccept (see page 1410)	This is DoAccept, a member of class TCustomTcpServer.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
	Listen (see page 1410)	This is Listen, a member of class TCustomTcpServer.
	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Events

	Name	Description
	OnError (see page 1393)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1393)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1394)	Occurs just before a client socket writes information to the socket connection.

Public Methods

	Name	Description
	Accept (see page 1409)	This is the overview for the Accept method overload.
	Close (see page 1373)	Shuts down the socket connection.
	Close (see page 1410)	Shuts down the socket connection.
	Create (see page 1371)	Creates an instance of TBaseSocket (see page 1370).
	Create (see page 1408)	Creates an instance of TCustomTcpServer (see page 1406).
	Create (see page 1418)	Creates an instance of TIpSocket (see page 1416).
	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	Destroy (see page 1408)	Frees the memory associated with the TCustomTcpServer (see page 1406) object.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.
	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
	Open (see page 1375)	Creates the socket connection.
	Open (see page 1411)	Opens the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.

	WaitForConnection (see page 1411)	Listens for TCP connections.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
R	Listening (see page 1412)	Sets the server application to listen for client requests.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	RemoteHost (see page 1426)	Specifies the name of the remote system.
	RemotePort (see page 1428)	Specifies the ID number of the port used by the RemoteHost (see page 1426) to form the socket connection.
	ServerSocketThread (see page 1412)	Specifies the TServerSocketThread (see page 1433) in use.
	SockType (see page 1387)	Sets or returns the socket type.

Published Events

	Name	Description
	OnAccept (see page 1469)	Occurs on server sockets just after the connection to a client socket is accepted.
	OnCreateHandle (see page 1472)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1474)	Occurs when a socket is deactivated.
	OnGetThread (see page 1477)	A wrapper for the TServerSocketThread event of the same name.
	OnListening (see page 1477)	Occurs when a server socket begins listening for connections.

Published Properties

	Name	Description
	Active (see page 1463)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1465)	Sets or returns the blocking mode of the socket.
	LocalHost (see page 1466)	Specifies the name of the local system.
	LocalPort (see page 1466)	Specifies the ID number of the port used by the socket connection.

24.1.10.2 TTcpServer Properties

The properties of the TTcpServer class are listed here.

Published Properties

	Name	Description
	Active (see page 1463)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1465)	Sets or returns the blocking mode of the socket.
	LocalHost (see page 1466)	Specifies the name of the local system.
	LocalPort (see page 1466)	Specifies the ID number of the port used by the socket connection.

24.1.10.2.1 TTcpServer.Active Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before attempting to use or change the socket connection, read Active to determine whether the connection is open and ready. For client sockets, setting Active opens or shuts down a socket connection to another machine. For server sockets, setting Active opens or shuts down a listening connection that makes the socket available for client requests.

At design time, set Active to **true** to make the socket open a connection when the application starts running (the default value is false). At runtime, use the Open or Close method to open or close the connection.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
```

```
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

Close (see page 1373)

Open (see page 1375)

24.1.10.2.2 TTcpServer.BlockMode Property

Sets or returns the blocking mode of the socket.

Pascal

```
property BlockMode: TSocketBlockMode;
```

C++

```
__property TServerSocketBlockMode BlockMode;__property TSocketBlockMode BlockMode;
```

Description

Use BlockMode to set or return the blocking mode for the socket. By default, the socket is set to bmThreadBlocking.

The TServerSocketBlockMode type defines the set of possible socket flags for the BlockMode property.

See Also

OnReceive (see page 1393)

OnSend (see page 1394)

TServerSocketBlockMode (see page 1500)

24.1.10.2.3 TTcpServer.LocalHost Property

Specifies the name of the local system.

Pascal

```
property LocalHost: TSocketHost;
```

C++

```
__property TSocketHost LocalHost;
```

Description

Use LocalHost to get the name of the system that is running the application that uses the socket. LocalHost is a string containing the domain name and service of the local socket endpoint, such as http://www.wSite.Com.

Port numbers allow a single system, identified by the LocalHostAddr function, to host multiple connections simultaneously. Each combination of LocalPort and LocalHostAddr can only be bound to a single socket connection.

LocalHost provides an alias for the local IP address given in the LocalHostAddr function. Most Intranets provide host names for the IP addresses of systems on the net. For more information on defining a host name for a given system, contact your network administrator.

See Also

LocalPort (see page 1424)

RemoteHost (see page 1426)

LocalHostAddr (see page 1420)

LookupHostName (see page 1421)

LookupPort (see page 1421)

24.1.10.2.4 TTcpServer.LocalPort Property

Specifies the ID number of the port used by the socket connection.

Pascal

```
property LocalPort: TSocketPort;
```

C++

```
__property TSocketPort LocalPort;
```

Description

Use LocalPort to determine the port number that is bound to the socket connection. For server endpoints of listening connections, LocalPort is the ID associated with the service the server socket provides. For client or server endpoints of connections to another socket, LocalPort is usually an arbitrary value picked when the connection was made.

Many values of LocalPort are associated by convention with a particular service such as FTP or HTTP.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------

24.1.10.3 TTcpServer Events

The events of the TTcpServer class are listed here.

Published Events

	Name	Description
	OnAccept (see page 1469)	Occurs on server sockets just after the connection to a client socket is accepted.
	OnCreateHandle (see page 1472)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1474)	Occurs when a socket is deactivated.
	OnGetThread (see page 1477)	A wrapper for the TServerSocketThread event of the same name.
	OnListening (see page 1477)	Occurs when a server socket begins listening for connections.

24.1.10.3.1 TTcpServer.OnAccept Event

Occurs on server sockets just after the connection to a client socket is accepted.

Pascal

```
property OnAccept: TSocketAcceptEvent;
```

C++

```
__property TSocketAcceptEvent OnAccept;
```

Description

Write an OnAccept event handler for a server socket to take specific action after the connection to a client socket has been accepted. This is the first point when information is available about the local port and IP address that is used in the server endpoint of the connection. The port number, and possibly the IP address, differs from those of the listening socket.

Server sockets open a socket connection for listening to establish a queue to hold client requests. After a request from the queue

is accepted by the server socket, an OnAccept event occurs. After the server socket accepts the connection, the client socket completes the connection, and an OnConnect event occurs for the client socket.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
```

```
    Memo1.Lines.Add('--------------------');

  end;

  procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
  end;

  procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
  begin
    if Self.Memo1 <> nil then
      Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
  end;
```

24.1.10.3.4 TTcpServer.OnGetThread Event

A wrapper for the TServerSocketThread event of the same name.

Pascal

```
property OnGetThread: TGetThreadEvent;
```

C++

```
__property TGetThreadEvent OnGetThread;
```

Description

This event is exactly the same as the OnGetThread event of the TServerSocketThread object referenced in ServerSocketThread.

See Also

TServerSocketThread (see page 1433)

ServerSocketThread (see page 1399)

OnGetThread (see page 1439)

24.1.10.3.5 TTcpServer.OnListening Event

Occurs when a server socket begins listening for connections.

Pascal

```
property OnListening: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnListening;
```

Description

Write an OnListening event to take specific action when a server begins listening for a connection.

See Also

Listening (see page 1412)

TNotifyEvent

24.1.11 TUdpSocket Class

UDP component.

Class Hierarchy

Pascal

```
TUdpSocket = class(TCustomIpClient);
```

C++

```
class TUdpSocket : public TCustomIpClient;
```

File

Sockets

Description

Use TUdpSocket to create UDP-based applications. Add a TUdpSocket object to a form or data module to turn an application into a UDP/IP client and server. TUdpSocket specifies a desired connection to a UDP/IP server, manages the connection when it is open, and terminates the connection when the application is through. It also listens for requests for UDP/IP connections from other machines and establishes connections when requests are received.

24.1.11.1 TUdpSocket Members

The following tables list the members exposed by TUdpSocket.

Protected Methods

	Name	Description
	Bind (see page 1419)	This is Bind, a member of class TIpSocket.
V	DoConnect (see page 1403)	This is DoConnect, a member of class TCustomIpClient.
	DoCreateHandle (see page 1373)	This is DoCreateHandle, a member of class TBaseSocket.
	DoDestroyHandle (see page 1373)	This is DoDestroyHandle, a member of class TBaseSocket.
V	DoDisconnect (see page 1404)	This is DoDisconnect, a member of class TCustomIpClient.
	DoHandleError (see page 1373)	This is DoHandleError, a member of class TBaseSocket.
V	DoReceive (see page 1374)	This is DoReceive, a member of class TBaseSocket.
V	DoSend (see page 1374)	This is DoSend, a member of class TBaseSocket.
V	ErrorCheck (see page 1374)	This is ErrorCheck, a member of class TBaseSocket.
V	Loaded (see page 1374)	Initializes the component after the form file has been read into memory.
	SetBytesReceived (see page 1382)	This is SetBytesReceived, a member of class TBaseSocket.
	SetBytesSent (see page 1382)	This is SetBytesSent, a member of class TBaseSocket.

Public Methods

	Name	Description
V	Close (see page 1373)	Shuts down the socket connection.
V	Close (see page 1402)	Shuts down the socket connection.
	Connect (see page 1403)	Connects the local socket to the remote socket.
V	Create (see page 1479)	Creates an instance of TUdpSocket (see page 1477).
V	Destroy (see page 1372)	Frees the memory associated with the TBaseSocket (see page 1370) object.
	Disconnect (see page 1403)	Disconnects the local socket from the remote socket.
	GetSocketAddr (see page 1419)	Builds a valid network socket address.
	GetThreadObject (see page 1404)	Returns a reference to the TThread object for the currently executing thread.
	LocalDomainName (see page 1419)	Returns the domain name for the local host.
	LocalHostAddr (see page 1420)	Returns the local IP address for the host machine.
	LocalHostName (see page 1420)	Returns the local host name.
	LookupHostAddr (see page 1420)	Looks up the host address based on the host name.
	LookupHostName (see page 1421)	Looks up the host name based on the IP address.

	LookupPort (see page 1421)	Returns the port number.
	LookupProtocol (see page 1421)	Returns the protocol number.
	MapDomain (see page 1375)	Maps the domain.
	MapSockType (see page 1375)	Maps the socket type.
V	Open (see page 1375)	Creates the socket connection.
V	Open (see page 1404)	Creates the socket connection.
	PeekBuf (see page 1376)	Reads the buffer.
	ReceiveBuf (see page 1376)	Reads data buffers to the socket.
	ReceiveFrom (see page 1422)	Receives a packet of information.
	ReceiveIn (see page 1379)	Reads delimited lines of data from the socket.
	Select (see page 1379)	Tests for socket activity.
	SendBuf (see page 1380)	Writes data buffers of size bufsize from the socket.
	SendIn (see page 1380)	Writes delimited lines of data to the socket.
	SendStream (see page 1380)	Writes a stream of data to the socket.
	SendTo (see page 1422)	Sends a packet of information.
	WaitForData (see page 1383)	Waits for the socket connection to be ready to transfer data.

Public Properties

	Name	Description
R	BytesReceived (see page 1386)	Returns the number of bytes received by the socket.
R	BytesSent (see page 1386)	Returns the number of bytes sent from the socket.
R	Connected (see page 1405)	Indicates whether the socket connection is open and available for communication with other machines.
	Domain (see page 1386)	Sets or returns the protocol family used by the socket.
	Domain (see page 1423)	Sets or returns the protocol family used by the socket.
R	Handle (see page 1387)	Provides access to the unique-4 byte identifier that represents the instance of the socket object.
	Protocol (see page 1387)	Sets or returns the protocol used by the socket.
	SockType (see page 1387)	Sets or returns the socket type.

Published Events

	Name	Description
	OnConnect (see page 1490)	Occurs on client sockets just after the connection to the server is opened.
	OnCreateHandle (see page 1490)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1493)	Occurs when a socket is deactivated.
	OnDisconnect (see page 1495)	Occurs on client sockets just after the connection to the server is closed.
	OnError (see page 1496)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1496)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1496)	Occurs just before a client socket writes information to the socket connection.

Published Properties

	Name	Description
	Active (see page 1480)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1482)	Sets or returns the blocking mode of the socket.
	LocalHost (see page 1482)	Specifies the name of the local system.
	LocalPort (see page 1483)	Specifies the ID number of the port used by the socket connection.
	RemoteHost (see page 1486)	Specifies the name of the remote system.
	RemotePort (see page 1488)	Specifies the ID number of the port used by the RemoteHost to form the socket connection.

24.1.11.2 TUdpSocket.Create Constructor

Creates an instance of TUdpSocket (see page 1477).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TUdpSocket(TComponent * AOwner);
```

Description

For C++, call Create indirectly, using the **new** keyword, to instantiate a TUdpSocket (see page 1477) object.

24.1.11.3 TUdpSocket Properties

The properties of the TUdpSocket class are listed here.

Published Properties

	Name	Description
	Active (see page 1480)	Indicates whether the socket connection is open and available for communication with other machines.
	BlockMode (see page 1482)	Sets or returns the blocking mode of the socket.
	LocalHost (see page 1482)	Specifies the name of the local system.
	LocalPort (see page 1483)	Specifies the ID number of the port used by the socket connection.
	RemoteHost (see page 1486)	Specifies the name of the remote system.
	RemotePort (see page 1488)	Specifies the ID number of the port used by the RemoteHost to form the socket connection.

24.1.11.3.1 TUdpSocket.Active Property

Indicates whether the socket connection is open and available for communication with other machines.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before attempting to use or change the socket connection, read Active to determine whether the connection is open and ready. For client sockets, setting Active opens or shuts down a socket connection to another machine. For server sockets, setting Active opens or shuts down a listening connection that makes the socket available for client requests.

At design time, set Active to **true** to make the socket open a connection when the application starts running (the default value is false). At runtime, use the Open or Close method to open or close the connection.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
```

```
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
```

```
    TcpClient1.Active := true;
    TcpClient1.SendStream(myStream);
    TcpClient1.Active := false;

    //free the stream
    myStream.Free;

  end;

  procedure TForm3.FormCreate(Sender: TObject);
  begin
    Edit1.Text := '0';
    Memo1.Lines.Clear;

    TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
    TcpClient1.RemoteHost := 'localhost';
    TcpClient1.Active := true;
  end;

  procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
    var DataLen: Integer);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
  end;
```

See Also

Close (see page 1373)

Open (see page 1375)

24.1.11.3.2 TUdpSocket.BlockMode Property

Sets or returns the blocking mode of the socket.

Pascal

```
property BlockMode: TSocketBlockMode;
```

C++

```
__property TSocketBlockMode BlockMode;
```

Description

Use BlockMode to set or return the blocking mode for the socket. By default, the socket is set to bmBlocking.

The TSocketBlockMode type defines the set of possible socket flags for the BlockMode property.

See Also

TSocketBlockMode (see page 1505)

OnReceive (see page 1393)

OnSend (see page 1394)

24.1.11.3.3 TUdpSocket.LocalHost Property

Specifies the name of the local system.

Pascal

```
property LocalHost: TSocketHost;
```

C++

```
__property TSocketHost LocalHost;
```

Description

Use LocalHost to get the name of the system that is running the application that uses the socket. LocalHost is a string containing the domain name and service of the local socket endpoint, such as http://www.wSite.Com.

Port numbers allow a single system, identified by the LocalHostAddr function, to host multiple connections simultaneously. Each combination of LocalPort and LocalHostAddr can only be bound to a single socket connection.

LocalHost provides an alias for the local IP address given in the LocalHostAddr function. Most Intranets provide host names for the IP addresses of systems on the net. For more information on defining a host name for a given system, contact your network administrator.

See Also

LocalPort (see page 1424)

RemoteHost (see page 1426)

LocalHostAddr (see page 1420)

LookupHostName (see page 1421)

LookupPort (see page 1421)

24.1.11.3.4 TUdpSocket.LocalPort Property

Specifies the ID number of the port used by the socket connection.

Pascal

```
property LocalPort: TSocketPort;
```

C++

```
__property TSocketPort LocalPort;
```

Description

Use LocalPort to determine the port number that is bound to the socket connection. For server endpoints of listening connections, LocalPort is the ID associated with the service the server socket provides. For client or server endpoints of connections to another socket, LocalPort is usually an arbitrary value picked when the connection was made.

Many values of LocalPort are associated by convention with a particular service such as FTP or HTTP.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
```

```
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();

    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}
```

```
procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

See Also

LocalHost (see page 1423)

RemotePort (see page 1428)

LookupPort (see page 1421)

24.1.11.3.5 TUdpSocket.RemoteHost Property

Specifies the name of the remote system.

Pascal

```
property RemoteHost: TSocketHost;
```

C++

```
__property TSocketHost RemoteHost;
```

Description

Use RemoteHost to get the name of the system on the other end of the socket connection. RemoteHost is a string containing the domain name and service of the remote endpoint of the socket connection, such as http://www.wSite.Com.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)
```

```
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

See Also

RemotePort (see page 1428)

LocalHostName (see page 1420)

LookupHostAddr (see page 1420)

LookupHostName (see page 1421)

24.1.11.3.6 TUdpSocket.RemotePort Property

Specifies the ID number of the port used by the RemoteHost to form the socket connection.

Pascal

```
property RemotePort: TSocketPort;
```

C++

```
__property TSocketPort RemotePort;
```

Description

Use RemotePort to determine the port number used by the socket on the other end of the socket connection.

Port numbers allow a single system, identified by the RemoteHost property, to host multiple connections simultaneously. Each combination of RemotePort and RemoteHost can only be bound to a single socket connection.

Many port numbers are associated by convention with a particular service such as ftp or http. To determine whether the value of RemotePort is associated with a specific service, use the LookupProtocol method.

Note: If a client socket requests a specific port to indicate a desired service, the value of RemotePort for the actual connection may differ from the requested port number. Most server sockets listen on the port associated with a service, but switch to an arbitrary available port number for forming connections.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);
```

```
    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
```

```
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

LookupPort (see page 1421)

LookupProtocol (see page 1421)

24.1.11.4 TUdpSocket Events

The events of the TUdpSocket class are listed here.

Published Events

	Name	Description
	OnConnect (see page 1490)	Occurs on client sockets just after the connection to the server is opened.
	OnCreateHandle (see page 1490)	Occurs when the handle to a socket becomes active.
	OnDestroyHandle (see page 1493)	Occurs when a socket is deactivated.
	OnDisconnect (see page 1495)	Occurs on client sockets just after the connection to the server is closed.
	OnError (see page 1496)	Occurs when the socket fails in making, using, or shutting down a connection.
	OnReceive (see page 1496)	Occurs after a socket receives data, but before it passes the data to the application.
	OnSend (see page 1496)	Occurs just before a client socket writes information to the socket connection.

24.1.11.4.1 TUdpSocket.OnConnect Event

Occurs on client sockets just after the connection to the server is opened.

Pascal

```
property OnConnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnConnect;
```

Description

Write an OnConnect event handler for a client socket to take specific action after the connection to a server socket has been established. Depending on the service, this may be the point when the socket should start reading or writing over the connection.

See Also

Connected (see page 1405)

OnDisconnect (see page 1406)

24.1.11.4.2 TUdpSocket.OnCreateHandle Event

Occurs when the handle to a socket becomes active.

Pascal

```
property OnCreateHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnCreateHandle;
```

Description

Write an OnCreateHandle event handler to take specific action when the handle to a socket becomes active.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------
```

```
void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

procedure TForm3.Button1Click(Sender: TObject);
begin
  //connectiong the server
  TcpServer1.Active := true;
end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;

procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
```

```
    Memo1.Lines.Add('--------------------');

  end;

  procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
  begin
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
  end;

  procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
  begin
    if Self.Memo1 <> nil then
      Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
  end;
```

Handle (see page 1387)

24.1.11.4.3 TUdpSocket.OnDestroyHandle Event

Occurs when a socket is deactivated.

Pascal

```
property OnDestroyHandle: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDestroyHandle;
```

Description

Write an OnDestroyHandle event handler to take specific action when the socket is deactivated.

C++ Examples:

```
/*
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
This example uses three buttons, one for activating the server, one
for deactivating it and the third for clearing the Memo.
*/
__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Memo1->Lines->Clear();

    //server initialization
    TcpServer1 = new TTcpServer(this);
    TcpServer1->OnAccept = TcpServer1Accept;
    TcpServer1->OnCreateHandle = TcpServer1CreateHandle;
    TcpServer1->OnDestroyHandle = TcpServer1DestroyHandle;

}
//---------------------------------------------------------------------------
void __fastcall TForm3::TcpServer1Accept(TObject *Sender,
                                         TCustomIpClient *ClientSocket)
{
    byte a[10];
    ClientSocket->ReceiveBuf(a,10,0);
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Data added width " +
                      IntToStr(a[9]));
```

```
    for (int i=0; i < 9; i++)
    {
        Memo1->Lines->Add(IntToStr(a[i] + a[9]));
    }
    Memo1->Lines->Add("--------------------");

}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button1Click(TObject *Sender)
{
    TcpServer1->LocalPort = DEFAULT_PORT;
    TcpServer1->Active = true;
}
//---------------------------------------------------------------------------
void __fastcall TForm3::Button2Click(TObject *Sender)
{
    TcpServer1->Active = false;
}

//---------------------------------------------------------------------------
void __fastcall TForm3::Button3Click(TObject *Sender)
{
    Memo1->Lines->Clear();
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1CreateHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Server started.");
}
//---------------------------------------------------------------------------

void __fastcall TForm3::TcpServer1DestroyHandle(TObject *Sender)
{
    TDateTime now = TDateTime::CurrentDateTime();
    if(this->Memo1)
    {
        Memo1->Lines->Add(DateTimeToStr(now) + " Server stopped.");
    }
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example demonstrated the use of TTcpServer in order to receive
a buffer (stream) and process it. It is to be used with the example
from TTcpClient section.
}

const DEFAULT_PORT = 2501;

{$R *.dfm}

end;

procedure TForm3.Button2Click(Sender: TObject);
begin
  //disconnecting the server
  TcpServer1.Active := false;
end;
```

```
procedure TForm3.Button3Click(Sender: TObject);
begin
  //clearing the memo
  Memo1.Lines.Clear;
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Memo1.Lines.Clear;

  //server initialization
  TcpServer1 := TTcpServer.Create(Self);
  TcpServer1.OnAccept := TCpServer1Accept;
  TcpServer1.OnCreateHandle := TcpServer1CreateHandle;
  TcpServer1.OnDestroyHandle := TcpServer1DestroyHandle;
  TcpServer1.LocalPort := IntToStr(DEFAULT_PORT);
end;

procedure TForm3.TcpServer1Accept(Sender: TObject;
  ClientSocket: TCustomIpClient);
var
  a : array[0..9] of byte;
  I : Cardinal;
begin

  ClientSocket.ReceiveBuf(a,10,0);
  Memo1.Lines.Add(DateTimeToStr(now) + ' Data added with ' +
                  IntToStr(a[9]));
  for I := 0 to 8 do
  begin
    Memo1.Lines.Add(IntToStr(a[I] + a[9]));
  end;
  Memo1.Lines.Add('--------------------');

end;

procedure TForm3.TcpServer1CreateHandle(Sender: TObject);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Server started.');
end;

procedure TForm3.TcpServer1DestroyHandle(Sender: TObject);
begin
  if Self.Memo1 <> nil then
    Memo1.Lines.Add(DateTimeToStr(now) + ' Server stopped.');
end;
```

24.1.11.4.4 TUdpSocket.OnDisconnect Event

Occurs on client sockets just after the connection to the server is closed.

Pascal

```
property OnDisconnect: TSocketNotifyEvent;
```

C++

```
__property TSocketNotifyEvent OnDisconnect;
```

Description

Write an OnDisconnect event handler for a client socket to take specific action just after the connection to a server socket is terminated.

See Also

Connected (see page 1405)

OnConnect (see page 1405)

24.1.11.4.5 TUdpSocket.OnError Event

Occurs when the socket fails in making, using, or shutting down a connection.

Pascal

```
property OnError: TSocketErrorEvent;
```

C++

```
__property TSocketErrorEvent OnError;
```

Description

Write an OnError event handler to respond to errors that arise with the socket connection. Set the **ErrorCode** parameter to 0 if the OnError event handler successfully deals with the error condition, to prevent an ESocketError exception from being raised.

See Also

ESocketError (see page 1369)

24.1.11.4.6 TUdpSocket.OnReceive Event

Occurs after a socket receives data, but before it passes the data to the application.

Pascal

```
property OnReceive: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnReceive;
```

Description

Write an OnReceive event handler to read from the socket connection. Use the OnReceive event to filter data before passing it back to the client application. If the socket is a blocking socket, use a TWinSocketStream object to read from the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual reading.

See Also

TWinSocketStream (see page 138)

BytesReceived (see page 1386)

ReceiveBuf (see page 1376)

ReceiveIn (see page 1379)

24.1.11.4.7 TUdpSocket.OnSend Event

Occurs just before a client socket writes information to the socket connection.

Pascal

```
property OnSend: TSocketDataEvent;
```

C++

```
__property TSocketDataEvent OnSend;
```

Description

Write an OnSend event handler to perform actions just prior to sending data. Use OnSend to monitor the data stream and

change it (for example, by removing linefeeds). If the socket is a blocking socket, use a TWinSocketStream object to write to the connection. Otherwise, use the methods of the **Socket** parameter to perform the actual writing.

C++ Examples:

```
/*
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
*/
#define DEFAULT_PORT 2501

__fastcall TForm3::TForm3(TComponent* Owner)
    : TForm(Owner)
{
    Edit1->Text = "0";
    Memo1->Lines->Clear();

    TcpClient1 = new TTcpClient(this);
    TcpClient1->OnSend = TcpClient1Send;
    TcpClient1->RemotePort = DEFAULT_PORT;
    TcpClient1->RemoteHost = "localhost";
}

#include <memory>       //for STL auto_ptr class

void __fastcall TForm3::Button1Click(TObject *Sender)
{
    //creating a stream
//  TMemoryStream* myStream = new TMemoryStream();
    std::auto_ptr<TMemoryStream> myStream(new TMemoryStream);
    for (byte i = 0; i < 9; i++)
    {
        myStream->WriteBuffer(&i,1);
    }
    int userValue = StrToIntDef(Edit1->Text, 0);
    myStream->WriteBuffer(&userValue, 1);

    //resetting the stream position
    myStream->Seek(0, 0);

    //sending the stream
    TcpClient1->Active = true;
    TcpClient1->SendStream(myStream.get());
    TcpClient1->Active = false;

    //free the stream
//  delete myStream;
}

//---------------------------------------------------------------------------

void __fastcall TForm3::TcpClient1Send(TObject *Sender, PWideChar Buf, int &DataLen)

{
    TDateTime now = TDateTime::CurrentDateTime();
    Memo1->Lines->Add(DateTimeToStr(now) + " Sent data with " + Edit1->Text);
}
```

Delphi Examples:

```
{
    This example demontrates the use of SendStream method. It is to be
    used with the example from TTcpServer section.
}
const DEFAULT_PORT = 2501;

procedure TForm3.Button1Click(Sender: TObject);
```

```
var
  myStream : TMemoryStream;
  I : Cardinal;
  userValue : Integer;
begin
  //creating a stream
  myStream := TMemoryStream.Create();
  for I := 0 to 8 do
  begin
    myStream.WriteBuffer(I,1);
  end;
  userValue := StrToIntDef(Edit1.Text, 0);
  myStream.WriteBuffer(userValue,1);

  //resetting the stream position
  myStream.Seek(0,0);

  //sending the stream
  TcpClient1.Active := true;
  TcpClient1.SendStream(myStream);
  TcpClient1.Active := false;

  //free the stream
  myStream.Free;

end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  Edit1.Text := '0';
  Memo1.Lines.Clear;

  TcpClient1.RemotePort := IntToStr(DEFAULT_PORT);
  TcpClient1.RemoteHost := 'localhost';
  TcpClient1.Active := true;
end;

procedure TForm3.TcpClient1Send(Sender: TObject; Buf: PWideChar;
  var DataLen: Integer);
begin
  Memo1.Lines.Add(DateTimeToStr(now) + ' Sent data with ' + Edit1.Text);
end;
```

See Also

TWinSocketStream (see page 138)

SendBuf (see page 1380)

SendIn (see page 1380)

24.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TServerSocketBlockMode (see page 1500)	Defines the set of possible socket flags for block mode.
	TSocketDomain (see page 1500)	Set of possible protocol family types used by a socket.
	TSocketType (see page 1502)	The TSocketType type defines the set of possible socket types.

Records

	Name	Description
	TIPHeader (see page 1499)	This is record Sockets.TIPHeader.

24.2.1 Sockets.TIPHeader Record

Pascal

```
TIPHeader = packed record
  iph_verlen: byte;
  iph_tos: byte;
  iph_length: word;
  iph_id: word;
  iph_offset: word;
  iph_ttl: byte;
  iph_protocol: byte;
  iph_xsum: word;
  iph_src: longword;
  iph_dest: longword;
end;
```

C++

```
struct TIPHeader {
  byte iph_verlen;
  byte iph_tos;
  word iph_length;
  word iph_id;
  word iph_offset;
  byte iph_ttl;
  byte iph_protocol;
  word iph_xsum;
  longword iph_src;
  longword iph_dest;
};
```

File

Sockets

Description

This is record Sockets.TIPHeader.

24.2.2 Sockets.TServerSocketBlockMode Enumeration

Defines the set of possible socket flags for block mode.

Pascal

```
TServerSocketBlockMode = (
  bmBlocking,
  bmNonBlocking,
  bmThreadBlocking
);
```

C++

```
enum TServerSocketBlockMode {
  bmBlocking,
  bmNonBlocking,
  bmThreadBlocking
};
```

File

Sockets

Description

The following table lists the possible values for the TServerSocketBlockMode type and the meaning corresponding to each value:

Value	Socket state
bmBlocking	The socket is set to block mode.
bmNonBlocking	The socket is set to non-blocking mode.
bmThreadBlocking	A separate thread is created so that listening can be performed in the background without blocking the entire server application.

24.2.3 Sockets.TSocketDomain Enumeration

Set of possible protocol family types used by a socket.

Pascal

```
TSocketDomain = (
  pfUnspec,
  pfUnix,
  pfInet,
  pfImpLink,
  pfPup,
  pfChaos,
  pfIpx,
  pfNs,
  pfIso,
  pfOsi,
  pfEcma,
  pfDataKit,
  pfCcitt,
  pfSna,
  pfDecNet,
```

```
    pfDli,
    pfLat,
    pfHylink,
    pfAppleTalk,
    pfVoiceView,
    pfFireFox,
    pfUnknown1,
    pfBan,
    pfMax
  );
```

C++

```
  enum TSocketDomain {
    pfUnspec,
    pfUnix,
    pfInet,
    pfImpLink,
    pfPup,
    pfChaos,
    pfIpx,
    pfNs,
    pfIso,
    pfOsi,
    pfEcma,
    pfDataKit,
    pfCcitt,
    pfSna,
    pfDecNet,
    pfDli,
    pfLat,
    pfHylink,
    pfAppleTalk,
    pfVoiceView,
    pfFireFox,
    pfUnknown1,
    pfBan,
    pfMax
  };
```

File

Sockets

Description

The following table lists the possible values for the TSocketDomain type and the meaning corresponding to each value:

Value	Description
pfAppleTalk	AppleTalk DDP
pfBan	Banyan Vines
pfCcitt	CCIT (International Telegraph and Telephone Consultative)
pfChaos	
pfDataKit	DataKit
pfDecNet	Reserved for DECnet project
pfDli	
pfEcma	EcmaScript
pfFireFox	FireFox
pfHylink	Hyperlink
pfImpLink	Imported link

pfInet	IP protocol family
pfIpx	Novell Interner Protocol
pfIso	International Standards Organization (ISO)
pfLat	
pfMax	Maximum protocol family number
pfNs	Network Services Protocol (used with DECnet)
pfOsi	Open Systems Interconnection (OSI)
pfPup	PUP protocol
pfSna	Linux SNA project
pfUnix	Local to host (old BSD name for local)
pfUnknown1	Unknown
pfUnspec	Unspecified
pfVoiceView	VoiceView

24.2.4 Sockets.TSocketType Enumeration

The TSocketType type defines the set of possible socket types.

Pascal

```
TSocketType = (
  stStream,
  stDgram,
  stRaw,
  stRdm,
  stSeqPacket
);
```

C++

```
enum TSocketType {
  stStream,
  stDgram,
  stRaw,
  stRdm,
  stSeqPacket
};
```

File

Sockets

Description

The following table lists the possible values for the TSocketType type and the meaning corresponding to each value:

Value	Description
stDgram	Single datagram packets, not used by IP. Non-reliable.
stRaw	The socket sends and receives raw datagram packets. Used by IP.
stRdm	Reliably delivered message.
stSeqPacket	Sequenced packet stream sends and receives any type of IP packet.

stStream	Reliable streaming data packets. Used by TCP.

24.3 Types

The following table lists types in this documentation.

Types

Name	Description
TGetThreadEvent (see page 1504)	This is type Sockets.TGetThreadEvent.
TSocketAcceptEvent (see page 1504)	This is type Sockets.TSocketAcceptEvent.
TSocketBlockMode (see page 1505)	Defines the set of possible flags for blocking mode of the socket.
TSocketDataEvent (see page 1505)	This is type Sockets.TSocketDataEvent.
TSocketErrorEvent (see page 1505)	This is type Sockets.TSocketErrorEvent.
TSocketHost (see page 1506)	This is type Sockets.TSocketHost.
TSocketNotifyEvent (see page 1506)	This is type Sockets.TSocketNotifyEvent.
TSocketPort (see page 1506)	This is type Sockets.TSocketPort.
TSocketProtocol (see page 1507)	TSocketProtocol is the code for a socket protocol.

24.3.1 Sockets.TGetThreadEvent Type

Pascal

```
TGetThreadEvent = procedure (Sender: TObject; var ClientSocketThread: TClientSocketThread) of object;
```

C++

```
(Sender: TObject; var ClientSocketThread: TClientSocketThread) ( TGetThreadEvent)();
```

File

Sockets

Description

This is type Sockets.TGetThreadEvent.

24.3.2 Sockets.TSocketAcceptEvent Type

Pascal

```
TSocketAcceptEvent = procedure (Sender: TObject; ClientSocket: TCustomIpClient) of object;
```

C++

```
(Sender: TObject; ClientSocket: TCustomIpClient) ( TSocketAcceptEvent)();
```

File

Sockets

Description

This is type Sockets.TSocketAcceptEvent.

24.3.3 Sockets.TSocketBlockMode Type

Defines the set of possible flags for blocking mode of the socket.

Pascal

```
TSocketBlockMode = bmBlocking..bmNonBlocking;
```

C++

```
bmBlocking..bmNonBlocking TSocketBlockMode;
```

File

Sockets

Description

The following table describes TSocketBlockMode values.

Value	Socket state
bmBlocking	The socket is set to block mode.
bmNonBlocking	The socket is set to non-blocking mode.

24.3.4 Sockets.TSocketDataEvent Type

Pascal

```
TSocketDataEvent = procedure (Sender: TObject; Buf: pchar; var DataLen: Integer) of object;
```

C++

```
(Sender: TObject; Buf: pchar; var DataLen: Integer) ( TSocketDataEvent)();
```

File

Sockets

Description

This is type Sockets.TSocketDataEvent.

24.3.5 Sockets.TSocketErrorEvent Type

Pascal

```
TSocketErrorEvent = procedure (Sender: TObject; SocketError: Integer) of object;
```

C++

```
(Sender: TObject; SocketError: Integer) ( TSocketErrorEvent)();
```

File

Sockets

Description

This is type Sockets.TSocketErrorEvent.

24.3.6 Sockets.TSocketHost Type

Pascal

```
TSocketHost = type string;
```

C++

```
type string TSocketHost;
```

File

Sockets

Description

This is type Sockets.TSocketHost.

24.3.7 Sockets.TSocketNotifyEvent Type

Pascal

```
TSocketNotifyEvent = procedure (Sender: TObject) of object;
```

C++

```
(Sender: TObject) ( TSocketNotifyEvent)();
```

File

Sockets

Description

This is type Sockets.TSocketNotifyEvent.

24.3.8 Sockets.TSocketPort Type

Pascal

```
TSocketPort = type string;
```

C++

```
type string TSocketPort;
```

File

Sockets

Description

This is type Sockets.TSocketPort.

24.3.9 Sockets.TSocketProtocol Type

TSocketProtocol is the code for a socket protocol.

Pascal

```
TSocketProtocol = Word;
```

C++

```
Word TSocketProtocol;
```

File

Sockets

Description

TSocketProtocol is a number that represents a network protocol such as IP, TCP, or UDP.

24.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CRLF (see page 1508)	This is constant Sockets.CRLF.

24.4.1 Sockets.CRLF Constant

Pascal

```
CRLF = #13#10;
```

C++

```
CRLF = #13#10;
```

File

Sockets

Description

This is constant Sockets.CRLF.

25 SqlExpr Namespace

This is namespace SqlExpr.

Topics

Name	Description
Classes (see page 1512)	The following table lists classes in this documentation.
Functions (see page 1696)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 1699)	The following table lists structs, records, enums in this documentation.
Types (see page 1706)	The following table lists types in this documentation.
Constants (see page 1711)	The following table lists constants in this documentation.

Classes

	Name	Description
	SPParamDesc (see page 1512)	SPParamDesc describes a parameter to a stored procedure that is accessed using dbExpress.
	TConnectionData (see page 1515)	This is class SqlExpr.TConnectionData.
	TCustomSQLDataSet (see page 1520)	TCustomSQLDataSet is the base class for all dbExpress dataset components.
	TFLDDesc (see page 1570)	This is class SqlExpr.TFLDDesc.
	TSQLBlobStream (see page 1577)	TSQLBlobStream lets applications read from or write to BLOB fields in a client dataset.
	TSQLConnection (see page 1580)	TSQLConnection encapsulates a dbExpress connection to a database server.
	TSQLDataLink (see page 1628)	TSQLDataLink allows a unidirectional dataset act as the detail in a master/detail relationship.
	TSQLDataSet (see page 1631)	TSQLDataSet represents data retrieved using dbExpress.
	TSQLMonitor (see page 1643)	TSQLMonitor intercepts messages that pass between an SQL connection component and a database server and saves them in a string list.
	TSQLQuery (see page 1654)	TSQLQuery represents a query that is executed using dbExpress.
	TSqlServerMethod (see page 1665)	TDataSet used to call DataSnap server methods.
	TSQLStoredProc (see page 1671)	TSQLStoredProc represents a stored procedure that is executed using dbExpress.
	TSQLTable (see page 1680)	TSQLTable represents a database table that is accessed using dbExpress.
	TTransactionItem (see page 1694)	This is class SqlExpr.TTransactionItem.

Constants

Name	Description
BlobTypeMap (see page 1711)	This is constant SqlExpr.BlobTypeMap.
DataTypeMap (see page 1712)	This is constant SqlExpr.DataTypeMap.

DefaultCursor (see page 1712)	This is constant SqlExpr.DefaultCursor.
DefaultMaxBlobSize (see page 1713)	This is constant SqlExpr.DefaultMaxBlobSize.
DefaultRowsetSize (see page 1713)	DefaultRowsetSize represents the default row buffering size.
eSQLAutoIncr (see page 1713)	This is constant SqlExpr.eSQLAutoIncr.
eSQLDefault (see page 1714)	This is constant SqlExpr.eSQLDefault.
eSQLFunction (see page 1714)	This is constant SqlExpr.eSQLFunction.
eSQLLocal (see page 1714)	This is constant SqlExpr.eSQLLocal.
eSQLNonUnique (see page 1715)	This is constant SqlExpr.eSQLNonUnique.
eSQLPackage (see page 1715)	This is constant SqlExpr.eSQLPackage.
eSQLPrimaryKey (see page 1715)	This is constant SqlExpr.eSQLPrimaryKey.
eSQLProcedure (see page 1716)	This is constant SqlExpr.eSQLProcedure.
eSQLRowId (see page 1716)	This is constant SqlExpr.eSQLRowId.
eSQLRowVersion (see page 1716)	This is constant SqlExpr.eSQLRowVersion.
eSQLSynonym (see page 1717)	This is constant SqlExpr.eSQLSynonym.
eSQLSysProcedure (see page 1717)	This is constant SqlExpr.eSQLSysProcedure.
eSQLSystemTable (see page 1717)	This is constant SqlExpr.eSQLSystemTable.
eSQLTable (see page 1718)	This is constant SqlExpr.eSQLTable.
eSQLTempTable (see page 1718)	This is constant SqlExpr.eSQLTempTable.
eSQLUnique (see page 1718)	This is constant SqlExpr.eSQLUnique.
eSQLView (see page 1719)	This is constant SqlExpr.eSQLView.
FldSubTypeMap (see page 1719)	This is constant SqlExpr.FldSubTypeMap.
FldTypeMap (see page 1719)	This is constant SqlExpr.FldTypeMap.
HourGlassCursor (see page 1720)	This is constant SqlExpr.HourGlassCursor.
SAnd (see page 1721)	This is constant SqlExpr.SAnd.
SOrderBy (see page 1721)	This is constant SqlExpr.SOrderBy.
SParam (see page 1721)	This is constant SqlExpr.SParam.
SSelect (see page 1722)	This is constant SqlExpr.SSelect.
SSelectSpaces (see page 1722)	This is constant SqlExpr.SSelectSpaces.
SSelectStar (see page 1722)	This is constant SqlExpr.SSelectStar.
SSelectStarFrom (see page 1723)	This is constant SqlExpr.SSelectStarFrom.
SUB_TYPE_MEMO (see page 1723)	This is constant SqlExpr.SUB_TYPE_MEMO.
SWhere (see page 1723)	This is constant SqlExpr.SWhere.
TErrorMessageSize (see page 1724)	This is constant SqlExpr.TErrorMessageSize.

Functions

	Name	Description
	FreeProcParams (see page 1696)	Frees a list of procedure parameters that is allocated by GetProcedureParams.
	GetConnectionNames (see page 1696)	This is function SqlExpr.GetConnectionNames.
	GetConnectionRegistryFile (see page 1697)	This is function SqlExpr.GetConnectionRegistryFile.
	GetDelegateDriverNames (see page 1697)	This is function SqlExpr.GetDelegateDriverNames.
	GetDriverNames (see page 1697)	Populates a string list with the names of all available dbExpress drivers.
	GetDriverRegistryFile (see page 1698)	This is function SqlExpr.GetDriverRegistryFile.
	LoadParamListItems (see page 1698)	Fills a TParams object with information from a list of parameter descriptors.

Structs, Records, Enums

	Name	Description
	EConnectFlag (see page 1699)	This is record SqlExpr.EConnectFlag.
	TConnectionState (see page 1700)	TConnectionState describes the state of a TSQLConnection (see page 1580) component.
	TConnectionUserType (see page 1700)	This is record SqlExpr.TConnectionUserType.
	TSchemaType (see page 1701)	TSchemaType and TSchemaInfo describe schema information (metadata) to access using dbXpress.
	TSQLExceptionType (see page 1702)	TSQLExceptionType indicates the type of operation that leads to an ESQLException exception.
	TSQLSchemaInfo (see page 1703)	This is record SqlExpr.TSQLSchemaInfo.

	TTableScope (see page 1703)	TTableScopes (see page 1710) and TTableScopess indicate the types of tables for which to fetch metadata.
	TTransactionDesc (see page 1704)	This is record SqlExpr.TTransactionDesc.
	TTransIsolationLevel (see page 1704)	This enumerated type (in C++) or type (in Delphi) identifies degree to which transactions are isolated from each other.

Types

Name	Description
SQLResult (see page 1706)	SQLResult is the return type for dbExpress function calls.
TFieldDescList (see page 1707)	This is type SqlExpr.TFieldDescList.
TFieldList (see page 1707)	This is type SqlExpr.TFieldList.
TGetDriverFunc (see page 1708)	This is type SqlExpr.TGetDriverFunc.
TLocale (see page 1708)	This is type SqlExpr.TLocale.
TLocaleCode (see page 1708)	TLocaleCode identifies a locale, which imposes a sort order on data.
TParseInsertSqlEvent (see page 1709)	This is type SqlExpr.TParseInsertSqlEvent.
TParseSqlEvent (see page 1709)	This is type SqlExpr.TParseSqlEvent.
TSQLConnectionLoginEvent (see page 1709)	This is type SqlExpr.TSQLConnectionLoginEvent.
TTableScopes (see page 1710)	This is type SqlExpr.TTableScopes.
TTraceEvent (see page 1710)	This is type SqlExpr.TTraceEvent.
TTraceLogEvent (see page 1710)	This is type SqlExpr.TTraceLogEvent.

25.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	SPParamDesc (see page 1512)	SPParamDesc describes a parameter to a stored procedure that is accessed using dbExpress.
	TConnectionData (see page 1515)	This is class SqlExpr.TConnectionData.
	TCustomSQLDataSet (see page 1520)	TCustomSQLDataSet is the base class for all dbExpress dataset components.
	TFLDDesc (see page 1570)	This is class SqlExpr.TFLDDesc.
	TSQLBlobStream (see page 1577)	TSQLBlobStream lets applications read from or write to BLOB fields in a client dataset.
	TSQLConnection (see page 1580)	TSQLConnection encapsulates a dbExpress connection to a database server.
	TSQLDataLink (see page 1628)	TSQLDataLink allows a unidirectional dataset act as the detail in a master/detail relationship.
	TSQLDataSet (see page 1631)	TSQLDataSet represents data retrieved using dbExpress.
	TSQLMonitor (see page 1643)	TSQLMonitor intercepts messages that pass between an SQL connection component and a database server and saves them in a string list.
	TSQLQuery (see page 1654)	TSQLQuery represents a query that is executed using dbExpress.
	TSqlServerMethod (see page 1665)	TDataSet used to call DataSnap server methods.
	TSQLStoredProc (see page 1671)	TSQLStoredProc represents a stored procedure that is executed using dbExpress.
	TSQLTable (see page 1680)	TSQLTable represents a database table that is accessed using dbExpress.
	TTransactionItem (see page 1694)	This is class SqlExpr.TTransactionItem.

25.1.1 SPParamDesc Class

SPParamDesc describes a parameter to a stored procedure that is accessed using dbExpress.

Class Hierarchy

SqlExpr.SPParamDesc

Pascal

```
SPParamDesc = class;
```

C++

```
class SPParamDesc;
```

File

SqlExpr

Description

PSPParamDesc is a pointer to a parameter descriptor. SPParamDesc is a parameter descriptor that describes a parameter for a stored procedure. SPParamDesc includes the following members:

Member	Meaning
iParamNum (see page 1514)	The ordinal position of the parameter.

szName (see page 1515)	The name of the parameter
iArgType (see page 1513)	The type of the parameter (input, output, and so on)
iDataType (see page 1514)	The data type of the parameter
iUnits1 (see page 1514)	The size for the datatype (number of characters, digits, etc)
iUnits2 (see page 1515)	Number of decimal places if datatype is BCD
iLen (see page 1514)	The number of bytes needed to store a parameter value

See Also

TSQLConnection (see page 1580)

25.1.1.1 SPParamDesc Members

The following tables list the members exposed by SPParamDesc.

Public Fields

	Name	Description
	iArgType (see page 1513)	This is iArgType, a member of class SPParamDesc.
	iDataType (see page 1514)	This is iDataType, a member of class SPParamDesc.
	iLen (see page 1514)	This is iLen, a member of class SPParamDesc.
	iParamNum (see page 1514)	This is iParamNum, a member of class SPParamDesc.
	iUnits1 (see page 1514)	This is iUnits1, a member of class SPParamDesc.
	iUnits2 (see page 1515)	This is iUnits2, a member of class SPParamDesc.
	szName (see page 1515)	This is szName, a member of class SPParamDesc.

25.1.1.2 SPParamDesc Fields

The fields of the SPParamDesc class are listed here.

Public Fields

	Name	Description
	iArgType (see page 1513)	This is iArgType, a member of class SPParamDesc.
	iDataType (see page 1514)	This is iDataType, a member of class SPParamDesc.
	iLen (see page 1514)	This is iLen, a member of class SPParamDesc.
	iParamNum (see page 1514)	This is iParamNum, a member of class SPParamDesc.
	iUnits1 (see page 1514)	This is iUnits1, a member of class SPParamDesc.
	iUnits2 (see page 1515)	This is iUnits2, a member of class SPParamDesc.
	szName (see page 1515)	This is szName, a member of class SPParamDesc.

25.1.1.2.1 SPParamDesc.iArgType Field

Pascal

```
iArgType: TParamType;
```

C++

```
TParamType iArgType;
```

Description

This is iArgType, a member of class SPParamDesc.

25.1.1.2.2 SPParamDesc.iDataType Field

Pascal

```
iDataType: TFieldType;
```

C++

```
TFieldType iDataType;
```

Description

This is iDataType, a member of class SPParamDesc.

25.1.1.2.3 SPParamDesc.iLen Field

Pascal

```
iLen: LongWord;
```

C++

```
LongWord iLen;
```

Description

This is iLen, a member of class SPParamDesc.

25.1.1.2.4 SPParamDesc.iParamNum Field

Pascal

```
iParamNum: Word;
```

C++

```
Word iParamNum;
```

Description

This is iParamNum, a member of class SPParamDesc.

25.1.1.2.5 SPParamDesc.iUnits1 Field

Pascal

```
iUnits1: SmallInt;
```

C++

```
SmallInt iUnits1;
```

Description

This is iUnits1, a member of class SPParamDesc.

25.1.1.2.6 SPParamDesc.iUnits2 Field

Pascal

```
iUnits2: SmallInt;
```

C++

```
SmallInt iUnits2;
```

Description

This is iUnits2, a member of class SPParamDesc.

25.1.1.2.7 SPParamDesc.szName Field

Pascal

```
szName: string;
```

C++

```
UnicodeString szName;
```

Description

This is szName, a member of class SPParamDesc.

25.1.2 TConnectionData Class

Class Hierarchy

Pascal

```
TConnectionData = class(TPersistent);
```

C++

```
class TConnectionData : public TPersistent;
```

File

SqlExpr

Description

This is class SqlExpr.TConnectionData.

25.1.2.1 TConnectionData Members

The following tables list the members exposed by TConnectionData.

Protected Methods

	Name	Description
	GetFullParams (see page 1518)	This is GetFullParams, a member of class TConnectionData.

Public Methods

	Name	Description
	AddProperties (see page 1517)	This is AddProperties, a member of class TConnectionData.
	BeginUpdate (see page 1518)	This is BeginUpdate, a member of class TConnectionData.
	Create (see page 1516)	This is the overview for the Create constructor overload.
V	Destroy (see page 1517)	Destroys the TPersistent instance and frees its memory.
	EndUpdate (see page 1518)	This is EndUpdate, a member of class TConnectionData.
	RefreshProperties (see page 1518)	This is RefreshProperties, a member of class TConnectionData.
	ReloadProperties (see page 1518)	This is ReloadProperties, a member of class TConnectionData.
	UpdateProperties (see page 1519)	This is UpdateProperties, a member of class TConnectionData.

Published Properties

	Name	Description
	ConnectionName (see page 1519)	This is ConnectionName, a member of class TConnectionData.
	DelegateConnection (see page 1519)	This is DelegateConnection, a member of class TConnectionData.
	DriverName (see page 1520)	This is DriverName, a member of class TConnectionData.
R	IsModified (see page 1520)	This is IsModified, a member of class TConnectionData.
	Properties (see page 1520)	This is Properties, a member of class TConnectionData.

25.1.2.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TConnectionData.Create (TConnectionData) (see page 1516)	This is Create, a member of class TConnectionData.
	TConnectionData.Create (TSQLConnection) (see page 1516)	This is Create, a member of class TConnectionData.

25.1.2.2.1 TConnectionData.Create Constructor (TConnectionData)

Pascal

```
constructor Create(AParentData: TConnectionData); overload;
```

C++

```
__fastcall TConnectionData(TConnectionData AParentData);
```

Description

This is Create, a member of class TConnectionData.

25.1.2.2.2 TConnectionData.Create Constructor (TSQLConnection)

Pascal

```
constructor Create(AConnection: TSQLConnection); overload;
```

C++

```
__fastcall TConnectionData(TSQLConnection AConnection);
```

Description

This is Create, a member of class TConnectionData.

25.1.2.3 TConnectionData.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TConnectionData();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

System::TObject::Destroy (see page 3356)

25.1.2.4 TConnectionData Methods

The methods of the TConnectionData class are listed here.

Protected Methods

	Name	Description
	GetFullParams (see page 1518)	This is GetFullParams, a member of class TConnectionData.

Public Methods

	Name	Description
	AddProperties (see page 1517)	This is AddProperties, a member of class TConnectionData.
	BeginUpdate (see page 1518)	This is BeginUpdate, a member of class TConnectionData.
	EndUpdate (see page 1518)	This is EndUpdate, a member of class TConnectionData.
	RefreshProperties (see page 1518)	This is RefreshProperties, a member of class TConnectionData.
	ReloadProperties (see page 1518)	This is ReloadProperties, a member of class TConnectionData.
	UpdateProperties (see page 1519)	This is UpdateProperties, a member of class TConnectionData.

25.1.2.4.1 TConnectionData.AddProperties Method

Pascal

```
procedure AddProperties(NewProperties: TStrings);
```

C++

```
__fastcall AddProperties(TStrings NewProperties);
```

Description

This is AddProperties, a member of class TConnectionData.

25.1.2.4.2 TConnectionData.BeginUpdate Method

Pascal

```
function BeginUpdate: Boolean;
```

C++

```
__fastcall Boolean BeginUpdate();
```

Description

This is BeginUpdate, a member of class TConnectionData.

25.1.2.4.3 TConnectionData.EndUpdate Method

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

This is EndUpdate, a member of class TConnectionData.

25.1.2.4.4 TConnectionData.GetFullParams Method

Pascal

```
procedure GetFullParams(Params: TStrings);
```

C++

```
__fastcall GetFullParams(TStrings Params);
```

Description

This is GetFullParams, a member of class TConnectionData.

25.1.2.4.5 TConnectionData.RefreshProperties Method

Pascal

```
procedure RefreshProperties;
```

C++

```
__fastcall RefreshProperties();
```

Description

This is RefreshProperties, a member of class TConnectionData.

25.1.2.4.6 TConnectionData.ReloadProperties Method

Pascal

```
procedure ReloadProperties;
```

C++

```
__fastcall ReloadProperties();
```

Description

This is ReloadProperties, a member of class TConnectionData.

25.1.2.4.7 TConnectionData.UpdateProperties Method

Pascal

```
procedure UpdateProperties(NewProperties: TStrings);
```

C++

```
__fastcall UpdateProperties(TStrings NewProperties);
```

Description

This is UpdateProperties, a member of class TConnectionData.

25.1.2.5 TConnectionData Properties

The properties of the TConnectionData class are listed here.

Published Properties

	Name	Description
	ConnectionName (see page 1519)	This is ConnectionName, a member of class TConnectionData.
	DelegateConnection (see page 1519)	This is DelegateConnection, a member of class TConnectionData.
	DriverName (see page 1520)	This is DriverName, a member of class TConnectionData.
R	IsModified (see page 1520)	This is IsModified, a member of class TConnectionData.
	Properties (see page 1520)	This is Properties, a member of class TConnectionData.

25.1.2.5.1 TConnectionData.ConnectionName Property

Pascal

```
property ConnectionName: string;
```

C++

```
__property UnicodeString ConnectionName;
```

Description

This is ConnectionName, a member of class TConnectionData.

25.1.2.5.2 TConnectionData.DelegateConnection Property

Pascal

```
property DelegateConnection: TConnectionData;
```

C++

```
__property TConnectionData DelegateConnection;
```

Description

This is DelegateConnection, a member of class TConnectionData.

25.1.2.5.3 TConnectionData.DriverName Property

Pascal

```
property DriverName: string;
```

C++

```
__property UnicodeString DriverName;
```

Description

This is DriverName, a member of class TConnectionData.

25.1.2.5.4 TConnectionData.IsModified Property

Pascal

```
property IsModified: Boolean;
```

C++

```
__property Boolean IsModified;
```

Description

This is IsModified, a member of class TConnectionData.

25.1.2.5.5 TConnectionData.Properties Property

Pascal

```
property Properties: TDBXProperties;
```

C++

```
__property TDBXProperties Properties;
```

Description

This is Properties, a member of class TConnectionData.

25.1.3 TCustomSQLDataSet Class

TCustomSQLDataSet is the base class for all dbExpress dataset components.

Class Hierarchy

Pascal

```
TCustomSQLDataSet = class(TWideDataSet);
```

C++

```
class TCustomSQLDataSet : public TWideDataSet;
```

File

SqlExpr

Description

TCustomSQLDataSet encapsulates the properties, events, and methods for working with data accessed through dbExpress. Applications should not instantiate TCustomSQLDataSet objects. Instead, instantiate one of the descendant classes: TSQLDataSet (see page 1631), TSQLTable (see page 1680), TSQLQuery (see page 1654), or TSQLStoredProc (see page 1671).

TCustomSQLDataSet and its descendants represent unidirectional datasets. Unlike other datasets, unidirectional datasets do not buffer multiple records in memory. Because of this, they have the following limitations:

There is no searching or navigation support except for moving to the first record or moving to the next record.

There is no built-in editing support. The data underlying an SQL dataset can only be edited by explicitly creating an SQL UPDATE command or by connecting the SQL dataset to a client dataset using a provider.

There is no support for filtering records or for lookup fields.

See Also

TSQLDataSet (see page 1631)

TSQLQuery (see page 1654)

TSQLStoredProc (see page 1671)

TSQLTable (see page 1680)

TSQLConnection (see page 1580)

TClientDataSet

TDataSetProvider

25.1.3.1 TCustomSQLDataSet Members

The following tables list the members exposed by TCustomSQLDataSet.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	ExecSQL (see page 1529)	This is ExecSQL, a member of class TCustomSQLDataSet.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.

	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.
V	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
V	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
V	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
V	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
V	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
V	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
V	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
V	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
V	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
V	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
V	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
V	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
R	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DataSource (see page 1557)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.

R	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	MaxBlobSize (see page 1559)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCheck (see page 1561)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
R	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	Params (see page 1562)	Represents the parameters for a query or stored procedure.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
R	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Methods

	Name	Description
V	Create (see page 1524)	This is the overview for the Create constructor overload.
V	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	Destroy (see page 1525)	Destroys the TCustomSQLDataSet (see page 1520) instance.
V	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
V	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
V	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
V	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
V	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
V	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
V	PrepareStatement (see page 1540)	Performs a prepare on the SQL statement.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	SQLConnection (see page 1566)	Specifies the SQL connection component that connects the dataset to a database server.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.

	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	SchemaName (see page 1565)	Specifies the name of the database schema.

25.1.3.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TCustomSQLDataSet.Create (TComponent) (see page 1524)	Creates an instance of a TCustomSQLDataSet (see page 1520) component.
	TCustomSQLDataSet.Create (TComponent, TDBXReader, Boolean) (see page 1524)	Creates an instance of a TCustomSQLDataSet (see page 1520) component.

25.1.3.2.1 TCustomSQLDataSet.Create Constructor (TComponent)

Creates an instance of a TCustomSQLDataSet (see page 1520) component.

Pascal

```
constructor Create(AOwner: TComponent); override; overload;
constructor Create(AOwner: TComponent; DBXReader: TDBXReader; AOwnsInstance: Boolean);
overload; reintroduce;
```

C++

```
virtual __fastcall TCustomSQLDataSet(TComponent * AOwner);
__fastcall TCustomSQLDataSet(TComponent * AOwner, TDBXReader DBXReader, Boolean AOwnsInstance);
```

Description

Call Create to instantiate an SQL dataset component at runtime. SQL datasets placed in forms or data modules at design time are created automatically.

TCustomSQLDataSet (see page 1520) is rarely used directly in applications because many of its properties are protected. Instead, applications instantiate TCustomSQLDataSet (see page 1520) descendants such as TSQLDataSet (see page 1631), TSQLTable (see page 1680), TSQLQuery (see page 1654), or TSQLStoredProc (see page 1671).

AOwner is the component that is responsible for freeing the dataset. It becomes the value of the Owner property.

See Also

Owner

Create

TSQLDataSet (see page 1631)

TSQLStoredProc (see page 1671)

TSQLTable (see page 1680)

TSQLQuery (see page 1654)

25.1.3.3 TCustomSQLDataSet.Destroy Destructor

Destroys the TCustomSQLDataSet (see page 1520) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomSQLDataSet();
```

Description

Do not call Destroy directly in an application. Usually destruction of datasets is handled automatically. If an application creates its own instances of a dataset, however, and does not assign an Owner that is responsible for freeing the dataset, then the application should call Free, which verifies that the dataset reference is not nil before calling Destroy.

Owner

Create (see page 1524)

System::TObject::Free (see page 3372)

25.1.3.4 TCustomSQLDataSet Methods

The methods of the TCustomSQLDataSet class are listed here.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	ExecSQL (see page 1529)	This is ExecSQL, a member of class TCustomSQLDataSet.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.

	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.
V	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
V	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
V	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
V	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
V	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
V	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
V	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
V	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
V	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
V	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
V	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
V	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Public Methods

	Name	Description
	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
	PrepareStatement (see page 1540)	Performs a prepare on the SQL statement.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

25.1.3.4.1 TCustomSQLDataSet.AddFieldDesc Method

Pascal

```
procedure AddFieldDesc(FieldDescs: TFieldDescList; DescNo: Integer; var FieldID: Integer;
RequiredFields: TBits; FieldDefs: TFieldDefs);
```

C++

```
__fastcall AddFieldDesc(TFieldDescList FieldDescs, int DescNo, int FieldID, TBits
RequiredFields, TFieldDefs FieldDefs);
```

Description

This is AddFieldDesc, a member of class TCustomSQLDataSet.

25.1.3.4.2 TCustomSQLDataSet.AddIndexDefs Method

Pascal

```
procedure AddIndexDefs(SourceDS: TCustomSQLDataSet; IndexName: string = '');
```

C++

```
__fastcall AddIndexDefs(TCustomSQLDataSet SourceDS, UnicodeString IndexName = '');
```

Description

This is AddIndexDefs, a member of class TCustomSQLDataSet.

25.1.3.4.3 TCustomSQLDataSet.CheckPrepareError Method

Pascal

```
procedure CheckPrepareError;
```

C++

```
__fastcall CheckPrepareError();
```

Description

This is CheckPrepareError, a member of class TCustomSQLDataSet.

25.1.3.4.4 TCustomSQLDataSet.ClearIndexDefs Method

Pascal

```
procedure ClearIndexDefs;
```

C++

```
__fastcall ClearIndexDefs();
```

Description

This is ClearIndexDefs, a member of class TCustomSQLDataSet.

25.1.3.4.5 TCustomSQLDataSet.CloseCursor Method

Pascal

```
procedure CloseCursor; override;
```

C++

```
virtual __fastcall CloseCursor();
```

Description

This is CloseCursor, a member of class TCustomSQLDataSet.

25.1.3.4.6 TCustomSQLDataSet.CloseStatement Method

Pascal

```
procedure CloseStatement;
```

C++

```
__fastcall CloseStatement();
```

Description

This is CloseStatement, a member of class TCustomSQLDataSet.

25.1.3.4.7 TCustomSQLDataSet.CreateBlobStream Method

Creates a blob stream for a Binary large object (BLOB) field in the dataset.

Pascal

```
function CreateBlobStream(Field: TField; Mode: TBlobStreamMode): TStream; override;
```

C++

```
virtual __fastcall TStream CreateBlobStream(TField Field, TBlobStreamMode Mode);
```

Description

Call CreateBlobStream to obtain a stream for reading and writing the value of the field specified by the Field parameter.

Field is a string containing the name of the BLOB field in the dataset. It must be an instance of TBlobField or one of its descendants.

Mode indicates whether the stream will be used for reading the field's value (bmRead), writing the field's value (bmWrite), or both (bmReadWrite).

CreateBlobStream returns the stream you can use for reading or writing data.

See Also

TSQLBlobStream (see page 1577)

TBlobField

25.1.3.4.8 TCustomSQLDataSet.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent overrides the DefineProperties method defined in TPersistent to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

Ancestor

DefineBinaryProperty

DefineProperties

DefineProperty

25.1.3.4.9 TCustomSQLDataSet.ExecSQL Method

Pascal

```
function ExecSQL(ExecDirect: Boolean = False): Integer; virtual;
```

C++

```
virtual __fastcall int ExecSQL(Boolean ExecDirect = False);
```

Description

This is ExecSQL, a member of class TCustomSQLDataSet.

25.1.3.4.10 TCustomSQLDataSet.ExecuteStatement Method

Pascal

```
procedure ExecuteStatement;
```

C++

```
__fastcall ExecuteStatement();
```

Description

This is ExecuteStatement, a member of class TCustomSQLDataSet.

25.1.3.4.11 TCustomSQLDataSet.FreeBuffers Method

Pascal

```
procedure FreeBuffers;
```

C++

```
__fastcall FreeBuffers();
```

Description

This is FreeBuffers, a member of class TCustomSQLDataSet.

25.1.3.4.12 TCustomSQLDataSet.FreeCommand Method

Pascal

```
procedure FreeCommand;
```

C++

```
__fastcall FreeCommand();
```

Description

This is FreeCommand, a member of class TCustomSQLDataSet.

25.1.3.4.13 TCustomSQLDataSet.FreeReader Method

Pascal

```
procedure FreeReader;
```

C++

```
__fastcall FreeReader();
```

Description

This is FreeReader, a member of class TCustomSQLDataSet.

25.1.3.4.14 TCustomSQLDataSet.GetBlobFieldData Method

Retrieves the current value of a BLOB field into a buffer.

Pascal

```
function GetBlobFieldData(FieldNo: Integer; var Buffer: TBlobByteData): Integer; override;
```

C++

```
virtual __fastcall int GetBlobFieldData(int FieldNo, TBlobByteData Buffer);
```

Description

This method is used internally to read BLOB data from the field specified by FieldNo into a Buffer. The buffer is a dynamic array of bytes, so that it can grow to accommodate the size of the BLOB data. GetBlobFieldData returns the size of the buffer.

GetBlobFieldData is intended primarily for internal use. Applications should use the BLOB stream returned by the CreateBlobStream (see page 1528) method to access BLOB data.

See Also

GetFieldData (see page 1532)

IsBlob

CreateBlobStream (see page 1528)

GetBlobSize

25.1.3.4.15 TCustomSQLDataSet.GetCanModify Method

Pascal

```
function GetCanModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetCanModify();
```

Description

This is GetCanModify, a member of class TCustomSQLDataSet.

25.1.3.4.16 TCustomSQLDataSet.GetCommandNames Method

Pascal

```
procedure GetCommandNames(List: TWideStrings);
```

C++

```
__fastcall GetCommandNames(TWideStrings List);
```

Description

This is GetCommandNames, a member of class TCustomSQLDataSet.

25.1.3.4.17 TCustomSQLDataSet.GetDataSource Method

Pascal

```
function GetDataSource: TDataSource; override;
```

C++

```
virtual __fastcall TDataSource GetDataSource();
```

Description

This is GetDataSource, a member of class TCustomSQLDataSet.

25.1.3.4.18 TCustomSQLDataSet.GetDetailLinkFields Method

Lists the field components that link this dataset as a detail of a master dataset.

Pascal

```
procedure GetDetailLinkFields(MasterFields: TList; DetailFields: TList); override;
```

C++

```
virtual __fastcall GetDetailLinkFields(TList MasterFields, TList DetailFields);
```

Description

GetDetailLInkFIelds fills the two lists with field components that define a master-detail relationship between this dataset and another (master) dataset. The MasterFields list is filled with fields from the master table whose values must equal the values of the fields in the DetailFields list. The DetailFields list is filled with fields from this dataset.

Applications seldom call GetDetailLinkFields. It is used internally by the Field Link designer when setting up master/detail relationships.

25.1.3.4.19 GetFieldData Method

This is the overview for the GetFieldData method overload.

Overload List

	Name	Description
	TCustomSQLDataSet.GetFieldData (Integer, Pointer) (see page 1532)	Retrieves the current value of a field into a buffer.
	TCustomSQLDataSet.GetFieldData (TField, Pointer) (see page 1532)	Retrieves the current value of a field into a buffer.

25.1.3.4.19.1 TCustomSQLDataSet.GetFieldData Method (Integer, Pointer)

Retrieves the current value of a field into a buffer.

Pascal

```
function GetFieldData(FieldNo: Integer; Buffer: Pointer): Boolean; override; overload;
function GetFieldData(Field: TField; Buffer: Pointer): Boolean; override; overload;
```

C++

```
virtual __fastcall Boolean GetFieldData(int FieldNo, void * Buffer);
virtual __fastcall Boolean GetFieldData(TField Field, void * Buffer);
```

Description

Most applications do not need to call GetFieldData. TField objects call this method to implement their GetData method.

The Field or FieldNo parameter indicates the field whose data should be fetched. Field specifies the component itself, while FieldNo indicates its field number.

Buffer is a memory buffer with sufficient space to accept the value of the field as it exists in the database (unformatted and untranslated). GetFieldData returns a value that indicates whether the data was successfully fetched.

GetFieldData returns a value that indicates whether the data was successfully fetched.

GetBlobFieldData (see page 1530)

IsBlob

GetData

25.1.3.4.20 GetKeyFieldNames Method

This is the overview for the GetKeyFieldNames method overload.

Overload List

	Name	Description
	TCustomSQLDataSet.GetKeyFieldNames (TStrings) (see page 1533)	Fills a list with the names of all fields in all indexes defined for the dataset.
	TCustomSQLDataSet.GetKeyFieldNames (TWideStrings) (see page 1533)	Fills a list with the names of all fields in all indexes defined for the dataset.

25.1.3.4.20.1 TCustomSQLDataSet.GetKeyFieldNames Method (TStrings)

Fills a list with the names of all fields in all indexes defined for the dataset.

Pascal

```
function GetKeyFieldNames(List: TStrings): Integer; overload;
function GetKeyFieldNames(List: TWideStrings): Integer; overload;
```

C++

```
__fastcall int GetKeyFieldNames(TStrings List);
__fastcall int GetKeyFieldNames(TWideStrings List);
```

Description

Call GetKeyFieldNames to fill a string list with information about the indexes that are available on the database server for this dataset.

For every index defined on the server for the dataset, GetKeyFieldNames adds a string to the string list specified by List. Each string is a semicolon-delimited set of field names that lists the fields in a single index.

TCustomSQLDataSet (see page 1520) does not explicitly use these indexes. GetKeyFieldNames can be useful for composing SQL commands dynamically that need to use an index to access fields.

See Also

IndexDefs (see page 1558)

25.1.3.4.21 TCustomSQLDataSet.GetObjectTypeNames Method

Pascal

```
procedure GetObjectTypeNames(Fields: TFields);
```

C++

```
__fastcall GetObjectTypeNames(TFields Fields);
```

Description

This is GetObjectTypeNames, a member of class TCustomSQLDataSet.

25.1.3.4.22 TCustomSQLDataSet.GetOutputParams Method

Pascal

```
procedure GetOutputParams(AProcParams: TList = nil);
```

C++

```
__fastcall GetOutputParams(TList AProcParams = nil);
```

Description

This is GetOutputParams, a member of class TCustomSQLDataSet.

25.1.3.4.23 TCustomSQLDataSet.GetQuoteChar Method

Returns the character or characters to use in generated SQL statements to enclose quoted strings.

Pascal

```
function GetQuoteChar: UnicodeString; virtual;
```

C++

```
virtual __fastcall UnicodeString GetQuoteChar();
```

Description

GetQuoteChar returns the character or characters that delimit quoted strings in automatically generated SQL statements. This string appears both before and after quoted strings.

25.1.3.4.24 TCustomSQLDataSet.GetRecord Method

Pascal

```
function GetRecord(Buffer: TRecordBuffer; GetMode: TGetMode; DoCheck: Boolean): TGetResult;
override;
```

C++

```
virtual __fastcall TGetResult GetRecord(TRecordBuffer Buffer, TGetMode GetMode, Boolean
DoCheck);
```

Description

This is GetRecord, a member of class TCustomSQLDataSet.

25.1.3.4.25 TCustomSQLDataSet.GetRecordCount Method

Pascal

```
function GetRecordCount: Integer; override;
```

C++

```
virtual __fastcall int GetRecordCount();
```

Description

This is GetRecordCount, a member of class TCustomSQLDataSet.

25.1.3.4.26 TCustomSQLDataSet.GetSortFieldNames Method

Pascal

```
function GetSortFieldNames: UnicodeString;
```

C++

```
__fastcall UnicodeString GetSortFieldNames();
```

Description

This is GetSortFieldNames, a member of class TCustomSQLDataSet.

25.1.3.4.27 TCustomSQLDataSet.InitRecord Method

Pascal

```
procedure InitRecord(Buffer: TRecordBuffer); override;
```

C++

```
virtual __fastcall InitRecord(TRecordBuffer Buffer);
```

Description

This is InitRecord, a member of class TCustomSQLDataSet.

25.1.3.4.28 TCustomSQLDataSet.InternalClose Method

Pascal

```
procedure InternalClose; override;
```

C++

```
virtual __fastcall InternalClose();
```

Description

This is InternalClose, a member of class TCustomSQLDataSet.

25.1.3.4.29 TCustomSQLDataSet.InternalFreeCommand Method

Pascal

```
procedure InternalFreeCommand;
```

C++

```
__fastcall InternalFreeCommand();
```

Description

This is InternalFreeCommand, a member of class TCustomSQLDataSet.

25.1.3.4.30 TCustomSQLDataSet.InternalHandleException Method

Pascal

```
procedure InternalHandleException; override;
```

C++

```
virtual __fastcall InternalHandleException();
```

Description

This is InternalHandleException, a member of class TCustomSQLDataSet.

25.1.3.4.31 TCustomSQLDataSet.InternalInitFieldDefs Method

Pascal

```
procedure InternalInitFieldDefs; override;
```

C++

```
virtual __fastcall InternalInitFieldDefs();
```

Description

This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.

25.1.3.4.32 TCustomSQLDataSet.InternalOpen Method

Pascal

```
procedure InternalOpen; override;
```

C++

```
virtual __fastcall InternalOpen();
```

Description

This is InternalOpen, a member of class TCustomSQLDataSet.

25.1.3.4.33 TCustomSQLDataSet.InternalRefresh Method

Pascal

```
procedure InternalRefresh; override;
```

C++

```
virtual __fastcall InternalRefresh();
```

Description

This is InternalRefresh, a member of class TCustomSQLDataSet.

25.1.3.4.34 TCustomSQLDataSet.IsCursorOpen Method

Pascal

```
function IsCursorOpen: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCursorOpen();
```

Description

This is IsCursorOpen, a member of class TCustomSQLDataSet.

25.1.3.4.35 TCustomSQLDataSet.IsSequenced Method

Indicates whether the dataset can use record numbers to indicate the order of records.

Pascal

```
function IsSequenced: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsSequenced();
```

Description

Datasets use IsSequenced to indicate whether the RecNo property corresponds to the order of records. When IsSequenced returns true, applications can safely use the RecNo property to navigate to records in the dataset.

Note: For TCustomSQLDataSet (see page 1520), IsSequenced always returns false because TCustomSQLDataSet (see page 1520) descendants do not support record numbers at all.

See Also

RecNo

RecordCount (see page 1564)

25.1.3.4.36 TCustomSQLDataSet.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling pointers can be used after being streamed in.

As implemented in TComponent, Loaded clears the csLoading flag in the ComponentState property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

ComponentState

Create

TReader

25.1.3.4.37 TCustomSQLDataSet.Locate Method

Implements a virtual method for searching a dataset for a specified record and making it the active record.

Pascal

```
function Locate(const KeyFields: string; const KeyValues: Variant; Options: TLocateOptions):
Boolean; override;
```

C++

```
virtual __fastcall Boolean Locate(const UnicodeString KeyFields, const Variant KeyValues,
TLocateOptions Options);
```

Description

This function:

Checks whether the dataset is unidirectional, and if so, raises an EDatabaseError exception.

Returns false, indicating that a matching record was not found and the active record was not changed.

Descendant classes that are not unidirectional override this method so that it locates the record where the fields identified by the semicolon-separated list of fields in KeyFields have the values specified by the Variant (see page 3421) or Variant (see page 3421) array KeyValues. Options indicates whether the search is case insensitive and whether partial matches are supported. Locate returns true if a record is found that matches the specified criteria and that record is now active.

See Also

FindField

Lookup

25.1.3.4.38 TCustomSQLDataSet.LocateRecord Method

Pascal

```
function LocateRecord(const KeyFields: string; const KeyValues: Variant; Options:
TLocateOptions; SyncCursor: Boolean): Boolean;
```

C++

```
__fastcall Boolean LocateRecord(const UnicodeString KeyFields, const Variant KeyValues,
TLocateOptions Options, Boolean SyncCursor);
```

Description

This is LocateRecord, a member of class TCustomSQLDataSet.

25.1.3.4.39 TCustomSQLDataSet.Lookup Method

Implements a virtual method to retrieve field values from a record that matches specified search values.

Pascal

```
function Lookup(const KeyFields: string; const KeyValues: Variant; const ResultFields:
string): Variant; override;
```

C++

```
virtual __fastcall Variant Lookup(const UnicodeString KeyFields, const Variant KeyValues,
const UnicodeString ResultFields);
```

Description

This function:

Checks whether the dataset is unidirectional, and if so, raises an EDatabaseError exception.

Returns a Variant (see page 3421) with the value false, indicating that a matching record was not found.

Descendant classes that are not unidirectional override this method so that it locates the record where the fields identified by the comma-delimited string KeyFields have the values specified by the Variant (see page 3421) or Variant (see page 3421) array KeyValues. In classes that implement Lookup, it returns a Variant (see page 3421) or Variant (see page 3421) array that contains the value or values of the fields specified by the comma-delimited string ResultFields on the specified record.

See Also

Locate (see page 1538)

25.1.3.4.40 TCustomSQLDataSet.OpenCursor Method

Pascal

```
procedure OpenCursor(InfoQuery: Boolean); override;
```

C++

```
virtual __fastcall OpenCursor(Boolean InfoQuery);
```

Description

This is OpenCursor, a member of class TCustomSQLDataSet.

25.1.3.4.41 TCustomSQLDataSet.OpenSchema Method

Pascal

```
procedure OpenSchema; virtual;
```

C++

```
virtual __fastcall OpenSchema();
```

Description

This is OpenSchema, a member of class TCustomSQLDataSet.

25.1.3.4.42 TCustomSQLDataSet.ParamByName Method

Locates a parameter in the Params (see page 1562) property collection.

Pascal

```
function ParamByName(const Value: string): TParam;
```

C++

```
__fastcall TParam ParamByName(const UnicodeString Value);
```

Description

Call ParamByName to access a specific parameter object, given its name. Value is the name of the parameter.

ParamByName is primarily used to set a parameter's value at runtime.

See Also

Params (see page 1562)

Name

25.1.3.4.43 TCustomSQLDataSet.PrepareStatement Method

Performs a prepare on the SQL statement.

Pascal

```
procedure PrepareStatement; virtual;
```

C++

```
virtual __fastcall PrepareStatement();
```

Description

The prepare operation is a type of pre-compile that checks the performance of the SQL statement. Some databases support a prepare statement that creates an execution plan that speeds processing.

25.1.3.4.44 TCustomSQLDataSet.PropertyChanged Method

Pascal

```
procedure PropertyChanged;
```

C++

```
__fastcall PropertyChanged();
```

Description

This is PropertyChanged, a member of class TCustomSQLDataSet.

25.1.3.4.45 TCustomSQLDataSet.PSEndTransaction Method

Ends a transaction that was started by a call to PSStartTransaction.

Pascal

```
procedure PSEndTransaction(Commit: Boolean); override;
```

C++

```
virtual __fastcall PSEndTransaction(Boolean Commit);
```

Description

The provider component applies updates within a transaction, if possible. To do so, it uses PSEndTransaction in conjunction with the PSStartTransaction method.

The Commit parameter indicates whether the dataset should commit the current transaction (Commit is true), or roll it back (Commit is false).

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there is no transaction already established. That is, it does not assume nested transaction support is available. Thus, there is no need to ensure that PSEndTransaction does not terminate a transaction that was not started by the provider.

See Also

PSStartTransaction

PSInTransaction

ApplyUpdates

25.1.3.4.46 TCustomSQLDataSet.PSExecute Method

Executes the SQL command associated with the dataset.

Pascal

```
procedure PSExecute; override;
```

C++

```
virtual __fastcall PSExecute();
```

Description

The provider component calls PSExecute to implement its Execute method. If the dataset represents a query or stored procedure that does not return a cursor, this method executes the query or stored procedure. If the provider Options includes poAllowCommandText and the dataset supports the PSSetCommandText method, the statement specified by PSSetCommandText may be executed instead.

If there is not statement to execute, PSExecute raises an EDatabaseError exception.

See Also

PSSetCommandText

Execute

Options

25.1.3.4.47 TCustomSQLDataSet.PSExecuteStatement Method

Pascal

```
function PSExecuteStatement(const ASQL: WideString; AParams: TParams; ResultSet: TPSResult =
nil): Integer; override;
```

C++

```
virtual __fastcall int PSExecuteStatement(const BSTR ASQL, TParams AParams, TPSResult
ResultSet = nil);
```

Description

This is PSExecuteStatement, a member of class TCustomSQLDataSet.

25.1.3.4.48 TCustomSQLDataSet.PSGetAttributes Method

Returns information that is stored in data packets as Name/Value pairs.

Pascal

```
procedure PSGetAttributes(List: TList); override;
```

C++

```
virtual __fastcall PSGetAttributes(TList List);
```

Description

The provider component calls PSGetAttributes to add information about the dataset to the metadata stored with generated data packets. This information is stored as Name/Value pairs that are added to the list specified by the List parameter.

See Also

DoGetProviderAttributes

25.1.3.4.49 TCustomSQLDataSet.PSGetCommandText Method

Gets the SQL command to be executed by PSExecute.

Pascal

```
function PSGetCommandText: string; override;
```

C++

```
virtual __fastcall UnicodeString PSGetCommandText();
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

See Also

CommandText

PSExecute

PSSetCommandText

GetRecords

Execute

Options

25.1.3.4.50 TCustomSQLDataSet.PSGetCommandType Method

Gets the command type to be executed by PSExecute.

Pascal

```
function PSGetCommandType: TPSCommandType; override;
```

C++

```
virtual __fastcall TPSCommandType PSGetCommandType();
```

Description

PSGetCommandType gets the command type executed by PSExecute. The type may be a type of SQL command or other command types, such as stored procedures.

See Also

CommandText

PSExecute

PSGetCommandText

Execute

Options

25.1.3.4.51 TCustomSQLDataSet.PSGetDefaultOrder Method

Returns the definition of an index that imposes the default order on the data included in data packets.

Pascal

```
function PSGetDefaultOrder: TIndexDef; override;
```

C++

```
virtual __fastcall TIndexDef PSGetDefaultOrder();
```

Description

The provider component calls PSGetDefaultOrder to generate a default index, called DEFAULT_ORDER, for the records that appear in data packets. This index defines the default sort order for records when they appear in the client dataset on the client.

PSGetDefaultOrder creates a TIndexDef object to describe the default index. The provider that calls PSGetDefaultOrder subsequently frees this TIndexDef object.

See Also

CreateDataPacket

25.1.3.4.52 TCustomSQLDataSet.PSGetIndexDefs Method

Returns the definitions of all specified indexes defined for the dataset.

Pascal

```
function PSGetIndexDefs(IndexTypes: TIndexOptions): TIndexDefs; override;
```

C++

```
virtual __fastcall TIndexDefs PSGetIndexDefs(TIndexOptions IndexTypes);
```

Description

The provider component calls PSGetIndexDefs to locate an index that contains information it needs. For example, it uses PSGetIndexDefs to locate an index that contains the key fields returned by PSGetKeyFields. This information allows the provider to locate the records that need to change when it applies updates. The provider also calls this method to locate indexes that it adds to the metadata of data packets.

IndexTypes indicates the options required of the returned indexes. PSGetIndexDefs returns all indexes whose Options property includes the specified flags.

PSGetIndexDefs returns a TIndexDefs object that contains all the indexes of the dataset that match the IndexTypes parameter.

See Also

Options

PSGetKeyFields

PSGetDefaultOrder

25.1.3.4.53 TCustomSQLDataSet.PSGetKeyFieldsW Method

Pascal

```
function PSGetKeyFieldsW: WideString; override;
```

C++

```
virtual __fastcall BSTR PSGetKeyFieldsW();
```

Description

This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.

25.1.3.4.54 TCustomSQLDataSet.PSGetParams Method

Returns the current parameter values of the dataset.

Pascal

```
function PSGetParams: TParams; override;
```

C++

```
virtual __fastcall TParams PSGetParams();
```

Description

The provider component calls PSGetParams to implement its GetParams method.

PSGetParams returns a TParams object that describes the current values of all parameters of the dataset. If the dataset does not have any parameters, PSGetParams returns nil (Delphi) or NULL (C++).

Note: The PSGetParams method should not create a new instance of TParams for the return value. The provider that calls PSGetParams does not free the returned value.

See Also

GetParams

25.1.3.4.55 TCustomSQLDataSet.PSGetQuoteCharW Method

Pascal

```
function PSGetQuoteCharW: WideString; override;
```

C++

```
virtual __fastcall BSTR PSGetQuoteCharW();
```

Description

This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.

25.1.3.4.56 TCustomSQLDataSet.PSGetTableNameW Method

Pascal

```
function PSGetTableNameW: WideString; override;
```

C++

```
virtual __fastcall BSTR PSGetTableNameW();
```

Description

This is PSGetTableNameW, a member of class TCustomSQLDataSet.

25.1.3.4.57 TCustomSQLDataSet.PSGetUpdateException Method

Generates an EUpdateError object based on another exception object.

Pascal

```
function PSGetUpdateException(E: Exception; Prev: EUpdateError): EUpdateError; override;
```

C++

```
virtual __fastcall EUpdateError PSGetUpdateException(Exception E, EUpdateError Prev);
```

Description

The provider component calls PSGetUpdateException when the exception E occurs while applying updates. This method allows the provider to create a single EUpdateError object that encapsulates all the exceptions that occur in an update operation.

PSGetUpdateError determines the error message, context string, and error code from the exception specified by E and creates a new EUpdateError exception that includes that information as well as the information about a previous error as specified by Prev. The context string and error code for E may be specific to the Exception class associated with the dataset. By default, TDataSet generates an EUpdateError with an error code of 1 and an empty context string.

See Also

Create

25.1.3.4.58 TCustomSQLDataSet.PSInTransaction Method

Indicates whether actions against the dataset occur in the context of a transaction.

Pascal

```
function PSInTransaction: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSInTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it first checks whether a transaction is already underway, and if not, generates one using PSStartTransaction. To determine whether a transaction is already underway, the provider calls PSInTransaction.

PSInTransaction returns true if there is a transaction underway, and false otherwise.

See Also

PSStartTransaction

PSEndTransaction

25.1.3.4.59 TCustomSQLDataSet.PSIsSQLBased Method

Indicates whether the dataset includes native SQL support.

Pascal

```
function PSIsSQLBased: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSIsSQLBased();
```

Description

The provider calls PSIsSQLBased to determine whether the dataset supports some form of native SQL. This information is used when generating SQL commands that are executed by PSExecuteStatement.

Even if the dataset is not SQL-based, it may still allow the provider to execute SQL statements for applying updates. For example, BDE-enabled local databases such as Paradox and DBASE provide SQL support via the BDE's local SQL engine, but are not SQL-based. However, table and field names are not specified in the same way for the local SQL engine as they are for native SQL. The provider uses PSIsSQLBased to determine how these names should appear in generated SQL.

Note: The PSIsSQLSupported method indicates whether the dataset can execute SQL commands at all, regardless of whether

the dataset is SQL-based.

See Also

PSIsSQLSupported

PSExecuteStatement

25.1.3.4.60 TCustomSQLDataSet.PSIsSQLSupported Method

Indicates whether the dataset can execute SQL statements.

Pascal

```
function PSIsSQLSupported: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSIsSQLSupported();
```

Description

PSIsSQLSupported indicates whether the provider can call PSExecuteStatement to execute an SQL statement. When PSIsSQLSupported returns false, calling PSExecuteStatement generates an exception. The provider can still work with a dataset that returns false from PSIsSQLSupported, but it must set the ResolveToDataSet property to true, or provide data on a read-only basis.

See Also

PSIsSQLBased

PSExecuteStatement

ResolveToDataSet

25.1.3.4.61 TCustomSQLDataSet.PSReset Method

Resets the dataset so that it is positioned on the first record.

Pascal

```
procedure PSReset; override;
```

C++

```
virtual __fastcall PSReset();
```

Description

The provider calls PSReset to reposition the dataset on the first record before fetching records.

See Also

GetRecords

AS_GetRecords

25.1.3.4.62 TCustomSQLDataSet.PSSetCommandText Method

Assigns a specified SQL command to be executed by PSExecute.

Pascal

```
procedure PSSetCommandText(const ACommandText: WideString); override;
```

C++

```
virtual __fastcall PSSetCommandText(const BSTR ACommandText);
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

The value of the CommandText parameter replaces the dataset's SQL statement (if it has one), or replaces the name of an underlying database table or stored procedure.

See Also

CommandText

PSExecute

GetRecords

Execute

Options

25.1.3.4.63 TCustomSQLDataSet.PSSetParams Method

Assigns the specified parameter values to the dataset.

Pascal

```
procedure PSSetParams(AParams: TParams); override;
```

C++

```
virtual __fastcall PSSetParams(TParams AParams);
```

Description

PSSetParams assigns the parameter values specified by AParams to the parameters of the dataset.

See Also

Params

PSGetParams

25.1.3.4.64 TCustomSQLDataSet.PSStartTransaction Method

Starts a transaction that encapsulates all activity until a call to PSEndTransaction.

Pascal

```
procedure PSStartTransaction; override;
```

C++

```
virtual __fastcall PSStartTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it calls PSStartTransaction to start a transaction before applying updates, and calls PSEndTransaction when all updates are applied or too many errors are encountered.

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there

is no transaction already established. That is, it does not assume nested transaction support is available.

See Also

PSEndTransaction

PSInTransaction

ApplyUpdates

25.1.3.4.65 TCustomSQLDataSet.PSUpdateRecord Method

Applies a single update to the underlying database table or tables.

Pascal

```
function PSUpdateRecord(UpdateKind: TUpdateKind; Delta: TDataSet): Boolean; override;
```

C++

```
virtual __fastcall Boolean PSUpdateRecord(TUpdateKind UpdateKind, TDataSet Delta);
```

Description

Before the provider generates SQL statements to apply an update, it calls PSUpdateRecord to let the dataset apply the update in some other fashion. For example, BDE-enabled datasets generate an OnUpdateRecord to allow the application to apply the update and, if the OnUpdateRecord event handler does not apply the update, uses any associated TUpdateSQL object to apply the update.

UpdateKind indicates whether the update is an insertion (ukInsert), deletion (ukDelete), or modification (ukModify).

Delta is the delta datapacket. The current record represents the record to be updated.

PSUpdateRecord returns true if it updates the record, false otherwise. If PSUpdateRecord returns false, the provider generates dynamic SQL to perform the update and calls PSExecuteStatement.

Note: PSUpdateRecord is only called if the provider's ResolveToDataSet property is false.

25.1.3.4.66 TCustomSQLDataSet.SetBufListSize Method

Pascal

```
procedure SetBufListSize(Value: Integer); override;
```

C++

```
virtual __fastcall SetBufListSize(int Value);
```

Description

This is SetBufListSize, a member of class TCustomSQLDataSet.

25.1.3.4.67 TCustomSQLDataSet.SetCommandText Method

Pascal

```
procedure SetCommandText(const Value: UnicodeString); virtual;
```

C++

```
virtual __fastcall SetCommandText(const UnicodeString Value);
```

Description

This is SetCommandText, a member of class TCustomSQLDataSet.

25.1.3.4.68 TCustomSQLDataSet.SetFCommandText Method

Pascal

```
procedure SetFCommandText(const Value: string);
```

C++

```
__fastcall SetFCommandText(const UnicodeString Value);
```

Description

This is SetFCommandText, a member of class TCustomSQLDataSet.

25.1.3.4.69 TCustomSQLDataSet.SetFieldData Method

Pascal

```
procedure SetFieldData(Field: TField; Buffer: Pointer); override;
```

C++

```
virtual __fastcall SetFieldData(TField Field, void * Buffer);
```

Description

This is SetFieldData, a member of class TCustomSQLDataSet.

25.1.3.4.70 TCustomSQLDataSet.SetMaxBlobSize Method

Pascal

```
procedure SetMaxBlobSize(MaxSize: Integer);
```

C++

```
__fastcall SetMaxBlobSize(int MaxSize);
```

Description

This is SetMaxBlobSize, a member of class TCustomSQLDataSet.

25.1.3.4.71 TCustomSQLDataSet.SetParamsFromCursor Method

Pascal

```
procedure SetParamsFromCursor;
```

C++

```
__fastcall SetParamsFromCursor();
```

Description

This is SetParamsFromCursor, a member of class TCustomSQLDataSet.

25.1.3.4.72 TCustomSQLDataSet.SetSchemaInfo Method

Indicates whether the dataset represents metadata from the server, and if so, what kind.

Pascal

```
procedure SetSchemaInfo(SchemaType: TSchemaType; SchemaObjectName: UnicodeString;
SchemaPattern: UnicodeString; PackageName: UnicodeString = '');
```

C++

```
__fastcall SetSchemaInfo(TSchemaType SchemaType, UnicodeString SchemaObjectName, UnicodeString
SchemaPattern, UnicodeString PackageName = '');
```

Description

Call SetSchemaInfo to indicate whether the SQL dataset represents the results of an SQL command (specified by CommandText (see page 1554)) or whether it represents a table of schema information (metadata).

The SchemaType parameter identifies the type of information you want. It can have any of the following values:

Value	Description
stNoSchema	No schema information. The SQL dataset is populated with the results of its query or stored procedure rather than metadata from the server.
stTables	Information about all the data tables on the database server that match the criteria specified by the SQL connection's TableScope property.
stSysTables	Information about all of the system tables on the database server. Not all servers use system tables to store metadata. Requesting a list of system tables from a server that does not use them results in an empty dataset.
stProcedures	Information about all of the stored procedures on the database server.
stColumns	Information about all of the columns (fields) in a specified table.
stProcedureParams	Information about all of the parameters of a specified stored procedure.
stIndexes	Information about all of the indexes defined for a specified table.

SchemaObjectName is the name of the table or stored procedure about whose columns, indexes, or parameters you want information. When SchemaType is stColumns or stIndexes, SchemaObjectName is the name of a table. When SchemaType is stProcedureParams, SchemaObjectName is the name of a stored procedure. When SchemaType is stNoSchema, stTables, stSysTables, or stProcedures, or stPackages, SchemaObjectName is ignored.

SchemaPattern is an SQL pattern mask that filters the resulting dataset. The name of each item (table, stored procedure, field, parameter, or index) must match this pattern mask or it does not appear as a record when the SQL dataset is opened. SchemaPattern uses the wildcards '%' (to match a string of arbitrary characters of any length) and '_' (to match a single arbitrary character). To use a literal percent or underscore in a pattern, the character is doubled (%% or __). If you do not want to use a pattern, set Pattern to nil (Delphi) or NULL (C++).

PackageName is the name of an Oracle package in which to find the stored procedure when SchemaType is stProcedures or stProcedureParams. If the server is not an Oracle server, or if the stored procedure is not defined in a package, PackageName should be an empty string.

After a call to SetSchemaInfo, opening the dataset results in a dataset populated with the specified information. If SchemaType is stNoSchema, the dataset reverts to the command specified by CommandText (see page 1554).

Note: When you change the CommandText (see page 1554) property, the dataset automatically reverts to a SchemaType of stNoSchema.

25.1.3.4.73 TCustomSQLDataSet.SetSortFieldNames Method

Pascal

```
procedure SetSortFieldNames(Value: UnicodeString);
```

C++

```
__fastcall SetSortFieldNames(UnicodeString Value);
```

Description

This is SetSortFieldNames, a member of class TCustomSQLDataSet.

25.1.3.4.74 TCustomSQLDataSet.UpdateIndexDefs Method

Pascal

```
procedure UpdateIndexDefs; override;
```

C++

```
virtual __fastcall UpdateIndexDefs();
```

Description

This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

25.1.3.5 TCustomSQLDataSet Properties

The properties of the TCustomSQLDataSet class are listed here.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
R	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DataSource (see page 1557)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.
R	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	MaxBlobSize (see page 1559)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.

	ParamCheck (see page 1561)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
R	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	Params (see page 1562)	Represents the parameters for a query or stored procedure.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
R	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	SQLConnection (see page 1566)	Specifies the SQL connection component that connects the dataset to a database server.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	SchemaName (see page 1565)	Specifies the name of the database schema.

25.1.3.5.1 TCustomSQLDataSet.Active Property

Specifies whether or not a dataset is open.

Pascal

```
property Active;
```

C++

```
__property Active;
```

Description

Use Active to determine or set whether a dataset is populated with data. When Active is false, the dataset is closed; the dataset cannot read or write data and data-aware controls can not use it to fetch data or post edits. When Active is true, the dataset can be populated with data. It can read data from a database or other source (such as a provider). Depending on the CanModify property, active datasets can post changes.

Setting Active to true:

1. Generates a BeforeOpen event.
2. Sets the dataset state to dsBrowse.
3. Establishes a way to fetch data (typically by opening a cursor).
4. Generates an AfterOpen event.

If an error occurs while opening the dataset, dataset state is set to dsInactive, and any cursor is closed.

Setting Active to false:

1. Triggers a BeforeClose event.
2. Sets the State property to dsInactive.
3. Closes the cursor.
4. Triggers an AfterClose event.

An application must set Active to false before changing other properties that affect the status of a database or the controls that display data in an application.

Note: Calling the Open method sets Active to true; calling the Close method sets Active to false.

Delphi Examples:

```
{
This example requires a database with the following name or
in the form of a *.DB file in the following path.  The table
should be closed when changing the database.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Active := False;
  try
  { First try to use an alias }
    Customers.DatabaseName := 'DBDEMOS';
    Customers.Active := True;
  except
    on EDatabaseError do
    begin
      { If that fails, try to use the drive and directory }
      Customers.TableName := 'Flights';
      // This path depends on the Demos directory of your RAD Studio installation.
      Customers.DatabaseName :=
        'c:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\IntraWeb\Win32\FlightInformation\Data';
      Customers.Active := True;
    end;
  end;
end;
```

25.1.3.5.2 TCustomSQLDataSet.BlobBuffer Property

Reserves a buffer for storing BLOB values.

Pascal

```
property BlobBuffer: TBlobByteData;
```

C++

```
__property TBlobByteData BlobBuffer;
```

Description

SQL datasets use the BlobBuffer property to allocate a special buffer for holding BLOB data. Applications do not access this protected property.

See Also

MaxBlobSize (see page 1559)

GetBlobFieldData

25.1.3.5.3 TCustomSQLDataSet.CommandText Property

Specifies the command the dataset executes.

Pascal

```
property CommandText: UnicodeString;
```

C++

```
__property UnicodeString CommandText;
```

Description

The value of CommandText depends on the CommandType (see page 1555) property:

When CommandType (see page 1555) is ctQuery, CommandText is an SQL statement that the dataset executes. If the statement is a SELECT statement, the SQL dataset executes the statement when it is opened. If the statement does not return a result set, the SQL dataset executes the statement when the ExecSQL (see page 1529) method is called.

When CommandType (see page 1555) is ctStoredProc, CommandText is the name of a stored procedure. The SQL dataset executes the stored procedure when it is opened or when the ExecSQL (see page 1529) method is called, depending on whether the stored procedure returns a set of records.

When CommandType (see page 1555) is ctTable, CommandText is the name of a table on the database server. The SQL dataset automatically generates a SELECT statement to fetch all the records on all the fields in this table, sorting by the fields listed in the SortFieldNames (see page 1566) property. The generated statement is executed when the dataset is opened.

If CommandText is an SQL statement that includes parameters or the name of a stored procedure that has parameters, use the Params (see page 1562) property to supply parameter values.

25.1.3.5.4 TCustomSQLDataSet.CommandType Property

Indicates the meaning of the CommandText (see page 1554) property.

Pascal

```
property CommandType: TSQLCommandType;
```

C++

```
__property TSQLCommandType CommandType;
```

Description

CommandType indicates the type of command that is contained in the CommandText (see page 1554) property. TCustomSQLDataSet (see page 1520) descendants set this value to the way in which they specify a query or stored procedure.

The following table lists the possible values:

CommandType	Corresponding CommandText (see page 1554)
ctQuery	An SQL statement that the dataset executes.
ctStoredProc	The name of a stored procedure.
ctTable	The name of a table on the database server. The SQL dataset automatically generates a SELECT statement to fetch all the records on all the fields in this table.

25.1.3.5.5 TCustomSQLDataSet.CurrentBlobSize Property

Indicates the size of the most recently read BLOB field.

Pascal

```
property CurrentBlobSize: Int64;
```

C++

```
__property Int64 CurrentBlobSize;
```

Description

Applications can't use this protected property. TCustomSQLDataSet (see page 1520) uses CurrentBlobSize internally to determine the size needed for BlobBuffer (see page 1554). When the dataset reads a BLOB field, it sets CurrentBlobSize to the number of bytes in the BLOB field, as reported by the database driver.

See Also

MaxBlobSize (see page 1559)

BlobBuffer (see page 1554)

25.1.3.5.6 TCustomSQLDataSet.DataLink Property

Identifies the datalink that manages communication between the SQL dataset and another, master dataset.

Pascal

```
property DataLink: TDataLink;
```

C++

```
__property TDataLink DataLink;
```

Description

The protected DataLink property is used internally when the SQL dataset acts as the detail dataset in a master/detail relationship that is not based on nested datasets. The datalink object manages communication between another (master) dataset and this SQL dataset. For example, it is the datalink that tells this SQL dataset to refresh its data when the active record of the master dataset changes.

Do not use DataLink to establish the relationship between an SQL dataset and another (master) dataset from which it obtains parameter values. Instead, use the DataSource (see page 1557) property, or, if the dataset is TSQLTable (see page 1680), the MasterSource property.

See Also

DataSource (see page 1557)

TSQLDataLink (see page 1628)

MasterSource (see page 1692)

25.1.3.5.7 TCustomSQLDataSet.DataSource Property

Links the SQL dataset to another (master) dataset.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

DataSource links this SQL dataset to another (master) dataset that supplies values for this dataset's parameters.

When the SQL dataset's CommandText (see page 1554) (or SQL) property specifies a parameterized query but the application does not provide values for the corresponding parameters in the Params (see page 1562) property, the SQL dataset fetches parameter values from the dataset identified with the specified data source. When the current record in the dataset associated with DataSource changes, the SQL dataset refreshes its data to reflect the new parameter values.

See Also

CommandText (see page 1554)

SQL (see page 1663)

Params (see page 1562)

25.1.3.5.8 TCustomSQLDataSet.DbxCommandType Property

Pascal

```
property DbxCommandType: UnicodeString;
```

C++

```
__property UnicodeString DbxCommandType;
```

Description

This is DbxCommandType, a member of class TCustomSQLDataSet.

25.1.3.5.9 TCustomSQLDataSet.DesignerData Property

Stores custom data.

Pascal

```
property DesignerData: string;
```

C++

```
__property UnicodeString DesignerData;
```

Description

DesignerData has no predefined meaning. Application developers can use the DesignerData property to associate application-specific information with an SQL dataset instance.

See Also

Tag

25.1.3.5.10 TCustomSQLDataSet.GetMetadata Property

Specifies whether the SQL dataset fetches metadata information along with the data.

Pascal

```
property GetMetadata: Boolean;
```

C++

```
__property Boolean GetMetadata;
```

Description

Use GetMetadata to turn on or off the fetching of metadata on a database object. Setting GetMetadata to False will improve performance because no additional SQL will execute in order to get index information. However, setting GetMetadata to False might slow any attempts to update data using a client dataset that is linked via a dataset provider because the resolver might not generate optimized SQL to perform the update.

GetMetadata must be True to perform any operations that require an index. These operations include setting up master/detail relationships, updating data from a client dataset when the provider's UpdateMode is not upWhereAll, and delayed fetching of BLOB data.

Set GetMetadata to False if you are fetching a dataset for read-only purposes.

See Also

TClientDataSet

TDataSetProvider

Fetching the Data using TSQLDataSet

25.1.3.5.11 TCustomSQLDataSet.IndexDefs Property

Contains the definitions of all indexes defined on the server for the dataset.

Pascal

```
property IndexDefs: TIndexDefs;
```

C++

```
__property TIndexDefs IndexDefs;
```

Description

Read (see page 3634) IndexDefs to obtain information about what indexes are available on the database server for this dataset.

TCustomSQLDataSet (see page 1520) does not explicitly use the information in IndexDefs. The order of its records is determined by the ORDER BY clause of its SQL statement.

If the SQL dataset is an instance of TSQLTable (see page 1680), you can use IndexDefs to identify the index to use for the IndexName property. Even with other TCustomSQLDataSet (see page 1520) descendants, IndexDefs can be useful for composing SQL commands dynamically that need to use an index on the server. For example, provider components use the index information to uniquely identify records when composing update commands.

25.1.3.5.12 TCustomSQLDataSet.InternalConnection Property

Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.

Pascal

```
property InternalConnection: TSqlConnection;
```

C++

```
__property TSqlConnection InternalConnection;
```

Description

Applications can't use this protected property. Instead, SQL datasets use InternalConnection internally when they need to access the dbExpress interfaces for the connection to the database server. Unlike the published SQLConnection (see page 1566) property, InternalConnection handles the case when the dataset must use a clone of the primary connection because the server limits the number of active statements that the connection supports.

It is not necessary to use InternalConnection except when using the connection component to reference its dbExpress interfaces.

See Also

CloneConnection (see page 1587)

AutoClone (see page 1608)

SQLConnection (see page 1566)

25.1.3.5.13 TCustomSQLDataSet.MaxBlobSize Property

Indicates the maximum number of bytes fetched for any BLOB field in the dataset.

Pascal

```
property MaxBlobSize: Integer;
```

C++

```
__property int MaxBlobSize;
```

Description

MaxBlobSize limits the amount of data that can be fetched from Binary Large Object (BLOB) fields. BLOB fields can hold an indefinite amount of data. However, SQL datasets read that data into a memory buffer. By limiting the amount of data that can be fetched from a BLOB field, you limit the size of the buffer.

If MaxBlobSize is –1, the dataset imposes no maximum BLOB size. If MaxBlobSize is 0, the dataset uses the parameters of the associated SQL connection, if any, to determine the maximum BLOB size.

Note: MaxBlobSize should agree with any parameters on the associated SQL connection component that limit the size of BLOB data.

See Also

GetBlobFieldData (see page 1530)

Params (see page 1621)

SQLConnection (see page 1566)

25.1.3.5.14 TCustomSQLDataSet.NativeCommand Property

Represents the SQL command that is sent to the server.

Pascal

```
property NativeCommand: UnicodeString;
```

C++

```
__property UnicodeString NativeCommand;
```

Description

SQL datasets sometimes need to alter a query before it can be sent to the dbExpress driver. For example, dbExpress does not support named parameters, so the SQL dataset converts named parameters to unnamed parameters before sending off a command.

NativeCommand is the adjusted command that is sent to the dbExpress driver. It is based on the value of CommandText (see page 1554).

See Also

CommandText (see page 1554)

25.1.3.5.15 TCustomSQLDataSet.NumericMapping Property

Maps fldBCD to either ftFMTBCD or ftBCD field types.

Pascal

```
property NumericMapping: Boolean;
```

C++

```
__property Boolean NumericMapping;
```

Description

Use NumericMapping to control how to map fldBCD (dbExpress Core logical type) to eitheir ftFMTBCD or ftBCD field types. The default is False. If True, all dbExpress fldBCD types will map to ftFMTBCD across all dbExpress drivers for field type compatibility.

See Also

TFieldType

25.1.3.5.16 TCustomSQLDataSet.ObjectView Property

Specifies whether fields are stored hierarchically or flattened out in the Fields property.

Pascal

```
property ObjectView;
```

C++

```
__property ObjectView;
```

Description

ObjectView affects the way the Fields property stores object fields and the way data-aware grids display ADT and array fields.

When ObjectView is true, the fields are stored hierarchically in the Fields property, meaning any child fields of an object field are referenced by the object field and don't appear sequentially after the object field in the TFields:: .Fields array. When ObjectView is false, the fields are stored sequentially in the Fields property, meaning any child fields of an object field are stored after the object field as siblings in the Fields array.

When ObjectView is false, object field types, such as TADTField, are not created. This switch is provided for increased compatibility with older data-aware controls, which may not handle object field types properly. The default is false for TBDEDataSet, and true for TClientDataSet.

Note: If the ObjectView property of the dataset provided to a TClientDataSet is false, then the TClientDataSet's ObjectView property always acts as false, since the data received is already flattened.

25.1.3.5.17 TCustomSQLDataSet.ParamCheck Property

Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.

Pascal

```
property ParamCheck: Boolean;
```

C++

```
__property Boolean ParamCheck;
```

Description

By default, the Params (see page 1562) property is updated automatically to reflect any parameters that appear in the query specified by the CommandText (see page 1554) property (or the SQL property for TSQLQuery (see page 1654)) at runtime. That is, whenever the CommandText (see page 1554) property changes, the Params (see page 1562) property is regenerated to reflect the new set of parameters.

There are times when you want to override this default behavior. For example, when specifying a data definition language (DDL) statement that defines a stored procedure, the resulting SQL command may include parameters. These parameters, however, should not be used as parameters of the SQL dataset, because they are not parameters of the DDL command, but rather, they are parameters of the stored procedure that the command creates.

In order to override the default generation of the Params (see page 1562) property in response to changes in CommandText (see page 1554), set ParamCheck to false.

See Also

Params (see page 1562)

CommandText (see page 1554)

SQL (see page 1663)

25.1.3.5.18 TCustomSQLDataSet.ParamCount Property

Indicates the number of parameters listed by the Params (see page 1562) property.

Pascal

```
property ParamCount: Integer;
```

C++

```
__property int ParamCount;
```

Description

ParamCount is the number of parameters listed in the Params (see page 1562) property. Applications can't use this protected property. It is used internally when preparing SQL statements for execution.

See Also

Params (see page 1562)

Prepared (see page 1563)

25.1.3.5.19 TCustomSQLDataSet.Params Property

Represents the parameters for a query or stored procedure.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Params is a collection of TParam objects that represent the parameters of a query or stored procedure specified by the SQL dataset. When you specify a query by setting the CommandText (see page 1554) property (or the SQL property in TSQLQuery (see page 1654)), the SQL dataset automatically parse the query and fills Params with a TParam object for every parameter in the query. Similarly, when you specify a stored procedure by setting the CommandText (see page 1554) property (or the StoredProcName property in TSQLStoredProc (see page 1671)), the SQL dataset automatically asks the server for a list of stored procedure parameters and fills Params with a TParam object for every parameter of the stored procedure.

At design-time, use the Params property editor to access the individual TParam objects. For queries, use this property editor to check the DataType property of each parameter and to assign values to the parameters. For stored procedures, you may need to do more, changing the type or number of parameters if the server does not supply complete information about stored procedure parameters.

You can also use Params to assign parameter properties in code at runtime.

Note: If you do not assign values to input parameters before opening the dataset, it fetches values from the dataset identified by the DataSource (see page 1557) property. However, this only works if the individual TParam objects have the same names as fields in the master dataset.

Using TSimpleDataSet

25.1.3.5.20 TCustomSQLDataSet.Prepared Property

Specifies whether the command is prepared before execution.

Pascal

```
property Prepared: Boolean;
```

C++

```
__property Boolean Prepared;
```

Description

SQL datasets are automatically prepared when you call Open or ExecSQL (see page 1529) (or ExecProc). When a SQL dataset is prepared, dbExpress and the server allocate resources for the SQL statement and its parameters. If CommandType (see page 1555) is ctTable, the dataset generates its SELECT query when it is prepared. Any parameters that are not bound by the server are folded into a query when it is prepared.

If you execute the query or stored procedure more than once, you can improve performance by setting Prepared to true before opening the dataset. Setting Prepared to true prepares the dataset at once, rather than waiting until the dataset is opened.

Conversely, set Prepared to false if you want to ensure that the dataset is re-prepared before it executes (for example, if you change a parameter value or the SortFieldNames (see page 1566) property).

See Also

Params (see page 1562)

ExecSQL (see page 1636)

Open

Executing the Command

Fetching the Data

25.1.3.5.21 TCustomSQLDataSet.ProcParams Property

ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.

Pascal

```
property ProcParams: TList;
```

C++

```
__property TList ProcParams;
```

Description

When the SQL dataset represents a stored procedure, it fetches information about stored procedure parameters from the server as a list of parameter descriptors. It stores this list as the value of ProcParams.

Applications never use the protected ProcParams directly. Instead, the information from the list is used to initialize the Params (see page 1562) property.

See Also

Params (see page 1562)

GetProcedureParams (see page 1597)

25.1.3.5.22 TCustomSQLDataSet.RecordCount Property

Indicates the total number of records associated with the dataset.

Pascal

```
property RecordCount: Integer;
```

C++

```
__property int RecordCount;
```

Description

Read (see page 3634) RecordCount to determine the total number of records in the dataset. An application can read RecordCount even if the dataset is not active.

Reading RecordCount will generate an exception if the dataset can't determine the number of records. Do not read RecordCount if

The dataset represents stored procedure.

The dataset represents a query that contains parameters.

The dataset represents a multi-table join.

See Also

RecNo

Eof

25.1.3.5.23 TCustomSQLDataSet.RowsAffected Property

Indicates the number of rows operated on by the latest query execution.

Pascal

```
property RowsAffected: Integer;
```

C++

```
__property int RowsAffected;
```

Description

When the SQL dataset represents a query that does not return a result set, you can't use the RecordCount (see page 1564) property to ascertain the number of records affected by the query. In such cases, read RowsAffected to determine how many rows were updated or deleted by the query when it executed. If no rows were updated or deleted, RowsAffected is zero. RowsAffected is –1 if the SQL statement could not be executed due to an error condition. (This latter situation typically follows the throwing of an exception.)

See Also

ExecSQL (see page 1636)

RecordCount (see page 1564)

ExecProc (see page 1675)

25.1.3.5.24 TCustomSQLDataSet.SchemaInfo Property

Identifies the metadata with which to populate the dataset.

Pascal

```
property SchemaInfo: TSQLSchemaInfo;
```

C++

```
__property TSQLSchemaInfo SchemaInfo;
```

Description

SQL datasets can be used to represent metadata from the database server rather than the results of a query or stored procedure. SchemaInfo controls whether the dataset represents metadata, and if so, what kind.

When SchemaInfo specifies that the dataset represents schema information, the dataset is populated with that information when it is opened. Each record in the resulting dataset represents a single entity (a single table, stored procedure, field, parameter, or index).

Each type of schema information results in a different set of columns (fields), so it is not advisable to use persistent fields when accessing metadata through an SQL dataset.

Applications do not work directly with the protected SchemaInfo property. Instead, they specify the desired schema information by calling the SetSchemaInfo (see page 1550) method.

See Also

SetSchemaInfo (see page 1550)

Open

25.1.3.5.25 TCustomSQLDataSet.SchemaName Property

Specifies the name of the database schema.

Pascal

```
property SchemaName: string;
```

C++

```
__property UnicodeString SchemaName;
```

Description

This name will be available in the appropriate drop down list box after you have connected to a given data source.

25.1.3.5.26 TCustomSQLDataSet.SortFieldNames Property

Indicates the sort order when CommandType (see page 1555) is ctTable.

Pascal

```
property SortFieldNames: UnicodeString;
```

C++

```
__property UnicodeString SortFieldNames;
```

Description

Use SortFieldNames to specify the fields that should be used to order the records in the dataset. SortFieldNames is only used when CommandType (see page 1555) is ctTable.

SortFieldNames is a semicolon-delimited list of field names. These names are used to generate the ORDER BY clause of the SQL statement the dataset creates to fetch data from a server table. Records are sorted by the first named field, and within that sort order, by the second named field, and so on.

See Also

CommandType (see page 1555)

Representing the Records in a Table

Specifying the Data to Display using TSQLDataSet

25.1.3.5.27 TCustomSQLDataSet.SQLConnection Property

Specifies the SQL connection component that connects the dataset to a database server.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Use SQLConnection to specify an SQL connection object that connects the dataset to a database server.

At design-time, select from the list of available TSQLConnection (see page 1580) components in the Object Inspector. At runtime, set SQLConnection to reference an existing TSQLConnection (see page 1580) object.

SQLConnection should be the first property you set on the dataset. Only after the SQLConnection property is set can you use the Command Text editor to specify a query for the CommandText (see page 1554) property or populate the dataset with data by setting Active (see page 1552) to true. Similarly, SQLConnection must be set before the dataset can initialize the Params (see page 1562) property when you set CommandText (see page 1554).

Using Stored Procedure-type Datasets

Using Table Type Datasets

Connecting Directly to a Database Server

Connecting to the Database Server

25.1.3.5.28 TCustomSQLDataSet.TransactionLevel Property

Indicates the transaction to which this dataset belongs.

Pascal

```
property TransactionLevel: SmallInt;
```

C++

```
__property SmallInt TransactionLevel;
```

Description

Use TransactionLevel to indicate the active transaction to use when opening this dataset or using it to execute commands. TransactionLevel is the same as the transaction identifier that is supplied to the connection's StartTransaction method. If TransactionLevel is unspecified (0), the dataset fetches its records or executes commands in the context of the most recently started transaction.

Note: Most applications do not need to use TransactionLevel because most database servers require that SQL commands belong to the most recently started transaction. However, the InterBase server allows multiple overlapping transactions to be active simultaneously.

25.1.3.6 TCustomSQLDataSet Events

The events of the TCustomSQLDataSet class are listed here.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.

	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

25.1.3.6.1 TCustomSQLDataSet.AfterClose Event

Occurs after a data source connection is closed.

Pascal

```
property AfterClose;
```

C++

```
__property AfterClose;
```

25.1.3.6.2 TCustomSQLDataSet.AfterOpen Event

Occurs after the connection to a data source is opened.

Pascal

```
property AfterOpen;
```

C++

```
__property AfterOpen;
```

25.1.3.6.3 TCustomSQLDataSet.AfterRefresh Event

Occurs after a DataSet has been changed and is refreshed.

Pascal

```
property AfterRefresh;
```

C++

```
__property AfterRefresh;
```

25.1.3.6.4 TCustomSQLDataSet.AfterScroll Event

Occurs after a result set is scrolled.

Pascal

```
property AfterScroll;
```

C++

```
__property AfterScroll;
```

25.1.3.6.5 TCustomSQLDataSet.BeforeClose Event

Occurs just before a data connection is closed.

Pascal

```
property BeforeClose;
```

C++

```
__property BeforeClose;
```

25.1.3.6.6 TCustomSQLDataSet.BeforeOpen Event

Occurs just before a data connection is opened, but after an open operation has been initiated.

Pascal

```
property BeforeOpen;
```

C++

```
__property BeforeOpen;
```

25.1.3.6.7 TCustomSQLDataSet.BeforeRefresh Event

Occurs before a DataSet refresh occurs.

Pascal

```
property BeforeRefresh;
```

C++

```
__property BeforeRefresh;
```

25.1.3.6.8 TCustomSQLDataSet.BeforeScroll Event

Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.

Pascal

```
property BeforeScroll;
```

C++

```
__property BeforeScroll;
```

25.1.3.6.9 TCustomSQLDataSet.OnCalcFields Event

Occurs when calculated or derived fields are updated.

Pascal

```
property OnCalcFields;
```

C++

```
__property OnCalcFields;
```

25.1.3.6.10 TCustomSQLDataSet.ParseDeleteSql Event

Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.

Pascal

```
property ParseDeleteSql: TParseSqlEvent;
```

C++

```
__property TParseSqlEvent ParseDeleteSql;
```

25.1.3.6.11 TCustomSQLDataSet.ParseInsertSql Event

Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.

Pascal

```
property ParseInsertSql: TParseInsertSqlEvent;
```

C++

```
__property TParseInsertSqlEvent ParseInsertSql;
```

25.1.3.6.12 TCustomSQLDataSet.ParseSelectSql Event

Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.

Pascal

```
property ParseSelectSql: TParseSqlEvent;
```

C++

```
__property TParseSqlEvent ParseSelectSql;
```

25.1.3.6.13 TCustomSQLDataSet.ParseUpdateSql Event

Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Pascal

```
property ParseUpdateSql: TParseSqlEvent;
```

C++

```
__property TParseSqlEvent ParseUpdateSql;
```

25.1.4 TFLDDesc Class

Class Hierarchy

Pascal

```
TFLDDesc = class;
```

C++

```
class TFLDDesc;
```

File

SqlExpr

Description

This is class SqlExpr.TFLDDesc.

25.1.4.1 TFLDDesc Members

The following tables list the members exposed by TFLDDesc.

Public Fields

	Name	Description
	FCalcField (see page 1572)	This is FCalcField, a member of class TFLDDesc.
	FFldNum (see page 1572)	This is FFldNum, a member of class TFLDDesc.
	FFLDRights (see page 1572)	This is FFLDRights, a member of class TFLDDesc.
	FFldType (see page 1572)	This is FFldType, a member of class TFLDDesc.
	FFLDVchk (see page 1573)	This is FFLDVchk, a member of class TFLDDesc.
	FLen (see page 1573)	This is FLen, a member of class TFLDDesc.
	FName (see page 1573)	This is FName, a member of class TFLDDesc.
	FNullOffset (see page 1573)	This is FNullOffset, a member of class TFLDDesc.
	FOffset (see page 1573)	This is FOffset, a member of class TFLDDesc.
	FSubType (see page 1574)	This is FSubType, a member of class TFLDDesc.
	FUnits1 (see page 1574)	This is FUnits1, a member of class TFLDDesc.
	FUnits2 (see page 1574)	This is FUnits2, a member of class TFLDDesc.

Public Properties

	Name	Description
	bCalcField (see page 1575)	This is bCalcField, a member of class TFLDDesc.
	efldrRights (see page 1575)	This is efldrRights, a member of class TFLDDesc.
	efldvVchk (see page 1575)	This is efldvVchk, a member of class TFLDDesc.
	iFldNum (see page 1575)	This is iFldNum, a member of class TFLDDesc.
	iFldType (see page 1576)	This is iFldType, a member of class TFLDDesc.
	iLen (see page 1576)	This is iLen, a member of class TFLDDesc.
	iNullOffset (see page 1576)	This is iNullOffset, a member of class TFLDDesc.
	iOffset (see page 1576)	This is iOffset, a member of class TFLDDesc.
	iSubType (see page 1576)	This is iSubType, a member of class TFLDDesc.
	iUnits1 (see page 1577)	This is iUnits1, a member of class TFLDDesc.
	iUnits2 (see page 1577)	This is iUnits2, a member of class TFLDDesc.
	szName (see page 1577)	This is szName, a member of class TFLDDesc.

25.1.4.2 TFLDDesc Fields

The fields of the TFLDDesc class are listed here.

Public Fields

	Name	Description
	FCalcField (see page 1572)	This is FCalcField, a member of class TFLDDesc.
	FFldNum (see page 1572)	This is FFldNum, a member of class TFLDDesc.
	FFLDRights (see page 1572)	This is FFLDRights, a member of class TFLDDesc.
	FFldType (see page 1572)	This is FFldType, a member of class TFLDDesc.
	FFLDVchk (see page 1573)	This is FFLDVchk, a member of class TFLDDesc.
	FLen (see page 1573)	This is FLen, a member of class TFLDDesc.
	FName (see page 1573)	This is FName, a member of class TFLDDesc.
	FNullOffset (see page 1573)	This is FNullOffset, a member of class TFLDDesc.

	FOffset (see page 1573)	This is FOffset, a member of class TFLDDesc.
	FSubType (see page 1574)	This is FSubType, a member of class TFLDDesc.
	FUnits1 (see page 1574)	This is FUnits1, a member of class TFLDDesc.
	FUnits2 (see page 1574)	This is FUnits2, a member of class TFLDDesc.

25.1.4.2.1 TFLDDesc.FCalcField Field

Pascal

```
FCalcField: WordBool;
```

C++

```
WordBool FCalcField;
```

Description

This is FCalcField, a member of class TFLDDesc.

25.1.4.2.2 TFLDDesc.FFldNum Field

Pascal

```
FFldNum: Word;
```

C++

```
Word FFldNum;
```

Description

This is FFldNum, a member of class TFLDDesc.

25.1.4.2.3 TFLDDesc.FFLDRights Field

Pascal

```
FFLDRights: FLDRights;
```

C++

```
FLDRights FFLDRights;
```

Description

This is FFLDRights, a member of class TFLDDesc.

25.1.4.2.4 TFLDDesc.FFldType Field

Pascal

```
FFldType: Word;
```

C++

```
Word FFldType;
```

Description

This is FFldType, a member of class TFLDDesc.

25.1.4.2.5 TFLDDesc.FFLDVchk Field

Pascal

```
FFLDVchk: FLDVchk;
```

C++

```
FLDVchk FFLDVchk;
```

Description

This is FFLDVchk, a member of class TFLDDesc.

25.1.4.2.6 TFLDDesc.FLen Field

Pascal

```
FLen: LongWord;
```

C++

```
LongWord FLen;
```

Description

This is FLen, a member of class TFLDDesc.

25.1.4.2.7 TFLDDesc.FName Field

Pascal

```
FName: string;
```

C++

```
UnicodeString FName;
```

Description

This is FName, a member of class TFLDDesc.

25.1.4.2.8 TFLDDesc.FNullOffset Field

Pascal

```
FNullOffset: Word;
```

C++

```
Word FNullOffset;
```

Description

This is FNullOffset, a member of class TFLDDesc.

25.1.4.2.9 TFLDDesc.FOffset Field

Pascal

```
FOffset: Word;
```

C++

```
Word FOffset;
```

Description

This is FOffset, a member of class TFLDDesc.

25.1.4.2.10 TFLDDesc.FSubType Field

Pascal

```
FSubType: Word;
```

C++

```
Word FSubType;
```

Description

This is FSubType, a member of class TFLDDesc.

25.1.4.2.11 TFLDDesc.FUnits1 Field

Pascal

```
FUnits1: SmallInt;
```

C++

```
SmallInt FUnits1;
```

Description

This is FUnits1, a member of class TFLDDesc.

25.1.4.2.12 TFLDDesc.FUnits2 Field

Pascal

```
FUnits2: SmallInt;
```

C++

```
SmallInt FUnits2;
```

Description

This is FUnits2, a member of class TFLDDesc.

25.1.4.3 TFLDDesc Properties

The properties of the TFLDDesc class are listed here.

Public Properties

	Name	Description
	bCalcField (see page 1575)	This is bCalcField, a member of class TFLDDesc.
	efldrRights (see page 1575)	This is efldrRights, a member of class TFLDDesc.
	efldvVchk (see page 1575)	This is efldvVchk, a member of class TFLDDesc.
	iFldNum (see page 1575)	This is iFldNum, a member of class TFLDDesc.
	iFldType (see page 1576)	This is iFldType, a member of class TFLDDesc.
	iLen (see page 1576)	This is iLen, a member of class TFLDDesc.
	iNullOffset (see page 1576)	This is iNullOffset, a member of class TFLDDesc.
	iOffset (see page 1576)	This is iOffset, a member of class TFLDDesc.

	iSubType (see page 1576)	This is iSubType, a member of class TFLDDesc.
	iUnits1 (see page 1577)	This is iUnits1, a member of class TFLDDesc.
	iUnits2 (see page 1577)	This is iUnits2, a member of class TFLDDesc.
	szName (see page 1577)	This is szName, a member of class TFLDDesc.

25.1.4.3.1 TFLDDesc.bCalcField Property

Pascal

```
property bCalcField: WordBool;
```

C++

```
__property WordBool bCalcField;
```

Description

This is bCalcField, a member of class TFLDDesc.

25.1.4.3.2 TFLDDesc.efldrRights Property

Pascal

```
property efldrRights: FLDRights;
```

C++

```
__property FLDRights efldrRights;
```

Description

This is efldrRights, a member of class TFLDDesc.

25.1.4.3.3 TFLDDesc.efldvVchk Property

Pascal

```
property efldvVchk: FLDVchk;
```

C++

```
__property FLDVchk efldvVchk;
```

Description

This is efldvVchk, a member of class TFLDDesc.

25.1.4.3.4 TFLDDesc.iFldNum Property

Pascal

```
property iFldNum: Word;
```

C++

```
__property Word iFldNum;
```

Description

This is iFldNum, a member of class TFLDDesc.

25.1.4.3.5 TFLDDesc.iFldType Property

Pascal

```
property iFldType: Word;
```

C++

```
__property Word iFldType;
```

Description

This is iFldType, a member of class TFLDDesc.

25.1.4.3.6 TFLDDesc.iLen Property

Pascal

```
property iLen: LongWord;
```

C++

```
__property LongWord iLen;
```

Description

This is iLen, a member of class TFLDDesc.

25.1.4.3.7 TFLDDesc.iNullOffset Property

Pascal

```
property iNullOffset: Word;
```

C++

```
__property Word iNullOffset;
```

Description

This is iNullOffset, a member of class TFLDDesc.

25.1.4.3.8 TFLDDesc.iOffset Property

Pascal

```
property iOffset: Word;
```

C++

```
__property Word iOffset;
```

Description

This is iOffset, a member of class TFLDDesc.

25.1.4.3.9 TFLDDesc.iSubType Property

Pascal

```
property iSubType: Word;
```

C++

```
__property Word iSubType;
```

Description

This is iSubType, a member of class TFLDDesc.

25.1.4.3.10 TFLDDesc.iUnits1 Property

Pascal

```
property iUnits1: SmallInt;
```

C++

```
__property SmallInt iUnits1;
```

Description

This is iUnits1, a member of class TFLDDesc.

25.1.4.3.11 TFLDDesc.iUnits2 Property

Pascal

```
property iUnits2: SmallInt;
```

C++

```
__property SmallInt iUnits2;
```

Description

This is iUnits2, a member of class TFLDDesc.

25.1.4.3.12 TFLDDesc.szName Property

Pascal

```
property szName: string;
```

C++

```
__property UnicodeString szName;
```

Description

This is szName, a member of class TFLDDesc.

25.1.5 TSQLBlobStream Class

TSQLBlobStream lets applications read from or write to BLOB fields in a client dataset.

Class Hierarchy

Pascal

```
TSQLBlobStream = class(TMemoryStream);
```

C++

```
class TSQLBlobStream : public TMemoryStream;
```

File

SqlExpr

Description

Use TSQLBlobStream to read the value of a Binary Large Object (BLOB) field in a dbExpress dataset (TSQLLDataSet, TSQLTable (see page 1680), TSQLQuery (see page 1654), or TSQLStoredProc (see page 1671)). BLOB fields are TBlobField objects and descendants of TBlobField such as TGraphicField and TMemoField. BLOB fields in client datasets use client BLOB streams to implement many of their data access properties and methods.

TSQLBlobStream allows objects that have no specialized knowledge of how data is stored in a BLOB field to read such data by employing the uniform stream interface.

To use an SQL BLOB stream, create an instance of TSQLBlobStream, use the methods of the stream to read the data, and then free the BLOB stream. If you use the same instance of TSQLBlobStream to access data from more than one record, you must call the ReadBlobData (see page 1580) method to update the stream when the current record changes.

Warning: Although TSQLBlobStream inherits several write methods from TMemoryStream, it can't be used to write data back to the dataset because dbExpress datasets are read-only. Writing to TSQLBlobStream simply alters the in-memory buffer that contains a BLOB field's data.

TGraphicField

TMemoField

TCustomSQLDataSet (see page 1520)

TSQLDataSet (see page 1631)

TSQLTable (see page 1680)

TSQLQuery (see page 1654)

TSQLStoredProc (see page 1671)

25.1.5.1 TSQLBlobStream Members

The following tables list the members exposed by TSQLBlobStream.

Public Methods

	Name	Description
	Create (see page 1578)	Creates and initializes an instance of TSQLBlobStream (see page 1577).
	Destroy (see page 1579)	Frees an instance of TSQLBlobStream (see page 1577).
	ReadBlobData (see page 1580)	Fills the BLOB stream's memory buffer with the contents of the associated BLOB field.

25.1.5.2 TSQLBlobStream.Create Constructor

Creates and initializes an instance of TSQLBlobStream (see page 1577).

Pascal

```
constructor Create(Field: TBlobField; Mode: TBlobStreamMode = bmRead);
```

C++

```
__fastcall TSQLBlobStream(TBlobField Field, TBlobStreamMode Mode = bmRead);
```

Description

Call Create to obtain an instance of TSQLBlobStream (see page 1577) for reading from a specific TBlobField object in a TCustomSQLDataSet (see page 1520) descendant.

Field specifies the BLOB field from which to read data.

The Mode parameter is provided for compatibility with other BLOB stream constructors. However, in TSQLBlobStream (see page 1577), the Mode parameter is ignored because dbExpress datasets are read-only. SQL Blob streams can only be used to read BLOB data.

Create links the TSQLBlobStream (see page 1577) to the field object specified by the Field parameter. It then calls ReadBlobData (see page 1580) to read the information from the BLOB field into a memory buffer, where it is available for reading.

Warning: If you write to the SQLBlobStream using inherited methods, you are overwriting the in-memory buffer that is filled by the constructor. This will cause subsequent read operations to provide inaccurate information, because the BLOB stream no longer accurately reflects the contents of the BLOB field.

Instead of calling the TSQLBlobStream (see page 1577) constructor, you can also use the dataset's CreateBlobStream method.

See Also

CreateBlobStream (see page 1528)

ReadBlobData (see page 1580)

25.1.5.3 TSQLBlobStream.Destroy Destructor

Frees an instance of TSQLBlobStream (see page 1577).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLBlobStream();
```

Description

Do not call Destroy directly in an application. Instead call Free. Free verifies that the TBlobStream object is not nil and only then calls Destroy.

Destroy the TSQLBlobStream (see page 1577) object by calling Free when it is no longer needed for reading from the BLOB field. BLOB streams should be destroyed when the dataset changes the current record.

See Also

System::TObject::Free (see page 3372)

OnDataChange

25.1.5.4 TSQLBlobStream Methods

The methods of the TSQLBlobStream class are listed here.

Public Methods

	Name	Description
	ReadBlobData (see page 1580)	Fills the BLOB stream's memory buffer with the contents of the associated BLOB field.

25.1.5.4.1 TSQLBlobStream.ReadBlobData Method

Fills the BLOB stream's memory buffer with the contents of the associated BLOB field.

Pascal

```
procedure ReadBlobData;
```

C++

```
__fastcall ReadBlobData();
```

Description

Call ReadBlobData to refresh the contents of the BLOB stream when the current record in the dataset changes. ReadBlobData reads the contents of a BLOB field into the SQL BLOB stream's in-memory buffer and sets the Size property to the number of bytes of BLOB data. It then sets Position to 0 so that the stream is ready for you to read the BLOB data.

Note: It is not necessary to call ReadBlobData when you first create a SQL BLOB stream, because the constructor already performs this task. You need only call ReadBlobData when the current record changes, so that the stream reflects the BLOB data for the new record.

Create (see page 1578)

25.1.6 TSQLConnection Class

TSQLConnection encapsulates a dbExpress connection to a database server.

Class Hierarchy

Pascal

```
TSQLConnection = class(TCustomConnection);
```

C++

```
class TSQLConnection : public TCustomConnection;
```

File

SqlExpr

Description

Use TSQLConnection to represent a dbExpress database connection. The connection provided by a single TSQLConnection component can be shared by multiple SQL dataset components through their TSQLConnection properties.

TSQLConnection interacts with a dbExpress driver and two files. The first, dbxdrivers.ini on Windows or dbxdrivers on Linux, lists the installed driver types (Interbase, Oracle, and so on) and, for each driver, lists the libraries (DLLs or shared objects) it requires

as well as the default settings for all connection parameters. The second file, dbxconnections.ini on Windows or dbxconnections on Linux, lists named sets of connection configurations. Each configuration represents a set of settings for TSQLConnection and describes a particular database connection.

You can use TSQLConnection to choose one of the named configurations in `dbxconnections.ini` and use it to connect to a database or to define new configurations. Use the ConnectionName (see page 1610) property to select an already created connection. To add and manage connections, use the Data Explorer (**View** ▸ **Data Explorer**) included in the RAD Studio IDE.

In addition to describing and establishing database connections, TSQLConnection surfaces properties, methods, and events for controlling server login, managing transactions, and fetching metadata from the server.

Protected Methods

	Name	Description
	CheckConnection (see page 1586)	This is CheckConnection, a member of class TSQLConnection.
V	CheckDisconnect (see page 1587)	This is CheckDisconnect, a member of class TSQLConnection.
V	ConnectionOptions (see page 1589)	This is ConnectionOptions, a member of class TSQLConnection.
V	DoConnect (see page 1589)	Provides the interface for a method that opens a connection.
V	DoDisconnect (see page 1589)	Provides the interface for a method that terminates the connection.
V	GetConnected (see page 1591)	Returns the value of the Connected property.
	GetDataSet (see page 1591)	Returns a dataset, given its index in the DataSets property array.
V	Loaded (see page 1600)	Initializes the connection component after all objects in the form or data module have been loaded.
V	Notification (see page 1601)	Forwards notification messages to all owned components.
	OpenSchema (see page 1601)	This is the overview for the OpenSchema method overload.
V	RegisterClient (see page 1602)	Registers an object that uses the connection component.
	SQLError (see page 1605)	This is SQLError, a member of class TSQLConnection.
V	UnRegisterClient (see page 1606)	Removes a registered client so that it is no longer associated with the connection component.

Protected Properties

	Name	Description
R	ConnectionRegistryFile (see page 1610)	This is ConnectionRegistryFile, a member of class TSQLConnection.
R	QuoteChar (see page 1623)	This is QuoteChar, a member of class TSQLConnection.

	SQLDllHandle (see page 1623)	This is SQLDllHandle, a member of class TSQLConnection.

Public Events

	Name	Description
R	TraceCallbackEvent (see page 1628)	Provides access to the callback function that executes for every SQL command passed to or from the server.

Public Methods

	Name	Description
	AddConnectNotification (see page 1585)	This is AddConnectNotification, a member of class TSQLConnection.
	BeginTransaction (see page 1585)	This is the overview for the BeginTransaction method overload.
	CloneConnection (see page 1587)	Returns a copy of the SQL connection object.
	CloseDataSets (see page 1587)	Closes all datasets associated with the SQL connection object component without disconnecting from the database.
	Commit (see page 1588)	Commits an open transaction.
	CommitFreeAndNil (see page 1588)	Commits an open transaction.
V	Create (see page 1583)	Creates and initializes an instance TSQLConnection (see page 1580).
V	Destroy (see page 1584)	Destroys the SQL connection object.
	Execute (see page 1590)	Executes an SQL command on the server.
	ExecuteDirect (see page 1590)	Executes an SQL command that does not include parameters.
	GetCommandTypes (see page 1591)	This is GetCommandTypes, a member of class TSQLConnection.
	GetDefaultSchemaName (see page 1592)	Returns the default schema name of the current object.
	GetFieldNames (see page 1592)	This is the overview for the GetFieldNames method overload.
	GetIndexNames (see page 1593)	This is the overview for the GetIndexNames method overload.
	GetLoginUsername (see page 1594)	Returns the username that is logged in on the current connection.
	GetPackageNames (see page 1594)	This is the overview for the GetPackageNames method overload.
	GetProcedureNames (see page 1595)	This is the overview for the GetProcedureNames method overload.
	GetProcedureParams (see page 1596)	This is the overview for the GetProcedureParams method overload.
	GetSchemaNames (see page 1598)	This is the overview for the GetSchemaNames method overload.
	GetServerMethodNames (see page 1598)	This is GetServerMethodNames, a member of class TSQLConnection.
	GetTableNames (see page 1598)	This is the overview for the GetTableNames method overload.
	HasTransaction (see page 1599)	This is HasTransaction, a member of class TSQLConnection.
	LoadParamsFromIniFile (see page 1600)	Sets the DriverName (see page 1612) and Params (see page 1621) properties to the values associated with the ConnectionName (see page 1610) property.
	RemoveConnectNotification (see page 1602)	This is RemoveConnectNotification, a member of class TSQLConnection.
	Rollback (see page 1603)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	RollbackFreeAndNil (see page 1603)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	RollbackIncompleteFreeAndNil (see page 1604)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	SetTraceEvent (see page 1605)	Associates the SQL connection with a callback function that executes for every SQL command passed to or from the server.
	StartTransaction (see page 1605)	Initiates a new transaction in the associated database.

Public Properties

	Name	Description
R	ActiveStatements (see page 1607)	Indicates the number of statements currently active with the database server.
	AutoClone (see page 1608)	Specifies whether the SQL connection automatically clones database connections when they are needed.
R	ConnectionData (see page 1609)	This is ConnectionData, a member of class TSQLConnection.
	ConnectionState (see page 1611)	Indicates the current state of the TSQLConnection (see page 1580) object.
R	DataSets (see page 1611)	Lists all active datasets for the connection component.
R	DBXConnection (see page 1611)	Provides an interface to the dbExpress object that represents a connection.
R	InTransaction (see page 1613)	Indicates whether a transaction is in progress.
	LocaleCode (see page 1615)	Identifies the locale that is used for sorting items from datasets that use this connection.

R	MaxStmtsPerConn (see page 1620)	Indicates the server limit on the number of statements supported by a single database connection.
R	MetaData (see page 1620)	Provides an interface to the dbExpress object that supplies server metadata.
R	MultipleTransactionsSupported (see page 1621)	Indicates whether the database server supports multiple transactions.
	ParamsLoaded (see page 1622)	Indicates when parameter values have been loaded from dbxconnections.ini.
	SQLHourGlass (see page 1623)	Specifies whether the cursor should change to crSQLWait during lengthy operations.
R	TransactionsSupported (see page 1624)	Indicates whether the database server supports transactions.

Published Events

	Name	Description
	AfterConnect (see page 1626)	Occurs after a connection is established.
	AfterDisconnect (see page 1626)	Occurs after the connection closes.
	BeforeConnect (see page 1626)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 1627)	Occurs immediately before the connection closes.
	OnLogin (see page 1627)	Occurs after the BeforeConnect (see page 1626) event and before a connection is established.

Published Properties

	Name	Description
	Connected (see page 1609)	Specifies whether the connection is active.
	ConnectionName (see page 1610)	Names the connection configuration.
	DriverName (see page 1612)	Specifies the database driver associated with the SQL connection.
	GetDriverFunc (see page 1613)	Specifies the function that returns the top-level dbExpress driver.
	KeepConnection (see page 1614)	Specifies whether the connection stays active when no datasets are open.
	LibraryName (see page 1614)	Specifies the dbExpress driver that TSQLConnection (see page 1580) uses to establish a connection.
	LoadParamsOnConnect (see page 1615)	Specifies whether the TSQLConnection (see page 1580) component loads the configuration named by ConnectionName (see page 1610) immediately before connecting to the server.
	LoginPrompt (see page 1616)	Specifies whether a login dialog appears immediately before opening a new connection.
	Params (see page 1621)	Lists the connection parameters.
	TableScope (see page 1623)	Indicates what types of tables are returned when fetching schema information about tables.
	VendorLib (see page 1625)	Specifies the client software library (DLL or shared object) supplied by the database vendor.

25.1.6.2 TSQLConnection.Create Constructor

Creates and initializes an instance TSQLConnection (see page 1580).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLConnection(TComponent * AOwner);
```

Description

Use Create to instantiate TSQLConnection (see page 1580) at runtime. SQL connections added to forms or data modules at design time are created automatically.

The AOwner parameter is the component, typically a form or data module, that is responsible for freeing the SQL connection.

See Also

Destroy (see page 1584)

Owner

25.1.6.3 TSQLConnection.Destroy Destructor

Destroys the SQL connection object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLConnection();
```

Description

To free a TSQLConnection (see page 1580) instance, do not call Destroy. Instead, call Free. Free verifies that the ADO connection is not nil, and only then calls Destroy.

There is no need to explicitly free instances of TSQLConnection (see page 1580) that were created with an Owner.

See Also

Owner

Create (see page 1583)

delete

System::TObject::Free (see page 3372)

25.1.6.4 TSQLConnection Methods

The methods of the TSQLConnection class are listed here.

Protected Methods

	Name	Description
	CheckConnection (see page 1586)	This is CheckConnection, a member of class TSQLConnection.
V	CheckDisconnect (see page 1587)	This is CheckDisconnect, a member of class TSQLConnection.
V	ConnectionOptions (see page 1589)	This is ConnectionOptions, a member of class TSQLConnection.
V	DoConnect (see page 1589)	Provides the interface for a method that opens a connection.
V	DoDisconnect (see page 1589)	Provides the interface for a method that terminates the connection.
V	GetConnected (see page 1591)	Returns the value of the Connected property.
	GetDataSet (see page 1591)	Returns a dataset, given its index in the DataSets property array.
V	Loaded (see page 1600)	Initializes the connection component after all objects in the form or data module have been loaded.
V	Notification (see page 1601)	Forwards notification messages to all owned components.
	OpenSchema (see page 1601)	This is the overview for the OpenSchema method overload.
V	RegisterClient (see page 1602)	Registers an object that uses the connection component.
	SQLError (see page 1605)	This is SQLError, a member of class TSQLConnection.
V	UnRegisterClient (see page 1606)	Removes a registered client so that it is no longer associated with the connection component.

Public Methods

	Name	Description
	AddConnectNotification (see page 1585)	This is AddConnectNotification, a member of class TSQLConnection.
	BeginTransaction (see page 1585)	This is the overview for the BeginTransaction method overload.
	CloneConnection (see page 1587)	Returns a copy of the SQL connection object.

	CloseDataSets (see page 1587)	Closes all datasets associated with the SQL connection object component without disconnecting from the database.
	Commit (see page 1588)	Commits an open transaction.
	CommitFreeAndNil (see page 1588)	Commits an open transaction.
	Execute (see page 1590)	Executes an SQL command on the server.
	ExecuteDirect (see page 1590)	Executes an SQL command that does not include parameters.
	GetCommandTypes (see page 1591)	This is GetCommandTypes, a member of class TSQLConnection.
	GetDefaultSchemaName (see page 1592)	Returns the default schema name of the current object.
	GetFieldNames (see page 1592)	This is the overview for the GetFieldNames method overload.
	GetIndexNames (see page 1593)	This is the overview for the GetIndexNames method overload.
	GetLoginUsername (see page 1594)	Returns the username that is logged in on the current connection.
	GetPackageNames (see page 1594)	This is the overview for the GetPackageNames method overload.
	GetProcedureNames (see page 1595)	This is the overview for the GetProcedureNames method overload.
	GetProcedureParams (see page 1596)	This is the overview for the GetProcedureParams method overload.
	GetSchemaNames (see page 1598)	This is the overview for the GetSchemaNames method overload.
	GetServerMethodNames (see page 1598)	This is GetServerMethodNames, a member of class TSQLConnection.
	GetTableNames (see page 1598)	This is the overview for the GetTableNames method overload.
	HasTransaction (see page 1599)	This is HasTransaction, a member of class TSQLConnection.
	LoadParamsFromIniFile (see page 1600)	Sets the DriverName (see page 1612) and Params (see page 1621) properties to the values associated with the ConnectionName (see page 1610) property.
	RemoveConnectNotification (see page 1602)	This is RemoveConnectNotification, a member of class TSQLConnection.
	Rollback (see page 1603)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	RollbackFreeAndNil (see page 1603)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	RollbackIncompleteFreeAndNil (see page 1604)	Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.
	SetTraceEvent (see page 1605)	Associates the SQL connection with a callback function that executes for every SQL command passed to or from the server.
	StartTransaction (see page 1605)	Initiates a new transaction in the associated database.

25.1.6.4.1 TSQLConnection.AddConnectNotification Method

Pascal

```
procedure AddConnectNotification(Listener: TObject; Event: TConnectChangeEvent);
```

C++

```
__fastcall AddConnectNotification(TObject * Listener, TConnectChangeEvent Event);
```

Description

This is AddConnectNotification, a member of class TSQLConnection.

25.1.6.4.2 BeginTransaction Method

This is the overview for the BeginTransaction method overload.

Overload List

	Name	Description
	TSQLConnection.BeginTransaction () (see page 1586)	Initiates a new transaction in the associated database.
	TSQLConnection.BeginTransaction (TDBXIsolation) (see page 1586)	Initiates a new transaction in the associated database.

25.1.6.4.2.1 TSQLConnection.BeginTransaction Method ()

Initiates a new transaction in the associated database.

Pascal

```
function BeginTransaction: TDBXTransaction; overload;
function BeginTransaction(Isolation: TDBXIsolation): TDBXTransaction; overload;
```

C++

```
__fastcall TDBXTransaction BeginTransaction();
__fastcall TDBXTransaction BeginTransaction(TDBXIsolation Isolation);
```

Description

Call BeginTransaction to start a new transaction against a database server that supports transactions. (MySQL servers do not support transactions.) You can check the TransactionsSupported (see page 1624) property to determine whether the server supports transactions. If the server does not support transactions, BeginTransaction does nothing.

The method returns a TDBXTransactioninstance.

If the transaction is successfully started, BeginTransaction sets the InTransaction (see page 1613) property to true.

Updates, insertions, and deletions that take place after a call to BeginTransaction are enlisted in that transaction until another overlapping transaction is started or until the application calls CommitFreeAndNil (see page 1588) to save the changes or RollbackFreeAndNil (see page 1603) to cancel them.

Tip: If the server does not support multiple transactions, check the status of the InTransaction (see page 1613) property to be sure that another transaction is not already in progress.

Tip: When working with overlapped transactions, you can indicate the transaction to which a dataset belongs by setting its TransactionLevel property to the transaction identifier you assign in this method.

See Also

InTransaction (see page 1613)

CommitFreeAndNil (see page 1588)

RollbackFreeAndNil (see page 1603)

Params (see page 1621)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.3 TSQLConnection.CheckConnection Method

Pascal

```
procedure CheckConnection(eFlag: eConnectFlag);
```

C++

```
__fastcall CheckConnection(eConnectFlag eFlag);
```

Description

This is CheckConnection, a member of class TSQLConnection.

25.1.6.4.4 TSQLConnection.CheckDisconnect Method

Pascal

```
procedure CheckDisconnect; virtual;
```

C++

```
virtual __fastcall CheckDisconnect();
```

Description

This is CheckDisconnect, a member of class TSQLConnection.

25.1.6.4.5 TSQLConnection.CloneConnection Method

Returns a copy of the SQL connection object.

Pascal

```
function CloneConnection: TSQLConnection;
```

C++

```
__fastcall TSQLConnection CloneConnection();
```

Description

Call CloneConnection to create a duplicate of this TSQLConnection (see page 1580) object. CloneConnection instantiates a new TSQLConnection (see page 1580) object and assigns its properties to match those of this TSQLConnection (see page 1580) object.

The returned TSQLConnection (see page 1580) is owned by this TSQLConnection (see page 1580). That is, this SQL connection component frees the clone from its own destructor.

See Also

AutoClone (see page 1608)

25.1.6.4.6 TSQLConnection.CloseDataSets Method

Closes all datasets associated with the SQL connection object component without disconnecting from the database.

Pascal

```
procedure CloseDataSets;
```

C++

```
__fastcall CloseDataSets();
```

Description

Call CloseDataSets to close all active datasets without disconnecting from the database server. Ordinarily, when an application calls Close (see page 3538), all datasets are closed, and the connection to the database server is dropped. Calling CloseDataSets instead of Close (see page 3538) ensures that an application can close all active datasets without having to reconnect to the database server at a later time.

See Also

Close

Close

DataSets (see page 1611)

KeepConnection (see page 1614)

25.1.6.4.7 TSQLConnection.Commit Method

Commits an open transaction.

Pascal

```
procedure Commit(TransDesc: TTransactionDesc); deprecated;
```

C++

```
__fastcall Commit(TTransactionDesc TransDesc);
```

Description

Call Commit to save any changes made during the transaction described by TransDesc and to end that transaction.

TransDesc is the transaction descriptor supplied to the StartTransaction (see page 1605) method when starting the transaction.

If the specified transaction is the only current transaction, Commit sets the InTransaction (see page 1613) property to false after committing the transaction.

Note: This method has been deprecated.

See Also

InTransaction (see page 1613)

StartTransaction (see page 1605)

Rollback (see page 1603)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.8 TSQLConnection.CommitFreeAndNil Method

Commits an open transaction.

Pascal

```
procedure CommitFreeAndNil(var Transaction: TDBXTransaction);
```

C++

```
__fastcall CommitFreeAndNil(TDBXTransaction Transaction);
```

Description

Call CommitFreeAndNil to save any changes made during the transaction described by **Transaction**and to end that transaction. **Transaction** is the TDBXTransaction instance returned by the BeginTransaction (see page 1586) method when starting the transaction.

If the specified transaction is the only current transaction, CommitFreeAndNil sets the InTransaction (see page 1613) property to `false` after committing the transaction.

Any active transactions that were begun after this transaction are effectively committed and freed as well.

The var **Transaction** instance is set to `nil`.

Note: This method raises an exception if Transaction

is not an active transaction.

See Also

InTransaction (see page 1613)

BeginTransaction (see page 1586)

RollbackFreeAndNil (see page 1603)

RollbackIncompleteFreeAndNil (see page 1604)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.9 TSQLConnection.ConnectionOptions Method

Pascal

```
procedure ConnectionOptions; virtual;
```

C++

```
virtual __fastcall ConnectionOptions();
```

Description

This is ConnectionOptions, a member of class TSQLConnection.

25.1.6.4.10 TSQLConnection.DoConnect Method

Provides the interface for a method that opens a connection.

Pascal

```
procedure DoConnect; override;
```

C++

```
virtual __fastcall DoConnect();
```

Description

The Connected property uses DoConnect to establish a connection. Descendant classes override the DoConnect method to establish their connection as appropriate. As implemented in TCustomConnection, DoConnect does nothing.

See Also

Connected

DoDisconnect

25.1.6.4.11 TSQLConnection.DoDisconnect Method

Provides the interface for a method that terminates the connection.

Pascal

```
procedure DoDisconnect; override;
```

C++

```
virtual __fastcall DoDisconnect();
```

Description

The Connected property uses DoDisconnect to close a connection. Descendant classes override the DoDisconnect method to

drop a connection. As implemented in TCustomConnection, DoDisconnect does nothing.

See Also

Connected

DoConnect

25.1.6.4.12 TSQLConnection.Execute Method

Executes an SQL command on the server.

Pascal

```
function Execute(const SQL: UnicodeString; Params: TParams; ResultSet: TPSResult = nil):
Integer;
```

C++

```
__fastcall int Execute(const UnicodeString SQL, TParams Params, TPSResult ResultSet = nil);
```

Description

Call Execute to execute a single command on the server without the overhead of using an SQL dataset. Execute is especially useful for statements that do not return a result set such as data definition language (DDL) statements.

SQL is the command to execute.

Params (see page 1621) is a TParams object that contains any parameters used by the SQL statement. Parameter binding is by index only (not by name), so the order of parameters is important and the order of the TParam objects in Params (see page 1621) corresponds to the order of the parameters in the SQL statement. Use properties and methods of TParams to create a TParams object, add TParam objects for each parameter, and assign parameter properties such as datatype and value. If the SQL statement does not include any parameters, pass a nil (Delphi) or NULL (C++) value for Params (see page 1621).

ResultSet is a pointer to a variable of type TCustomSQLDataSet (see page 1520)*. If the SQL statement returns a cursor, Execute creates a new TCustomSQLDataSet (see page 1520) instance and populates it with the result set. The new TCustomSQLDataSet (see page 1520) reference is returned as the value to which ResultSet points. If the SQL statement does not return a result set, pass a nil (Delphi) or NULL (C++) value for ResultSet. TPSResult is is set to Pointer for native code and TObject (see page 3354) for managed code.

Execute returns the number of records affected by executing the SQL statement.

Tip: If the SQL statement does not include any parameters, you can use the ExecuteDirect (see page 1590) method instead.

See Also

ExecSQL (see page 1636)

ExecuteDirect (see page 1590)

25.1.6.4.13 TSQLConnection.ExecuteDirect Method

Executes an SQL command that does not include parameters.

Pascal

```
function ExecuteDirect(const SQL: UnicodeString): Integer;
```

C++

```
__fastcall int ExecuteDirect(const UnicodeString SQL);
```

Description

Call ExecuteDirect to execute a single parameterless command on the server without the overhead of using an SQL dataset or

preparing the statement before it executes. If the statement ordinarily returns a cursor, ExecuteDirect executes the statement, but does not return a cursor.

SQL is the command to execute.

ExecuteDirect returns the number of rows that were affected by the execution of the SQL query.

Note: To execute an SQL statement that includes parameters or that returns a cursor, use the Execute (see page 1590) method instead.

See Also

ExecSQL (see page 1636)

Execute (see page 1590)

25.1.6.4.14 TSQLConnection.GetCommandTypes Method

Pascal

```
procedure GetCommandTypes(List: TWideStrings);
```

C++

```
__fastcall GetCommandTypes(TWideStrings List);
```

Description

This is GetCommandTypes, a member of class TSQLConnection.

25.1.6.4.15 TSQLConnection.GetConnected Method

Returns the value of the Connected property.

Pascal

```
function GetConnected: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection, GetConnected always returns false.

See Also

Connected

SetConnected

25.1.6.4.16 TSQLConnection.GetDataSet Method

Returns a dataset, given its index in the DataSets property array.

Pascal

```
function GetDataSet(Index: Integer): TCustomSQLDataSet; reintroduce;
```

C++

```
__fastcall TCustomSQLDataSet GetDataSet(int Index);
```

Description

GetDataSet is the protected read implementation of the DataSets property.

See Also

DataSets

25.1.6.4.17 TSQLConnection.GetDefaultSchemaName Method

Returns the default schema name of the current object.

Pascal

```
function GetDefaultSchemaName: UnicodeString;
```

C++

```
__fastcall UnicodeString GetDefaultSchemaName();
```

25.1.6.4.18 GetFieldNames Method

This is the overview for the GetFieldNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetFieldNames (string, string, TStrings) (see page 1592)	Populates a string list with the names of fields in a table.
	TSQLConnection.GetFieldNames (string, TStrings) (see page 1592)	Populates a string list with the names of fields in a table.
	TSQLConnection.GetFieldNames (WideString, TWideStrings) (see page 1592)	Populates a string list with the names of fields in a table.
	TSQLConnection.GetFieldNames (WideString, WideString, TWideStrings) (see page 1592)	Populates a string list with the names of fields in a table.

25.1.6.4.18.1 TSQLConnection.GetFieldNames Method (WideString, TWideStrings)

Populates a string list with the names of fields in a table.

Pascal

```
procedure GetFieldNames(const TableName: string; List: TStrings); overload; deprecated;
procedure GetFieldNames(const TableName: string; SchemaName: string; List: TStrings);
overload; deprecated;
procedure GetFieldNames(const TableName: WideString; SchemaName: WideString; List:
TWideStrings); overload;
procedure GetFieldNames(const TableName: WideString; List: TWideStrings); overload;
```

C++

```
__fastcall GetFieldNames(const UnicodeString TableName, TStrings List);
__fastcall GetFieldNames(const UnicodeString TableName, UnicodeString SchemaName, TStrings
List);
__fastcall GetFieldNames(const BSTR TableName, BSTR SchemaName, TWideStrings List);
__fastcall GetFieldNames(const BSTR TableName, TWideStrings List);
```

Description

Call GetFieldNames to retrieve a list of fields in a table.

TableName names the table whose field names you want added to the list.

List is a TStrings descendant that receives the field names. Any existing strings are deleted from the list before GetFieldNames adds the names of all the fields in TableName.

For example, the following line fills a list box with the names of all fields in the Employee table:

```
SQLConnection1.GetFieldNames('Employee', ListBox1.Items);
SQLConnection1->GetFieldNames("Employee", ListBox1->Items);
```

See Also

GetProcedureNames (see page 1595)

GetPackageNames (see page 1594)

GetTableNames (see page 1599)

GetIndexNames (see page 1593)

GetProcedureParams (see page 1597)

SetSchemaInfo (see page 1550)

25.1.6.4.19 GetIndexNames Method

This is the overview for the GetIndexNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetIndexNames (string, string, TStrings) (see page 1593)	Populates a string list with the names of indexes on a table.
	TSQLConnection.GetIndexNames (string, TStrings) (see page 1593)	Populates a string list with the names of indexes on a table.
	TSQLConnection.GetIndexNames (UnicodeString, TWideStrings) (see page 1593)	Populates a string list with the names of indexes on a table.
	TSQLConnection.GetIndexNames (UnicodeString, UnicodeString, TWideStrings) (see page 1593)	Populates a string list with the names of indexes on a table.

25.1.6.4.19.1 TSQLConnection.GetIndexNames Method (UnicodeString, TWideStrings)

Populates a string list with the names of indexes on a table.

Pascal

```
procedure GetIndexNames(const TableName: string; List: TStrings); overload; deprecated;
procedure GetIndexNames(const TableName: string; const SchemaName: string; List: TStrings);
overload; deprecated;
procedure GetIndexNames(const TableName: UnicodeString; List: TWideStrings); overload;
procedure GetIndexNames(const TableName: UnicodeString; const SchemaName: UnicodeString; List:
TWideStrings); overload;
```

C++

```
__fastcall GetIndexNames(const UnicodeString TableName, TStrings List);
__fastcall GetIndexNames(const UnicodeString TableName, const UnicodeString SchemaName,
TStrings List);
__fastcall GetIndexNames(const UnicodeString TableName, TWideStrings List);
__fastcall GetIndexNames(const UnicodeString TableName, const UnicodeString SchemaName,
TWideStrings List);
```

Description

Call GetIndexNames to retrieve a list of the indexes defined for a table.

List is a TStrings descendant that receives the index names. Any existing strings are deleted from the list before GetIndexNames adds the names of all the indexes on TableName.

TableName names the table whose indexes you want added to the list.

For example, the following line fills a list box with the names of all indexes on the Employee table:

```
SQLConnection1.GetIndexNames('Employee', ListBox1.Items);
SQLConnection1->GetIndexNames("Employee", ListBox1->Items);
```

Obtaining Information About Indexes

25.1.6.4.20 TSQLConnection.GetLoginUsername Method

Returns the username that is logged in on the current connection.

Pascal

```
function GetLoginUsername: UnicodeString;
```

C++

```
__fastcall UnicodeString GetLoginUsername();
```

25.1.6.4.21 GetPackageNames Method

This is the overview for the GetPackageNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetPackageNames (TStrings) (see page 1594)	Populates a string list with the names of all packages defined on the server.
	TSQLConnection.GetPackageNames (TWideStrings) (see page 1594)	Populates a string list with the names of all packages defined on the server.

25.1.6.4.21.1 TSQLConnection.GetPackageNames Method (TStrings)

Populates a string list with the names of all packages defined on the server.

Pascal

```
procedure GetPackageNames(List: TStrings); overload; deprecated;
procedure GetPackageNames(List: TWideStrings); overload;
```

C++

```
__fastcall GetPackageNames(TStrings List);
__fastcall GetPackageNames(TWideStrings List);
```

Description

Call GetPackageNames to retrieve a list of packages defined on the associated database. This method is only relevant to Oracle servers.

List is a TStrings descendant that receives the package names. Any existing strings are deleted from the list before GetPackageNames adds the names of all packages that the database defines.

The following example fills a list box with the names of all packages defined by the database:

```
SQLConnection1.GetPackageNames(ListBox1.Items);
SQLConnection1->GetPackageNames(ListBox1->Items);
```

See Also

SetSchemaInfo (see page 1550)

25.1.6.4.22 GetProcedureNames Method

This is the overview for the GetProcedureNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetProcedureNames (string, string, TStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.
	TSQLConnection.GetProcedureNames (string, TStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.
	TSQLConnection.GetProcedureNames (TStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.
	TSQLConnection.GetProcedureNames (TWideStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.
	TSQLConnection.GetProcedureNames (UnicodeString, TWideStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.
	TSQLConnection.GetProcedureNames (UnicodeString, UnicodeString, TWideStrings) (see page 1595)	Populates a string list with the names of stored procedures in the database.

25.1.6.4.22.1 TSQLConnection.GetProcedureNames Method (TStrings)

Populates a string list with the names of stored procedures in the database.

Pascal

```
procedure GetProcedureNames(List: TStrings); overload; deprecated;
procedure GetProcedureNames(const PackageName: string; List: TStrings); overload; deprecated;
procedure GetProcedureNames(const PackageName: string; const SchemaName: string; List:
TStrings); overload; deprecated;
procedure GetProcedureNames(List: TWideStrings); overload;
procedure GetProcedureNames(const PackageName: UnicodeString; List: TWideStrings); overload;
procedure GetProcedureNames(const PackageName: UnicodeString; const SchemaName: UnicodeString;
List: TWideStrings); overload;
```

C++

```
__fastcall GetProcedureNames(TStrings List);
__fastcall GetProcedureNames(const UnicodeString PackageName, TStrings List);
__fastcall GetProcedureNames(const UnicodeString PackageName, const UnicodeString SchemaName,
TStrings List);
__fastcall GetProcedureNames(TWideStrings List);
__fastcall GetProcedureNames(const UnicodeString PackageName, TWideStrings List);
__fastcall GetProcedureNames(const UnicodeString PackageName, const UnicodeString SchemaName,
TWideStrings List);
```

Description

Call GetProcedureNames to retrieve a list of stored procedures in the associated database.

List is a TStrings descendant that receives the stored procedure names. Any existing strings are deleted from the list before GetProcedureNames adds the names of all stored procedures in the database.

PackageName is the name of an Oracle package that contains the stored procedures. This syntax should only be used with Oracle servers when you only want the stored procedures from a specific package.

The following example fills a list box with the names of all stored procedures in the database:

```
SQLConnection1.GetProcedureNames(ListBox1.Items);
SQLConnection1->GetProcedureNames(ListBox1->Items);
```

See Also

GetIndexNames (see page 1593)

SetSchemaInfo (see page 1550)

25.1.6.4.23 GetProcedureParams Method

This is the overview for the GetProcedureParams method overload.

Overload List

	Name	Description
	TSQLConnection.GetProcedureParams (UnicodeString, TList) (see page 1597)	Populates a list with parameter descriptors for the parameters in a stored procedure.
	TSQLConnection.GetProcedureParams (UnicodeString, UnicodeString, TList) (see page 1597)	Populates a list with parameter descriptors for the parameters in a stored procedure.

	TSQLConnection.GetProcedureParams (UnicodeString, UnicodeString, UnicodeString, TList) (see page 1597)	Populates a list with parameter descriptors for the parameters in a stored procedure.

25.1.6.4.23.1 TSQLConnection.GetProcedureParams Method (UnicodeString, TList)

Populates a list with parameter descriptors for the parameters in a stored procedure.

Pascal

```
procedure GetProcedureParams(ProcedureName: UnicodeString; List: TList); overload;
procedure GetProcedureParams(ProcedureName: UnicodeString; PackageName: UnicodeString; List:
TList); overload;
procedure GetProcedureParams(ProcedureName: UnicodeString; PackageName: UnicodeString;
SchemaName: UnicodeString; List: TList); overload;
```

C++

```
__fastcall GetProcedureParams(UnicodeString ProcedureName, TList List);
__fastcall GetProcedureParams(UnicodeString ProcedureName, UnicodeString PackageName, TList
List);
__fastcall GetProcedureParams(UnicodeString ProcedureName, UnicodeString PackageName,
UnicodeString SchemaName, TList List);
```

Description

Call GetProcedureParams to retrieve information about the parameters of a specified stored procedure.

ProcedureName is the name of the stored procedure for whose parameters you want descriptions.

PackageName is the name of the Oracle package to which the stored procedure belongs. This parameter should only be used if TSQLConnection (see page 1580) connects to an Oracle server.

List is a TList object that receives the parameter descriptions. It should be an empty list on entry. For each parameter, GetProcedureParams adds a reference to an SPParamDesc (see page 1512) class (Delphi) or structure (C++). Each SPParamDesc (see page 1512) entity describes a parameter of a specified stored procedure, including its name, index, parameter type, field type, and so on. You are responsible for freeing the individual SPPParamDesc entities that GetProcedureParams dynamically allocates. (You can use FreeProcParams (see page 1696) to free all the entries and the list object as well).

Note: You can convert the list of SPParamDesc (see page 1512) entities to the more familiar TParams object by calling the global LoadParamListItems (see page 1698) procedure.

25.1.6.4.24 GetSchemaNames Method

This is the overview for the GetSchemaNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetSchemaNames (TStrings) (see page 1598)	Returns the schema names for all objects in the given data source.
	TSQLConnection.GetSchemaNames (TWideStrings) (see page 1598)	Returns the schema names for all objects in the given data source.

25.1.6.4.24.1 TSQLConnection.GetSchemaNames Method (TStrings)

Returns the schema names for all objects in the given data source.

Pascal

```
procedure GetSchemaNames(List: TStrings); overload;
procedure GetSchemaNames(List: TWideStrings); overload;
```

C++

```
__fastcall GetSchemaNames(TStrings List);
__fastcall GetSchemaNames(TWideStrings List);
```

25.1.6.4.25 TSQLConnection.GetServerMethodNames Method

Pascal

```
procedure GetServerMethodNames(List: TWideStrings);
```

C++

```
__fastcall GetServerMethodNames(TWideStrings List);
```

Description

This is GetServerMethodNames, a member of class TSQLConnection.

25.1.6.4.26 GetTableNames Method

This is the overview for the GetTableNames method overload.

Overload List

	Name	Description
	TSQLConnection.GetTableNames (TStrings, Boolean) (see page 1599)	Populates a string list with the names of tables in the database.
	TSQLConnection.GetTableNames (TStrings, WideString, Boolean) (see page 1599)	Populates a string list with the names of tables in the database.
	TSQLConnection.GetTableNames (TWideStrings, Boolean) (see page 1599)	Populates a string list with the names of tables in the database.
	TSQLConnection.GetTableNames (TWideStrings, WideString, Boolean) (see page 1599)	Populates a string list with the names of tables in the database.

25.1.6.4.26.1 TSQLConnection.GetTableNames Method (TStrings, Boolean)

Populates a string list with the names of tables in the database.

Pascal

```
procedure GetTableNames(List: TStrings; SystemTables: Boolean = False); overload;
procedure GetTableNames(List: TStrings; SchemaName: WideString; SystemTables: Boolean =
False); overload;
procedure GetTableNames(List: TWideStrings; SchemaName: WideString; SystemTables: Boolean =
False); overload;
procedure GetTableNames(List: TWideStrings; SystemTables: Boolean = False); overload;
```

C++

```
__fastcall GetTableNames(TStrings List, Boolean SystemTables = False);
__fastcall GetTableNames(TStrings List, BSTR SchemaName, Boolean SystemTables = False);
__fastcall GetTableNames(TWideStrings List, BSTR SchemaName, Boolean SystemTables = False);
__fastcall GetTableNames(TWideStrings List, Boolean SystemTables = False);
```

Description

Call GetTableNames to retrieve a list of tables in the associated database.

List is a TStrings descendant that receives the table names. Any existing strings are deleted from the list before GetTableNames adds the names of all tables in the database.

SystemTables specifies whether the list of table names should include only the database's system tables. If SystemTables is true, only the system tables are added to List. If SystemTables is false, the list is filled with any tables that match the criteria specified by the TableScope (see page 1623) property.

For example, the following line fills a list box with the names of all data tables in the database:

```
SQLConnection1.GetTableNames(ListBox1.Items, False);
SQLConnection1->GetTableNames(ListBox1->Items, false);
```

See Also

GetIndexNames (see page 1593)

25.1.6.4.27 TSQLConnection.HasTransaction Method

Pascal

```
function HasTransaction(Transaction: TDBXTransaction): Boolean;
```

C++

```
__fastcall Boolean HasTransaction(TDBXTransaction Transaction);
```

Description

This is HasTransaction, a member of class TSQLConnection.

25.1.6.4.28 TSQLConnection.Loaded Method

Initializes the connection component after all objects in the form or data module have been loaded.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. It is called automatically after the form or data module that contains the connection component has loaded all its owned objects. TCustomConnection overrides the inherited method to establish a connection if the Connected property is true.

See Also

StreamedConnected

Loaded

25.1.6.4.29 TSQLConnection.LoadParamsFromIniFile Method

Sets the DriverName (see page 1612) and Params (see page 1621) properties to the values associated with the ConnectionName (see page 1610) property.

Pascal

```
procedure LoadParamsFromIniFile(FFileName: UnicodeString = '');
```

C++

```
__fastcall LoadParamsFromIniFile(UnicodeString FFileName = '');
```

Description

Call LoadParamsFromIniFile to ensure that the DriverName (see page 1612) and Params (see page 1621) properties accurately reflect the connection configuration for the ConnectionName (see page 1610) property that is stored in the file specified by the AFileName parameter. If the AFileName parameter is omitted, LoadParamsFromIniFile uses the dbxconnections.ini file. Otherwise, itis a fully-qualified path name to a file that has the same format as the dbxconnections.ini file. Typically, this file is created by making a copy of the dbxconnections.ini file under a different name.

In most cases, it is unnecessary to load connection configurations at runtime because when you set ConnectionName (see page 1610) at design time, the DriverName (see page 1612) and Params (see page 1621) properties are automatically set as well. However, LoadParamsFromIniFile lets you use a customized set of connection configurations at runtime that differ from those stored in the dbxconnections.ini file, or to temporarily override the DriverName (see page 1612) or connection parameter values at design time and then reestablish the defaults at runtime.

Note: Do not set the LoadParamsOnConnect (see page 1615) property to true if your application calls LoadParamsFromIniFile and specifies an alternate connections file. When LoadParamsOnConnect (see page 1615) is true, it loads the connection configuration from the dbxconnections.ini

file immediately before opening a connection, overriding any values loaded by this method.

See Also

ConnectionName (see page 1610)

LoadParamsOnConnect (see page 1615)

DriverName (see page 1612)

Params (see page 1621)

Setting Up TSQLConnection

Configuring TSQL Connection

25.1.6.4.30 TSQLConnection.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

25.1.6.4.31 OpenSchema Method

This is the overview for the OpenSchema method overload.

Overload List

	Name	Description
	TSQLConnection.OpenSchema (TSchemaType, UnicodeString, TWideStrings) (see page 1601)	This is OpenSchema, a member of class TSQLConnection.
	TSQLConnection.OpenSchema (TSchemaType, UnicodeString, UnicodeString, TWideStrings) (see page 1602)	This is OpenSchema, a member of class TSQLConnection.

25.1.6.4.31.1 TSQLConnection.OpenSchema Method (TSchemaType, UnicodeString, TWideStrings)

Pascal

```
procedure OpenSchema(eKind: TSchemaType; sInfo: UnicodeString; List: TWideStrings); overload;
```

C++

```
__fastcall OpenSchema(TSchemaType eKind, UnicodeString sInfo, TWideStrings List);
```

Description

This is OpenSchema, a member of class TSQLConnection.

25.1.6.4.31.2 TSQLConnection.OpenSchema Method (TSchemaType, UnicodeString, UnicodeString, TWideStrings)

Pascal

```
procedure OpenSchema(eKind: TSchemaType; sInfo: UnicodeString; SSchemaName: UnicodeString;
List: TWideStrings); overload;
```

C++

```
__fastcall OpenSchema(TSchemaType eKind, UnicodeString sInfo, UnicodeString SSchemaName,
TWideStrings List);
```

Description

This is OpenSchema, a member of class TSQLConnection.

25.1.6.4.32 TSQLConnection.RegisterClient Method

Registers an object that uses the connection component.

Pascal

```
procedure RegisterClient(Client: TObject; Event: TConnectChangeEvent = nil); override;
```

C++

```
virtual __fastcall RegisterClient(TObject * Client, TConnectChangeEvent Event = nil);
```

Description

RegisterClient is used internally to associate objects with the connection component. Registered components can supply an event handler that responds when the connection is created or terminated.

Client is the object to register. If Client is a dataset, it is added to the DataSets property.

Event is an event handler that is called after the connection is established or before it is terminated.

Datasets call this method when they start using the connection component. For BDE-enabled datasets, ADO datasets, and dbExpress datasets, this is when they are activated. For client datasets, this is when the RemoteServer property is assigned.

See Also

DataSets

UnRegisterClient

25.1.6.4.33 TSQLConnection.RemoveConnectNotification Method

Pascal

```
procedure RemoveConnectNotification(Listener: TObject);
```

C++

```
__fastcall RemoveConnectNotification(TObject * Listener);
```

Description

This is RemoveConnectNotification, a member of class TSQLConnection.

25.1.6.4.34 TSQLConnection.Rollback Method

Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.

Pascal

```
procedure Rollback(TransDesc: TTransactionDesc); deprecated;
```

C++

```
__fastcall Rollback(TTransactionDesc TransDesc);
```

Description

Call Rollback to cancel any changes made during the transaction described by TransDesc and to end it.

TransDesc is the transaction descriptor supplied to the StartTransaction (see page 1605) method when starting the transaction.

If the specified transaction is the only current transaction, Rollback sets the InTransaction (see page 1613) property to false after canceling the transaction.

Note: This method has been deprecated.

See Also

InTransaction (see page 1613)

StartTransaction (see page 1605)

Commit (see page 1588)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.35 TSQLConnection.RollbackFreeAndNil Method

Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.

Pascal

```
procedure RollbackFreeAndNil(var Transaction: TDBXTransaction);
```

C++

```
__fastcall RollbackFreeAndNil(TDBXTransaction Transaction);
```

Description

Call RollbackFreeAndNil to cancel any changes made during the transaction described by Transaction and to end it. **Transaction** is the TDBXTransaction returned by the BeginTransaction (see page 1586) method when starting the transaction.

If the specified transaction is the only current transaction, RollbackFreeAndNil sets the InTransaction (see page 1613) property to false after canceling the transaction.

Any active transactions that were begun after this transaction are effectively rolled back and freed as well.

The var **Transaction** instance is set to `nil`.

Note: This method raises an exception if Transaction

is not an active transaction.

See Also

TDBXTransaction

InTransaction (see page 1613)

BeginTransaction (see page 1586)

CommitFreeAndNil (see page 1588)

RollbackIncompleteFreeAndNil (see page 1604)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.36 TSQLConnection.RollbackIncompleteFreeAndNil Method

Cancels all updates, insertions, and deletions for a specified transaction and ends the transaction.

Pascal

```
procedure RollbackIncompleteFreeAndNil(var Transaction: TDBXTransaction);
```

C++

```
__fastcall RollbackIncompleteFreeAndNil(TDBXTransaction Transaction);
```

Description

Call RollbackIncompleteFreeAndNil to cancel any changes made during the transaction described by Transaction and to end it. **Transaction** is the TDBXTransaction returned by the BeginTransaction (see page 1586) method when starting the transaction.

If the specified transaction is the only current transaction, RollbackFreeAndNil (see page 1603) sets the InTransaction (see page 1613) property to false after canceling the transaction.

Any active transactions that were begun after this transaction are effectively rolled back and freed as well.

The var **Transaction** instance is set to `nil`.

Unlike the RollbackFreeAndNil (see page 1603) procedure, this procedure does not throw an exception if **Transaction** is invalid or set to `nil`. This method is ideally used in a `finally` (or `except`) block. The `try` block uses either CommitFreeAndNil (see page 1588) or RollbackFreeAndNil (see page 1603), and the **Transaction** has already been completed, freed, and set to `nil`. If an exception is not raised in the `try` block, a call to RollbackIncompleteFreeAndNil in the `finally` block does nothing, because the **Transaction** instance is no longer valid. If an exception is raised, a call to RollbackIncompleteFreeAndNil in the `finally` block rolls back, frees, and sets the **Transaction** instance to `nil`.

TransactionLevel (see page 1567)

25.1.6.4.37 TSQLConnection.SetTraceEvent Method

Associates the SQL connection with a callback function that executes for every SQL command passed to or from the server.

Pascal

```
procedure SetTraceEvent(Event: TDBXTraceEvent);
```

C++

```
__fastcall SetTraceEvent(TDBXTraceEvent Event);
```

Description

Call SetTraceEvent to assign a callback that responds every time an SQL command passes between the associated dbExpress driver and the database server. The callback function becomes the value of the TraceCallbackEvent (see page 1628) property.

Event is the TDBXTraceEvent event that is called for every message that passes between the dbExpress driver and the SQL server.

Tip: Read (see page 3634) the TraceCallbackEvent (see page 1628) property to determine whether a callback is already assigned before calling the SetTraceEvent method. That way, you can avoid interfering with an existing callback when assigning a new one.

See Also

TSQLMonitor (see page 1643)

Debugging dbExpress Applications using TSQLMonitor

25.1.6.4.38 TSQLConnection.SQLError Method

Pascal

```
procedure SQLError(Error: TDBXError);
```

C++

```
__fastcall SQLError(TDBXError Error);
```

Description

This is SQLError, a member of class TSQLConnection.

25.1.6.4.39 TSQLConnection.StartTransaction Method

Initiates a new transaction in the associated database.

Pascal

```
procedure StartTransaction(TransDesc: TTransactionDesc); deprecated;
```

C++

```
__fastcall StartTransaction(TTransactionDesc TransDesc);
```

Description

Call StartTransaction to start a new transaction against a database server that supports transactions. (MySQL servers do not support transactions.) You can check the TransactionsSupported (see page 1624) property to determine whether the server supports transactions. If the server does not support transactions, StartTransaction does nothing.

TransDesc describes the transaction you are starting. It lets you specify

A user-defined transaction identifier. If the server supports nested or overlapped transactions, you can initiate multiple transactions by calling StartTransaction and providing each transaction with its own unique identifier.

The transaction isolation level. This indicates the degree to which this transaction can "see" changes made by other transactions.

If the transaction is successfully started, StartTransaction sets the InTransaction (see page 1613) property to true.

Updates, insertions, and deletions that take place after a call to StartTransaction are enlisted in that transaction until another overlapping transaction is started or until the application calls Commit (see page 1588) to save the changes or Rollback (see page 1603) to cancel them.

Tip: If the server does not support multiple transactions, check the status of the InTransaction (see page 1613) property to be sure that another transaction is not already in progress.

Tip: When working with overlapped transactions, you can indicate the transaction to which a dataset belongs by setting its TransactionLevel property to the transaction identifier you assign in this method.

Note: This method has been deprecated.

See Also

InTransaction (see page 1613)

Commit (see page 1588)

Rollback (see page 1603)

Params (see page 1621)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

25.1.6.4.40 TSQLConnection.UnRegisterClient Method

Removes a registered client so that it is no longer associated with the connection component.

Pascal

```
procedure UnRegisterClient(Client: TObject); override;
```

C++

```
virtual __fastcall UnRegisterClient(TObject * Client);
```

Description

UnRegisterClient is used internally to remove objects from the internal list of objects that are informed when a connection is created or terminated.

Client is the object that is removed from the list. It should be an object that was previously registered by a call to RegisterClient. If Client is a dataset, it is removed from the DataSets property list.

Datasets call this method when they stop using the connection component. For BDE-enabled datasets, ADO datasets, and dbExpress datasets, this is when they are deactivated. For client datasets, this is when the RemoteServer property is changed.

See Also

DataSets

RegisterClient

25.1.6.5 TSQLConnection Properties

The properties of the TSQLConnection class are listed here.

Protected Properties

	Name	Description
R	ConnectionRegistryFile (see page 1610)	This is ConnectionRegistryFile, a member of class TSQLConnection.
R	QuoteChar (see page 1623)	This is QuoteChar, a member of class TSQLConnection.
	SQLDllHandle (see page 1623)	This is SQLDllHandle, a member of class TSQLConnection.

Public Properties

	Name	Description
R	ActiveStatements (see page 1607)	Indicates the number of statements currently active with the database server.
	AutoClone (see page 1608)	Specifies whether the SQL connection automatically clones database connections when they are needed.
R	ConnectionData (see page 1609)	This is ConnectionData, a member of class TSQLConnection.
	ConnectionState (see page 1611)	Indicates the current state of the TSQLConnection (see page 1580) object.
R	DataSets (see page 1611)	Lists all active datasets for the connection component.
R	DBXConnection (see page 1611)	Provides an interface to the dbExpress object that represents a connection.
R	InTransaction (see page 1613)	Indicates whether a transaction is in progress.
	LocaleCode (see page 1615)	Identifies the locale that is used for sorting items from datasets that use this connection.
R	MaxStmtsPerConn (see page 1620)	Indicates the server limit on the number of statements supported by a single database connection.
R	MetaData (see page 1620)	Provides an interface to the dbExpress object that supplies server metadata.
R	MultipleTransactionsSupported (see page 1621)	Indicates whether the database server supports multiple transactions.
	ParamsLoaded (see page 1622)	Indicates when parameter values have been loaded from dbxconnections.ini.
	SQLHourGlass (see page 1623)	Specifies whether the cursor should change to crSQLWait during lengthy operations.
R	TransactionsSupported (see page 1624)	Indicates whether the database server supports transactions.

Published Properties

	Name	Description
	Connected (see page 1609)	Specifies whether the connection is active.
	ConnectionName (see page 1610)	Names the connection configuration.
	DriverName (see page 1612)	Specifies the database driver associated with the SQL connection.
	GetDriverFunc (see page 1613)	Specifies the function that returns the top-level dbExpress driver.
	KeepConnection (see page 1614)	Specifies whether the connection stays active when no datasets are open.
	LibraryName (see page 1614)	Specifies the dbExpress driver that TSQLConnection (see page 1580) uses to establish a connection.
	LoadParamsOnConnect (see page 1615)	Specifies whether the TSQLConnection (see page 1580) component loads the configuration named by ConnectionName (see page 1610) immediately before connecting to the server.
	LoginPrompt (see page 1616)	Specifies whether a login dialog appears immediately before opening a new connection.
	Params (see page 1621)	Lists the connection parameters.
	TableScope (see page 1623)	Indicates what types of tables are returned when fetching schema information about tables.
	VendorLib (see page 1625)	Specifies the client software library (DLL or shared object) supplied by the database vendor.

25.1.6.5.1 TSQLConnection.ActiveStatements Property

Indicates the number of statements currently active with the database server.

Pascal

```
property ActiveStatements: LongWord;
```

C++

```
__property LongWord ActiveStatements;
```

Description

Read (see page 3634) ActiveStatements to determine how many statements are currently executing using the database connection. While a dataset is prepared, it creates an active statement that lasts until the dataset is unprepared. When you set a dataset's Prepared property to true, the statement remains active until you change the Prepared property to false. When the Prepared property is false, the dataset implicitly prepares its statement when you open the dataset, and the statement remains active until you close the dataset. In addition, executing an SQL statement (for example, using the Execute (see page 1590) method) creates an active statement temporarily, until the statement finishes executing.

Use ActiveStatements to check whether an application has reached the server-imposed limit on the number of active statements allowed to a connection (the MaxStmtsPerConn (see page 1620) property). This is especially important if AutoClone (see page 1608) is false, because if you exceed MaxStmtsPerConn (see page 1620) when AutoClone (see page 1608) is false, the SQL connection raises an exception. To avoid exceeding the server-imposed limit, do not open any datasets or execute SQL statements when ActiveStatements is the same as MaxStmtsPerConn (see page 1620) (unless MaxStmtsPerConn (see page 1620) is 0).

See Also

DataSets (see page 1611)

Execute (see page 1590)

MaxStmtsPerConn (see page 1620)

Prepared (see page 1563)

AutoClone (see page 1608)

25.1.6.5.2 TSQLConnection.AutoClone Property

Specifies whether the SQL connection automatically clones database connections when they are needed.

Pascal

```
property AutoClone: Boolean;
```

C++

```
__property Boolean AutoClone;
```

Description

AutoClone controls whether the TSQLConnection (see page 1580) component automatically creates duplicate database connections when the number of statements allowed by the database server is exceeded. By default, AutoClone is true, meaning that when the ActiveStatements (see page 1607) property is the same as MaxStmtsPerConn (see page 1620), trying to execute another statement (open another dataset or call the Execute (see page 1590) method) causes TSQLConnection (see page 1580) to open a secondary (cloned) connection. The result behaves just like a connection to a server that does not limit the number of statements, except that it consumes more resources (for the additional, cloned connections).

Change AutoClone to false to prevent TSQLConnection (see page 1580) from cloning the database connection when the application attempts to exceed the maximum number of statements. When AutoClone is false, attempts to exceed MaxStmtsPerConn (see page 1620) result in an exception.

Tip: When AutoClone is false, you can check the ActiveStatements (see page 1607) property to ensure that you do not

exceed the server-imposed limit on the number of statements. If you are about to exceed that limit, you can explicitly call CloneConnection (see page 1587) to clone the connection yourself.

MaxStmtsPerConn (see page 1620)

ActiveStatements (see page 1607)

CloneConnection (see page 1587)

Connecting to the Database Server

25.1.6.5.3 TSQLConnection.Connected Property

Specifies whether the connection is active.

Pascal

```
property Connected;
```

C++

```
__property Connected;
```

Description

Set Connected to trueto establish a connection to the database server. When a dataset that uses the TSQLConnection (see page 1580) object is activated, it automatically sets Connected to true. Set Connected to false to close a connection.

Setting Connected to true generates a BeforeConnect (see page 1626) event, establishes the connection, and generates an AfterConnect (see page 1626) event. In addition, when setting Connected to true, TSQLConnection (see page 1580) may display a login dialog, depending on the value of LoginPrompt (see page 1616).

Setting Connected to false generates a BeforeDisconnect (see page 1627) event, drops the connection, and generates an AfterDisconnect (see page 1626) event.

25.1.6.5.4 TSQLConnection.ConnectionData Property

Pascal

```
property ConnectionData: TConnectionData;
```

C++

```
__property TConnectionData ConnectionData;
```

Description

This is ConnectionData, a member of class TSQLConnection.

25.1.6.5.5 TSQLConnection.ConnectionName Property

Names the connection configuration.

Pascal

```
property ConnectionName: string;
```

C++

```
__property UnicodeString ConnectionName;
```

Description

Set ConnectionName to use a named connection configuration. Setting ConnectionName automatically sets the DriverName (see page 1612) and Params (see page 1621) properties to reflect the driver and connection parameters stored under that name in the dbxconnections.ini file.

Tip: You can define new connection configurations using the Connection Editor. To launch the Connection Editor, double-click on the TSQLConnection (see page 1580) component.

If you are using a different dbxconnections.ini file at design time than the one used at runtime, you can force the configuration to reload at runtime by setting the LoadParamsOnConnect (see page 1615) property or calling LoadParamsFromIniFile (see page 1600). In most cases, however, this is unnecessary, because the DriverName (see page 1612) and Params (see page 1621) property settings that are loaded when you set ConnectionName are saved in the form file. In fact, unless you set LoadParamsOnConnect (see page 1615) or call LoadParamsFromIniFile (see page 1600), you do not need to deploy the dbxconnections.ini file with your application even if you are using named connections.

Configuring TSQL Connection

25.1.6.5.6 TSQLConnection.ConnectionRegistryFile Property

Pascal

```
property ConnectionRegistryFile: string;
```

C++

```
__property UnicodeString ConnectionRegistryFile;
```

Description

This is ConnectionRegistryFile, a member of class TSQLConnection.

25.1.6.5.7 TSQLConnection.ConnectionState Property

Indicates the current state of the TSQLConnection (see page 1580) object.

Pascal

```
property ConnectionState: TConnectionState;
```

C++

```
__property TConnectionState ConnectionState;
```

Description

Read (see page 3634) ConnectionState at runtime to determine the activity being performed, if any, by the connection at a specific point in time. Use ConnectionState to coordinate the activities of the connection component, so that you do not start one activity while it is currently engaged in another.

See Also

Connected (see page 1609)

Close

Execute (see page 1590)

25.1.6.5.8 TSQLConnection.DataSets Property

Lists all active datasets for the connection component.

Pascal

```
property DataSets [Index: Integer]: TCustomSQLDataSet;
```

C++

```
__property TCustomSQLDataSet DataSets[int Index];
```

Description

Use DataSets to access active datasets associated with a connection component. An active dataset is one that is currently open.

The Index parameter ranges between 0 and DataSetCount.

The value of DataSets changes as the datasets that use this TSQLConnection (see page 1580) component open and close.

Note: If a TSQLClientDataSet uses the connection component to connect to a database server, DataSets lists the internal dataset that the client dataset creates to access data, not the client dataset itself.

See Also

DataSetCount

Active

MaxStmtsPerConn (see page 1620)

25.1.6.5.9 TSQLConnection.DBXConnection Property

Provides an interface to the dbExpress object that represents a connection.

Pascal

```
property DBXConnection: TDBXConnection;
```

C++

```
__property TDBXConnection DBXConnection;
```

Description

DBXConnection is an interface to the underlying dbExpress object for a database connection. Typically, you would not need to interact directly with this dbExpress object because all of its methods are surfaced, directly or indirectly, in the implementation of TSQLConnection (see page 1580).

25.1.6.5.10 TSQLConnection.DriverName Property

Specifies the database driver associated with the SQL connection.

Pascal

```
property DriverName: string;
```

C++

```
__property UnicodeString DriverName;
```

Description

If you are not using named connections, set DriverName to the name of an installed dbExpress driver such as INTERBASE, MYSQL, INFORMIX, ORACLE, or DB2. Installed drivers are listed in the dbxdrivers.ini file, and their names can be retrieved using the GetDriverNames (see page 1697) function.

If you are using named connections, the DriverName property is automatically set when you set the ConnectionName (see page 1610) property.

When you set DriverName, TSQLConnection (see page 1580) automatically sets the LibraryName (see page 1614) and VendorLib (see page 1625) properties to the names of the libraries (DLLs or shared objects) that implement the specified driver.

See Also

LibraryName (see page 1614)

VendorLib (see page 1625)

Connecting to Databases with TDatabase

25.1.6.5.11 TSQLConnection.GetDriverFunc Property

Specifies the function that returns the top-level dbExpress driver.

Pascal

```
property GetDriverFunc: string;
```

C++

```
__property UnicodeString GetDriverFunc;
```

Description

GetDriverFunc is the name of a function in the dbExpress driver specified by the LibraryName (see page 1614) property. The specified function returns the top-level dbExpress interface. Typically, this property is set to the function name that is stored in the dbxdrivers.ini file.

Note: The GetDriverFunc, LibraryName (see page 1614), and VenderLib properties all reflect the values in the dbxdrivers.ini file. Because these property values are published (stored with the connection component), it is possible to deploy an application without deploying the dbxdrivers.ini file.

See Also

LibraryName (see page 1614)

VendorLib (see page 1625)

25.1.6.5.12 TSQLConnection.InTransaction Property

Indicates whether a transaction is in progress.

Pascal

```
property InTransaction: Boolean;
```

C++

```
__property Boolean InTransaction;
```

Description

Read (see page 3634) InTransaction at runtime to ascertain whether a transaction is currently active for the SQL connection component. If the connection component is currently in a transaction, all communication with the server that passes through the connection is enlisted in that transaction.

InTransaction is true if there is an active transaction. If no transaction is active, InTransaction is false.

A transaction begins when the application calls BeginTransaction (see page 1586) and lasts until the application calls CommitFreeAndNil (see page 1588), RollbackFreeAndNil (see page 1603), or RollbackIncompleteFreeAndNil (see page 1604). If there are multiple transactions, InTransaction remains true until all transactions are either committed or rolled back.

See Also

BeginTransaction (see page 1586)

CommitFreeAndNil (see page 1588)

RollbackFreeAndNil (see page 1603)

RollbackIncompleteFreeAndNil (see page 1604)

TransactionsSupported (see page 1624)

TransactionLevel (see page 1567)

MultipleTransactionsSupported (see page 1621)

25.1.6.5.13 TSQLConnection.KeepConnection Property

Specifies whether the connection stays active when no datasets are open.

Pascal

```
property KeepConnection: Boolean;
```

C++

```
__property Boolean KeepConnection;
```

Description

Use KeepConnection to specify whether TSQLConnection (see page 1580) maintains an open database connection even if no associated dataset components are currently active. When KeepConnection is true (the default) the connection is maintained. For connections to remote database servers, or in applications that frequently open and close datasets, set KeepConnection to true to reduce network traffic, speed up applications, and avoid logging in to the server each time the connection is reestablished.

When KeepConnection is false a connection is dropped when there are no open datasets. Dropping a connection releases system resources allocated to the connection, but if a dataset is later opened that uses the database, the connection must be reestablished and initialized.

See Also

DataSets (see page 1611)

Connected (see page 1609)

25.1.6.5.14 TSQLConnection.LibraryName Property

Specifies the dbExpress driver that TSQLConnection (see page 1580) uses to establish a connection.

Pascal

```
property LibraryName: string;
```

C++

```
__property UnicodeString LibraryName;
```

Description

LibraryName is the dbExpress library associated with the driver specified by DriverName (see page 1612). Most applications do not need to use LibraryName directly, because this property is set automatically when the DriverName (see page 1612) property is set.

Note: The association between a dbExpress library and a driver name is stored in the dbxdrivers.ini

file when you install the dbExpress driver. The file named by this property is the only dbExpress file that must be deployed with your application.

Note: The LibraryName, GetDriverFunc (see page 1613), and VenderLib properties all reflect the values in the dbxdrivers.ini

file. Because these property values are published (stored with the connection component), it is possible to deploy an application without deploying the dbxdrivers.ini file.

See Also

DriverName (see page 1612)

VendorLib (see page 1625)

GetDriverFunc (see page 1613)

Setting Up TSQLConnection

Configuring TSQL Connection

25.1.6.5.15 TSQLConnection.LoadParamsOnConnect Property

Specifies whether the TSQLConnection (see page 1580) component loads the configuration named by ConnectionName (see page 1610) immediately before connecting to the server.

Pascal

```
property LoadParamsOnConnect: Boolean;
```

C++

```
__property Boolean LoadParamsOnConnect;
```

Description

Set LoadParamsOnConnect to true if you want the TSQLConnection (see page 1580) object to load the connection configuration (DriverName (see page 1612) and Params (see page 1621) properties) associated with ConnectionName (see page 1610) at runtime. Typically, this is unnecessary because when you set ConnectionName (see page 1610) at design time, the DriverName (see page 1612) and Params (see page 1621) properties are automatically set as well. However, if you use a different dbxconnections.ini file at runtime, or if you temporarily override the DriverName (see page 1612) or any connection parameter values at design time, setting LoadParamsOnConnect to true ensures that at runtime the connection is established using the configuration associated with ConnectionName (see page 1610) in the dbxconnections.ini file.

Note: If you set LoadParamsOnConnect to true, you must be sure to deploy the dbxconnections.ini

file with your application. When you rely on the design-time associations, dbxconnections.ini is not needed at runtime.

Warning: If you set LoadParamsOnConnect to true, you must specify a valid connection name as the value for ConnectionName (see page 1610).

Setting Up TSQLConnection

Configuring TSQL Connection

25.1.6.5.16 TSQLConnection.LocaleCode Property

Identifies the locale that is used for sorting items from datasets that use this connection.

Pascal

```
property LocaleCode: TLocaleCode;
```

C++

```
__property TLocaleCode LocaleCode;
```

Description

LocaleCode represents the locale that client datasets use to sort strings when they are provided in fields from a dataset associated with this connection. By default, this value is 0, which signals that strings should be sorted without regard to a locale. Changing LocaleCode can affect performance, because sorting is slower when it must take locale into account. Therefore, it is recommended that you only change LocaleCode if the data is known to contain extended characters that will affect the sort order.

Note: Locale codes are treated as connection parameters: they are stored in the dbxconnections.ini

file along with the other parameters, and appear in the Params (see page 1621) property list. Changes to this property change the entry in the Params (see page 1621) property list.

LoadParamsOnConnect (see page 1615)

TClientDataSet

25.1.6.5.17 TSQLConnection.LoginPrompt Property

Specifies whether a login dialog appears immediately before opening a new connection.

Pascal

```
property LoginPrompt;
```

C++

```
__property LoginPrompt;
```

Description

Set LoginPrompt to true to provide login support when establishing a connection. LoginPrompt controls two things: the occurrence of the OnLogin event, and the appearance of a default login dialog that prompts users for a name and password when you include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi). When the OnLogin event occurs and when the default login dialog appears depend on the type of connection component:

For TDatabase, TIBDatabase, and TSQLConnection, the dialog appears after the BeforeConnect event and before the AfterConnect event, unless you supply an OnLogin event handler. If there is an OnLogin event handler, that event occurs in place of the login dialog, and there is no need to include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi). If correct values for the user name and password are not supplied in the dialog or by the OnLogin event handler, the connection fails. The OnLogin event does not fire unless LoginPrompt is set to true.

For TADOConnection components, the dialog appears after the OnWillConnect event and before the BeforeConnect event. If there is an OnLogin event handler, that event occurs after the login dialog. If you do not include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi), the OnLogin event occurs but there is no default login dialog. If correct values for the user name and password are not supplied in the dialog or by the OnLogin event handler, the connection fails. The OnLogin event does not fire unless LoginPrompt is set to true.

For DataSnap SOAP connection components, the dialog appears after the OnGetUsername event and before the BeforeConnect, AfterConnect, and OnLogin events. If the user cancels from the login dialog, no attempt is made to open a connection.

When LoginPrompt is false, the application must supply user name and password values programmatically:

For TDatabase, the user name and password can be supplied as USER_NAME and PASSWORD parameters in the Params property.

For TADOConnection, the user name and password can be supplied as the ConnectionString property.

For TSQLConnection, the user name, password, and database can be supplied as UserName, Password, and Database parameters in the Params property, or provided as connection parameters associated with the connection name.

For DataSnap SOAP connection components, there is no built-in use for the user name and password supplied by the login dialog. (The UserName and Password properties of TWebConnection are unrelated).

Warning: Storing hard-coded user name and password entries as property values or in code for an OnLogin event handler can compromise server security.

C++ Examples:

```
//
//This example demostrates the use of ADO for database conectivity.
//Example assumes that a TDBGrid is placed on the form.
//
void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Login details */
    String UserName = "db_user_name";
    String PassWord = "db_pass_word";
    String Server = "my.db.server";

    /* Connection String */
    String ConnString =
        "Provider=SQLOLEDB.1;Persist Security Info=False;";
    ConnString +=
        "User ID=%s;Password=%s;Data Source=%s;Use Procedure for Prepare=1;";
    ConnString +=
        "Auto Translate=True;Packet Size=4096;Use Encryption for Data=False;";
    ConnString +=
        "Tag with column collation when possible=False";

    /* SQL Query */
    String SQLStr = "SELECT * FROM customer WHERE customer_id = :AnId;";

    /* All ADO variables */
    TADOConnection* ADOConn;
    TADOQuery* ADOQuery;
    TDataSource* DataSrc;
    TParameter* Param;

    /* Create an ADO connection */
    ADOConn = new TADOConnection(this);

    /* Setup the connection string */
    ADOConn->ConnectionString = Format(ConnString,
        ARRAYOFCONST((UserName, PassWord, Server)));

    /* Disable login prompt */
    ADOConn->LoginPrompt = False;

    try
    {
        ADOConn->Connected = true;
    }
    catch (EADOError *e)
    {
```

```
        MessageDlg("Error while connecting", mtError,
                   TMsgDlgButtons() << mbOK, 0);
        return;
    }

    /* Create the query */
    ADOQuery = new TADOQuery(this);
    ADOQuery->Connection = ADOConn;
    ADOQuery->SQL->Add(SQLStr);

    /* Update the parameter that was parsed from the SQL query: AnId */
    Param = ADOQuery->Parameters->ParamByName("AnId");
    Param->DataType = ftInteger;
    Param->Value = 1;

    /* Set the query to Prepared - will improve performance */
    ADOQuery->Prepared = true;

    try
    {
        ADOQuery->Active = true;
    }
    catch (EADOError *e)
    {
        MessageDlg("Error while connecting", mtError,
                   TMsgDlgButtons() << mbOK, 0);
        return;
    }

    /* Create the data source */
    DataSrc = new TDataSource(this);
    DataSrc->DataSet = ADOQuery;
    DataSrc->Enabled = true;

    /* Finally initilalize the grid */
    DBGrid1->DataSource = DataSrc;
}
```

Delphi Examples:

```
{
This example demostrates the use of ADO for database conectivity.
Example assumes that a TDBGrid is placed on the form.
}
procedure TForm2.FormCreate(Sender: TObject);
const
  { Connection string }
  ConnString =
  'Provider=SQLOLEDB.1;Persist Security Info=False;' +
  'User ID=%s;Password=%s;Data Source=%s;Use Procedure for Prepare=1;' +
  'Auto Translate=True;Packet Size=4096;Use Encryption for Data=False;'+
  'Tag with column collation when possible=False';

  { SQL Query }
  SQLStr = 'SELECT * FROM customer WHERE customer_id = :AnId;';

  { User access }
  UserName = 'db_user_name';
  PassWord = 'db_pass_word';
  Server = 'my.db.server';

var
  ADOConn  : TADOConnection;
  ADOQuery : TADOQuery;
  DataSrc  : TDataSource;
  Param    : TParameter;
```

```
begin
  { Create an ADO connection }
  ADOConn := TADOConnection.Create(Self);
  { Setup the provider engine }

  { Setup the connection string }
  ADOConn.ConnectionString := Format(ConnString,
    [UserName, PassWord, Server]);

  { Disable login prompt }
  ADOConn.LoginPrompt := False;

  try
    ADOConn.Connected := True;
  except
    on e: EADOError do
    begin
      MessageDlg('Error while connecting', mtError,
                 [mbOK], 0);

      Exit;
    end;
  end;

  { Create the query }
  ADOQuery := TADOQuery.Create(Self);
  ADOQuery.Connection := ADOConn;
  ADOQuery.SQL.Add(SQLStr);

  { Update the parameter that was parsed from the SQL query: AnId }
  Param := ADOQuery.Parameters.ParamByName('AnId');
  Param.DataType := ftInteger;
  Param.Value := 1;

  { Set the query to Prepared - will improve performance }
  ADOQuery.Prepared := true;

  try
    ADOQuery.Active := True;
  except
    on e: EADOError do
    begin
      MessageDlg('Error while doing query', mtError,
                 [mbOK], 0);

      Exit;
    end;
  end;

  { Create the data source }
  DataSrc := TDataSource.Create(Self);
  DataSrc.DataSet := ADOQuery;
  DataSrc.Enabled := true;

  { Finally initilalize the grid }
  DBGrid1.DataSource := DataSrc;
end;

Controlling Server Login

25.1.6.5.18 TSQLConnection.MaxStmtsPerConn Property

Indicates the server limit on the number of statements supported by a single database connection.

Pascal

```
property MaxStmtsPerConn: LongWord;
```

C++

```
__property LongWord MaxStmtsPerConn;
```

Description

Read (see page 3634) MaxStmtsPerConn when a connection is active to determine whether the database server imposes a limit on the number of statements that can be executed using the current connection. When MaxStmtsPerConn is 0, the server imposes no restrictions: a single database connection can be used to fetch multiple datasets and execute statements while there are active datasets. When MaxStmtsPerConn is greater than 0, the database server limits the number of statements that can execute. The server allows only MaxStmtsPerConn datasets to be opened using a single connection, and when that number of datasets are open, no more statements can be executed (for example, using the Execute (see page 1590) method).

By default, when MaxStmtsPerConn is greater than 0, TSQLConnection (see page 1580) clones the database connection when this server-imposed limit is reached. For example, if MaxStmtsPerConn is 1, then trying to open a second dataset using the same TSQLConnection (see page 1580) component causes TSQLConnection (see page 1580) to establish a second database connection for the second dataset. If AutoClone (see page 1608) is false, however, TSQLConnection (see page 1580) does not clone connections, but rather generates an exception when the application tries to exceed MaxStmtsPerConn.

Note: The value of MaxStmtsPerConn is only valid when the Connected (see page 1609) property is true.

Connecting to the Database Server

25.1.6.5.19 TSQLConnection.MetaData Property

Provides an interface to the dbExpress object that supplies server metadata.

Pascal

```
property MetaData: TDBXDatabaseMetaData;
```

C++

```
__property TDBXDatabaseMetaData MetaData;
```

Description

Typically, applications do not use the MetaData property to work directly with the dbExpress MetaData interface. Instead, they

use one of methods that assembles schema information into a list (GetFieldNames (see page 1592), GetIndexNames (see page 1593), GetProcedureNames (see page 1595), GetProcedureParams (see page 1597), or GetTableNames (see page 1599)). When more detailed metadata is required, you can also use the SQL dataset's SetSchemaInfo method to populate an SQL dataset with metadata.

See Also

GetFieldNames (see page 1592)

GetIndexNames (see page 1593)

GetProcedureNames (see page 1595)

GetProcedureParams (see page 1597)

GetTableNames (see page 1599)

SetSchemaInfo (see page 1550)

25.1.6.5.20 TSQLConnection.MultipleTransactionsSupported Property

Indicates whether the database server supports multiple transactions.

Pascal

```
property MultipleTransactionsSupported: LongBool;
```

C++

```
__property LongBool MultipleTransactionsSupported;
```

Description

Read (see page 3634) MultipleTransactionsSupported at runtime to ascertain whether the database server supports multiple transactions (either nested or overlapping).

Note: To determine whether the server supports transactions at all, use the TransactionsSupported (see page 1624) property. If a server supports only a single transaction at a time, TransactionsSupported (see page 1624) is true, and MultipleTransactionsSupported is false.

See Also

CommitFreeAndNil (see page 1588)

BeginTransaction (see page 1586)

RollbackFreeAndNil (see page 1603)

InTransaction (see page 1613)

TransactionsSupported (see page 1624)

25.1.6.5.21 TSQLConnection.Params Property

Lists the connection parameters.

Pascal

```
property Params: TStrings;
```

C++

```
__property TStrings Params;
```

Description

Params is a TStrings object listing the connection parameters. Each entry in the string list has the form

```
Name=Value
```

where Name is the name of the parameter and Value is its value. If you are using named connection configurations (the ConnectionName (see page 1610) property), the values for each parameter are loaded from the dbxconnections.ini file when you set ConnectName.

At design time, you can set parameter values using the string list editor by double clicking on the Params property in the Object Inspector. Any new values you set override the values loaded when you set ConnectionName (see page 1610) unless you load the connection configuration at runtime using LoadParamsFromIniFile (see page 1600) or LoadParamsOnConnect (see page 1615).

The particular parameters that appear depend on the database server. The Params property is initialized to include a string for each parameter when you set the DriverName (see page 1612) property. One particular parameter, Database, is required for all servers. Its value depends on the server you are using. For example, with InterBase, Database is the name of the .gdb file, while with MySQL, it is the database name that was assigned by the CREATE DATABASE command.

Other typical parameters include HostName (the machine name or IP address of where the server is located), and TransIsolation (the degree to which transactions are isolated from changes made by other users of the database).

See Also

ConnectionName (see page 1610)

LoadParamsFromIniFile (see page 1600)

LoadParamsOnConnect (see page 1615)

DriverName (see page 1612)

LocaleCode (see page 1615)

Setting Up TSQLConnection

25.1.6.5.22 TSQLConnection.ParamsLoaded Property

Indicates when parameter values have been loaded from dbxconnections.ini.

Pascal

```
property ParamsLoaded: Boolean;
```

C++

```
__property Boolean ParamsLoaded;
```

Description

Do not use the ParamsLoaded property. It is used internally by the Connections Editor to keep track of when parameter values have been loaded from the dbxconnections.ini file.

See Also

Params (see page 1621)

LoadParamsFromIniFile (see page 1600)

LoadParamsOnConnect (see page 1615)

25.1.6.5.23 TSQLConnection.QuoteChar Property

Pascal

```
property QuoteChar: UnicodeString;
```

C++

```
__property UnicodeString QuoteChar;
```

Description

This is QuoteChar, a member of class TSQLConnection.

25.1.6.5.24 TSQLConnection.SQLDllHandle Property

Pascal

```
property SQLDllHandle: THandle;
```

C++

```
__property THandle SQLDllHandle;
```

Description

This is SQLDllHandle, a member of class TSQLConnection.

25.1.6.5.25 TSQLConnection.SQLHourGlass Property

Specifies whether the cursor should change to crSQLWait during lengthy operations.

Pascal

```
property SQLHourGlass: Boolean;
```

C++

```
__property Boolean SQLHourGlass;
```

Description

Set SQLHourGlass to true to specify that the cursor should indicate when the connection is performing a potentially lengthy operation. Such operations include

Establishing a connection to the database server.

Fetching metadata from the database server.

Executing a statement using the Execute (see page 1590) method.

When SQLHourGlass is false, the cursor is not changed when the SQL connection performs such operations.

See Also

Execute (see page 1590)

Open

TCursorType

25.1.6.5.26 TSQLConnection.TableScope Property

Indicates what types of tables are returned when fetching schema information about tables.

Pascal

```
property TableScope: TTableScopes;
```

C++

```
__property TTableScopes TableScope;
```

Description

Set TableScope to determine the type of tables listed by the GetTableNames (see page 1599) method or that populate an SQL dataset after calling its SetSchemaInfo method with a parameter of stTables. TableScope lets you request information about a combination of table types. By default, TableScope requests only ordinary tables and views (tsTable and tsView).

Note: TableScope only affects GetTableNames (see page 1599) when the SystemTables parameter is false and only affects SetSchemaInfo when the SchemaType parameter is stTables. If an application calls GetTablesNames with SystemTables set to true, or calls SetSchemaInfo with SchemaType set to stSysTables, system tables, and only system tables are returned, regardless of the value of TableScope.

See Also

GetTableNames (see page 1599)

SetSchemaInfo (see page 1550)

Fetching Metadata into a Unidirectional Dataset

25.1.6.5.27 TSQLConnection.TransactionsSupported Property

Indicates whether the database server supports transactions.

Pascal

```
property TransactionsSupported: LongBool;
```

C++

```
__property LongBool TransactionsSupported;
```

Description

Read (see page 3634) TransactionsSupported at runtime to ascertain whether the database server supports transactions. If TransactionsSupported is false, then the BeginTransaction (see page 1586), CommitFreeAndNil (see page 1588), RollbackFreeAndNil (see page 1603), and RollbackIncompleteFreeAndNil (see page 1604) methods do nothing. If TransactionsSupported is true, you can use the SQL connection component to manage transactions.

Note: Some servers support multiple transactions (either nested or overlapping). When TransactionsSupported is true, you can test whether the server supports multiple transactions by reading the MultipleTransactionsSupported (see page 1621) property.

See Also

BeginTransaction (see page 1586)

CommitFreeAndNil (see page 1588)

RollbackFreeAndNil (see page 1603)

RollbackIncompleteFreeAndNil (see page 1604)

InTransaction (see page 1613)

MultipleTransactionsSupported (see page 1621)

25.1.6.5.28 TSQLConnection.VendorLib Property

Specifies the client software library (DLL or shared object) supplied by the database vendor.

Pascal

```
property VendorLib: string;
```

C++

```
__property UnicodeString VendorLib;
```

Description

VendorLib is the library supplied by the database vendor to support client-side use of the database. Most applications do not need to use VendorLib directly, because this property is set automatically when the DriverName (see page 1612) property is set.

Note: The association between a vendor library and a driver name is stored in the dbxdrivers.ini

file when you install the associated dbExpress driver. The file named by this property must be running on the same system as your application when it is deployed. Typically, it is installed when the database is installed rather than with your application.

Note: The VendorLib, LibraryName (see page 1614), and GetDriverFunc (see page 1613) properties all reflect the values in the dbxdrivers.ini

file. Because these property values are published (stored with the connection component), it is possible to deploy an application without deploying the dbxdrivers.ini file.

See Also

DriverName (see page 1612)

GetDriverFunc (see page 1613)

Setting Up TSQLConnection

Configuring TSQL Connection

25.1.6.6 TSQLConnection Events

The events of the TSQLConnection class are listed here.

Public Events

	Name	Description
	TraceCallbackEvent (see page 1628)	Provides access to the callback function that executes for every SQL command passed to or from the server.

Published Events

	Name	Description
	AfterConnect (see page 1626)	Occurs after a connection is established.
	AfterDisconnect (see page 1626)	Occurs after the connection closes.
	BeforeConnect (see page 1626)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 1627)	Occurs immediately before the connection closes.
	OnLogin (see page 1627)	Occurs after the BeforeConnect (see page 1626) event and before a connection is established.

25.1.6.6.1 TSQLConnection.AfterConnect Event

Occurs after a connection is established.

Pascal

```
property AfterConnect;
```

C++

```
__property AfterConnect;
```

Description

Write an AfterConnect event handler to take application-specific actions immediately after the connection component opens a connection to the remote source of database information.

See Also

BeforeConnect

Connected

Connecting to a Database Server

25.1.6.6.2 TSQLConnection.AfterDisconnect Event

Occurs after the connection closes.

Pascal

```
property AfterDisconnect;
```

C++

```
__property AfterDisconnect;
```

Description

Write an AfterDisconnect event handler to take application-specific actions after the connection component drops a connection.

See Also

BeforeDisconnect

Connected

Disconnecting from a Database Server

25.1.6.6.3 TSQLConnection.BeforeConnect Event

Occurs immediately before establishing a connection.

Pascal

```
property BeforeConnect;
```

C++

```
__property BeforeConnect;
```

Description

Write a BeforeConnect event handler to take application-specific actions before the connection component opens a connection to the remote source of database information.

See Also

AfterConnect

Connected

Connecting to a Database Server

25.1.6.6.4 TSQLConnection.BeforeDisconnect Event

Occurs immediately before the connection closes.

Pascal

```
property BeforeDisconnect;
```

C++

```
__property BeforeDisconnect;
```

Description

Write a BeforeDisconnect event handler to take application-specific actions before dropping a connection.

Delphi Examples:

```
{
This BeforeDisconnect event handler makes sure that the
client dataset has applied all its pending updates before
terminating the connection to the server.
}
procedure TForm1.RemoteServer1BeforeDisconnect(Sender: TObject);
begin
  if (ClientDataSet1.ChangeCount > 0) then
    ClientDataSet1.ApplyUpdates(-1);
end;
```

See Also

AfterDisconnect

Connected

Disconnecting from a Database Server

25.1.6.6.5 TSQLConnection.OnLogin Event

Occurs after the BeforeConnect (see page 1626) event and before a connection is established.

Pascal

```
property OnLogin: TSQLConnectionLoginEvent;
```

C++

```
__property TSQLConnectionLoginEvent OnLogin;
```

Description

Use the OnLogin event to assign values to the User_Name, Password, and Database parameters immediately before TSQLConnection (see page 1580) attempts to connect to the database server. OnLogin only occurs if the LoginPrompt (see page 1616) property is true. If LoginPrompt (see page 1616) is true but there is no OnLogin event handler, a default login dialog appears in which the user can enter a user name and password. The connection fails if correct values for the user name and password are not supplied in the dialog or by the OnLogin event handler.

See Also

Params (see page 1621)

LoginPrompt

BeforeConnect

25.1.6.6.6 TSQLConnection.TraceCallbackEvent Event

Provides access to the callback function that executes for every SQL command passed to or from the server.

Pascal

```
property TraceCallbackEvent: TDBXTraceEvent;
```

C++

```
__property TDBXTraceEvent TraceCallbackEvent;
```

Description

Read (see page 3634) TraceCallbackEvent to determine whether the SQL connection is monitoring communication between the application and the SQL server to which it connects. For example, if the application uses a TSQLMonitor (see page 1643) component, that component assigns a value to TraceCallbackEvent, which it uses to monitor SQL commands. Changing the value of the callback would then interfere with the operation of the TSQLMonitor (see page 1643) component.

TraceCallbackEvent is a read-only property. To assign a callback for monitoring SQL commands, use the SetTraceEvent (see page 1605) method.

See Also

SetTraceEvent (see page 1605)

Procedural types

Creating events

25.1.7 TSQLDataLink Class

TSQLDataLink allows a unidirectional dataset act as the detail in a master/detail relationship.

Class Hierarchy

Pascal

```
TSQLDataLink = class(TDetailDataLink);
```

C++

```
class TSQLDataLink : public TDetailDataLink;
```

File

SqlExpr

Description

SQL datasets use TSQLDataLink to coordinate with another (master) dataset when they represent the detail records for that other dataset. TSQLDataLink passes on data events to the data source that owns it. It is also used to implement the DataSource

or MasterSource property of the dataset that owns it.

Do not confuse the dataset that is the value of the TSQLDataLink object's DataSet property with the dataset that uses TSQLDataLink to link to a master dataset. The DataSet property is the master dataset, while the dataset that owns the TSQLDataLink object is the detail set.

See Also

TSQLDataSet (see page 1631)

TSQLQuery (see page 1654)

TSQLTable (see page 1680)

TMasterDataLink

TCustomSQLDataSet (see page 1520)

25.1.7.1 TSQLDataLink Members

The following tables list the members exposed by TSQLDataLink.

Protected Methods

	Name	Description
	ActiveChanged (see page 1630)	Refreshes the parameter values of the detail dataset and re-executes it.
	CheckBrowseMode (see page 1630)	Informs the dataset that owns the TSQLDataLink (see page 1628) object when the current record in the source dataset is about to change.
	GetDetailDataSet (see page 1631)	Returns the value of the DetailDataSet property.
	RecordChanged (see page 1631)	Refreshes the parameter values of the detail dataset and re-executes it.

Public Methods

	Name	Description
	Create (see page 1629)	Creates an instance of TSQLDataLink (see page 1628).

25.1.7.2 TSQLDataLink.Create Constructor

Creates an instance of TSQLDataLink (see page 1628).

Pascal

```
constructor Create(ADataSet: TCustomSQLDataSet);
```

C++

```
__fastcall TSQLDataLink(TCustomSQLDataSet ADataSet);
```

Description

Do not create instances of TSQLDataLink (see page 1628). It is instantiated by the SQL dataset that uses it to link to a master dataset. The ADataSet parameter is the dataset that creates and owns this SQL datalink. It becomes the value of the DetailDataSet property.

See Also

DetailDataSet

25.1.7.3 TSQLDataLink Methods

The methods of the TSQLDataLink class are listed here.

Protected Methods

	Name	Description
	ActiveChanged (see page 1630)	Refreshes the parameter values of the detail dataset and re-executes it.
	CheckBrowseMode (see page 1630)	Informs the dataset that owns the TSQLDataLink (see page 1628) object when the current record in the source dataset is about to change.
	GetDetailDataSet (see page 1631)	Returns the value of the DetailDataSet property.
	RecordChanged (see page 1631)	Refreshes the parameter values of the detail dataset and re-executes it.

25.1.7.3.1 TSQLDataLink.ActiveChanged Method

Refreshes the parameter values of the detail dataset and re-executes it.

Pascal

```
procedure ActiveChanged; override;
```

C++

```
virtual __fastcall ActiveChanged();
```

Description

SQL datasets establish master/detail relationships by supplying parameter values from the master dataset. ActiveChanged updates these parameter values on the detail dataset to reflect the current values of the master dataset and then refreshes the dataset so that it is populated with the new detail set.

See Also

Active

Params (see page 1562)

DetailDataSet

25.1.7.3.2 TSQLDataLink.CheckBrowseMode Method

Informs the dataset that owns the TSQLDataLink (see page 1628) object when the current record in the source dataset is about to change.

Pascal

```
procedure CheckBrowseMode; override;
```

C++

```
virtual __fastcall CheckBrowseMode();
```

Description

Applications cannot call the protected CheckBrowseMode procedure. CheckBrowseMode is called immediately before the current record in the source dataset changes. It calls the CheckBrowseMode method of the dataset that owns the TSQLDataLink (see page 1628) object.

See Also

CheckBrowseMode

25.1.7.3.3 TSQLDataLink.GetDetailDataSet Method

Returns the value of the DetailDataSet property.

Pascal

```
function GetDetailDataSet: TDataSet; override;
```

C++

```
virtual __fastcall TDataSet GetDetailDataSet();
```

Description

GetDetailDataSet is the protected read implementation of the DetailDataSet property.

See Also

DetailDataSet

25.1.7.3.4 TSQLDataLink.RecordChanged Method

Refreshes the parameter values of the detail dataset and re-executes it.

Pascal

```
procedure RecordChanged(Field: TField); override;
```

C++

```
virtual __fastcall RecordChanged(TField Field);
```

Description

Applications cannot call the protected RecordChanged method. It is called automatically when the contents of the current record change. The Field parameter indicates which field in the current record has changed. If Field is nil (Delphi) or NULL (C++), the entire record has changed.

SQL datasets establish master/detail relationships by supplying parameter values from the master dataset. RecordChanged updates these parameter values on the detail dataset to reflect the current values of the master dataset and then refreshes the dataset so that it is populated with the new detail set.

See Also

Params (see page 1562)

DetailDataSet

25.1.8 TSQLDataSet Class

TSQLDataSet represents data retrieved using dbExpress.

Class Hierarchy

Pascal

```
TSQLDataSet = class(TCustomSQLDataSet);
```

C++

```
class TSQLDataSet : public TCustomSQLDataSet;
```

File

SqlExpr

Description

TSQLDataSet is a general-purpose unidirectional dataset for accessing database information using dbExpress. You can add a TSQLDataSet component to a form or data module at design time, or create one dynamically at runtime.

Use TSQLDataSet to

Represent the records in a database table, the result set of a SELECT query, or the result set returned by a stored procedure.

Execute a query or stored procedure that does not return a result set.

Represent metadata that describes what is available on the database server (tables, stored procedures, fields in a table, and so on).

TSQLDataSet is a unidirectional dataset. Unlike other datasets, unidirectional datasets do not buffer multiple records in memory. Because of this, you can only navigate using the First and Next methods. There is no built-in editing support: you can only edit the data in an SQL dataset by explicitly creating an SQL UPDATE command or by connecting the dataset to a client dataset using a provider. Features that require buffering multiple records, such as filters or lookup fields, are not available.

Before you can use a TSQLDataSet component, it must be connected to the database server. Therefore, the first step to take when working with TSQLDataSet is to set the SQLConnection (see page 1642) property.

Once the dataset is connected to a server, you can use the Command Text editor to set the CommandText (see page 1637) property if you are using the dataset to execute a query. To execute a stored procedure or represent a single database table, set the CommandType (see page 1638) property and then choose the table or stored procedure name from a drop-down list on the CommandText (see page 1637) property. If you want to access metadata with the SQL dataset, you must specify the metadata you want at runtime by calling the SetSchemaInfo (see page 1550) method.

DefaultRowsetSize (see page 1713) is 20 (DefaultRowsetSize (see page 1713) = 20). To use a different RowSetSize for existing Oracle database connections, manually add the RowSetSize property (for example, RowsetSize = 200) to dbxconnections.ini (Windows) or dbxconnections.conf (Linux). To have the RowSetSize property included in new connections, manually add the RowSetSize property to dbxdrivers.ini (Windows) or dbxdrivers.conf (Linux). RowsetSize can also be modified in code (for example, SQLConnection1.Params.Values['RowsetSize'] := '200'). Currently, only Oracle databases support this feature.

25.1.8.1 TSQLDataSet Members

The following tables list the members exposed by TSQLDataSet.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.

	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.

Public Methods

	Name	Description
	Create (see page 1635)	Creates an instance of a TSQLDataSet (see page 1631) component.
	Create (see page 1524)	This is the overview for the Create constructor overload.
	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	Destroy (see page 1525)	Destroys the TCustomSQLDataSet (see page 1520) instance.
	ExecSQL (see page 1636)	Executes a query or stored procedure that does not return a set of records.
	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
	PrepareStatement (see page 1540)	Performs a prepare on the SQL statement.

	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	CommandText (see page 1637)	Specifies the command the dataset executes.
	CommandType (see page 1638)	Command type of CommandText (see page 1637) property.
	DataSource (see page 1639)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1639)	Command type in String format.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	MaxBlobSize (see page 1640)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	ParamCheck (see page 1641)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1641)	Represents the parameters for a query or stored procedure.
	SchemaName (see page 1565)	Specifies the name of the database schema.
	SortFieldNames (see page 1642)	Indicates the sort order when CommandType (see page 1638) is ctTable.
	SQLConnection (see page 1642)	Specifies the SQL connection component that connects the dataset to a database server.

25.1.8.2 TSQLDataSet.Create Constructor

Creates an instance of a TSQLDataSet (see page 1631) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLDataSet(TComponent * AOwner);
```

Description

Call Create to instantiate an SQL dataset component at runtime. SQL datasets placed in forms or data modules at design time are created automatically.

AOwner is the component, typically the form or data module, that is responsible for freeing the dataset. It becomes the value of the Owner property.

See Also

Owner

25.1.8.3 TSQLDataSet Methods

The methods of the TSQLDataSet class are listed here.

Public Methods

	Name	Description
	ExecSQL (see page 1636)	Executes a query or stored procedure that does not return a set of records.

25.1.8.3.1 TSQLDataSet.ExecSQL Method

Executes a query or stored procedure that does not return a set of records.

Pascal

```
function ExecSQL(ExecDirect: Boolean = False): Integer; override;
```

C++

```
virtual __fastcall int ExecSQL(Boolean ExecDirect = False);
```

Description

Call ExecSQL to execute an SQL command that does not return a set of records. This command is a query other than a SELECT query, such as an INSERT, UPDATE, DELETE, or CREATE TABLE query.

ExecDirect indicates that the query does not need to be prepared before it is executed. This parameter can be set to true if the query does not include any parameters. When ExecDirect is false, the query will be prepared before it is executed. Even when ExecDirect is false, you can avoid preparing the query every time ExecSQL is called by setting the Prepared (see page 1563) property to true before calling ExecSQL the first time.

ExecSQL returns the number of rows affected by the executed command. This becomes the value of the RowsAffected (see page 1564) property.

Note: Do not use ExecSQL for commands that return data. These include any use of the ctTable command type, SELECT queries, and stored procedures that return a cursor. When the command returns data, use the Open method or set the Active (see page 1552) property to true.

25.1.8.4 TSQLDataSet Properties

The properties of the TSQLDataSet class are listed here.

Published Properties

	Name	Description
	CommandText (see page 1637)	Specifies the command the dataset executes.
	CommandType (see page 1638)	Command type of CommandText (see page 1637) property.
	DataSource (see page 1639)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1639)	Command type in String format.
	MaxBlobSize (see page 1640)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	ParamCheck (see page 1641)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1641)	Represents the parameters for a query or stored procedure.
	SortFieldNames (see page 1642)	Indicates the sort order when CommandType (see page 1638) is ctTable.
	SQLConnection (see page 1642)	Specifies the SQL connection component that connects the dataset to a database server.

25.1.8.4.1 TSQLDataSet.CommandText Property

Specifies the command the dataset executes.

Pascal

```
property CommandText: UnicodeString;
```

C++

```
__property UnicodeString CommandText;
```

Description

The value of CommandText depends on the CommandType (see page 1638) property:

When CommandType (see page 1638) is ctQuery, CommandText is an SQL statement that the dataset executes. If the statement is a SELECT statement, the SQL dataset executes the statement when it is opened. If the statement does not return a result set, the SQL dataset executes the statement when the ExecSQL (see page 1636) method is called.

When CommandType (see page 1638) is ctStoredProc, CommandText is the name of a stored procedure. The SQL dataset executes the stored procedure when it is opened or when the ExecSQL (see page 1636) method is called, depending on whether the stored procedure returns a set of records.

When CommandType (see page 1638) is ctTable, CommandText is the name of a table on the database server. The SQL dataset automatically generates a SELECT statement to fetch all the records on all the fields in this table, sorting by the fields listed in the SortFieldNames (see page 1642) property. The generated statement is executed when the dataset is opened.

If CommandText is an SQL statement that includes parameters or the name of a stored procedure that has parameters, use the Params (see page 1641) property to supply parameter values.

This command is passed on to the TDBXCommand.Text property.

25.1.8.4.2 TSQLDataSet.CommandType Property

Command type of CommandText (see page 1637) property.

Pascal

```
property CommandType: TSQLCommandType;
```

C++

```
__property TSQLCommandType CommandType;
```

Description

CommandType indicates the command type of the CommandText (see page 1637) property.

The following table lists the possible values:

CommandType	Corresponding CommandText (see page 1637)
ctQuery	An SQL statement that the dataset executes.
ctStoredProc	The name of a stored procedure.
ctTable	The name of a table on the database server. The SQL dataset automatically generates a SELECT statement to fetch all the records on all the fields in this table.

Note: Changing CommandType automatically changes the DbxCommandType (see page 1639) property and vice versa. The additional settings supported by DbxCommandType (see page 1639) are converted to ctQuery for CommandType.

25.1.8.4.3 TSQLDataSet.DataSource Property

Links the SQL dataset to another (master) dataset.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

DataSource links this SQL dataset to another (master) dataset that supplies values for this dataset's parameters.

When the SQL dataset's CommandText (see page 1637) (or SQL) property specifies a parameterized query but the application does not provide values for the corresponding parameters in the Params (see page 1641) property, the SQL dataset fetches parameter values from the dataset identified with the specified data source. When the current record in the dataset associated with DataSource changes, the SQL dataset refreshes its data to reflect the new parameter values.

CommandText (see page 1637)

SQL (see page 1663)

Params (see page 1641)

MasterSource (see page 1692)

25.1.8.4.4 TSQLDataSet.DbxCommandType Property

Command type in String format.

Pascal

```
property DbxCommandType: UnicodeString;
```

C++

```
__property UnicodeString DbxCommandType;
```

Description

DbxCommandType indicates the type of command that is contained in the CommandText (see page 1637) property. This can be set to one of the constant strings in the TDBXCommandTypes class. However, DbxCommandType is a `String`, unlike the CommandType (see page 1638) property. This makes it easier to define new command types, making this approach more

extensible. DbxCommandType is a superset of CommandType (see page 1638).

Note: Changing DbxCommandType automatically changes the CommandType (see page 1638) property and vice versa. The additional settings supported by DbxCommandType are converted to ctQuery for CommandType (see page 1638).

25.1.8.4.5 TSQLDataSet.MaxBlobSize Property

Indicates the maximum number of bytes fetched for any BLOB field in the dataset.

Pascal

```
property MaxBlobSize: Integer;
```

C++

```
__property int MaxBlobSize;
```

Description

MaxBlobSize limits the amount of data that can be fetched from Binary Large Object (BLOB) fields. BLOB fields can hold an indefinite amount of data. However, SQL datasets read that data into a memory buffer. By limiting the amount of data that can be fetched from a BLOB field, you limit the size of the buffer.

If MaxBlobSize is –1, the dataset imposes no maximum BLOB size. If MaxBlobSize is 0, the dataset uses the parameters of the associated SQL connection, if any, to determine the maximum BLOB size.

Note: MaxBlobSize should agree with any parameters on the associated SQL connection component that limit the size of BLOB data.

See Also

GetBlobFieldData (see page 1530)

Params (see page 1641)

SQLConnection (see page 1642)

25.1.8.4.6 TSQLDataSet.ParamCheck Property

Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.

Pascal

```
property ParamCheck: Boolean;
```

C++

```
__property Boolean ParamCheck;
```

Description

By default, the Params (see page 1641) property is updated automatically to reflect any parameters that appear in the query specified by the CommandText (see page 1637) property (or the SQL property for TSQLQuery (see page 1654)). That is, whenever the CommandText (see page 1637) property changes, the Params (see page 1641) property is regenerated to reflect the new set of parameters.

There are times when you want to override this default behavior. For example, when specifying a data definition language (DDL) statement that defines a stored procedure, the resulting SQL command may include parameters. These parameters, however, should not be used as parameters of the SQL dataset, because they are not parameters of the DDL command, but rather, they are parameters of the stored procedure that the command creates.

In order to override the default generation of the Params (see page 1641) property in response to changes in CommandText (see page 1637), set ParamCheck to false.

See Also

Params (see page 1641)

CommandText (see page 1637)

SQL (see page 1663)

25.1.8.4.7 TSQLDataSet.Params Property

Represents the parameters for a query or stored procedure.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Params is a collection of TParam objects that represent the parameters of a query or stored procedure specified by the SQL dataset. When you specify a query by setting the CommandText (see page 1637) property (or the SQL property in TSQLQuery (see page 1654)), the SQL dataset automatically parse the query and fills Params with a TParam object for every parameter in the query. Similarly, when you specify a stored procedure by setting the CommandText (see page 1637) property (or the StoredProcName property in TSQLStoredProc (see page 1671)), the SQL dataset automatically asks the server for a list of stored procedure parameters and fills Params with a TParam object for every parameter of the stored procedure.

At design-time, use the Params property editor to access the individual TParam objects. For queries, use this property editor to check the DataType property of each parameter and to assign values to the parameters. For stored procedures, you may need to do more, changing the type or number of parameters if the server does not supply complete information about stored procedure parameters.

You can also use Params to assign parameter properties in code at runtime.

Note: If you do not assign values to input parameters before opening the dataset, it fetches values from the dataset identified by the DataSource (see page 1639) property. However, this only works if the individual TParam objects have the same names as fields in the master dataset.

Using TSimpleDataSet

25.1.8.4.8 TSQLDataSet.SortFieldNames Property

Indicates the sort order when CommandType (see page 1638) is ctTable.

Pascal

```
property SortFieldNames: UnicodeString;
```

C++

```
__property UnicodeString SortFieldNames;
```

Description

Use SortFieldNames to specify the fields that should be used to order the records in the dataset. SortFieldNames is only used when CommandType (see page 1638) is ctTable.

SortFieldNames is a semicolon-delimited list of field names. These names are used to generate the ORDER BY clause of the SQL statement the dataset creates to fetch data from a server table. Records are sorted by the first named field, and within that sort order, by the second named field, and so on.

See Also

CommandType (see page 1638)

Representing the Records in a Table

Specifying the Data to Display using TSQLDataSet

25.1.8.4.9 TSQLDataSet.SQLConnection Property

Specifies the SQL connection component that connects the dataset to a database server.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Use SQLConnection to specify an SQL connection object that connects the dataset to a database server.

At design-time, select from the list of available TSQLConnection (see page 1580) components in the Object Inspector. At runtime, set SQLConnection to reference an existing TSQLConnection (see page 1580) object.

SQLConnection should be the first property you set on the dataset. Only after the SQLConnection property is set can you use the Command Text editor to specify a query for the CommandText (see page 1637) property or populate the dataset with data by setting Active (see page 1552) to true. Similarly, SQLConnection must be set before the dataset can initialize the Params (see page 1641) property when you set CommandText (see page 1637).

25.1.9 TSQLMonitor Class

TSQLMonitor intercepts messages that pass between an SQL connection component and a database server and saves them in a string list.

Class Hierarchy

Pascal

```
TSQLMonitor = class(TComponent);
```

C++

```
class TSQLMonitor : public TComponent;
```

File

SqlExpr

Description

Use TSQLMonitor when debugging the communication between your application and a database server. Each TSQLMonitor instance logs the SQL commands from a particular SQL connection component, adding them to a string list. This allows you to see not only the commands you explicitly add to a SQL dataset or SQL connection component, but also any commands that are

generated on your behalf, such as those created by a dataset provider. Use the TraceList (see page 1652) property to access the list of SQL commands that has already been logged. The TraceList (see page 1652) property is automatically updated when the connection component passes a message to the database server.

Note: TSQLMonitor uses the TraceCallbackEvent property of the SQL connection component whose messages it monitors. If you assign your own callback to that property, the SQL monitor instance will cease to function.

25.1.9.1 TSQLMonitor Members

The following tables list the members exposed by TSQLMonitor.

Protected Methods

	Name	Description
	InvokeCallBack (see page 1646)	This is InvokeCallBack, a member of class TSQLMonitor.
	SetActive (see page 1647)	This is SetActive, a member of class TSQLMonitor.
	SetFileName (see page 1647)	This is SetFileName, a member of class TSQLMonitor.
	SetSQLConnection (see page 1647)	This is SetSQLConnection, a member of class TSQLMonitor.
	SetStreamedActive (see page 1648)	This is SetStreamedActive, a member of class TSQLMonitor.
	SetTraceList (see page 1648)	This is SetTraceList, a member of class TSQLMonitor.
	SwitchConnection (see page 1648)	This is SwitchConnection, a member of class TSQLMonitor.
V	Trace (see page 1648)	This is Trace, a member of class TSQLMonitor.
	UpdateTraceCallBack (see page 1648)	This is UpdateTraceCallBack, a member of class TSQLMonitor.

Public Methods

	Name	Description
V	Create (see page 1645)	Creates and initializes new TSQLMonitor (see page 1643) object.
V	Destroy (see page 1645)	Frees the memory associated with the TSQLMonitor (see page 1643) object.
	LoadFromFile (see page 1646)	Sets the contents of TraceList (see page 1652) to the strings contained in a file.
	SaveToFile (see page 1646)	Saves the contents of TraceList (see page 1652) to a file.

Public Properties

	Name	Description
	MaxTraceCount (see page 1651)	Indicates the maximum number of messages that can be logged.
R	TraceCount (see page 1651)	Indicates the number of messages currently logged.

Published Events

	Name	Description
	OnLogTrace (see page 1653)	Occurs immediately after a new message is logged to the list.
	OnTrace (see page 1653)	Occurs when a message is detected but before it is logged to the list.

Published Properties

	Name	Description
	Active (see page 1649)	Starts or stops the monitor from recording SQL commands passed to the database server.
	AutoSave (see page 1650)	Specifies whether the monitored messages are automatically saved to a file.

	FileName (see page 1650)	Specifies the default file to which monitored messages are saved.
	SQLConnection (see page 1651)	Specifies the connection components whose messages are to be monitored.
	TraceList (see page 1652)	Lists the messages that have passed between SQLConnection (see page 1651) and the database server.

25.1.9.2 TSQLMonitor.Create Constructor

Creates and initializes new TSQLMonitor (see page 1643) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLMonitor(TComponent * AOwner);
```

Description

Call Create to create a TSQLMonitor (see page 1643) component at runtime. SQL monitors added to forms or data modules at design time are created automatically.

The Owner parameter specifies the component (usually the form or data module) that is responsible for freeing the SQL monitor.

See Also

Owner

25.1.9.3 TSQLMonitor.Destroy Destructor

Frees the memory associated with the TSQLMonitor (see page 1643) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLMonitor();
```

Description

Do not call Destroy directly. Instead, call Free, which verifies that the SQL monitor instance is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

25.1.9.4 TSQLMonitor Methods

The methods of the TSQLMonitor class are listed here.

Protected Methods

	Name	Description
	InvokeCallBack (see page 1646)	This is InvokeCallBack, a member of class TSQLMonitor.
	SetActive (see page 1647)	This is SetActive, a member of class TSQLMonitor.
	SetFileName (see page 1647)	This is SetFileName, a member of class TSQLMonitor.
	SetSQLConnection (see page 1647)	This is SetSQLConnection, a member of class TSQLMonitor.
	SetStreamedActive (see page 1648)	This is SetStreamedActive, a member of class TSQLMonitor.
	SetTraceList (see page 1648)	This is SetTraceList, a member of class TSQLMonitor.

	SwitchConnection (see page 1648)	This is SwitchConnection, a member of class TSQLMonitor.
	Trace (see page 1648)	This is Trace, a member of class TSQLMonitor.
	UpdateTraceCallBack (see page 1648)	This is UpdateTraceCallBack, a member of class TSQLMonitor.

Public Methods

	Name	Description
	LoadFromFile (see page 1646)	Sets the contents of TraceList (see page 1652) to the strings contained in a file.
	SaveToFile (see page 1646)	Saves the contents of TraceList (see page 1652) to a file.

25.1.9.4.1 TSQLMonitor.InvokeCallBack Method

Pascal

```
function InvokeCallBack(TraceInfo: TDBXTraceInfo): CBRType;
```

C++

```
__fastcall CBRType InvokeCallBack(TDBXTraceInfo TraceInfo);
```

Description

This is InvokeCallBack, a member of class TSQLMonitor.

25.1.9.4.2 TSQLMonitor.LoadFromFile Method

Sets the contents of TraceList (see page 1652) to the strings contained in a file.

Pascal

```
procedure LoadFromFile(AFileName: string);
```

C++

```
__fastcall LoadFromFile(UnicodeString AFileName);
```

Description

Call LoadFromFile to initialize the message log with the contents of a file. This method can be used to start the log with standard header information you have saved in a file, or to pre-load the list with a log you saved previously using the SaveToFile (see page 1646) method.

AFileName is the file from which to load the contents of the message log. If AFileName is an empty string, LoadFromFile uses the value of the FileName (see page 1650) property.

Note: Any information currently in TraceList (see page 1652) is lost when you call LoadFromFile.

See Also

TraceList (see page 1652)

SaveToFile (see page 1646)

FileName (see page 1650)

25.1.9.4.3 TSQLMonitor.SaveToFile Method

Saves the contents of TraceList (see page 1652) to a file.

Pascal

```
procedure SaveToFile(AFileName: string);
```

C++

```
__fastcall SaveToFile(UnicodeString AFileName);
```

Description

Call SaveToFile to save all of the currently logged messages to a file.

AFileName specifies the file to which the strings in TraceList (see page 1652) are saved. If AFileName is an empty string, SaveToFile uses the value of the FileName (see page 1650) property.

Note: If the AutoSave (see page 1650) property is true, SaveToFile is called automatically whenever a message is added to TraceList (see page 1652).

See Also

TraceList (see page 1652)

LoadFromFile (see page 1646)

FileName (see page 1650)

AutoSave (see page 1650)

25.1.9.4.4 TSQLMonitor.SetActive Method

Pascal

```
procedure SetActive(Value: Boolean);
```

C++

```
__fastcall SetActive(Boolean Value);
```

Description

This is SetActive, a member of class TSQLMonitor.

25.1.9.4.5 TSQLMonitor.SetFileName Method

Pascal

```
procedure SetFileName(const Value: String);
```

C++

```
__fastcall SetFileName(const UnicodeString Value);
```

Description

This is SetFileName, a member of class TSQLMonitor.

25.1.9.4.6 TSQLMonitor.SetSQLConnection Method

Pascal

```
procedure SetSQLConnection(Value: TSQLConnection);
```

C++

```
__fastcall SetSQLConnection(TSQLConnection Value);
```

Description

This is SetSQLConnection, a member of class TSQLMonitor.

25.1.9.4.7 TSQLMonitor.SetStreamedActive Method

Pascal

```
procedure SetStreamedActive;
```

C++

```
__fastcall SetStreamedActive();
```

Description

This is SetStreamedActive, a member of class TSQLMonitor.

25.1.9.4.8 TSQLMonitor.SetTraceList Method

Pascal

```
procedure SetTraceList(Value: TWideStrings);
```

C++

```
__fastcall SetTraceList(TWideStrings Value);
```

Description

This is SetTraceList, a member of class TSQLMonitor.

25.1.9.4.9 TSQLMonitor.SwitchConnection Method

Pascal

```
procedure SwitchConnection(const Value: TSQLConnection);
```

C++

```
__fastcall SwitchConnection(const TSQLConnection Value);
```

Description

This is SwitchConnection, a member of class TSQLMonitor.

25.1.9.4.10 TSQLMonitor.Trace Method

Pascal

```
procedure Trace(TraceInfo: TDBXTraceInfo; LogTrace: Boolean); virtual;
```

C++

```
virtual __fastcall Trace(TDBXTraceInfo TraceInfo, Boolean LogTrace);
```

Description

This is Trace, a member of class TSQLMonitor.

25.1.9.4.11 TSQLMonitor.UpdateTraceCallBack Method

Pascal

```
procedure UpdateTraceCallBack;
```

C++

```
__fastcall UpdateTraceCallBack();
```

Description

This is UpdateTraceCallBack, a member of class TSQLMonitor.

25.1.9.5 TSQLMonitor Properties

The properties of the TSQLMonitor class are listed here.

Public Properties

	Name	Description
	MaxTraceCount (see page 1651)	Indicates the maximum number of messages that can be logged.
R	TraceCount (see page 1651)	Indicates the number of messages currently logged.

Published Properties

	Name	Description
	Active (see page 1649)	Starts or stops the monitor from recording SQL commands passed to the database server.
	AutoSave (see page 1650)	Specifies whether the monitored messages are automatically saved to a file.
	FileName (see page 1650)	Specifies the default file to which monitored messages are saved.
	SQLConnection (see page 1651)	Specifies the connection components whose messages are to be monitored.
	TraceList (see page 1652)	Lists the messages that have passed between SQLConnection (see page 1651) and the database server.

25.1.9.5.1 TSQLMonitor.Active Property

Starts or stops the monitor from recording SQL commands passed to the database server.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Set Active to true to start monitoring the communication between SQLConnection (see page 1651) and its database server. Set Active to false to stop the monitoring.

When you set Active to true, TSQLMonitor (see page 1643) sets the TraceCallbackEvent property of the associated SQL connection component. This causes all commands sent to the database server that match the criteria established by `TraceFlags` to be added to the monitor's string list.

When you set Active to false, TSQLMonitor (see page 1643) clears the TraceCallbackEvent property of the associated SQL connection component. No subsequent commands are added to TraceList (see page 1652), but the list is not cleared. That is, any commands currently in the list remain there until you explicitly clear the list.

TraceCallbackEvent (see page 1628)

SQLConnection (see page 1651)

TraceList (see page 1652)

Debugging dbExpress Applications

Fetching the Data using TSQLDataSet

Using TSimpleDataSet

Using TSQLQuery

Using TSQLStoredProc

25.1.9.5.2 TSQLMonitor.AutoSave Property

Specifies whether the monitored messages are automatically saved to a file.

Pascal

```
property AutoSave: Boolean;
```

C++

```
__property Boolean AutoSave;
```

Description

Set AutoSave to true to automatically save all messages that match the criteria established by `TraceFlags` to the file specified by the FileName (see page 1650) property. The FileName (see page 1650) property must be set to a valid file name.

When AutoSave is false, messages that match the criteria specified by `TraceFlags` are automatically added to TraceList (see page 1652), but are not saved to a file.

See Also

FileName (see page 1650)

TraceList (see page 1652)

SaveToFile (see page 1646)

Debugging dbExpress Applications

25.1.9.5.3 TSQLMonitor.FileName Property

Specifies the default file to which monitored messages are saved.

Pascal

```
property FileName: string;
```

C++

```
__property UnicodeString FileName;
```

Description

Set FileName to the name of a file to which the messages listed in TraceList (see page 1652) are saved. FileName can be a fully-qualified path name.

Once FileName is specified, setting AutoSave (see page 1650) to true causes all monitored messages to be automatically saved to the specified file. Even if AutoSave (see page 1650) is false, FileName specifies the default file name used by the LoadFromFile (see page 1646) and SaveToFile (see page 1646) methods when they are called with an empty string for the AFileName parameter.

See Also

AutoSave (see page 1650)

SaveToFile (see page 1646)

TraceList (see page 1652)

Debugging dbExpress Applications

25.1.9.5.4 TSQLMonitor.MaxTraceCount Property

Indicates the maximum number of messages that can be logged.

Pascal

```
property MaxTraceCount: Integer;
```

C++

```
__property int MaxTraceCount;
```

Description

Set MaxTraceCount to limit the number of messages that can be added to the TraceList (see page 1652) property. When MaxTraceCount is 0 or greater, the SQL monitor logs every message until the limit specified by MaxTraceCount. Once that limit has been reached, the SQL monitor discards messages until the number of messages in TraceList (see page 1652) has been reduced or the value of MaxTraceCount is changed.

If MaxTraceCount is –1, there is no limit on the number of messages that can be added to TraceList (see page 1652).

If MaxTraceCount is 0, the SQL monitor does not log any messages.

Note: Setting MaxTraceCount affects whether messages can be added to TraceList (see page 1652), but does not affect messages that have already been logged. Thus, if you set MaxTraceCount to a value less than the number of strings currently in TraceList (see page 1652), the number of logged messages will exceed MaxTraceCount.

See Also

TraceList (see page 1652)

TraceCount (see page 1651)

25.1.9.5.5 TSQLMonitor.SQLConnection Property

Specifies the connection components whose messages are to be monitored.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Set SQLConnection to identify the TSQLConnection (see page 1580) component whose communication with a database server you want to monitor.

Note: Changing the value of SQLConnection automatically sets the Active (see page 1649) property to false.

See Also

Active (see page 1649)

Debugging dbExpress Applications

25.1.9.5.6 TSQLMonitor.TraceCount Property

Indicates the number of messages currently logged.

Pascal

```
property TraceCount: Integer;
```

C++

```
__property int TraceCount;
```

Description

TraceCount indicates the number of messages listed by the TraceList (see page 1652) property.

See Also

TraceList (see page 1652)

MaxTraceCount (see page 1651)

25.1.9.5.7 TSQLMonitor.TraceList Property

Lists the messages that have passed between SQLConnection (see page 1651) and the database server.

Pascal

```
property TraceList: TWideStrings;
```

C++

```
__property TWideStrings TraceList;
```

Description

Use the TraceList property to access the list of SQL commands that has already been logged. While the SQL monitor is active, the TraceList property is automatically updated when the connection component passes a message to the database server.

Only messages that meet the criteria specified by the `TraceFlags` property are added to TraceList.

TraceList is a TStrings descendant. As such, you can use its methods to

Clear the list.

Access the individual commands in the list.

Add your own comments to the list. For example, you may want to indicate when your application initiates certain actions so that you can see clearly what SQL messages correspond to what actions.

See Also

TraceCount (see page 1651)

Debugging dbExpress Applications

25.1.9.6 TSQLMonitor Events

The events of the TSQLMonitor class are listed here.

Published Events

	Name	Description
	OnLogTrace (see page 1653)	Occurs immediately after a new message is logged to the list.
	OnTrace (see page 1653)	Occurs when a message is detected but before it is logged to the list.

25.1.9.6.1 TSQLMonitor.OnLogTrace Event

Occurs immediately after a new message is logged to the list.

Pascal

```
property OnLogTrace: TTraceLogEvent;
```

C++

```
__property TTraceLogEvent OnLogTrace;
```

Description

Write (see page 3707) an OnLogTrace event handler to respond immediately after a new string is added to the TraceList (see page 1652) property. For example, you can use this event to periodically save the contents of the list to a file and clear the list so that it does not get prohibitively long. OnLogTrace occurs after the message is added to TraceList (see page 1652) but before the list is saved to a file when AutoSave (see page 1650) is true.

Note: OnLogTrace occurs only after logging messages that meet the criteria specified by TraceFlags.

See Also

TraceList (see page 1652)

OnTrace (see page 1653)

TraceFlags

AutoSave (see page 1650)

Debugging dbExpress Applications

25.1.9.6.2 TSQLMonitor.OnTrace Event

Occurs when a message is detected but before it is logged to the list.

Pascal

```
property OnTrace: TTraceEvent;
```

C++

```
__property TTraceEvent OnTrace;
```

Description

Write (see page 3707) an OnTrace event handler to screen or edit messages before they are added to TraceList (see page 1652). OnTrace occurs for every message that passes between the dbExpress driver and the database server, not just those that meet the criteria specified by `TraceFlags`.

See Also

TraceList (see page 1652)

OnLogTrace (see page 1653)

25.1.10 TSQLQuery Class

TSQLQuery represents a query that is executed using dbExpress.

Class Hierarchy

Pascal

```
TSQLQuery = class(TCustomSQLDataSet);
```

C++

```
class TSQLQuery : public TCustomSQLDataSet;
```

File

SqlExpr

Description

Use TSQLQuery to execute an SQL (see page 1663) command on a database server that is accessed via TSQLConnection (see page 1580). TSQLQuery can represent the results of a SELECT statement or perform actions on the database server using statements such as INSERT, DELETE, UPDATE, ALTER TABLE, and so on. You can add a TSQLQuery component to a form or data module at design time, or create one dynamically at runtime.

TSQLQuery is a unidirectional dataset. Unlike other datasets, unidirectional datasets do not buffer multiple records in memory. Because of this, you can only navigate using the First and Next methods. There is no built-in editing support: you can only edit the data in an SQL (see page 1663) query by explicitly creating an SQL (see page 1663) UPDATE command or by connecting the dataset to a client dataset using a provider. Features that require buffering multiple records, such as filters or lookup fields, are not available.

Before you can use a TSQLQuery component, it must be connected to the database server. Therefore, the first step to take when working with TSQLQuery is to set the SQLConnection (see page 1664) property. Once the query is connected to a server, use the SQL (see page 1663) property to specify the command your query executes.

25.1.10.1 TSQLQuery Members

The following tables list the members exposed by TSQLQuery.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.
V	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
V	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
V	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
V	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
V	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
V	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.

	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.
	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Methods

	Name	Description
	Create (see page 1657)	Creates an instance of a TSQLQuery (see page 1654) component.
	Create (see page 1524)	This is the overview for the Create constructor overload.
	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	Destroy (see page 1658)	Destroys the TSQLQuery (see page 1654) instance.
	ExecSQL (see page 1658)	Executes a query that does not return a set of records.
	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
	PrepareStatement (see page 1659)	Prepares the query for execution.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.

	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	RowsAffected (see page 1663)	Indicates the number of rows operated on by the latest query execution.
R	Text (see page 1665)	Indicates the SQL (see page 1663) statement as a single string.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	DataSource (see page 1660)	Links the SQL dataset to another (master) dataset.
	GetMetadata (see page 1660)	Specifies whether the SQL dataset fetches metadata information along with the data.
	MaxBlobSize (see page 1661)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	ParamCheck (see page 1661)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1662)	Represents the parameters for a query or stored procedure.
	SchemaName (see page 1565)	Specifies the name of the database schema.
	SQL (see page 1663)	Specifies the SQL statement to execute on the database server.
	SQLConnection (see page 1664)	Specifies the SQL connection component that connects the dataset to a database server.

25.1.10.2 TSQLQuery.Create Constructor

Creates an instance of a TSQLQuery (see page 1654) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLQuery(TComponent * AOwner);
```

Description

Call Create to instantiate an SQL (see page 1663) query component at runtime. SQL (see page 1663) queries placed in forms or data modules at design time are created automatically.

See Also

Create

25.1.10.3 TSQLQuery.Destroy Destructor

Destroys the TSQLQuery (see page 1654) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLQuery();
```

Description

Do not call Destroy directly in an application. Usually destruction of datasets is handled automatically. If an application creates its own instances of a dataset, however, and does not assign an Owner that is responsible for freeing the dataset, then the application should call Free, which verifies that the dataset reference is not nil before calling Destroy.

See Also

Owner

Create (see page 1657)

System::TObject::Free (see page 3372)

25.1.10.4 TSQLQuery Methods

The methods of the TSQLQuery class are listed here.

Public Methods

	Name	Description
	ExecSQL (see page 1658)	Executes a query that does not return a set of records.
	PrepareStatement (see page 1659)	Prepares the query for execution.

25.1.10.4.1 TSQLQuery.ExecSQL Method

Executes a query that does not return a set of records.

Pascal

```
function ExecSQL(ExecDirect: Boolean = False): Integer; override;
```

C++

```
virtual __fastcall int ExecSQL(Boolean ExecDirect = False);
```

Description

Call ExecSQL to execute an SQL (see page 1663) command that does not return a set of records. This command is a query other than a SELECT query, such as an INSERT, UPDATE, DELETE, or CREATE TABLE query.

ExecDirect indicates that the query does not need to be prepared before it is executed. This parameter can be set to true if the query does not include any parameters. When ExecDirect is false, the query will be prepared before it is executed. Even when ExecDirect is false, you can avoid preparing the query every time ExecSQL is called by setting the Prepared (see page 1563) property to true before calling ExecSQL the first time.

ExecSQL returns the number of rows affected by the executed command. This becomes the value of the RowsAffected (see page 1663) property.

Note: Do not use ExecSQL for commands such as SELECT queries that return data. When the command returns data, use the Open method or set the Active (see page 1552) property to true.

See Also

SQL (see page 1663)

RowsAffected (see page 1564)

Open

Active

Prepared (see page 1563)

ExecuteDirect (see page 1590)

25.1.10.4.2 TSQLQuery.PrepareStatement Method

Prepares the query for execution.

Pascal

```
procedure PrepareStatement; override;
```

C++

```
virtual __fastcall PrepareStatement();
```

Description

PrepareStatement performs most of the necessary tasks for preparing a query to be executed on the server. It ensures the dbExpress and the database server have allocated any resources they need for executing the query and binding its parameters. Any named parameters are temporarily converted to unnamed parameters because dbExpress does not support named parameters.

Do not call PrepareStatement when preparing a query for execution. Instead, set the Prepared (see page 1563) property to true. When you use the Prepared (see page 1563) property instead, the query keeps track of the fact that it has already been prepared and need not repeat the process every time it executes the query. In addition, when you set the Prepared (see page 1563) property, the query initializes internal properties that keep track of the number of rows affected by the query.

See Also

Prepared (see page 1563)

25.1.10.5 TSQLQuery Properties

The properties of the TSQLQuery class are listed here.

Public Properties

	Name	Description
	RowsAffected (see page 1663)	Indicates the number of rows operated on by the latest query execution.

R	Text (see page 1665)	Indicates the SQL (see page 1663) statement as a single string.

Published Properties

	Name	Description
	DataSource (see page 1660)	Links the SQL dataset to another (master) dataset.
	GetMetadata (see page 1660)	Specifies whether the SQL dataset fetches metadata information along with the data.
	MaxBlobSize (see page 1661)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	ParamCheck (see page 1661)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1662)	Represents the parameters for a query or stored procedure.
	SQL (see page 1663)	Specifies the SQL statement to execute on the database server.
	SQLConnection (see page 1664)	Specifies the SQL connection component that connects the dataset to a database server.

25.1.10.5.1 TSQLQuery.DataSource Property

Links the SQL dataset to another (master) dataset.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

DataSource links this SQL dataset to another (master) dataset that supplies values for this dataset's parameters.

When the SQL dataset's CommandText (or SQL) property specifies a parameterized query but the application does not provide values for the corresponding parameters in the Params property, the SQL dataset fetches parameter values from the dataset identified with the specified data source. When the current record in the dataset associated with DataSource changes, the SQL dataset refreshes its data to reflect the new parameter values.

See Also

CommandText (see page 1554)

SQL (see page 1663)

Params (see page 1562)

MasterSource (see page 1692)

25.1.10.5.2 TSQLQuery.GetMetadata Property

Specifies whether the SQL dataset fetches metadata information along with the data.

Pascal

```
property GetMetadata: Boolean;
```

C++

```
__property Boolean GetMetadata;
```

Description

Use GetMetadata to turn on or off the fetching of metadata on a database object. Setting GetMetadata to False will improve performance because no additional SQL will execute in order to get index information. However, setting GetMetadata to False might slow any attempts to update data using a client dataset that is linked via a dataset provider because the resolver might not

generate optimized SQL to perform the update.

GetMetadata must be True to perform any operations that require an index. These operations include setting up master/detail relationships, updating data from a client dataset when the provider's UpdateMode is not upWhereAll, and delayed fetching of BLOB data.

Set GetMetadata to False if you are fetching a dataset for read-only purposes.

TClientDataSet

TDataSetProvider

Fetching the Data using TSQLDataSet

25.1.10.5.3 TSQLQuery.MaxBlobSize Property

Indicates the maximum number of bytes fetched for any BLOB field in the dataset.

Pascal

```
property MaxBlobSize: Integer;
```

C++

```
__property int MaxBlobSize;
```

Description

MaxBlobSize limits the amount of data that can be fetched from Binary Large Object (BLOB) fields. BLOB fields can hold an indefinite amount of data. However, SQL datasets read that data into a memory buffer. By limiting the amount of data that can be fetched from a BLOB field, you limit the size of the buffer.

If MaxBlobSize is –1, the dataset imposes no maximum BLOB size. If MaxBlobSize is 0, the dataset uses the parameters of the associated SQL connection, if any, to determine the maximum BLOB size.

Note: MaxBlobSize should agree with any parameters on the associated SQL connection component that limit the size of BLOB data.

GetBlobFieldData (see page 1530)

Params (see page 1621)

SQLConnection (see page 1566)

25.1.10.5.4 TSQLQuery.ParamCheck Property

Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.

Pascal

```
property ParamCheck: Boolean;
```

C++

```
__property Boolean ParamCheck;
```

Description

By default, the Params property is updated automatically to reflect any parameters that appear in the query specified by the CommandText property (or the SQL property for TSQLQuery) at runtime. That is, whenever the CommandText property changes, the Params property is regenerated to reflect the new set of parameters.

There are times when you want to override this default behavior. For example, when specifying a data definition language (DDL) statement that defines a stored procedure, the resulting SQL command may include parameters. These parameters, however, should not be used as parameters of the SQL dataset, because they are not parameters of the DDL command, but rather, they are parameters of the stored procedure that the command creates.

In order to override the default generation of the Params property in response to changes in CommandText, set ParamCheck to false.

See Also

Params (see page 1562)

CommandText (see page 1554)

SQL (see page 1663)

25.1.10.5.5 TSQLQuery.Params Property

Represents the parameters for a query or stored procedure.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Params is a collection of TParam objects that represent the parameters of a query or stored procedure specified by the SQL dataset. When you specify a query by setting the CommandText property (or the SQL property in TSQLQuery), the SQL dataset automatically parse the query and fills Params with a TParam object for every parameter in the query. Similarly, when you specify a stored procedure by setting the CommandText property (or the StoredProcName property in TSQLStoredProc), the SQL dataset automatically asks the server for a list of stored procedure parameters and fills Params with a TParam object for every parameter of the stored procedure.

At design-time, use the Params property editor to access the individual TParam objects. For queries, use this property editor to check the DataType property of each parameter and to assign values to the parameters. For stored procedures, you may need to do more, changing the type or number of parameters if the server does not supply complete information about stored procedure parameters.

You can also use Params to assign parameter properties in code at runtime.

Note: If you do not assign values to input parameters before opening the dataset, it fetches values from the dataset identified by the DataSource property. However, this only works if the individual TParam objects have the same names as fields in the master dataset.

Using TSimpleDataSet

25.1.10.5.6 TSQLQuery.RowsAffected Property

Indicates the number of rows operated on by the latest query execution.

Pascal

```
property RowsAffected: Integer;
```

C++

```
__property int RowsAffected;
```

Description

When the SQL dataset represents a query that does not return a result set, you can't use the RecordCount property to ascertain the number of records affected by the query. In such cases, read RowsAffected to determine how many rows were updated or deleted by the query when it executed. If no rows were updated or deleted, RowsAffected is zero. RowsAffected is –1 if the SQL statement could not be executed due to an error condition. (This latter situation typically follows the throwing of an exception.)

See Also

ExecSQL (see page 1636)

RecordCount (see page 1564)

ExecProc (see page 1675)

25.1.10.5.7 TSQLQuery.SQL Property

Specifies the SQL statement to execute on the database server.

Pascal

```
property SQL: TWideStrings;
```

C++

```
__property TWideStrings SQL;
```

Description

Use the properties and methods of SQL to specify the query that should be executed on the database server. If SQL is a SELECT statement, the query executes the statement when you call Open or set the Active (see page 1552) property to true. If the statement does not return a result set, call the ExecSQL (see page 1658) method to execute the statement.

When you set the SQL property, TSQLQuery (see page 1654) checks the statement for parameters and initializes the Params (see page 1662) property to reflect any parameters in the statement. You can subsequently use the Params (see page 1662) property to adjust the datatype of any parameters and supply values for the parameters.

At design-time, edit the SQL statement using the property editor that appears when you click the ellipsis button for the property in the Object Inspector. At runtime, use properties and methods of TStrings to clear the current contents, add new contents, or to modify existing contents:

SQLQuery1.SQL.Clear;

```
SQLQuery1.SQL.Add('SELECT ' + Edit1.Text + ' FROM ' + Edit2.Text);
if Length(Edit3.Text) <> 0 then
```

SQLQuery1.SQL.Add('ORDER BY ' + Edit3.Text (see page 1665))

```
SQLQuery1->SQL->Clear();
SQLQuery1->SQL->Add("SELECT " + Edit1->Text + " FROM " + Edit2.Text);
if (!Edit3->Text->IsEmpty())
```

SQLQuery1->SQL->Add("ORDER BY " + Edit3.Text (see page 1665));

You can also use the methods of SQL to load a query from a file.

Note: The SQL you supply for this property must be valid for the database server to which the TSQLQuery (see page 1654) object is connected.

Representing the Results of a Query

Specifying the Command to Execute

25.1.10.5.8 TSQLQuery.SQLConnection Property

Specifies the SQL connection component that connects the dataset to a database server.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Use SQLConnection to specify an SQL connection object that connects the dataset to a database server.

At design-time, select from the list of available TSQLConnection components in the Object Inspector. At runtime, set SQLConnection to reference an existing TSQLConnection object.

SQLConnection should be the first property you set on the dataset. Only after the SQLConnection property is set can you use the Command Text editor to specify a query for the CommandText property or populate the dataset with data by setting Active to true. Similarly, SQLConnection must be set before the dataset can initialize the Params property when you set CommandText.

25.1.10.5.9 TSQLQuery.Text Property

Indicates the SQL (see page 1663) statement as a single string.

Pascal

```
property Text: string;
```

C++

```
__property UnicodeString Text;
```

Description

Use Text as a convenient way to read the entire SQL (see page 1663) query as a single string, rather than using the SQL (see page 1663) property, which may divide the query into substrings. Text is the same as the Text property of the TStrings object that implements the SQL (see page 1663) property.

25.1.11 TSqlServerMethod Class

TDataSet used to call DataSnap server methods.

Class Hierarchy

Pascal

```
TSqlServerMethod = class(TCustomSQLDataSet);
```

C++

```
class TSqlServerMethod : public TCustomSQLDataSet;
```

File

SqlExpr

Description

TSqlServerMethod is a TDataSet used to call DataSnap server methods and retrieve results from them.

See Also

TCustomSQLDataSet (see page 1520)

TDataSet

25.1.11.1 TSqlServerMethod Members

The following tables list the members exposed by TSqlServerMethod.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	ExecSQL (see page 1529)	This is ExecSQL, a member of class TCustomSQLDataSet.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.

	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DataSource (see page 1557)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.
	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	MaxBlobSize (see page 1559)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCheck (see page 1561)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Methods

	Name	Description
	Create (see page 1668)	Create new instance of TSqlServerMethod (see page 1665).
	Create (see page 1524)	This is the overview for the Create constructor overload.
	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	Destroy (see page 1525)	Destroys the TCustomSQLDataSet (see page 1520) instance.
	ExecuteMethod (see page 1669)	Executes remote server method.
	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.

	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
	PrepareStatement (see page 1540)	Performs a prepare on the SQL statement.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	Params (see page 1669)	TParams for method to be executed.
	SchemaName (see page 1565)	Specifies the name of the database schema.
	ServerMethodName (see page 1670)	Sets method name of remote DataSnap server method.
	SQLConnection (see page 1670)	TSQLConnection (see page 1580) used.

25.1.11.2 TSqlServerMethod.Create Constructor

Create new instance of TSqlServerMethod (see page 1665).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSqlServerMethod(TComponent * AOwner);
```

Description

This method creates a new instance of TSqlServerMethod (see page 1665).

25.1.11.3 TSqlServerMethod Methods

The methods of the TSqlServerMethod class are listed here.

Public Methods

	Name	Description
	ExecuteMethod (see page 1669)	Executes remote server method.

25.1.11.3.1 TSqlServerMethod.ExecuteMethod Method

Executes remote server method.

Pascal

```
procedure ExecuteMethod;
```

C++

```
__fastcall ExecuteMethod();
```

Description

ExecuteMethod executes a remote server method. It does not return a result set. Instead, it uses the property Params (see page 1669) for input and output parameters of the server method.

See Also

Params (see page 1669)

25.1.11.4 TSqlServerMethod Properties

The properties of the TSqlServerMethod class are listed here.

Published Properties

	Name	Description
	Params (see page 1669)	TParams for method to be executed.
	ServerMethodName (see page 1670)	Sets method name of remote DataSnap server method.
	SQLConnection (see page 1670)	TSQLConnection (see page 1580) used.

25.1.11.4.1 TSqlServerMethod.Params Property

TParams for method to be executed.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Params contains TParams for a server method to be executed by ExecuteMethod (see page 1669). ExecuteMethod (see page 1669) uses Params for input and output parameters of the server method.

See Also

TParams

ExecuteMethod (see page 1669)

25.1.11.4.2 TSqlServerMethod.ServerMethodName Property

Sets method name of remote DataSnap server method.

Pascal

```
property ServerMethodName: UnicodeString;
```

C++

```
__property UnicodeString ServerMethodName;
```

Description

ServerMethodName sets the method name of the remote DataSnap server method to be executed by ExecuteMethod (see page 1669).

The method name may also be specified in CommandText (see page 1554). In this case, it is of the form *partialClassName.methodName*, where *partialClassName* is the name of the server methods class without the T prefix and *methodName* is the server method name.

See Also

CommandText (see page 1554)

Params (see page 1669)

ExecuteMethod (see page 1669)

25.1.11.4.3 TSqlServerMethod.SQLConnection Property

TSQLConnection (see page 1580) used.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

SQLConnection contains the TSQLConnection (see page 1580).

25.1.12 TSQLStoredProc Class

TSQLStoredProc represents a stored procedure that is executed using dbExpress.

Class Hierarchy

Pascal

```
TSQLStoredProc = class(TCustomSQLDataSet);
```

C++

```
class TSQLStoredProc : public TCustomSQLDataSet;
```

File

SqlExpr

Description

Use TSQLStoredProc to execute a stored procedure on a database server that is accessed via TSQLConnection (see page 1580). TSQLStoredProc can represent the result set if the stored procedure returns a cursor. You can add a TSQLStoredProc component to a form or data module at design time, or create one dynamically at runtime.

TSQLStoredProc is a unidirectional dataset. Unlike other datasets, unidirectional datasets do not buffer multiple records in memory. Because of this, you can only navigate using the First and Next methods. There is no built-in editing support: you can only edit the data in an SQL stored procedure by explicitly creating an SQL UPDATE command or by connecting the dataset to a client dataset using a provider. Features that require buffering multiple records, such as filters or lookup fields, are not available.

Before you can use a TSQLStoredProc component, it must be connected to the database server. Therefore, the first step to take when working with TSQLStoredProc is to set the SQLConnection (see page 1679) property. Once the dataset is connected to a server, use the StoredProcName (see page 1680) property to specify the stored procedure to execute.

25.1.12.1 TSQLStoredProc Members

The following tables list the members exposed by TSQLStoredProc.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
V	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
V	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	ExecSQL (see page 1529)	This is ExecSQL, a member of class TCustomSQLDataSet.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
V	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
V	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.
	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1539)	This is OpenCursor, a member of class TCustomSQLDataSet.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.
V	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
V	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
V	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
V	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
V	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.

	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.
	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DataSource (see page 1557)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.
	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Methods

	Name	Description
	Create (see page 1674)	Creates an instance of a TSQLStoredProc (see page 1671) component.
	Create (see page 1524)	This is the overview for the Create constructor overload.
	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	Destroy (see page 1525)	Destroys the TCustomSQLDataSet (see page 1520) instance.
	ExecProc (see page 1675)	Executes the stored procedure when it does not return a cursor.
	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	NextRecordSet (see page 1676)	Provides access to a secondary recordset.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
	PrepareStatement (see page 1676)	Prepares the stored procedure for execution.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1552)	Specifies whether or not a dataset is open.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	MaxBlobSize (see page 1677)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	PackageName (see page 1677)	Specifies the name of the Oracle package to which the stored procedure belongs.
	ParamCheck (see page 1678)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1678)	Represents the parameters for a query or stored procedure.
	SchemaName (see page 1565)	Specifies the name of the database schema.
	SQLConnection (see page 1679)	Specifies the SQL connection component that connects the dataset to a database server.
	StoredProcName (see page 1680)	Specifies the SQL statement to execute on the database server.

25.1.12.2 TSQLStoredProc.Create Constructor

Creates an instance of a TSQLStoredProc (see page 1671) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLStoredProc(TComponent * AOwner);
```

Description

Call Create to instantiate an SQL stored procedure component at runtime. SQL stored procedures placed in forms or data modules at design time are created automatically.

AOwner is the component, typically a form or data module, that is responsible for freeing the TSQLStoredProc (see page 1671) instance. It becomes the value of the Owner property.

See Also

Owner

Create

25.1.12.3 TSQLStoredProc Methods

The methods of the TSQLStoredProc class are listed here.

Public Methods

	Name	Description
	ExecProc (see page 1675)	Executes the stored procedure when it does not return a cursor.
	NextRecordSet (see page 1676)	Provides access to a secondary recordset.
	PrepareStatement (see page 1676)	Prepares the stored procedure for execution.

25.1.12.3.1 TSQLStoredProc.ExecProc Method

Executes the stored procedure when it does not return a cursor.

Pascal

```
function ExecProc: Integer; virtual;
```

C++

```
virtual __fastcall int ExecProc();
```

Description

Call ExecProc to execute the stored procedure specified by StoredProcName (see page 1680) if it does not return a cursor. ExecProc returns the number of rows affected by the stored procedure. This becomes the value of the RowsAffected (see page 1564) property.

To speed performance, an application should ordinarily prepare the stored procedure by setting the Prepared (see page 1563) property to true before calling ExecProc the first time.

Note: Do not use ExecProc for stored procedures that return a cursor. When the stored procedure returns data, use the Open method or set the Active (see page 1552) property to true.

See Also

StoredProcName (see page 1680)

RowsAffected (see page 1564)

Prepared (see page 1563)

Executing the Command

25.1.12.3.2 TSQLStoredProc.NextRecordSet Method

Provides access to a secondary recordset.

Pascal

```
function NextRecordSet: TCustomSQLDataSet;
```

C++

```
__fastcall TCustomSQLDataSet NextRecordSet();
```

Description

Call NextRecordSet to obtain secondary datasets when accessing the results of a stored procedure that returns multiple sets of records. Opening the dataset fetches the first set of records. NextRecordSet provides access to the subsequent sets.

NextRecordSet returns a newly created TCustomSQLDataSet (see page 1520) component that provides access to the next set of records. The first time you call NextRecordSet, it returns a dataset for the second set of records. The next call returns a third dataset, and so on, until there are no more sets of records. When there are no additional datasets, NextRecordSet returns nil (Delphi) or NULL (C++).

Fetching the Data

Fetching the Data using TSQLDataSet

25.1.12.3.3 TSQLStoredProc.PrepareStatement Method

Prepares the stored procedure for execution.

Pascal

```
procedure PrepareStatement; override;
```

C++

```
virtual __fastcall PrepareStatement();
```

Description

PrepareStatement performs most of the necessary tasks for preparing a stored procedure to be executed on the server. It ensures that dbExpress and the database server have allocated any resources they need for executing the stored procedure and binding its parameters.

Do not call PrepareStatement when preparing a stored procedure for execution. Instead, set the Prepared (see page 1563) property to true. When you use the Prepared (see page 1563) property instead, the stored procedure component keeps track of the fact that it has already been prepared and need not repeat the process every time it executes. In addition, when you set the Prepared (see page 1563) property, the component initializes internal properties that keep track of the number of rows affected by the stored procedure.

See Also

Prepared (see page 1563)

25.1.12.4 TSQLStoredProc Properties

The properties of the TSQLStoredProc class are listed here.

Published Properties

	Name	Description
	MaxBlobSize (see page 1677)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	PackageName (see page 1677)	Specifies the name of the Oracle package to which the stored procedure belongs.
	ParamCheck (see page 1678)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
	Params (see page 1678)	Represents the parameters for a query or stored procedure.
	SQLConnection (see page 1679)	Specifies the SQL connection component that connects the dataset to a database server.
	StoredProcName (see page 1680)	Specifies the SQL statement to execute on the database server.

25.1.12.4.1 TSQLStoredProc.MaxBlobSize Property

Indicates the maximum number of bytes fetched for any BLOB field in the dataset.

Pascal

```
property MaxBlobSize: Integer;
```

C++

```
__property int MaxBlobSize;
```

Description

MaxBlobSize limits the amount of data that can be fetched from Binary Large Object (BLOB) fields. BLOB fields can hold an indefinite amount of data. However, SQL datasets read that data into a memory buffer. By limiting the amount of data that can be fetched from a BLOB field, you limit the size of the buffer.

If MaxBlobSize is –1, the dataset imposes no maximum BLOB size. If MaxBlobSize is 0, the dataset uses the parameters of the associated SQL connection, if any, to determine the maximum BLOB size.

Note: MaxBlobSize should agree with any parameters on the associated SQL connection component that limit the size of BLOB data.

See Also

GetBlobFieldData (see page 1530)

Params (see page 1621)

SQLConnection (see page 1566)

25.1.12.4.2 TSQLStoredProc.PackageName Property

Specifies the name of the Oracle package to which the stored procedure belongs.

Pascal

```
property PackageName: UnicodeString;
```

C++

```
__property UnicodeString PackageName;
```

Description

Set PackageName to specify the name of the Oracle package that contains the stored procedure which the StoredProcName (see page 1680) property specifies. This property is only used when the stored procedure is defined on an Oracle server.

If the stored procedure does not belong to a package, the value of PackageName is an empty string.

See Also

StoredProcName (see page 1680)

GetPackageNames (see page 1594)

25.1.12.4.3 TSQLStoredProc.ParamCheck Property

Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.

Pascal

```
property ParamCheck: Boolean;
```

C++

```
__property Boolean ParamCheck;
```

Description

By default, the Params property is updated automatically to reflect any parameters that appear in the query specified by the CommandText property (or the SQL property for TSQLQuery) at runtime. That is, whenever the CommandText property changes, the Params property is regenerated to reflect the new set of parameters.

There are times when you want to override this default behavior. For example, when specifying a data definition language (DDL) statement that defines a stored procedure, the resulting SQL command may include parameters. These parameters, however, should not be used as parameters of the SQL dataset, because they are not parameters of the DDL command, but rather, they are parameters of the stored procedure that the command creates.

In order to override the default generation of the Params property in response to changes in CommandText, set ParamCheck to false.

See Also

Params (see page 1562)

CommandText (see page 1554)

SQL (see page 1663)

25.1.12.4.4 TSQLStoredProc.Params Property

Represents the parameters for a query or stored procedure.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Params is a collection of TParam objects that represent the parameters of a query or stored procedure specified by the SQL dataset. When you specify a query by setting the CommandText property (or the SQL property in TSQLQuery), the SQL dataset automatically parse the query and fills Params with a TParam object for every parameter in the query. Similarly, when you specify a stored procedure by setting the CommandText property (or the StoredProcName property in TSQLStoredProc), the SQL dataset automatically asks the server for a list of stored procedure parameters and fills Params with a TParam object for every parameter of the stored procedure.

At design-time, use the Params property editor to access the individual TParam objects. For queries, use this property editor to check the DataType property of each parameter and to assign values to the parameters. For stored procedures, you may need

to do more, changing the type or number of parameters if the server does not supply complete information about stored procedure parameters.

You can also use Params to assign parameter properties in code at runtime.

Note: If you do not assign values to input parameters before opening the dataset, it fetches values from the dataset identified by the DataSource property. However, this only works if the individual TParam objects have the same names as fields in the master dataset.

Configuring TSQL Connection

Connecting to Databases with TDatabase

Using TQuery

Using TSimpleDataSet

25.1.12.4.5 TSQLStoredProc.SQLConnection Property

Specifies the SQL connection component that connects the dataset to a database server.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Use SQLConnection to specify an SQL connection object that connects the dataset to a database server.

At design-time, select from the list of available TSQLConnection components in the Object Inspector. At runtime, set SQLConnection to reference an existing TSQLConnection object.

SQLConnection should be the first property you set on the dataset. Only after the SQLConnection property is set can you use the Command Text editor to specify a query for the CommandText property or populate the dataset with data by setting Active to true. Similarly, SQLConnection must be set before the dataset can initialize the Params property when you set CommandText.

Connecting to the Database Server

25.1.12.4.6 TSQLStoredProc.StoredProcName Property

Specifies the SQL statement to execute on the database server.

Pascal

```
property StoredProcName: UnicodeString;
```

C++

```
__property UnicodeString StoredProcName;
```

Description

Set StoredProcName to specify the name of the stored procedure to call on the server. If StoredProcName does not match the name of an existing stored procedure on the server, an exception is raised.

When you set the StoredProcName property, TSQLStoredProc (see page 1671) queries the database server to ascertain the parameters of the specified stored procedure. It uses this information to initialize the Params (see page 1678) property. You can subsequently use the Params (see page 1678) property to adjust the properties of any parameters and supply values for the parameters. Some servers do not supply information about stored procedure parameters. In those cases, you must explicitly add the parameters.

25.1.13 TSQLTable Class

TSQLTable represents a database table that is accessed using dbExpress.

Class Hierarchy

Pascal

```
TSQLTable = class(TCustomSQLDataSet);
```

C++

```
class TSQLTable : public TCustomSQLDataSet;
```

File

SqlExpr

Description

Use TSQLTable to represent a table on a database server that is accessed via TSQLConnection (see page 1580). TSQLTable generates a query to fetch all of the rows and columns in a table you specify. You can add a TSQLTable component to a form or data module at design time, or create one dynamically at runtime.

TSQLTable is a unidirectional dataset. Unlike other datasets, unidirectional datasets do not buffer multiple records in memory. Because of this, you can only navigate using the First and Next methods. There is no built-in editing support: you can only edit the data in an SQL table by explicitly creating an SQL UPDATE command or by connecting the table to a client dataset using a provider. Features that require buffering multiple records, such as filters or lookup fields, are not available.

Before you can use a TSQLTable component, it must be connected to the database server. Therefore, the first step to take when working with TSQLTable is to set the SQLConnection (see page 1693) property. Once the dataset is connected to a server, use the TableName (see page 1693) property to specify the table this component represents.

Types of Datasets

Types of Unidirectional Datasets

25.1.13.1 TSQLTable Members

The following tables list the members exposed by TSQLTable.

Protected Methods

	Name	Description
	AddFieldDesc (see page 1527)	This is AddFieldDesc, a member of class TCustomSQLDataSet.
	AddIndexDefs (see page 1527)	This is AddIndexDefs, a member of class TCustomSQLDataSet.
	CheckPrepareError (see page 1527)	This is CheckPrepareError, a member of class TCustomSQLDataSet.
	ClearIndexDefs (see page 1528)	This is ClearIndexDefs, a member of class TCustomSQLDataSet.
	CloseCursor (see page 1528)	This is CloseCursor, a member of class TCustomSQLDataSet.
	CloseStatement (see page 1528)	This is CloseStatement, a member of class TCustomSQLDataSet.
	DefineProperties (see page 1529)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	ExecSQL (see page 1529)	This is ExecSQL, a member of class TCustomSQLDataSet.
	ExecuteStatement (see page 1529)	This is ExecuteStatement, a member of class TCustomSQLDataSet.
	FreeBuffers (see page 1530)	This is FreeBuffers, a member of class TCustomSQLDataSet.
	FreeCommand (see page 1530)	This is FreeCommand, a member of class TCustomSQLDataSet.
	FreeReader (see page 1530)	This is FreeReader, a member of class TCustomSQLDataSet.
	GetCanModify (see page 1531)	This is GetCanModify, a member of class TCustomSQLDataSet.
	GetDataSource (see page 1531)	This is GetDataSource, a member of class TCustomSQLDataSet.
	GetObjectTypeNames (see page 1533)	This is GetObjectTypeNames, a member of class TCustomSQLDataSet.

	GetOutputParams (see page 1534)	This is GetOutputParams, a member of class TCustomSQLDataSet.
V	GetRecord (see page 1534)	This is GetRecord, a member of class TCustomSQLDataSet.
V	GetRecordCount (see page 1534)	This is GetRecordCount, a member of class TCustomSQLDataSet.
	GetSortFieldNames (see page 1535)	This is GetSortFieldNames, a member of class TCustomSQLDataSet.
V	InitRecord (see page 1535)	This is InitRecord, a member of class TCustomSQLDataSet.
V	InternalClose (see page 1535)	This is InternalClose, a member of class TCustomSQLDataSet.
	InternalFreeCommand (see page 1535)	This is InternalFreeCommand, a member of class TCustomSQLDataSet.
V	InternalHandleException (see page 1535)	This is InternalHandleException, a member of class TCustomSQLDataSet.
V	InternalInitFieldDefs (see page 1536)	This is InternalInitFieldDefs, a member of class TCustomSQLDataSet.
V	InternalOpen (see page 1536)	This is InternalOpen, a member of class TCustomSQLDataSet.
V	InternalRefresh (see page 1536)	This is InternalRefresh, a member of class TCustomSQLDataSet.
V	IsCursorOpen (see page 1536)	This is IsCursorOpen, a member of class TCustomSQLDataSet.
V	Loaded (see page 1537)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 1538)	This is LocateRecord, a member of class TCustomSQLDataSet.
V	OpenCursor (see page 1686)	This is OpenCursor, a member of class TSQLTable.
V	OpenSchema (see page 1539)	This is OpenSchema, a member of class TCustomSQLDataSet.
	PropertyChanged (see page 1540)	This is PropertyChanged, a member of class TCustomSQLDataSet.
V	PSEndTransaction (see page 1540)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 1541)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 1541)	This is PSExecuteStatement, a member of class TCustomSQLDataSet.
V	PSGetAttributes (see page 1541)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 1542)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandType (see page 1542)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 1542)	Returns the definition of an index that imposes the default order on the data included in data packets.
V	PSGetIndexDefs (see page 1543)	Returns the definitions of all specified indexes defined for the dataset.
V	PSGetKeyFieldsW (see page 1543)	This is PSGetKeyFieldsW, a member of class TCustomSQLDataSet.
V	PSGetParams (see page 1544)	Returns the current parameter values of the dataset.
V	PSGetQuoteCharW (see page 1544)	This is PSGetQuoteCharW, a member of class TCustomSQLDataSet.
V	PSGetTableNameW (see page 1544)	This is PSGetTableNameW, a member of class TCustomSQLDataSet.
V	PSGetUpdateException (see page 1544)	Generates an EUpdateError object based on another exception object.
V	PSInTransaction (see page 1545)	Indicates whether actions against the dataset occur in the context of a transaction.
V	PSIsSQLBased (see page 1545)	Indicates whether the dataset includes native SQL support.
V	PSIsSQLSupported (see page 1546)	Indicates whether the dataset can execute SQL statements.
V	PSReset (see page 1546)	Resets the dataset so that it is positioned on the first record.
V	PSSetCommandText (see page 1546)	Assigns a specified SQL command to be executed by PSExecute.
V	PSSetParams (see page 1547)	Assigns the specified parameter values to the dataset.
V	PSStartTransaction (see page 1547)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
V	PSUpdateRecord (see page 1548)	Applies a single update to the underlying database table or tables.
V	SetBufListSize (see page 1548)	This is SetBufListSize, a member of class TCustomSQLDataSet.
V	SetCommandText (see page 1549)	This is SetCommandText, a member of class TCustomSQLDataSet.
	SetFCommandText (see page 1549)	This is SetFCommandText, a member of class TCustomSQLDataSet.
V	SetFieldData (see page 1549)	This is SetFieldData, a member of class TCustomSQLDataSet.
	SetIndexField (see page 1687)	This is SetIndexField, a member of class TSQLTable.
	SetMaxBlobSize (see page 1549)	This is SetMaxBlobSize, a member of class TCustomSQLDataSet.
	SetParamsFromCursor (see page 1549)	This is SetParamsFromCursor, a member of class TCustomSQLDataSet.
	SetSortFieldNames (see page 1551)	This is SetSortFieldNames, a member of class TCustomSQLDataSet.
V	UpdateIndexDefs (see page 1551)	This is UpdateIndexDefs, a member of class TCustomSQLDataSet.

Protected Properties

	Name	Description
	BlobBuffer (see page 1554)	Reserves a buffer for storing BLOB values.
	CommandType (see page 1555)	Indicates the meaning of the CommandText (see page 1554) property.
	CurrentBlobSize (see page 1556)	Indicates the size of the most recently read BLOB field.

R	DataLink (see page 1556)	Identifies the datalink that manages communication between the SQL dataset and another, master dataset.
	DataSource (see page 1557)	Links the SQL dataset to another (master) dataset.
	DbxCommandType (see page 1557)	This is DbxCommandType, a member of class TCustomSQLDataSet.
R	InternalConnection (see page 1559)	Indicates the component that connects the dataset to its database server, taking into account whether the connection was cloned.
R	MasterLink (see page 1692)	This is MasterLink, a member of class TSQLTable.
	NativeCommand (see page 1560)	Represents the SQL command that is sent to the server.
	ParamCheck (see page 1561)	Specifies whether the parameter list for an SQL dataset is regenerated when the SQL command changes.
R	ParamCount (see page 1562)	Indicates the number of parameters listed by the Params (see page 1562) property.
	Params (see page 1562)	Represents the parameters for a query or stored procedure.
	ProcParams (see page 1564)	ProcParams lists the parameter descriptors obtained from the server for any stored procedure parameters.
R	RowsAffected (see page 1564)	Indicates the number of rows operated on by the latest query execution.
	SchemaInfo (see page 1565)	Identifies the metadata with which to populate the dataset.
	SortFieldNames (see page 1566)	Indicates the sort order when CommandType (see page 1555) is ctTable.

Public Methods

	Name	Description
V	Create (see page 1684)	Creates an instance of a TSQLTable (see page 1680) component.
V	Create (see page 1524)	This is the overview for the Create constructor overload.
V	CreateBlobStream (see page 1528)	Creates a blob stream for a Binary large object (BLOB) field in the dataset.
	DeleteRecords (see page 1685)	Empties the underlying database table.
V	Destroy (see page 1685)	Destroys the TSQLTable (see page 1680) instance.
V	GetBlobFieldData (see page 1530)	Retrieves the current value of a BLOB field into a buffer.
	GetCommandNames (see page 1531)	This is GetCommandNames, a member of class TCustomSQLDataSet.
V	GetDetailLinkFields (see page 1531)	Lists the field components that link this dataset as a detail of a master dataset.
V	GetFieldData (see page 1532)	This is the overview for the GetFieldData method overload.
	GetIndexNames (see page 1686)	Retrieves a list of available indexes defined for the table.
	GetKeyFieldNames (see page 1533)	This is the overview for the GetKeyFieldNames method overload.
V	GetQuoteChar (see page 1534)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
V	IsSequenced (see page 1536)	Indicates whether the dataset can use record numbers to indicate the order of records.
V	Locate (see page 1538)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Lookup (see page 1538)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	ParamByName (see page 1539)	Locates a parameter in the Params (see page 1562) property collection.
V	PrepareStatement (see page 1686)	Generates the query that TSQLTable (see page 1680) uses to fetch data from the database server.
	SetSchemaInfo (see page 1550)	Indicates whether the dataset represents metadata from the server, and if so, what kind.

Public Properties

	Name	Description
	CommandText (see page 1554)	Specifies the command the dataset executes.
	DesignerData (see page 1557)	Stores custom data.
	IndexDefs (see page 1558)	Contains the definitions of all indexes defined on the server for the dataset.
R	IndexFieldCount (see page 1689)	Indicates the number of fields that make up the current index.
	IndexFields (see page 1690)	Specifies the fields associated with the current index.
	Prepared (see page 1563)	Specifies whether the command is prepared before execution.
R	RecordCount (see page 1564)	Indicates the total number of records associated with the dataset.
	TransactionLevel (see page 1567)	Indicates the transaction to which this dataset belongs.

Published Events

	Name	Description
	AfterClose (see page 1568)	Occurs after a data source connection is closed.
	AfterOpen (see page 1568)	Occurs after the connection to a data source is opened.
	AfterRefresh (see page 1568)	Occurs after a DataSet has been changed and is refreshed.
	AfterScroll (see page 1568)	Occurs after a result set is scrolled.
	BeforeClose (see page 1569)	Occurs just before a data connection is closed.
	BeforeOpen (see page 1569)	Occurs just before a data connection is opened, but after an open operation has been initiated.
	BeforeRefresh (see page 1569)	Occurs before a DataSet refresh occurs.
	BeforeScroll (see page 1569)	Occurs when a DataSet scroll operation has been initiated but before the scrolling actually takes place.
	OnCalcFields (see page 1569)	Occurs when calculated or derived fields are updated.
	ParseDeleteSql (see page 1569)	Occurs when an application attempts to parse the DELETE statement stored in the CommandText (see page 1554) property.
	ParseInsertSql (see page 1570)	Occurs when an application attempts to parse the INSERT statement stored in the CommandText (see page 1554) property.
	ParseSelectSql (see page 1570)	Occurs when an application attempts to parse the SELECT statement specified in the CommandText (see page 1554) property.
	ParseUpdateSql (see page 1570)	Occurs when an application attempts to parse a SQL UPDATE statement stored in the CommandText (see page 1554) property.

Published Properties

	Name	Description
	Active (see page 1687)	Specifies whether or not a dataset is open.
	GetMetadata (see page 1558)	Specifies whether the SQL dataset fetches metadata information along with the data.
	IndexFieldNames (see page 1689)	Lists the fields to use for sorting records and for linking in master/detail relationships.
	IndexName (see page 1690)	Identifies an index to use for sorting records and for linking the table as the detail of a master/detail relationship.
	MasterFields (see page 1691)	Identifies the fields from the master dataset to use for linking this table as the detail of a master/detail relationship.
	MasterSource (see page 1692)	Identifies the master dataset to use when linking this table as the detail of a master/detail relationship.
	MaxBlobSize (see page 1692)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	NumericMapping (see page 1560)	Maps fldBCD to either ftFMTBCD or ftBCD field types.
	ObjectView (see page 1560)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	SchemaName (see page 1565)	Specifies the name of the database schema.
	SQLConnection (see page 1693)	Specifies the SQL connection component that connects the dataset to a database server.
	TableName (see page 1693)	Specifies the table on the database server represented by this component.

25.1.13.2 TSQLTable.Create Constructor

Creates an instance of a TSQLTable (see page 1680) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSQLTable(TComponent * AOwner);
```

Description

Call Create to instantiate an SQL table at runtime. SQL tables placed in forms or data modules at design time are created automatically.

See Also

Create

25.1.13.3 TSQLTable.Destroy Destructor

Destroys the TSQLTable (see page 1680) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLTable();
```

Description

Usually destruction of datasets is handled automatically by Delphi. If an application creates its own instances of a dataset, however, and does not assign an Owner that is responsible for freeing the dataset, then the application should call Free, which verifies that the dataset reference is not nil before calling Destroy.

See Also

Owner

Create (see page 1684)

System::TObject::Free (see page 3372)

25.1.13.4 TSQLTable Methods

The methods of the TSQLTable class are listed here.

Protected Methods

	Name	Description
	OpenCursor (see page 1686)	This is OpenCursor, a member of class TSQLTable.
	SetIndexField (see page 1687)	This is SetIndexField, a member of class TSQLTable.

Public Methods

	Name	Description
	DeleteRecords (see page 1685)	Empties the underlying database table.
	GetIndexNames (see page 1686)	Retrieves a list of available indexes defined for the table.
	PrepareStatement (see page 1686)	Generates the query that TSQLTable (see page 1680) uses to fetch data from the database server.

25.1.13.4.1 TSQLTable.DeleteRecords Method

Empties the underlying database table.

Pascal

```
procedure DeleteRecords;
```

C++

```
__fastcall DeleteRecords();
```

Description

Call DeleteRecords to delete all the records in the underlying database table.

See Also

RecordCount

25.1.13.4.2 TSQLTable.GetIndexNames Method

Retrieves a list of available indexes defined for the table.

Pascal

```
procedure GetIndexNames(List: TWideStrings);
```

C++

```
__fastcall GetIndexNames(TWideStrings List);
```

Description

Call GetIndexNames to retrieve a list of all indexes on the server defined for the table. List is a string list object, created and maintained by the application, into which to retrieve the index names.

See Also

IndexName (see page 1690)

IndexDefs (see page 1558)

Obtaining Information About Indexes

25.1.13.4.3 TSQLTable.OpenCursor Method

Pascal

```
procedure OpenCursor(InfoQuery: Boolean); override;
```

C++

```
virtual __fastcall OpenCursor(Boolean InfoQuery);
```

Description

This is OpenCursor, a member of class TSQLTable.

25.1.13.4.4 TSQLTable.PrepareStatement Method

Generates the query that TSQLTable (see page 1680) uses to fetch data from the database server.

Pascal

```
procedure PrepareStatement; override;
```

C++

```
virtual __fastcall PrepareStatement();
```

Description

PrepareStatement generates a SELECT query to fetch the records from the table specified by TableName (see page 1693), ordering by the fields in IndexFieldNames (see page 1689) or the index in IndexName (see page 1690). If you have specified a master/detail relationship, PrepareStatement sets that up as well.

Do not call PrepareStatement in your applications. Instead, set the Prepared (see page 1563) property to true. When you use

the Prepared (see page 1563) property instead, the SQL table keeps track of the fact that it has already been prepared and need not repeat the process every time it executes.

See Also

Prepared (see page 1563)

TableName (see page 1693)

IndexName (see page 1690)

IndexFieldNames (see page 1689)

25.1.13.4.5 TSQLTable.SetIndexField Method

Pascal

```
procedure SetIndexField(Index: Integer; Value: TField);
```

C++

```
__fastcall SetIndexField(int Index, TField Value);
```

Description

This is SetIndexField, a member of class TSQLTable.

25.1.13.5 TSQLTable Properties

The properties of the TSQLTable class are listed here.

Protected Properties

	Name	Description
	MasterLink (see page 1692)	This is MasterLink, a member of class TSQLTable.

Public Properties

	Name	Description
	IndexFieldCount (see page 1689)	Indicates the number of fields that make up the current index.
	IndexFields (see page 1690)	Specifies the fields associated with the current index.

Published Properties

	Name	Description
	Active (see page 1687)	Specifies whether or not a dataset is open.
	IndexFieldNames (see page 1689)	Lists the fields to use for sorting records and for linking in master/detail relationships.
	IndexName (see page 1690)	Identifies an index to use for sorting records and for linking the table as the detail of a master/detail relationship.
	MasterFields (see page 1691)	Identifies the fields from the master dataset to use for linking this table as the detail of a master/detail relationship.
	MasterSource (see page 1692)	Identifies the master dataset to use when linking this table as the detail of a master/detail relationship.
	MaxBlobSize (see page 1692)	Indicates the maximum number of bytes fetched for any BLOB field in the dataset.
	SQLConnection (see page 1693)	Specifies the SQL connection component that connects the dataset to a database server.
	TableName (see page 1693)	Specifies the table on the database server represented by this component.

25.1.13.5.1 TSQLTable.Active Property

Specifies whether or not a dataset is open.

Pascal

```
property Active;
```

C++

```
__property Active;
```

Description

Use Active to determine or set whether a dataset is populated with data. When Active is false, the dataset is closed; the dataset cannot read or write data and data-aware controls can not use it to fetch data or post edits. When Active is true, the dataset can be populated with data. It can read data from a database or other source (such as a provider). Depending on the CanModify property, active datasets can post changes.

Setting Active to true:

1. Generates a BeforeOpen event.
2. Sets the dataset state to dsBrowse.
3. Establishes a way to fetch data (typically by opening a cursor).
4. Generates an AfterOpen event.

If an error occurs while opening the dataset, dataset state is set to dsInactive, and any cursor is closed.

Setting Active to false:

1. Triggers a BeforeClose event.
2. Sets the State property to dsInactive.
3. Closes the cursor.
4. Triggers an AfterClose event.

An application must set Active to false before changing other properties that affect the status of a database or the controls that display data in an application.

Note: Calling the Open method sets Active to true; calling the Close method sets Active to false.

Delphi Examples:

```
{
This example requires a database with the following name or
in the form of a *.DB file in the following path.  The table
should be closed when changing the database.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Active := False;
  try
  { First try to use an alias }
    Customers.DatabaseName := 'DBDEMOS';
    Customers.Active := True;
  except
    on EDatabaseError do
    begin
      { If that fails, try to use the drive and directory }
      Customers.TableName := 'Flights';
      // This path depends on the Demos directory of your RAD Studio installation.
      Customers.DatabaseName :=
        'c:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\IntraWeb\Win32\FlightInformation\Data';
      Customers.Active := True;
    end;
```

```
  end;
end;
```

25.1.13.5.2 TSQLTable.IndexFieldCount Property

Indicates the number of fields that make up the current index.

Pascal

```
property IndexFieldCount: Integer;
```

C++

```
__property int IndexFieldCount;
```

Description

Check IndexFieldCount to determine how many fields are in the current index. If the IndexName (see page 1690) property is not set, IndexFieldCount is 0.

See Also

IndexFieldNames (see page 1689)

IndexDefs (see page 1558)

IndexName (see page 1690)

25.1.13.5.3 TSQLTable.IndexFieldNames Property

Lists the fields to use for sorting records and for linking in master/detail relationships.

Pascal

```
property IndexFieldNames: UnicodeString;
```

C++

```
__property UnicodeString IndexFieldNames;
```

Description

IndexFieldNames is a semicolon-delimited set of field names, where each name specifies a field in the table.

Use IndexFieldNames to identify the fields in the SQL table that are used to sort records in the table. IndexFieldNames are used to generate the ORDER BY clause of the SQL statement automatically generated to fetch records for the dataset.

IndexFieldNames is also used to link this table as the detail in a master/detail relationship. Each of these fields must be matched to a corresponding field from the MasterFields (see page 1691) property.

Instead of explicitly setting the sorting and linking fields using IndexFieldNames, you can indicate them using an existing index. To specify the sorting and linking fields implicitly through an index, use the IndexName (see page 1690) property instead.

Note: The IndexName (see page 1690) and IndexFieldNames properties are mutually exclusive. Setting one automatically clears the other.

See Also

IndexName (see page 1690)

MasterFields (see page 1691)

MasterSource (see page 1692)

Creating an Index with IndexFieldNames

Representing the Records in a Table

25.1.13.5.4 TSQLTable.IndexFields Property

Specifies the fields associated with the current index.

Pascal

```
property IndexFields [Index: Integer]: TField;
```

C++

```
__property TField IndexFields[int Index];
```

Description

IndexFields is a zero-based array of field objects, each of which corresponds to a field in the current index. Index is an ordinal value indicating the position of a field in the index. The first field in the index is IndexFields[0], the second is IndexFields[1], and so on.

Note: Do not set IndexFields directly. Instead use the IndexFieldNames (see page 1689) property to specify the sort order for records in the table.

See Also

IndexDefs (see page 1558)

IndexFieldNames (see page 1689)

IndexName (see page 1690)

25.1.13.5.5 TSQLTable.IndexName Property

Identifies an index to use for sorting records and for linking the table as the detail of a master/detail relationship.

Pascal

```
property IndexName: UnicodeString;
```

C++

```
__property UnicodeString IndexName;
```

Description

Use IndexName to specify an existing index that is defined for the underlying database table.

IndexName is used to sort records in the table by appearing in the ORDER BY clause of the SQL statement automatically generated to fetch records for the dataset.

IndexName is also used to link this table as the detail in a master/detail relationship. Each of the fields in the index must be matched to a corresponding field from the MasterFields (see page 1691) property.

Note: The IndexName and IndexFieldNames (see page 1689) properties are mutually exclusive. Setting one automatically clears the other.

See Also

IndexFieldNames (see page 1689)

MasterFields (see page 1691)

MasterSource (see page 1692)

GetIndexNames (see page 1686)

Representing the Records in a Table

25.1.13.5.6 TSQLTable.MasterFields Property

Identifies the fields from the master dataset to use for linking this table as the detail of a master/detail relationship.

Pascal

```
property MasterFields: UnicodeString;
```

C++

```
__property UnicodeString MasterFields;
```

Description

Use MasterFields to identify the fields in another (master) dataset that can be used as link fields in a master/detail relationship. MasterFields is a semicolon-delimited set of field names, where each name identifies a field in the master dataset. The master dataset is the dataset associated with the datasource specified by MasterSource (see page 1692). Each of the fields in MasterFields must be matched to a corresponding field from the IndexFieldNames (see page 1689) property.

At design-time, double-click on the MasterFields property in the Object Inspector to use the Field Link designer to help you define the master/detail relationship. You can only use the Field Link designer if you have already specified the IndexName (see page 1690) or IndexFieldNames (see page 1689) property and the MasterSource (see page 1692) property.

See Also

IndexFieldNames (see page 1689)

IndexName (see page 1690)

MasterSource (see page 1692)

Making the Table a Detail of Another Dataset

Setting Up Master/detail Linked Cursors

25.1.13.5.7 TSQLTable.MasterLink Property

Pascal

```
property MasterLink: TMasterDataLink;
```

C++

```
__property TMasterDataLink MasterLink;
```

Description

This is MasterLink, a member of class TSQLTable.

25.1.13.5.8 TSQLTable.MasterSource Property

Identifies the master dataset to use when linking this table as the detail of a master/detail relationship.

Pascal

```
property MasterSource: TDataSource;
```

C++

```
__property TDataSource MasterSource;
```

Description

Use MasterSource to indicate the dataset that serves as a master table when establishing a master/detail relationship. Specify a TDataSource component whose DataSet property identifies the desired master dataset.

A master/detail relationship is established when you set the MasterSource property to identify a master dataset, the MasterFields (see page 1691) property to identify the fields in that master dataset whose values must be matched by linking fields in this (detail) SQL table, and the IndexName (see page 1690) or IndexFieldNames (see page 1689) property to identify the linking fields in this SQL table.

MasterSource is the same as the DataSource (see page 1557) property, except that it is published.

See Also

IndexFieldNames (see page 1689)

IndexName (see page 1690)

MasterFields (see page 1691)

DataSource (see page 1557)

DataSet

Making the Table a Detail of Another Dataset

Setting Up Master/detail Linked Cursors

25.1.13.5.9 TSQLTable.MaxBlobSize Property

Indicates the maximum number of bytes fetched for any BLOB field in the dataset.

Pascal

```
property MaxBlobSize: Integer;
```

C++

```
__property int MaxBlobSize;
```

Description

MaxBlobSize limits the amount of data that can be fetched from Binary Large Object (BLOB) fields. BLOB fields can hold an indefinite amount of data. However, SQL datasets read that data into a memory buffer. By limiting the amount of data that can be fetched from a BLOB field, you limit the size of the buffer.

If MaxBlobSize is –1, the dataset imposes no maximum BLOB size. If MaxBlobSize is 0, the dataset uses the parameters of the associated SQL connection, if any, to determine the maximum BLOB size.

Note: MaxBlobSize should agree with any parameters on the associated SQL connection component that limit the size of BLOB data.

See Also

GetBlobFieldData (see page 1530)

Params (see page 1621)

SQLConnection (see page 1566)

25.1.13.5.10 TSQLTable.SQLConnection Property

Specifies the SQL connection component that connects the dataset to a database server.

Pascal

```
property SQLConnection: TSQLConnection;
```

C++

```
__property TSQLConnection SQLConnection;
```

Description

Use SQLConnection to specify an SQL connection object that connects the dataset to a database server.

At design-time, select from the list of available TSQLConnection components in the Object Inspector. At runtime, set SQLConnection to reference an existing TSQLConnection object.

SQLConnection should be the first property you set on the dataset. Only after the SQLConnection property is set can you use the Command Text editor to specify a query for the CommandText property or populate the dataset with data by setting Active to true. Similarly, SQLConnection must be set before the dataset can initialize the Params property when you set CommandText.

See Also

Active

CommandText (see page 1554)

Params (see page 1562)

Connecting Directly to a Database Server

Connecting to the Database Server

25.1.13.5.11 TSQLTable.TableName Property

Specifies the table on the database server represented by this component.

Pascal

```
property TableName: UnicodeString;
```

C++

```
__property UnicodeString TableName;
```

Description

Set TableName to the name of a table on the database server. TSQLTable (see page 1680) automatically generates an SQL query to fetch all of the records and all of the fields in that table.

Note: In the automatically generated SQL query, the ORDER BY clause is determined by the IndexName (see page 1690) or IndexFieldNames (see page 1689) property.

See Also

IndexFieldNames (see page 1689)

IndexName (see page 1690)

Representing the Records in a Table

25.1.14 TTransactionItem Class

Class Hierarchy

Pascal

```
TTransactionItem = class;
```

C++

```
class TTransactionItem;
```

File

SqlExpr

Description

This is class SqlExpr.TTransactionItem.

25.1.14.1 TTransactionItem Members

The following tables list the members exposed by TTransactionItem.

Public Fields

	Name	Description
	FNext (see page 1695)	This is FNext, a member of class TTransactionItem.
	FTransaction (see page 1695)	This is FTransaction, a member of class TTransactionItem.
	FTransactionDesc (see page 1695)	This is FTransactionDesc, a member of class TTransactionItem.

25.1.14.2 TTransactionItem Fields

The fields of the TTransactionItem class are listed here.

Public Fields

	Name	Description
	FNext (see page 1695)	This is FNext, a member of class TTransactionItem.
	FTransaction (see page 1695)	This is FTransaction, a member of class TTransactionItem.
	FTransactionDesc (see page 1695)	This is FTransactionDesc, a member of class TTransactionItem.

25.1.14.2.1 TTransactionItem.FNext Field

Pascal

```
FNext: TTransactionItem;
```

C++

```
TTransactionItem FNext;
```

Description

This is FNext, a member of class TTransactionItem.

25.1.14.2.2 TTransactionItem.FTransaction Field

Pascal

```
FTransaction: TDBXTransaction;
```

C++

```
TDBXTransaction FTransaction;
```

Description

This is FTransaction, a member of class TTransactionItem.

25.1.14.2.3 TTransactionItem.FTransactionDesc Field

Pascal

```
FTransactionDesc: TTransactionDesc;
```

C++

```
TTransactionDesc FTransactionDesc;
```

Description

This is FTransactionDesc, a member of class TTransactionItem.

25.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FreeProcParams (see page 1696)	Frees a list of procedure parameters that is allocated by GetProcedureParams.
	GetConnectionNames (see page 1696)	This is function SqlExpr.GetConnectionNames.
	GetConnectionRegistryFile (see page 1697)	This is function SqlExpr.GetConnectionRegistryFile.
	GetDelegateDriverNames (see page 1697)	This is function SqlExpr.GetDelegateDriverNames.
	GetDriverNames (see page 1697)	Populates a string list with the names of all available dbExpress drivers.
	GetDriverRegistryFile (see page 1698)	This is function SqlExpr.GetDriverRegistryFile.
	LoadParamListItems (see page 1698)	Fills a TParams object with information from a list of parameter descriptors.

25.2.1 SqlExpr.FreeProcParams Function

Frees a list of procedure parameters that is allocated by GetProcedureParams.

Pascal

```
procedure FreeProcParams(var ProcParams: TList);
```

C++

```
FreeProcParams(TList ProcParams);
```

File

SqlExpr

Description

Use FreeProcParams to free a list of stored procedure parameters after using them. FreeProcParams takes a single parameter, ProcParams, which is a list of parameter information that was returned from a call to the GetProcedureParams method of TSQLConnection (see page 1580). It frees all of the parameter structures in the list, and then frees the list itself, changing the parameter that was passed in to nil (Delphi) or NULL (C++).

See Also

TSQLConnection (see page 1580)

LoadParamListItems (see page 1698)

25.2.2 SqlExpr.GetConnectionNames Function

Pascal

```
procedure GetConnectionNames(List: TStrings; Driver: string = ''; DesignMode: Boolean = True);
```

C++

```
GetConnectionNames(TStrings List, UnicodeString Driver = '', Boolean DesignMode = True);
```

File

SqlExpr

Description

This is function SqlExpr.GetConnectionNames.

25.2.3 SqlExpr.GetConnectionRegistryFile Function

Pascal

```
function GetConnectionRegistryFile(DesignMode: Boolean = False): string;
```

C++

```
UnicodeString GetConnectionRegistryFile(Boolean DesignMode = False);
```

File

SqlExpr

Description

This is function SqlExpr.GetConnectionRegistryFile.

25.2.4 SqlExpr.GetDelegateDriverNames Function

Pascal

```
procedure GetDelegateDriverNames(List: TStrings; DesignMode: Boolean = True);
```

C++

```
GetDelegateDriverNames(TStrings List, Boolean DesignMode = True);
```

File

SqlExpr

Description

This is function SqlExpr.GetDelegateDriverNames.

25.2.5 SqlExpr.GetDriverNames Function

Populates a string list with the names of all available dbExpress drivers.

Pascal

```
procedure GetDriverNames(List: TStrings; DesignMode: Boolean = True);
```

C++

```
GetDriverNames(TStrings List, Boolean DesignMode = True);
```

File

SqlExpr

Description

GetDriverNames fills the string list specified by List with the names of all installed dbExpress drivers. GetDriverNames fetches the names of Installed drivers from the drivers.ini file.

List is a string list object, created and maintained by the application, into which to store the driver names.

DesignMode indicates whether the names are fetched at design time (true) or at runtime (false).

See Also

TSQLConnection (see page 1580)

25.2.6 SqlExpr.GetDriverRegistryFile Function

Pascal

```
function GetDriverRegistryFile(DesignMode: Boolean = False): string;
```

C++

```
UnicodeString GetDriverRegistryFile(Boolean DesignMode = False);
```

File

SqlExpr

Description

This is function SqlExpr.GetDriverRegistryFile.

25.2.7 SqlExpr.LoadParamListItems Function

Fills a TParams object with information from a list of parameter descriptors.

Pascal

```
procedure LoadParamListItems(Params: TParams; ProcParams: TList);
```

C++

```
LoadParamListItems(TParams Params, TList ProcParams);
```

File

SqlExpr

Description

Call LoadParamListItems to convert the list of parameter descriptors that is returned from the GetProcedureParams method of TSQLConnection (see page 1580) to a collection of TParam objects.

Params is an empty TParams collection that the procedure fills with information from the list of parameter descriptors.

ProcParams is the list of parameter descriptors that GetProcedureParams returns.

See Also

FreeProcParams (see page 1696)

TSQLConnection (see page 1580)

25.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	EConnectFlag (see page 1699)	This is record SqlExpr.EConnectFlag.
	TConnectionState (see page 1700)	TConnectionState describes the state of a TSQLConnection (see page 1580) component.
	TConnectionUserType (see page 1700)	This is record SqlExpr.TConnectionUserType.
	TSchemaType (see page 1701)	TSchemaType and TSchemaInfo describe schema information (metadata) to access using dbXpress.
	TSQLExceptionType (see page 1702)	TSQLExceptionType indicates the type of operation that leads to an ESQLException exception.
	TTableScope (see page 1703)	TTableScopes (see page 1710) and TTableScopess indicate the types of tables for which to fetch metadata.
	TTransIsolationLevel (see page 1704)	This enumerated type (in C++) or type (in Delphi) identifies degree to which transactions are isolated from each other.

Records

	Name	Description
	TSQLSchemaInfo (see page 1703)	This is record SqlExpr.TSQLSchemaInfo.
	TTransactionDesc (see page 1704)	This is record SqlExpr.TTransactionDesc.

25.3.1 SqlExpr.EConnectFlag Enumeration

Pascal

```
EConnectFlag = (
  eConnect,
  eReconnect,
  eDisconnect
);
```

C++

```
enum EConnectFlag {
  eConnect,
  eReconnect,
  eDisconnect
};
```

File

SqlExpr

Description

This is record SqlExpr.EConnectFlag.

25.3.2 SqlExpr.TConnectionState Enumeration

TConnectionState describes the state of a TSQLConnection (see page 1580) component.

Pascal

```
TConnectionState = (
  csStateClosed,
  csStateOpen,
  csStateConnecting,
  csStateExecuting,
  csStateFetching,
  csStateDisconnecting
);
```

C++

```
enum TConnectionState {
  csStateClosed,
  csStateOpen,
  csStateConnecting,
  csStateExecuting,
  csStateFetching,
  csStateDisconnecting
};
```

File

SqlExpr

Description

TConnectionState can have any of the following values:

Value	Meaning
csStateClosed	The connection is closed. (The Connected property is false)
csStateOpen	The connection is open. (The Connected property is true)
csStateConnecting	The component is establishing a connection but has not completed the process.
csStateExecuting	The component has passed an SQL command to the server and it is currently executing.
csStateFetching	The component is fetching database information from the server.
csStateDisconnecting	The component is terminating a connection but has not completed the process.

25.3.3 SqlExpr.TConnectionUserType Enumeration

Pascal

```
TConnectionUserType = (
  eUserMonitor,
  eUserDataSet
);
```

C++

```
enum TConnectionUserType {
  eUserMonitor,
```

```
  eUserDataSet
};
```

File

SqlExpr

Description

This is record SqlExpr.TConnectionUserType.

25.3.4 SqlExpr.TSchemaType Enumeration

TSchemaType and TSchemaInfo describe schema information (metadata) to access using dbXpress.

Pascal

```
TSchemaType = (
  stNoSchema,
  stTables,
  stSysTables,
  stProcedures,
  stColumns,
  stProcedureParams,
  stIndexes,
  stPackages,
  stUserNames
);
```

C++

```
enum TSchemaType {
  stNoSchema,
  stTables,
  stSysTables,
  stProcedures,
  stColumns,
  stProcedureParams,
  stIndexes,
  stPackages,
  stUserNames
};
```

File

SqlExpr

Description

Use TSchemaInfo to describe the metadata you want to fetch from a database server when you are using an SQL dataset. TSchemaInfo has three members: FType, ObjectName, and Pattern, which are described below.

Use TSchemaInfo to describe the metadata you want to fetch from a database server when you are using an SQL dataset. TSchemaInfo has four members: FType, ObjectName, Pattern, and PackageName, which are described below.

FType is of type TSchemaType. It identifies the type of information you want. It can have any of the following values:

Value	Description
stNoSchema	No schema information. When FType is stNoSchema, the SQL dataset is populated with the results of its query or stored procedure rather than metadata from the server.
stTables	Information about all the data tables on the database server that match the criteria specified by the SQL connection's TableScope property.

stSysTables	Information about all of the system tables on the database server. Not all servers use system tables to store metadata. Requesting a list of system tables from a server that does not use them results in an empty dataset.
stProcedures	Information about all of the stored procedures on the database server.
stColumns	Information about all of the columns (fields) in a specified table.
stProcedureParams	Information about all of the parameters of a specified stored procedure.
stIndexes	Information about all of the indexes defined for a specified table.
stPackages	Information about all of the packages defined on the database server (Oracle only).

ObjectName is the name of the table or stored procedure about whose columns, indexes, or parameters you want information. When FType is stColumns or stIndexes, ObjectName is the name of a table. When FType is stProcedureParams, ObjectName is the name of a stored procedure. When FType is stNone, stTables, stSysTables, or stProcedures, ObjectName is ignored.

Pattern is an SQL pattern mask that limits the items returned. The name of each item (table, stored procedure, field, parameter, or index) must match this pattern mask or it does not appear as a record when the SQL dataset is opened. Pattern uses the wildcards '%' (to match a string of arbitrary characters of any length) and '_' (to match a single arbitrary character). To use a literal percent or underscore in a pattern, the character is doubled (%% or __). If you do not want to use a pattern, set Pattern to nil (Delphi) or NULL (C++).

PackageName is the name of an Oracle package that contains the stored procedure about which you are requesting information. This member is used when FType is stProcedures or stProcedureParams. PackageName is ignored if the server is not an Oracle database.

25.3.5 SqlExpr.TSQLExceptionType Enumeration

TSQLExceptionType indicates the type of operation that leads to an ESQLException exception.

Pascal

```
TSQLExceptionType = (
  exceptConnection,
  exceptCommand,
  exceptCursor,
  exceptMetaData,
  exceptUseLast
);
```

C++

```
enum TSQLExceptionType {
  exceptConnection,
  exceptCommand,
  exceptCursor,
  exceptMetaData,
  exceptUseLast
};
```

File

SqlExpr

Description

ESQLException objects use TSQLExceptionType to identify the dbExpress object from which an error code originated. By identifying the underlying dbExpress object, ESQLException identifies that object's interface, which it then uses to obtain an error message.

TSQLExceptionType includes the following values:

Value	Description
exceptConnection	Error (see page 3560) arose when establishing a connection to the database server, obtaining an interface for sending a command, fetching server metadata, or controlling a transaction.
exceptCommand	Error (see page 3560) occurred while preparing or executing an SQL command.
exceptCursor	Error (see page 3560) occurred while fetching data from a dbExpress cursor.
exceptMetaData	Error (see page 3560) occurred while trying to fetch metadata (schema information).
exceptUseLast	The error is cached by the TSQLConnection (see page 1580) component.

25.3.6 SqlExpr.TSQLSchemaInfo Record

Pascal

```
TSQLSchemaInfo = record
  FType: TSchemaType;
  ObjectName: UnicodeString;
  Pattern: UnicodeString;
  PackageName: UnicodeString;
end;
```

C++

```
struct TSQLSchemaInfo {
  TSchemaType FType;
  UnicodeString ObjectName;
  UnicodeString Pattern;
  UnicodeString PackageName;
};
```

File

SqlExpr

Description

This is record SqlExpr.TSQLSchemaInfo.

25.3.7 SqlExpr.TTableScope Enumeration

TTableScopes (see page 1710) and TTableScopess indicate the types of tables for which to fetch metadata.

Pascal

```
TTableScope = (
  tsSynonym,
  tsSysTable,
  tsTable,
  tsView
);
```

C++

```
enum TTableScope {
  tsSynonym,
  tsSysTable,
```

```
  tsTable,
  tsView
};
```

File

SqlExpr

Description

TTableScopess is a set that indicates the types of tables for which to fetch metadata. It is a set of TTableScopes (see page 1710) values. The following table describes the possible values:

Value	Meaning
tsSynonym	synonyms
tsSysTable	system tables
tsTable	ordinary tables
tsView	views

25.3.8 SqlExpr.TTransactionDesc Record

Pascal

```
TTransactionDesc = packed record
  TransactionID: LongWord;
  GlobalID: LongWord;
  IsolationLevel: TTransIsolationLevel;
  CustomIsolation: LongWord;
end;
```

C++

```
struct TTransactionDesc {
  LongWord TransactionID;
  LongWord GlobalID;
  TTransIsolationLevel IsolationLevel;
  LongWord CustomIsolation;
};
```

File

SqlExpr

Description

This is record SqlExpr.TTransactionDesc.

25.3.9 SqlExpr.TTransIsolationLevel Enumeration

This enumerated type (in C++) or type (in Delphi) identifies degree to which transactions are isolated from each other.

Pascal

```
TTransIsolationLevel = (
  xilREADCOMMITTED,
  xilREPEATABLEREAD,
  xilDIRTYREAD,
```

```
    xilCUSTOM
  );
```

C++

```
  enum TTransIsolationLevel {
    xilREADCOMMITTED,
    xilREPEATABLEREAD,
    xilDIRTYREAD,
    xilCUSTOM
  };
```

File

SqlExpr

Description

The following table describes the possible values.

Element	Description
xilDIRTYREAD	Current transaction sees all changes made by other transactions, even if they have not yet been committed. This option is not available for the Oracle driver.
xilREADCOMMITTED	Current transaction sees only changes that have been committed, but can receive an inconsistent view of the data if additional changes are committed before the transaction ends.
xilREPEATABLEREAD	Current transaction is guaranteed a consistent view of the data, which includes only changes committed by other transactions at the start of the transaction.
xilCUSTOM	Current transaction uses a database-specific isolation level. When the eConnTxnIsoLevel option is xilCUSTOM, the transaction descriptor gives the actual isolation level. This is not currently supported by any drivers, but allows future drivers the ability to expand the number of isolation levels.

25.4 Types

The following table lists types in this documentation.

Types

Name	Description
SQLResult (see page 1706)	SQLResult is the return type for dbExpress function calls.
TFieldDescList (see page 1707)	This is type SqlExpr.TFieldDescList.
TFieldList (see page 1707)	This is type SqlExpr.TFieldList.
TGetDriverFunc (see page 1708)	This is type SqlExpr.TGetDriverFunc.
TLocale (see page 1708)	This is type SqlExpr.TLocale.
TLocaleCode (see page 1708)	TLocaleCode identifies a locale, which imposes a sort order on data.
TParseInsertSqlEvent (see page 1709)	This is type SqlExpr.TParseInsertSqlEvent.
TParseSqlEvent (see page 1709)	This is type SqlExpr.TParseSqlEvent.
TSQLConnectionLoginEvent (see page 1709)	This is type SqlExpr.TSQLConnectionLoginEvent.
TTableScopes (see page 1710)	This is type SqlExpr.TTableScopes.
TTraceEvent (see page 1710)	This is type SqlExpr.TTraceEvent.
TTraceLogEvent (see page 1710)	This is type SqlExpr.TTraceLogEvent.

25.4.1 SqlExpr.SQLResult Type

SQLResult is the return type for dbExpress function calls.

Pascal

```
SQLResult = TDBXErrorCode;
```

C++

```
TDBXErrorCode SQLResult;
```

File

SqlExpr

Description

SQLResult indicates the success or failure of a dbExpress function. The following table lists the error codes defined for dbExpress.

SQLResult Value	Meaning
SQL_SUCCESS	The function call was successful.
DBXERR_NONE	Same as SQL_SUCCESS.
DBXERR_NOMEMORY	Insufficient memory.
DBXERR_INVALIDFLDTYPE	Invalid field type.
DBXERR_INVALIDHNDL	Invalid handle.
DBXERR_INVALIDTIME	Invalid time value.
DBXERR_NOTSUPPORTED	Feature not supported.
DBXERR_INVALIDXLATION	Invalid translation.

DBXERR_INVALIDPARAM	Invalid parameter.
DBXERR_OUTOFRANGE	Value out of range.
DBXERR_SQLPARAMNOTSET	Parameter not set.
DBXERR_EOF	Unexpected end-of-file.
DBXERR_INVALIDUSRPASS	Invalid user password.
DBXERR_INVALIDPRECISION	Invalid precision on a BCD value.
DBXERR_INVALIDLEN	Invalid length.
DBXERR_INVALIDTXNISOLEVEL	Invalid transaction isolation level.
DBXERR_INVALIDTXNID	Invalid transaction id.
DBXERR_DUPLICATETXNID	Duplicate transaction id.
DBXERR_DRIVERRESTRICTED	Driver restricted.
DBXERR_LOCALTRANSACTIVE	An attempt to start multiple local transactions (only 1 allowed).

25.4.2 SqlExpr.TFieldDescList Type

Pascal

```
TFieldDescList = array of TFLDDesc;
```

C++

```
array of TFLDDesc TFieldDescList;
```

File

SqlExpr

Description

This is type SqlExpr.TFieldDescList.

25.4.3 SqlExpr.TFieldList Type

Pascal

```
TFieldList = TList;
```

C++

```
TList TFieldList;
```

File

SqlExpr

Description

This is type SqlExpr.TFieldList.

25.4.4 SqlExpr.TGetDriverFunc Type

Pascal

```
TGetDriverFunc = function (SVendorLib, SResourceFile: PChar; out Obj): TDBXErrorCode;
```

C++

```
(SVendorLib, SResourceFile: PChar; out Obj): TDBXErrorCode ( TGetDriverFunc)();
```

File

SqlExpr

Description

This is type SqlExpr.TGetDriverFunc.

25.4.5 SqlExpr.TLocale Type

Pascal

```
TLocale = Pointer;
```

C++

```
void * TLocale;
```

File

SqlExpr

Description

This is type SqlExpr.TLocale.

25.4.6 SqlExpr.TLocaleCode Type

TLocaleCode identifies a locale, which imposes a sort order on data.

Pascal

```
TLocaleCode = Integer;
```

C++

```
int TLocaleCode;
```

File

SqlExpr

Description

TLocaleCode is an integer that corresponds to a locale. A locale identifies the language of a string, and character set. The TLocaleCode type corresponds to the Windows LCID, but omits an explicit sort order.

25.4.7 SqlExpr.TParseInsertSqlEvent Type

Pascal

```
TParseInsertSqlEvent = procedure (var FieldNames: TWideStrings; SQL: UnicodeString; var
BindAllFields: Boolean; var TableName: UnicodeString) of object;
```

C++

```
(var FieldNames: TWideStrings; SQL: UnicodeString; var BindAllFields: Boolean; var TableName:
UnicodeString) ( TParseInsertSqlEvent)();
```

File

SqlExpr

Description

This is type SqlExpr.TParseInsertSqlEvent.

25.4.8 SqlExpr.TParseSqlEvent Type

Pascal

```
TParseSqlEvent = procedure (var FieldNames: TWideStrings; SQL: UnicodeString; var TableName:
UnicodeString) of object;
```

C++

```
(var FieldNames: TWideStrings; SQL: UnicodeString; var TableName: UnicodeString) (
TParseSqlEvent)();
```

File

SqlExpr

Description

This is type SqlExpr.TParseSqlEvent.

25.4.9 SqlExpr.TSQLConnectionLoginEvent Type

Pascal

```
TSQLConnectionLoginEvent = procedure (Database: TSQLConnection; LoginParams: TWideStrings) of
object;
```

C++

```
(Database: TSQLConnection; LoginParams: TWideStrings) ( TSQLConnectionLoginEvent)();
```

File

SqlExpr

Description

This is type SqlExpr.TSQLConnectionLoginEvent.

25.4.10 SqlExpr.TTableScopes Type

Pascal

```
TTableScopes = set of TTableScope;
```

C++

```
TTableScope TTableScopes;
```

File

SqlExpr

Description

This is type SqlExpr.TTableScopes.

25.4.11 SqlExpr.TTraceEvent Type

Pascal

```
TTraceEvent = procedure (Sender: TObject; TraceInfo: TDBXTraceInfo; var LogTrace: Boolean) of
object;
```

C++

```
(Sender: TObject; TraceInfo: TDBXTraceInfo; var LogTrace: Boolean) ( TTraceEvent)();
```

File

SqlExpr

Description

This is type SqlExpr.TTraceEvent.

25.4.12 SqlExpr.TTraceLogEvent Type

Pascal

```
TTraceLogEvent = procedure (Sender: TObject; TraceInfo: TDBXTraceInfo) of object;
```

C++

```
(Sender: TObject; TraceInfo: TDBXTraceInfo) ( TTraceLogEvent)();
```

File

SqlExpr

Description

This is type SqlExpr.TTraceLogEvent.

25.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
BlobTypeMap (see page 1711)	This is constant SqlExpr.BlobTypeMap.
DataTypeMap (see page 1712)	This is constant SqlExpr.DataTypeMap.
DefaultCursor (see page 1712)	This is constant SqlExpr.DefaultCursor.
DefaultMaxBlobSize (see page 1713)	This is constant SqlExpr.DefaultMaxBlobSize.
DefaultRowsetSize (see page 1713)	DefaultRowsetSize represents the default row buffering size.
eSQLAutoIncr (see page 1713)	This is constant SqlExpr.eSQLAutoIncr.
eSQLDefault (see page 1714)	This is constant SqlExpr.eSQLDefault.
eSQLFunction (see page 1714)	This is constant SqlExpr.eSQLFunction.
eSQLLocal (see page 1714)	This is constant SqlExpr.eSQLLocal.
eSQLNonUnique (see page 1715)	This is constant SqlExpr.eSQLNonUnique.
eSQLPackage (see page 1715)	This is constant SqlExpr.eSQLPackage.
eSQLPrimaryKey (see page 1715)	This is constant SqlExpr.eSQLPrimaryKey.
eSQLProcedure (see page 1716)	This is constant SqlExpr.eSQLProcedure.
eSQLRowId (see page 1716)	This is constant SqlExpr.eSQLRowId.
eSQLRowVersion (see page 1716)	This is constant SqlExpr.eSQLRowVersion.
eSQLSynonym (see page 1717)	This is constant SqlExpr.eSQLSynonym.
eSQLSysProcedure (see page 1717)	This is constant SqlExpr.eSQLSysProcedure.
eSQLSystemTable (see page 1717)	This is constant SqlExpr.eSQLSystemTable.
eSQLTable (see page 1718)	This is constant SqlExpr.eSQLTable.
eSQLTempTable (see page 1718)	This is constant SqlExpr.eSQLTempTable.
eSQLUnique (see page 1718)	This is constant SqlExpr.eSQLUnique.
eSQLView (see page 1719)	This is constant SqlExpr.eSQLView.
FldSubTypeMap (see page 1719)	This is constant SqlExpr.FldSubTypeMap.
FldTypeMap (see page 1719)	This is constant SqlExpr.FldTypeMap.
HourGlassCursor (see page 1720)	This is constant SqlExpr.HourGlassCursor.
SAnd (see page 1721)	This is constant SqlExpr.SAnd.
SOrderBy (see page 1721)	This is constant SqlExpr.SOrderBy.
SParam (see page 1721)	This is constant SqlExpr.SParam.
SSelect (see page 1722)	This is constant SqlExpr.SSelect.
SSelectSpaces (see page 1722)	This is constant SqlExpr.SSelectSpaces.
SSelectStar (see page 1722)	This is constant SqlExpr.SSelectStar.
SSelectStarFrom (see page 1723)	This is constant SqlExpr.SSelectStarFrom.
SUB_TYPE_MEMO (see page 1723)	This is constant SqlExpr.SUB_TYPE_MEMO.
SWhere (see page 1723)	This is constant SqlExpr.SWhere.
TErrorMessageSize (see page 1724)	This is constant SqlExpr.TErrorMessageSize.

25.5.1 SqlExpr.BlobTypeMap Constant

Pascal

```
BlobTypeMap: array[SUB_TYPE_MEMO..TDBXDataTypes.BFileSubType] of TFieldType = ( ftMemo,
ftBlob, ftFmtMemo, ftParadoxOle, ftGraphic, ftDBaseOle, ftTypedBinary, ftBlob, ftBlob, ftBlob,
ftWideMemo, ftOraClob, ftOraBlob, ftBlob, ftBlob);
```

C++

```
array[SUB_TYPE_MEMO..TDBXDataTypes.BFileSubType] of TFieldType BlobTypeMap = ( ftMemo, ftBlob,
ftFmtMemo, ftParadoxOle, ftGraphic, ftDBaseOle, ftTypedBinary, ftBlob, ftBlob, ftBlob,
ftWideMemo, ftOraClob, ftOraBlob, ftBlob, ftBlob);
```

File

SqlExpr

Description

This is constant SqlExpr.BlobTypeMap.

25.5.2 SqlExpr.DataTypeMap Constant

Pascal

```
DataTypeMap: array[0..TDBXDataTypes.MaxBaseTypes - 1] of TFieldType = ( ftUnknown, ftString,
ftDate, ftBlob, ftBoolean, ftSmallint, ftInteger, ftFloat, ftFMTBCD, ftBytes, ftTime,
ftDateTime, ftWord, ftInteger, ftUnknown, ftVarBytes, ftUnknown, ftCursor, ftLargeInt,
ftLargeInt, ftADT, ftArray, ftReference, ftDataSet, ftTimeStamp, ftBCD, ftWideString);
```

C++

```
array[0..TDBXDataTypes.MaxBaseTypes - 1] of TFieldType DataTypeMap = ( ftUnknown, ftString,
ftDate, ftBlob, ftBoolean, ftSmallint, ftInteger, ftFloat, ftFMTBCD, ftBytes, ftTime,
ftDateTime, ftWord, ftInteger, ftUnknown, ftVarBytes, ftUnknown, ftCursor, ftLargeInt,
ftLargeInt, ftADT, ftArray, ftReference, ftDataSet, ftTimeStamp, ftBCD, ftWideString);
```

File

SqlExpr

Description

This is constant SqlExpr.DataTypeMap.

25.5.3 SqlExpr.DefaultCursor Constant

Pascal

```
DefaultCursor = 0;
```

C++

```
DefaultCursor = 0;
```

File

SqlExpr

Description

This is constant SqlExpr.DefaultCursor.

25.5.4 SqlExpr.DefaultMaxBlobSize Constant

Pascal

```
DefaultMaxBlobSize = -1;
```

C++

```
DefaultMaxBlobSize = -1;
```

File

SqlExpr

Description

This is constant SqlExpr.DefaultMaxBlobSize.

25.5.5 SqlExpr.DefaultRowsetSize Constant

DefaultRowsetSize represents the default row buffering size.

Pascal

```
DefaultRowsetSize = DBXDefaultRowSetSize;
```

C++

```
DefaultRowsetSize = DBXDefaultRowSetSize;
```

File

SqlExpr

Description

The value of the DefaultRowsetSize constant is 20. To use a different RowSetSize for existing Oracle database connections, manually add the RowSetSize property (for example, RowSetSize = 200) to dbxconnections.ini (Windows) or dbxconnections.conf (Linux).

DBXDefaultRowSetSize

RowSetSize

25.5.6 SqlExpr.eSQLAutoIncr Constant

Pascal

```
eSQLAutoIncr = $0004;
```

C++

```
eSQLAutoIncr = 0x0004;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLAutoIncr.

25.5.7 SqlExpr.eSQLDefault Constant

Pascal

```
eSQLDefault = $0008;
```

C++

```
eSQLDefault = 0x0008;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLDefault.

25.5.8 SqlExpr.eSQLFunction Constant

Pascal

```
eSQLFunction = $0002;
```

C++

```
eSQLFunction = 0x0002;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLFunction.

25.5.9 SqlExpr.eSQLLocal Constant

Pascal

```
eSQLLocal = $0020;
```

C++

```
eSQLLocal = 0x0020;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLLocal.

25.5.10 SqlExpr.eSQLNonUnique Constant

Pascal

```
eSQLNonUnique = $0001;
```

C++

```
eSQLNonUnique = 0x0001;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLNonUnique.

25.5.11 SqlExpr.eSQLPackage Constant

Pascal

```
eSQLPackage = $0004;
```

C++

```
eSQLPackage = 0x0004;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLPackage.

25.5.12 SqlExpr.eSQLPrimaryKey Constant

Pascal

```
eSQLPrimaryKey = $0004;
```

C++

```
eSQLPrimaryKey = 0x0004;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLPrimaryKey.

25.5.13 SqlExpr.eSQLProcedure Constant

Pascal

```
eSQLProcedure = $0001;
```

C++

```
eSQLProcedure = 0x0001;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLProcedure.

25.5.14 SqlExpr.eSQLRowId Constant

Pascal

```
eSQLRowId = $0001;
```

C++

```
eSQLRowId = 0x0001;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLRowId.

25.5.15 SqlExpr.eSQLRowVersion Constant

Pascal

```
eSQLRowVersion = $0002;
```

C++

```
eSQLRowVersion = 0x0002;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLRowVersion.

25.5.16 SqlExpr.eSQLSynonym Constant

Pascal

```
eSQLSynonym = $0008;
```

C++

```
eSQLSynonym = 0x0008;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLSynonym.

25.5.17 SqlExpr.eSQLSysProcedure Constant

Pascal

```
eSQLSysProcedure = $0008;
```

C++

```
eSQLSysProcedure = 0x0008;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLSysProcedure.

25.5.18 SqlExpr.eSQLSystemTable Constant

Pascal

```
eSQLSystemTable = $0004;
```

C++

```
eSQLSystemTable = 0x0004;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLSystemTable.

25.5.19 SqlExpr.eSQLTable Constant

Pascal

```
eSQLTable = $0001;
```

C++

```
eSQLTable = 0x0001;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLTable.

25.5.20 SqlExpr.eSQLTempTable Constant

Pascal

```
eSQLTempTable = $0010;
```

C++

```
eSQLTempTable = 0x0010;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLTempTable.

25.5.21 SqlExpr.eSQLUnique Constant

Pascal

```
eSQLUnique = $0002;
```

C++

```
eSQLUnique = 0x0002;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLUnique.

25.5.22 SqlExpr.eSQLView Constant

Pascal

```
eSQLView = $0002;
```

C++

```
eSQLView = 0x0002;
```

File

SqlExpr

Description

This is constant SqlExpr.eSQLView.

25.5.23 SqlExpr.FldSubTypeMap Constant

Pascal

```
FldSubTypeMap: array[TFieldType] of Word = ( 0, 0, 0, 0, 0, 0, 0, TDBXDataTypes.MoneySubType,
0, 0, 0, 0, 0, 0, TDBXDataTypes.AutoIncSubType, TDBXDataTypes.BinarySubType,
TDBXDataTypes.MemoSubType, 0, 0, 0, 0, 0, 0, TDBXDataTypes.FixedSubType, 0, 0, 0, 0, 0, 0,
TDBXDataTypes.HBinarySubType, TDBXDataTypes.HMemoSubType, 0, 0, 0, 0, 0, 0,
TDBXDataTypes.FixedSubType, TDBXDataTypes.WideMemoSubType,
TDBXDataTypes.OracleTimeStampSubType, TDBXDataTypes.OracleIntervalSubType, 0, 0, 0, 0, 0, 0,
0);
```

C++

```
array[TFieldType] of Word FldSubTypeMap = ( 0, 0, 0, 0, 0, 0, 0, TDBXDataTypes.MoneySubType,
0, 0, 0, 0, 0, 0, TDBXDataTypes.AutoIncSubType, TDBXDataTypes.BinarySubType,
TDBXDataTypes.MemoSubType, 0, 0, 0, 0, 0, 0, TDBXDataTypes.FixedSubType, 0, 0, 0, 0, 0, 0,
TDBXDataTypes.HBinarySubType, TDBXDataTypes.HMemoSubType, 0, 0, 0, 0, 0, 0,
TDBXDataTypes.FixedSubType, TDBXDataTypes.WideMemoSubType,
TDBXDataTypes.OracleTimeStampSubType, TDBXDataTypes.OracleIntervalSubType, 0, 0, 0, 0, 0, 0,
0);
```

File

SqlExpr

Description

This is constant SqlExpr.FldSubTypeMap.

25.5.24 SqlExpr.FldTypeMap Constant

Pascal

```
FldTypeMap: TFieldMap = ( TDBXDataTypes.UnknownType, TDBXDataTypes.AnsiStringType,
TDBXDataTypes.Int16Type, TDBXDataTypes.Int32Type, TDBXDataTypes.UInt16Type,
TDBXDataTypes.BooleanType, TDBXDataTypes.DoubleType, TDBXDataTypes.DoubleType,
TDBXDataTypes.CurrencyType, TDBXDataTypes.DateType, TDBXDataTypes.TimeType,
TDBXDataTypes.TimeStampType, TDBXDataTypes.BytesType, TDBXDataTypes.VarBytesType,
```

```
  TDBXDataTypes.Int32Type, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.BlobType, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.BlobType, TDBXDataTypes.BlobType, TDBXDataTypes.CursorType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.WideStringType, TDBXDataTypes.Int64Type,
  TDBXDataTypes.AdtType, TDBXDataTypes.ArrayType, TDBXDataTypes.RefType,
  TDBXDataTypes.TableType, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.VariantType, TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.TimeStampType, TDBXDataTypes.BcdType,
  TDBXDataTypes.WideStringType, TDBXDataTypes.BlobType, TDBXDataTypes.TimeStampType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType,
  TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType, TDBXDataTypes.DBXConnectionType,
  TDBXDataTypes.TableType, TDBXDataTypes.BinaryBlobType);
```

C++

```
  TFieldMap FldTypeMap = ( TDBXDataTypes.UnknownType, TDBXDataTypes.AnsiStringType,
  TDBXDataTypes.Int16Type, TDBXDataTypes.Int32Type, TDBXDataTypes.UInt16Type,
  TDBXDataTypes.BooleanType, TDBXDataTypes.DoubleType, TDBXDataTypes.DoubleType,
  TDBXDataTypes.CurrencyType, TDBXDataTypes.DateType, TDBXDataTypes.TimeType,
  TDBXDataTypes.TimeStampType, TDBXDataTypes.BytesType, TDBXDataTypes.VarBytesType,
  TDBXDataTypes.Int32Type, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.BlobType, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.BlobType, TDBXDataTypes.BlobType, TDBXDataTypes.CursorType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.WideStringType, TDBXDataTypes.Int64Type,
  TDBXDataTypes.AdtType, TDBXDataTypes.ArrayType, TDBXDataTypes.RefType,
  TDBXDataTypes.TableType, TDBXDataTypes.BlobType, TDBXDataTypes.BlobType,
  TDBXDataTypes.VariantType, TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.TimeStampType, TDBXDataTypes.BcdType,
  TDBXDataTypes.WideStringType, TDBXDataTypes.BlobType, TDBXDataTypes.TimeStampType,
  TDBXDataTypes.AnsiStringType, TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType,
  TDBXDataTypes.UnknownType, TDBXDataTypes.UnknownType, TDBXDataTypes.DBXConnectionType,
  TDBXDataTypes.TableType, TDBXDataTypes.BinaryBlobType);
```

File

SqlExpr

Description

This is constant SqlExpr.FldTypeMap.

25.5.25 SqlExpr.HourGlassCursor Constant

Pascal

```
  HourGlassCursor = -11;
```

C++

```
  HourGlassCursor = -11;
```

File

SqlExpr

Description

This is constant SqlExpr.HourGlassCursor.

25.5.26 SqlExpr.SAnd Constant

Pascal

```
SAnd = ' and ';
```

C++

```
SAnd = ' and ';
```

File

SqlExpr

Description

This is constant SqlExpr.SAnd.

25.5.27 SqlExpr.SOrderBy Constant

Pascal

```
SOrderBy = ' order by ';
```

C++

```
SOrderBy = ' order by ';
```

File

SqlExpr

Description

This is constant SqlExpr.SOrderBy.

25.5.28 SqlExpr.SParam Constant

Pascal

```
SParam = '?';
```

C++

```
SParam = '?';
```

File

SqlExpr

Description

This is constant SqlExpr.SParam.

25.5.29 SqlExpr.SSelect Constant

Pascal

```
SSelect = 'select';
```

C++

```
SSelect = 'select';
```

File

SqlExpr

Description

This is constant SqlExpr.SSelect.

25.5.30 SqlExpr.SSelectSpaces Constant

Pascal

```
SSelectSpaces = ' select ';
```

C++

```
SSelectSpaces = ' select ';
```

File

SqlExpr

Description

This is constant SqlExpr.SSelectSpaces.

25.5.31 SqlExpr.SSelectStar Constant

Pascal

```
SSelectStar = ' select * ';
```

C++

```
SSelectStar = ' select * ';
```

File

SqlExpr

Description

This is constant SqlExpr.SSelectStar.

25.5.32 SqlExpr.SSelectStarFrom Constant

Pascal

```
SSelectStarFrom = ' select * from ';
```

C++

```
SSelectStarFrom = ' select * from ';
```

File

SqlExpr

Description

This is constant SqlExpr.SSelectStarFrom.

25.5.33 SqlExpr.SUB_TYPE_MEMO Constant

Pascal

```
SUB_TYPE_MEMO = TDBXDataTypes.MemoSubType;
```

C++

```
SUB_TYPE_MEMO = TDBXDataTypes.MemoSubType;
```

File

SqlExpr

Description

This is constant SqlExpr.SUB_TYPE_MEMO.

25.5.34 SqlExpr.SWhere Constant

Pascal

```
SWhere = ' where ';
```

C++

```
SWhere = ' where ';
```

File

SqlExpr

Description

This is constant SqlExpr.SWhere.

25.5.35 SqlExpr.TErrorMessageSize Constant

Pascal

```
TErrorMessageSize = 2048;
```

C++

```
TErrorMessageSize = 2048;
```

File

SqlExpr

Description

This is constant SqlExpr.TErrorMessageSize.

26 SqlTimSt Namespace

This is namespace SqlTimSt.

Topics

Name	Description
Classes (see page 1727)	The following table lists classes in this documentation.
Functions (see page 1729)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 1737)	The following table lists structs, records, enums in this documentation.
Types (see page 1739)	The following table lists types in this documentation.
Constants (see page 1740)	The following table lists constants in this documentation.

Classes

	Name	Description
	TTimeZone (see page 1727)	This is class SqlTimSt.TTimeZone.

Constants

Name	Description
NullSQLTimeStamp (see page 1740)	Represents a NULL TSQLTimeStamp (see page 1737) value.

Functions

	Name	Description
	CheckSqlTimeStamp (see page 1729)	Checks whether a TSQLTimeStamp (see page 1737) value represents a valid date and time.
	DateTimeToSQLTimeStamp (see page 1730)	Converts a TDateTime (see page 3323) value to a TSQLTimeStamp (see page 1737) value.
	LocalToUTC (see page 1730)	This is function SqlTimSt.LocalToUTC.
	SQLDayOfWeek (see page 1731)	Indicates the day of the week when a specified TSQLTimeStamp (see page 1737) value occurs.
	SQLTimeStampToDateTime (see page 1731)	Converts a TSQLTimeStamp (see page 1737) value to a TDateTime (see page 3323) value.
	SQLTimeStampToStr (see page 1732)	Converts a TSQLTimeStamp (see page 1737) value to a string.
	StrToSQLTimeStamp (see page 1732)	Converts a string to a TSQLTimeStamp (see page 1737) value.
	TryStrToSQLTimeStamp (see page 1733)	Converts a string to a TSQLTimeStamp (see page 1737) value.
	UTCToLocal (see page 1733)	This is function SqlTimSt.UTCToLocal.
	VarIsSQLTimeStamp (see page 1734)	Indicates whether a specified Variant (see page 3421) represents a TSQLTimeStamp (see page 1737) value.

	VarSQLTimeStamp (see page 1734)	Returns the TVarType (see page 3801) constant that identifies the internal type of a Variant (see page 3421) as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarToSQLTimeStamp (see page 1736)	Converts a Variant (see page 3421) that represents a TSQLTimeStamp (see page 1737) value to the corresponding TSQLTimeStamp (see page 1737).

Structs, Records, Enums

	Name	Description
	TSQLTimeStamp (see page 1737)	TSQLTimeStamp represents time and date values with a high degree of accuracy.

Types

Name	Description
PSQLTimeStamp (see page 1739)	This is type SqlTimSt.PSQLTimeStamp.

26.1 Classes

The following table lists classes in this documentation.

Records

	Name	Description
	TTimeZone (see page 1727)	This is class SqlTimSt.TTimeZone.

26.1.1 TTimeZone Record

Pascal

```
TTimeZone = record
  FUsesDayligtSavings: Boolean;
  FInfo: TTimeZoneInformation;
end;
```

C++

```
struct TTimeZone {
  Boolean FUsesDayligtSavings;
  TTimeZoneInformation FInfo;
};
```

File

SqlTimSt

Description

This is class SqlTimSt.TTimeZone.

26.1.1.1 TTimeZone Members

The following tables list the members exposed by TTimeZone.

Public Fields

	Name	Description
	FInfo (see page 1728)	This is FInfo, a member of class TTimeZone.
	FUsesDayligtSavings (see page 1728)	This is FUsesDayligtSavings, a member of class TTimeZone.

Public Methods

	Name	Description
	GetTimeZone (see page 1728)	This is GetTimeZone, a member of class TTimeZone.

26.1.1.2 TTimeZone Fields

The fields of the TTimeZone class are listed here.

Public Fields

	Name	Description
	FInfo (see page 1728)	This is FInfo, a member of class TTimeZone.
	FUsesDayligtSavings (see page 1728)	This is FUsesDayligtSavings, a member of class TTimeZone.

26.1.1.2.1 TTimeZone.FInfo Field

Pascal

```
FInfo: TTimeZoneInformation;
```

C++

```
TTimeZoneInformation FInfo;
```

Description

This is FInfo, a member of class TTimeZone.

26.1.1.2.2 TTimeZone.FUsesDayligtSavings Field

Pascal

```
FUsesDayligtSavings: Boolean;
```

C++

```
Boolean FUsesDayligtSavings;
```

Description

This is FUsesDayligtSavings, a member of class TTimeZone.

26.1.1.3 TTimeZone Methods

The methods of the TTimeZone class are listed here.

Public Methods

	Name	Description
	GetTimeZone (see page 1728)	This is GetTimeZone, a member of class TTimeZone.

26.1.1.3.1 TTimeZone.GetTimeZone Method

Pascal

```
class function GetTimeZone: TTimeZone; static;
```

C++

```
static __fastcall TTimeZone GetTimeZone();
```

Description

This is GetTimeZone, a member of class TTimeZone.

26.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CheckSqlTimeStamp (see page 1729)	Checks whether a TSQLTimeStamp (see page 1737) value represents a valid date and time.
	DateTimeToSQLTimeStamp (see page 1730)	Converts a TDateTime (see page 3323) value to a TSQLTimeStamp (see page 1737) value.
	LocalToUTC (see page 1730)	This is function SqlTimSt.LocalToUTC.
	SQLDayOfWeek (see page 1731)	Indicates the day of the week when a specified TSQLTimeStamp (see page 1737) value occurs.
	SQLTimeStampToDateTime (see page 1731)	Converts a TSQLTimeStamp (see page 1737) value to a TDateTime (see page 3323) value.
	SQLTimeStampToStr (see page 1732)	Converts a TSQLTimeStamp (see page 1737) value to a string.
	StrToSQLTimeStamp (see page 1732)	Converts a string to a TSQLTimeStamp (see page 1737) value.
	TryStrToSQLTimeStamp (see page 1733)	Converts a string to a TSQLTimeStamp (see page 1737) value.
	UTCToLocal (see page 1733)	This is function SqlTimSt.UTCToLocal.
	VarIsSQLTimeStamp (see page 1734)	Indicates whether a specified Variant (see page 3421) represents a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStamp (see page 1734)	Returns the TVarType (see page 3801) constant that identifies the internal type of a Variant (see page 3421) as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarSQLTimeStampCreate (see page 1735)	Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.
	VarToSQLTimeStamp (see page 1736)	Converts a Variant (see page 3421) that represents a TSQLTimeStamp (see page 1737) value to the corresponding TSQLTimeStamp (see page 1737).

26.2.1 SqlTimSt.CheckSqlTimeStamp Function

Checks whether a TSQLTimeStamp (see page 1737) value represents a valid date and time.

Pascal

```
procedure CheckSqlTimeStamp(const ASQLTimeStamp: TSQLTimeStamp);
```

C++

```
CheckSqlTimeStamp(const TSQLTimeStamp ASQLTimeStamp);
```

File

SqlTimSt

Description

CheckSqlTimeStamp checks that the specified TSQLTimeStamp (see page 1737) value represents a valid date and time. If

the fields of the ASQLTimeStamp parameter are out of the valid range, CheckSqlTimeStamp raises an EConversionError exception.

See Also

EConvertError (see page 3919)

26.2.2 SqlTimSt.DateTimeToSQLTimeStamp Function

Converts a TDateTime (see page 3323) value to a TSQLTimeStamp (see page 1737) value.

Pascal

```
function DateTimeToSQLTimeStamp(const DateTime: TDateTime): TSQLTimeStamp;
```

C++

```
TSQLTimeStamp DateTimeToSQLTimeStamp(const TDateTime DateTime);
```

File

SqlTimSt

Description

Use DateTimeToSQLTimeStamp to convert the TDateTime (see page 3323) value specified by DateTime to a TSQLTimeStamp (see page 1737) value.

See Also

SQLTimeStampToDateTime (see page 1731)

SQLTimeStampToStr (see page 1732)

StrToSQLTimeStamp (see page 1732)

TSQLTimeStampField

26.2.3 SqlTimSt.LocalToUTC Function

Pascal

```
function LocalToUTC(var TZInfo: TTimeZone; var Value: TSQLTimeStamp): TSQLTimeStamp;
```

C++

```
TSQLTimeStamp LocalToUTC(TTimeZone TZInfo, TSQLTimeStamp Value);
```

File

SqlTimSt

Description

This is function SqlTimSt.LocalToUTC.

26.2.4 SqlTimSt.SQLDayOfWeek Function

Indicates the day of the week when a specified TSQLTimeStamp (see page 1737) value occurs.

Pascal

```
function SQLDayOfWeek(const DateTime: TSQLTimeStamp): integer;
```

C++

```
int SQLDayOfWeek(const TSQLTimeStamp DateTime);
```

File

SqlTimSt

Description

SQLDayOfWeek returns the day of the week of the specified date as an integer between 1 and 7, where Sunday is the first day of the week and Saturday is the seventh.

See Also

DayOfWeek (see page 4094)

26.2.5 SqlTimSt.SQLTimeStampToDateTime Function

Converts a TSQLTimeStamp (see page 1737) value to a TDateTime (see page 3323) value.

Pascal

```
function SQLTimeStampToDateTime(const DateTime: TSQLTimeStamp): TDateTime;
```

C++

```
TDateTime SQLTimeStampToDateTime(const TSQLTimeStamp DateTime);
```

File

SqlTimSt

Description

Use SQLTimeStampToDateTime to convert the TSQLTimeStamp (see page 1737) value specified by DateTime to a TDateTime (see page 3323) value.

See Also

DateTimeToSQLTimeStamp (see page 1730)

SQLTimeStampToStr (see page 1732)

StrToSQLTimeStamp (see page 1732)

TSQLTimeStampField

26.2.6 SqlTimSt.SQLTimeStampToStr Function

Converts a TSQLTimeStamp (see page 1737) value to a string.

Pascal

```
function SQLTimeStampToStr(const Format: string; DateTime: TSQLTimeStamp): string;
```

C++

```
UnicodeString SQLTimeStampToStr(const UnicodeString Format, TSQLTimeStamp DateTime);
```

File

SqlTimSt

Description

Use SQLTimeStampToStr to convert a TSQLTimeStamp (see page 1737) value to a string an AnsiString.

DateTimeToStr converts the TSQLTimeStamp (see page 1737) value given by DateTime using the format given by Format and returns the resulting string.

If the string specified by the Format parameter is empty, the TSQLTimeStamp (see page 1737) value is formatted using the ShortDateFormat global variable followed by the LongTimeFormat global variable. The time is not displayed if all time fields in the DateTime parameter are 0.

To create a format string for the Format parameter, use the standard date-time format specifiers:

DateTimeToSQLTimeStamp (see page 1730)

SQLTimeStampToDateTime (see page 1731)

StrToSQLTimeStamp (see page 1732)

TSQLTimeStampField

TryStrToSQLTimeStamp (see page 1733)

26.2.7 SqlTimSt.StrToSQLTimeStamp Function

Converts a string to a TSQLTimeStamp (see page 1737) value.

Pascal

```
function StrToSQLTimeStamp(const S: string): TSQLTimeStamp;
```

C++

```
TSQLTimeStamp StrToSQLTimeStamp(const UnicodeString S);
```

File

SqlTimSt

Description

Use StrToSQLTimeStamp to convert the string S to a TSQLTimeStamp (see page 1737) value. If S does not represent a valid date-and-time value, StrToSQLTimeStamp raises an EConvertError exception.

Tip: To convert strings to TSQLTimeStamp (see page 1737) values without raising an exception when the string is not a valid date-and-time, use TryStrToSQLTimeStamp (see page 1733) instead.

See Also

DateTimeToSQLTimeStamp (see page 1730)

SQLTimeStampToStr (see page 1732)

SQLTimeStampToDateTime (see page 1731)

TSQLTimeStampField

EConvertError (see page 3919)

TryStrToSQLTimeStamp (see page 1733)

26.2.8 SqlTimSt.TryStrToSQLTimeStamp Function

Converts a string to a TSQLTimeStamp (see page 1737) value.

Pascal

```
function TryStrToSQLTimeStamp(const S: string; var TimeStamp: TSQLTimeStamp): Boolean;
```

C++

```
Boolean TryStrToSQLTimeStamp(const UnicodeString S, TSQLTimeStamp TimeStamp);
```

File

SqlTimSt

Description

Use TryStrToSQLTimeStamp to convert the string S to a TSQLTimeStamp (see page 1737) value.

If S can be converted to a TSQLTimeStamp (see page 1737) value, the result is returned as the TimeStamp parameter and TryStrToSQLTimeStamp returns true.

If S can't be converted to a TSQLTimeStamp (see page 1737) value, TimeStamp is set to NullSQLTimeStamp (see page 1740) and TryStrToSQLTimeStamp returns false.

See Also

DateTimeToSQLTimeStamp (see page 1730)

SQLTimeStampToStr (see page 1732)

SQLTimeStampToDateTime (see page 1731)

NullSQLTimeStamp (see page 1740)

StrToSQLTimeStamp (see page 1732)

26.2.9 SqlTimSt.UTCToLocal Function

Pascal

```
function UTCToLocal(var TZInfo: TTimeZone; var Value: TSQLTimeStamp): TSQLTimeStamp;
```

C++

```
TSQLTimeStamp UTCToLocal(TTimeZone TZInfo, TSQLTimeStamp Value);
```

File

SqlTimSt

Description

This is function SqlTimSt.UTCToLocal.

26.2.10 SqlTimSt.VarIsSQLTimeStamp Function

Indicates whether a specified Variant (see page 3421) represents a TSQLTimeStamp (see page 1737) value.

Pascal

```
function VarIsSQLTimeStamp(const aValue: Variant): Boolean; overload;
```

C++

```
Boolean VarIsSQLTimeStamp(const Variant aValue);
```

File

SqlTimSt

Description

VarIsSQLTimeStamp returns true if the Variant (see page 3421) aValue stores its value internally as a TSQLTimeStamp (see page 1737) value. VarIsSQLTimeStamp returns false otherwise.

See Also

VarToSQLTimeStamp (see page 1736)

TSQLTimeStamp (see page 1737)

26.2.11 SqlTimSt.VarSQLTimeStamp Function

Returns the TVarType (see page 3801) constant that identifies the internal type of a Variant (see page 3421) as a TSQLTimeStamp (see page 1737) value.

Pascal

```
function VarSQLTimeStamp: TVarType;
```

C++

```
TVarType VarSQLTimeStamp();
```

File

SqlTimSt

Description

VarSQLTimeStamp returns the TVarType (see page 3801) constant that identifies a TSQLTimeStamp (see page 1737)-valued Variant (see page 3421). This is the value that the VarType (see page 5090) function returns when the Variant (see page 3421) stores its value as a TSQLTimeStamp (see page 1737) value.

The Variant (see page 3421) type codes for custom Variants (see page 4973) are dynamically allocated when the application loads the unit that implements them. VarSQLTimeStamp allows the application to identify the Variant (see page 3421) type code that is currently used for custom Variants (see page 4973) that represent an SQL time stamp. This value, however, may not match the type code used by another application that uses a different set of custom Variant (see page 3421) types.

See Also

VarIsSQLTimeStamp (see page 1734)

VarType (see page 5090)

TSQLTimeStamp (see page 1737)

VarToSQLTimeStamp (see page 1736)

26.2.12 SqlTimSt.VarSQLTimeStampCreate Function

Creates a new Variant (see page 3421) that stores its value internally as a TSQLTimeStamp (see page 1737) value.

Pascal

```
procedure VarSQLTimeStampCreate(var aDest: Variant; const ASQLTimeStamp: TSQLTimeStamp);
overload;
function VarSQLTimeStampCreate: Variant; overload;
function VarSQLTimeStampCreate(const AValue: string): Variant; overload;
function VarSQLTimeStampCreate(const AValue: TDateTime): Variant; overload;
function VarSQLTimeStampCreate(const ASQLTimeStamp: TSQLTimeStamp): Variant; overload;
```

C++

```
VarSQLTimeStampCreate(Variant aDest, const TSQLTimeStamp ASQLTimeStamp);
Variant VarSQLTimeStampCreate();
Variant VarSQLTimeStampCreate(const UnicodeString AValue);
Variant VarSQLTimeStampCreate(const TDateTime AValue);
Variant VarSQLTimeStampCreate(const TSQLTimeStamp ASQLTimeStamp);
```

File

SqlTimSt

Description

Call VarSQLTimeStampCreate to obtain a Variant (see page 3421) that stores its value as a TSQLTimeStamp (see page 1737) value.

Using the first syntax, the Variant (see page 3421) returned as aDest has the same value as ASQLTimeStamp.

Using the second syntax (passing no arguments), the returned Variant (see page 3421) has a value of NullSQLTimeStamp (see page 1740).

Using the third syntax, the returned Variant (see page 3421) has the same value as ASQLTimeStamp.

Using the fourth syntax, the returned Variant (see page 3421) represents the same date and time as the TDateTime (see page 3323) value AValue.

See Also

VarIsSQLTimeStamp (see page 1734)

VarToSQLTimeStamp (see page 1736)

NullSQLTimeStamp (see page 1740)

26.2.13 SqlTimSt.VarToSQLTimeStamp Function

Converts a Variant (see page 3421) that represents a TSQLTimeStamp (see page 1737) value to the corresponding TSQLTimeStamp (see page 1737).

Pascal

```
function VarToSQLTimeStamp(const aValue: Variant): TSQLTimeStamp;
```

C++

```
TSQLTimeStamp VarToSQLTimeStamp(const Variant aValue);
```

File

SqlTimSt

Description

Use VarToSQLTimeStamp to obtain a TSQLTimeStamp (see page 1737) from a variant whose value represents a date-and-time value. If the Variant (see page 3421) is a Null (see page 5056) Variant (see page 3421), VarToSQLTimeStamp returns NullSQLTimeStamp (see page 1740).

See Also

VarIsSQLTimeStamp (see page 1734)

TSQLTimeStamp (see page 1737)

NullSQLTimeStamp (see page 1740)

26.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TSQLTimeStamp (see page 1737)	TSQLTimeStamp represents time and date values with a high degree of accuracy.

26.3.1 SqlTimSt.TSQLTimeStamp Record

TSQLTimeStamp represents time and date values with a high degree of accuracy.

Pascal

```
TSQLTimeStamp = packed record
  Year: SmallInt;
  Month: Word;
  Day: Word;
  Hour: Word;
  Minute: Word;
  Second: Word;
  Fractions: LongWord;
end;
```

C++

```
struct TSQLTimeStamp {
  SmallInt Year;
  Word Month;
  Word Day;
  Word Hour;
  Word Minute;
  Word Second;
  LongWord Fractions;
};
```

File

SqlTimSt

Description

The dbExpress database drivers use TSQLTimeStamp when working with date and time information. Year specifies a year from 1 to 9999. Month specifies a month from 1 to 12. Day specifies a day of the month, from 1 through 28, 29, 30, or 31, depending on the Month value. Hour specifies the hour from 0 to 23. Minute and Second can range from 0 to 59. Fractions specifies milliseconds from 0 to 999.

You can create a Variant (see page 3421) that represents a TSQLTimeStamp value using the VarSQLTimeStampCreate (see page 1735) function. In fact, the easiest way to manipulate TSQLTimeStamp values is to create such a Variant (see page 3421) and use the built-in operators provided by the Variant (see page 3421) type.

See Also

TDateTime (see page 3787)

TTimeStamp (see page 4334)

TSQLTimeStampField

SQLTimeStampToDateTime (see page 1731)

SQLTimeStampToStr (see page 1732)

SQLDayOfWeek (see page 1731)

26.4 Types

The following table lists types in this documentation.

Types

Name	Description
PSQLTimeStamp (see page 1739)	This is type SqlTimSt.PSQLTimeStamp.

26.4.1 SqlTimSt.PSQLTimeStamp Type

Pascal

```
PSQLTimeStamp = ^TSQLTimeStamp;
```

C++

```
^TSQLTimeStamp PSQLTimeStamp;
```

File

SqlTimSt

Description

This is type SqlTimSt.PSQLTimeStamp.

26.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
NullSQLTimeStamp (see page 1740)	Represents a NULL TSQLTimeStamp (see page 1737) value.

26.5.1 SqlTimSt.NullSQLTimeStamp Constant

Represents a NULL TSQLTimeStamp (see page 1737) value.

Pascal

```
NullSQLTimeStamp: TSQLTimeStamp = (Year: 0; Month: 0; Day: 0; Hour: 0; Minute: 0; Second: 0;
Fractions: 0);
```

C++

```
TSQLTimeStamp NullSQLTimeStamp = (Year: 0; Month: 0; Day: 0; Hour: 0; Minute: 0; Second: 0;
Fractions: 0);
```

File

SqlTimSt

Description

Use NullSQLTimeStamp to indicate an unknown or missing TSQLTimeStamp (see page 1737) value.

See Also

Null (see page 5056)

27 StdActnMenus Namespace

This is namespace StdActnMenus.

Topics

Name	Description
Classes (see page 1742)	The following table lists classes in this documentation.
Functions (see page 1760)	The following table lists functions in this documentation.

Classes

	Name	Description
	TStandardAddRemoveItem (see page 1742)	TStandardAddRemoveItem is the ActionBand menu class for customizing action bands.
	TStandardButtonControl (see page 1744)	This is class StdActnMenus.TStandardButtonControl.
	TStandardCustomizePopup (see page 1745)	This is class StdActnMenus.TStandardCustomizePopup.
	TStandardDropDownButton (see page 1747)	This is class StdActnMenus.TStandardDropDownButton.
	TStandardMenuButton (see page 1748)	TStandardMenuButton is the standard ActionBand menu button class.
	TStandardMenuExpandBtn (see page 1750)	This is class StdActnMenus.TStandardMenuExpandBtn.
	TStandardMenuItem (see page 1751)	TStandardMenuItem is the default class for menu items in an action band.
	TStandardMenuPopup (see page 1756)	TStandardMenuPopup is the default menu popup style.
	TStandardToolScrollBtn (see page 1758)	This is class StdActnMenus.TStandardToolScrollBtn.

Functions

	Name	Description
	RegisterStandardMenus (see page 1760)	This is function StdActnMenus.RegisterStandardMenus.

27.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TStandardAddRemoveItem (see page 1742)	TStandardAddRemoveItem is the ActionBand menu class for customizing action bands.
	TStandardButtonControl (see page 1744)	This is class StdActnMenus.TStandardButtonControl.
	TStandardCustomizePopup (see page 1745)	This is class StdActnMenus.TStandardCustomizePopup.
	TStandardDropDownButton (see page 1747)	This is class StdActnMenus.TStandardDropDownButton.
	TStandardMenuButton (see page 1748)	TStandardMenuButton is the standard ActionBand menu button class.
	TStandardMenuExpandBtn (see page 1750)	This is class StdActnMenus.TStandardMenuExpandBtn.
	TStandardMenuItem (see page 1751)	TStandardMenuItem is the default class for menu items in an action band.
	TStandardMenuPopup (see page 1756)	TStandardMenuPopup is the default menu popup style.
	TStandardToolScrollBtn (see page 1758)	This is class StdActnMenus.TStandardToolScrollBtn.

27.1.1 TStandardAddRemoveItem Class

TStandardAddRemoveItem is the ActionBand menu class for customizing action bands.

Class Hierarchy

Pascal

```
TStandardAddRemoveItem = class(TCustomAddRemoveItem);
```

C++

```
class TStandardAddRemoveItem : public TCustomAddRemoveItem;
```

File

StdActnMenus

Description

TStandardAddRemoveItem is the standard ActionBand menu for customizing action bands at runtime.

Do not create instances of TStandardAddRemoveItem as this will be done for you automatically if the class is the default customization menu. If you would like to replace the standard customization menu, use the class TCustomAddRemoveItem as a parent class for your replacement class. To make the change for your application, set the value of MenuAddRemoveItemClass (a global variable) to your own subclass of TCustomAddRemoveItem instead of TStandardAddRemoveItem.

See Also

TCustomAddRemoveItem

27.1.1.1 TStandardAddRemoveItem Members

The following tables list the members exposed by TStandardAddRemoveItem.

Protected Methods

	Name	Description
	DrawBackground (see page 1743)	Draws a background image on the customization menu.
	DrawGlyph (see page 1743)	Draws a symbol on the control.

27.1.1.2 TStandardAddRemoveItem Methods

The methods of the TStandardAddRemoveItem class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 1743)	Draws a background image on the customization menu.
	DrawGlyph (see page 1743)	Draws a symbol on the control.

27.1.1.2.1 TStandardAddRemoveItem.DrawBackground Method

Draws a background image on the customization menu.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

This method is largely the same as the inherited method, with some modifications to account for the method of selection. See the inherited method for more details.

See Also

DrawBackground

DrawGlyph (see page 1743)

DrawText

27.1.1.2.2 TStandardAddRemoveItem.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

DrawGlyph performs the same function as the method it inherits from, and it does call the inherited method. The override sets many of the draw parameters based on the present state of the menu and how it has been selected.

See Also

DrawGlyph

DrawBackground (see page 1743)

DrawText

27.1.2 TStandardButtonControl Class

Class Hierarchy

Pascal

```
TStandardButtonControl = class(TCustomButtonControl);
```

C++

```
class TStandardButtonControl : public TCustomButtonControl;
```

File

StdActnMenus

Description

This is class StdActnMenus.TStandardButtonControl.

27.1.2.1 TStandardButtonControl Members

The following tables list the members exposed by TStandardButtonControl.

Protected Methods

	Name	Description
	DrawFrame (see page 1744)	This is DrawFrame, a member of class TStandardButtonControl.
	DrawGlyph (see page 1745)	Draws a symbol on the control.
	DrawText (see page 1745)	This is DrawText, a member of class TStandardButtonControl.

27.1.2.2 TStandardButtonControl Methods

The methods of the TStandardButtonControl class are listed here.

Protected Methods

	Name	Description
	DrawFrame (see page 1744)	This is DrawFrame, a member of class TStandardButtonControl.
	DrawGlyph (see page 1745)	Draws a symbol on the control.
	DrawText (see page 1745)	This is DrawText, a member of class TStandardButtonControl.

27.1.2.2.1 TStandardButtonControl.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TStandardButtonControl.

27.1.2.2.2 TStandardButtonControl.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

27.1.2.2.3 TStandardButtonControl.DrawText Method

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TStandardButtonControl.

27.1.3 TStandardCustomizePopup Class

Class Hierarchy

Pascal

```
TStandardCustomizePopup = class(TCustomizeActionToolBar);
```

C++

```
class TStandardCustomizePopup : public TCustomizeActionToolBar;
```

File

StdActnMenus

Description

This is class StdActnMenus.TStandardCustomizePopup.

27.1.3.1 TStandardCustomizePopup Members

The following tables list the members exposed by TStandardCustomizePopup.

Protected Methods

	Name	Description
	CanAutoSize (see page 1746)	Indicates how the control can be resized.
	NCPaint (see page 1746)	This is NCPaint, a member of class TStandardCustomizePopup.
	PositionPopup (see page 1747)	This is PositionPopup, a member of class TStandardCustomizePopup.

27.1.3.2 TStandardCustomizePopup Methods

The methods of the TStandardCustomizePopup class are listed here.

Protected Methods

	Name	Description
	CanAutoSize (see page 1746)	Indicates how the control can be resized.
	NCPaint (see page 1746)	This is NCPaint, a member of class TStandardCustomizePopup.
	PositionPopup (see page 1747)	This is PositionPopup, a member of class TStandardCustomizePopup.

27.1.3.2.1 TStandardCustomizePopup.CanAutoSize Method

Indicates how the control can be resized.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize property before the resize sequence that begins with the OnCanResize and OnConstrainedResize events and ends with the OnResize event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width and Height, CanAutoSize returns false, and the resize sequence is aborted.

As implemented in TWinControl, CanAutoSize returns true, adjusting NewWidth and NewHeight so that all the control's children fit.

Constraints

ConstrainedResize

AdjustSize

27.1.3.2.2 TStandardCustomizePopup.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TStandardCustomizePopup.

27.1.3.2.3 TStandardCustomizePopup.PositionPopup Method

Pascal

```
procedure PositionPopup(AnOwner: TCustomActionBar; ParentItem: TCustomActionControl); override;
```

C++

```
virtual __fastcall PositionPopup(TCustomActionBar AnOwner, TCustomActionControl ParentItem);
```

Description

This is PositionPopup, a member of class TStandardCustomizePopup.

27.1.4 TStandardDropDownButton Class

Class Hierarchy

Pascal

```
TStandardDropDownButton = class(TCustomDropDownButton);
```

C++

```
class TStandardDropDownButton : public TCustomDropDownButton;
```

File

StdActnMenus

Description

This is class StdActnMenus.TStandardDropDownButton.

27.1.4.1 TStandardDropDownButton Members

The following tables list the members exposed by TStandardDropDownButton.

Protected Methods

	Name	Description
	DrawFrame (see page 1748)	This is DrawFrame, a member of class TStandardDropDownButton.
	GetPopupClass (see page 1748)	This is GetPopupClass, a member of class TStandardDropDownButton.

27.1.4.2 TStandardDropDownButton Methods

The methods of the TStandardDropDownButton class are listed here.

Protected Methods

	Name	Description
	DrawFrame (see page 1748)	This is DrawFrame, a member of class TStandardDropDownButton.
	GetPopupClass (see page 1748)	This is GetPopupClass, a member of class TStandardDropDownButton.

27.1.4.2.1 TStandardDropDownButton.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TStandardDropDownButton.

27.1.4.2.2 TStandardDropDownButton.GetPopupClass Method

Pascal

```
function GetPopupClass: TCustomActionBarClass; override;
```

C++

```
virtual __fastcall TCustomActionBarClass GetPopupClass();
```

Description

This is GetPopupClass, a member of class TStandardDropDownButton.

27.1.5 TStandardMenuButton Class

TStandardMenuButton is the standard ActionBand menu button class.

Class Hierarchy

Pascal

```
TStandardMenuButton = class(TCustomMenuButton);
```

C++

```
class TStandardMenuButton : public TCustomMenuButton;
```

File

StdActnMenus

Description

TStandardMenuButton is the standard menu button class. If you would like to replace the standard menu button behaviors, use the class TCustomMenuButton as a parent class for your replacement class. To make the change for your application, set the value of MenuButtonControlClass (a global variable) to your own subclass of TCustomMenuButton instead of TStandardMenuButton.

See Also

TCustomMenuButton

27.1.5.1 TStandardMenuButton Members

The following tables list the members exposed by TStandardMenuButton.

Protected Methods

	Name	Description
	DrawBackground (see page 1749)	Draws a background image on the control.
	DrawDesignFocus (see page 1749)	This is DrawDesignFocus, a member of class TStandardMenuButton.
	DrawFrame (see page 1750)	This is DrawFrame, a member of class TStandardMenuButton.
	DrawText (see page 1750)	This is DrawText, a member of class TStandardMenuButton.

27.1.5.2 TStandardMenuButton Methods

The methods of the TStandardMenuButton class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 1749)	Draws a background image on the control.
	DrawDesignFocus (see page 1749)	This is DrawDesignFocus, a member of class TStandardMenuButton.
	DrawFrame (see page 1750)	This is DrawFrame, a member of class TStandardMenuButton.
	DrawText (see page 1750)	This is DrawText, a member of class TStandardMenuButton.

27.1.5.2.1 TStandardMenuButton.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

27.1.5.2.2 TStandardMenuButton.DrawDesignFocus Method

Pascal

```
procedure DrawDesignFocus(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawDesignFocus(TRect PaintRect);
```

Description

This is DrawDesignFocus, a member of class TStandardMenuButton.

27.1.5.2.3 TStandardMenuButton.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TStandardMenuButton.

27.1.5.2.4 TStandardMenuButton.DrawText Method

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TStandardMenuButton.

27.1.6 TStandardMenuExpandBtn Class

Class Hierarchy

Pascal

```
TStandardMenuExpandBtn = class(TCustomMenuExpandBtn);
```

C++

```
class TStandardMenuExpandBtn : public TCustomMenuExpandBtn;
```

File

StdActnMenus

Description

This is class StdActnMenus.TStandardMenuExpandBtn.

27.1.6.1 TStandardMenuExpandBtn Members

The following tables list the members exposed by TStandardMenuExpandBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 1751)	Draws a background image on the control.
	DrawFrame (see page 1751)	This is DrawFrame, a member of class TStandardMenuExpandBtn.

27.1.6.2 TStandardMenuExpandBtn Methods

The methods of the TStandardMenuExpandBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 1751)	Draws a background image on the control.
	DrawFrame (see page 1751)	This is DrawFrame, a member of class TStandardMenuExpandBtn.

27.1.6.2.1 TStandardMenuExpandBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

DrawGlyph

DrawText

27.1.6.2.2 TStandardMenuExpandBtn.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TStandardMenuExpandBtn.

27.1.7 TStandardMenuItem Class

TStandardMenuItem is the default class for menu items in an action band.

Class Hierarchy

Pascal

```
TStandardMenuItem = class(TCustomMenuItem);
```

C++

```
class TStandardMenuItem : public TCustomMenuItem;
```

File

StdActnMenus

Description

TStandardMenuItem is the class that action bands use to generate child controls that are menu items. Do not create instances of TStandardMenuItem. The action manager automatically handles the creating of TStandardMenuItem instances to represent the actions it contains.

If you want to replace the class used for menu items, derive your own replacement class from TCustomMenuItem. To substitute your replacement class, set the value of the global MenuItemControlClass variable to your TCustomMenuItem descendant.

TStandardMenuButton (see page 1748)

TStandardMenuPopup (see page 1756)

MenuItemControlClass

27.1.7.1 TStandardMenuItem Members

The following tables list the members exposed by TStandardMenuItem.

Protected Methods

	Name	Description
	CMTextchanged (see page 1753)	Responds when this menu item's caption changes.
V	DrawBackground (see page 1753)	Draws the background of the menu item.
V	DrawDesignFocus (see page 1753)	This is DrawDesignFocus, a member of class TStandardMenuItem.
V	DrawEdge (see page 1754)	This is DrawEdge, a member of class TStandardMenuItem.
V	DrawGlyph (see page 1754)	Draws a symbol on the menu item.
	DrawGlyphFrame (see page 1754)	This is DrawGlyphFrame, a member of class TStandardMenuItem.
V	DrawLargeGlyph (see page 1755)	This is DrawLargeGlyph, a member of class TStandardMenuItem.
V	DrawSeparator (see page 1755)	Draws a separator.
V	DrawText (see page 1755)	Draws the menu item's text.

27.1.7.2 TStandardMenuItem Methods

The methods of the TStandardMenuItem class are listed here.

Protected Methods

	Name	Description
	CMTextchanged (see page 1753)	Responds when this menu item's caption changes.
V	DrawBackground (see page 1753)	Draws the background of the menu item.
V	DrawDesignFocus (see page 1753)	This is DrawDesignFocus, a member of class TStandardMenuItem.
V	DrawEdge (see page 1754)	This is DrawEdge, a member of class TStandardMenuItem.
V	DrawGlyph (see page 1754)	Draws a symbol on the menu item.
	DrawGlyphFrame (see page 1754)	This is DrawGlyphFrame, a member of class TStandardMenuItem.
V	DrawLargeGlyph (see page 1755)	This is DrawLargeGlyph, a member of class TStandardMenuItem.

	DrawSeparator (see page 1755)	Draws a separator.
	DrawText (see page 1755)	Draws the menu item's text.

27.1.7.2.1 TStandardMenuItem.CMTextchanged Method

Responds when this menu item's caption changes.

Pascal

```
procedure CMTextchanged(var Message: TMessage); message CM_TEXTCHANGED;
```

C++

```
__fastcall CMTextchanged(TMessage Message);
```

Description

This method is called automatically in response to Windows messages containing a notification that the text of this menu item has changed.

Message represents the Windows message that notifies this menu item of a change to its text.

CMTextchanged recalculates the string it displays when the menu item is not underlining its accelerator key.

See Also

PersistentHotKeys

27.1.7.2.2 TStandardMenuItem.DrawBackground Method

Draws the background of the menu item.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

This method is called automatically when the menu item needs to render its background (everything except the text and glyph).

PaintRect indicates the dimensions of the menu item on its canvas.

DrawBackground paints the background of the menu item so that its color reflects whether the item currently has focus, adjusting PaintRect to accommodate any glyph or checkmark that appears on the menu item.

See Also

DrawBackground

DrawGlyph (see page 1754)

DrawText (see page 1755)

27.1.7.2.3 TStandardMenuItem.DrawDesignFocus Method

Pascal

```
procedure DrawDesignFocus(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawDesignFocus(TRect PaintRect);
```

Description

This is DrawDesignFocus, a member of class TStandardMenuItem.

27.1.7.2.4 TStandardMenuItem.DrawEdge Method

Pascal

```
procedure DrawEdge(Edges: TMenuEdges); override;
```

C++

```
virtual __fastcall DrawEdge(TMenuEdges Edges);
```

Description

This is DrawEdge, a member of class TStandardMenuItem.

27.1.7.2.5 TStandardMenuItem.DrawGlyph Method

Draws a symbol on the menu item.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

DrawGlyph is called automatically when the menu item needs to render its glyph. This occurs if the menu item is checked or if the associated action client item specifies a glyph for this menu item using its ImageIndex property.

Location is the position on this menu item's canvas for the upper left corner of the glyph.

See Also

DrawGlyph

DrawBackground (see page 1753)

DrawText (see page 1755)

ImageIndex

27.1.7.2.6 TStandardMenuItem.DrawGlyphFrame Method

Pascal

```
procedure DrawGlyphFrame(const Location: TPoint);
```

C++

```
__fastcall DrawGlyphFrame(const TPoint Location);
```

Description

This is DrawGlyphFrame, a member of class TStandardMenuItem.

27.1.7.2.7 TStandardMenuItem.DrawLargeGlyph Method

Pascal

```
procedure DrawLargeGlyph(Location: TPoint); override;
```

C++

```
virtual __fastcall DrawLargeGlyph(TPoint Location);
```

Description

This is DrawLargeGlyph, a member of class TStandardMenuItem.

27.1.7.2.8 TStandardMenuItem.DrawSeparator Method

Draws a separator.

Pascal

```
procedure DrawSeparator(const Offset: Integer); override;
```

C++

```
virtual __fastcall DrawSeparator(const int Offset);
```

Description

DrawSeparator is called automatically when the menu item represents a separator bar in the menu and it needs to paint itself. This method paints the separator bar.

Offset indicates the offset of the separator, in pixels, from the top of the menu item. DrawSeparator ignores this value and always uses a fixed value for menu items.

27.1.7.2.9 TStandardMenuItem.DrawText Method

Draws the menu item's text.

Pascal

```
procedure DrawText(var Rect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect Rect, unsigned Flags, UnicodeString Text);
```

Description

DrawText is called automatically when the menu item needs to render its text.

ARect indicates the rectangle on the menu item's canvas where the text label should appear.

Flags supplies the value to use for the TextFlags property of the canvas.

Text is the text of the menu item.

DrawText checks whether the menu item should display underlines on accelerator keys, and draws the text accordingly, using a font color that reflects whether the menu item is selected and whether it is enabled.

27.1.8 TStandardMenuPopup Class

TStandardMenuPopup is the default menu popup style.

Class Hierarchy

Pascal

```
TStandardMenuPopup = class(TCustomActionPopupMenu);
```

C++

```
class TStandardMenuPopup : public TCustomActionPopupMenu;
```

File

StdActnMenus

Description

TStandardMenuPopup is the default menu popup style. If you would like to replace it with a style of your own, subclass TCustomActionPopupMenu to provide your own behaviors. To make the change for your application, set the value of MenuPopupClass (a global variable) to your own subclass of TCustomActionPopupMenu instead of TStandardMenuPopup.

27.1.8.1 TStandardMenuPopup Members

The following tables list the members exposed by TStandardMenuPopup.

Protected Methods

	Name	Description
	CanAutoSize (see page 1757)	Indicates how the control can be resized.
	GetExpandBtnClass (see page 1757)	This is GetExpandBtnClass, a member of class TStandardMenuPopup.
	NCPaint (see page 1757)	This is NCPaint, a member of class TStandardMenuPopup.
	PositionPopup (see page 1758)	This is PositionPopup, a member of class TStandardMenuPopup.

27.1.8.2 TStandardMenuPopup Methods

The methods of the TStandardMenuPopup class are listed here.

Protected Methods

	Name	Description
	CanAutoSize (see page 1757)	Indicates how the control can be resized.

	GetExpandBtnClass (see page 1757)	This is GetExpandBtnClass, a member of class TStandardMenuPopup.
	NCPaint (see page 1757)	This is NCPaint, a member of class TStandardMenuPopup.
	PositionPopup (see page 1758)	This is PositionPopup, a member of class TStandardMenuPopup.

27.1.8.2.1 TStandardMenuPopup.CanAutoSize Method

Indicates how the control can be resized.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize property before the resize sequence that begins with the OnCanResize and OnConstrainedResize events and ends with the OnResize event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width and Height, CanAutoSize returns false, and the resize sequence is aborted.

As implemented in TWinControl, CanAutoSize returns true, adjusting NewWidth and NewHeight so that all the control's children fit.

ConstrainedResize

AdjustSize

27.1.8.2.2 TStandardMenuPopup.GetExpandBtnClass Method

Pascal

```
function GetExpandBtnClass: TCustomMenuExpandBtnClass; override;
```

C++

```
virtual __fastcall TCustomMenuExpandBtnClass GetExpandBtnClass();
```

Description

This is GetExpandBtnClass, a member of class TStandardMenuPopup.

27.1.8.2.3 TStandardMenuPopup.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TStandardMenuPopup.

27.1.8.2.4 TStandardMenuPopup.PositionPopup Method

Pascal

```
procedure PositionPopup(AnOwner: TCustomActionBar; ParentItem: TCustomActionControl); override;
```

C++

```
virtual __fastcall PositionPopup(TCustomActionBar AnOwner, TCustomActionControl ParentItem);
```

Description

This is PositionPopup, a member of class TStandardMenuPopup.

27.1.9 TStandardToolScrollBtn Class

Class Hierarchy

Pascal

```
TStandardToolScrollBtn = class(TCustomToolScrollBtn);
```

C++

```
class TStandardToolScrollBtn : public TCustomToolScrollBtn;
```

File

StdActnMenus

Description

This is class StdActnMenus.TStandardToolScrollBtn.

27.1.9.1 TStandardToolScrollBtn Members

The following tables list the members exposed by TStandardToolScrollBtn.

Protected Methods

	Name	Description
	DrawFrame (see page 1759)	This is DrawFrame, a member of class TStandardToolScrollBtn.

27.1.9.2 TStandardToolScrollBtn Methods

The methods of the TStandardToolScrollBtn class are listed here.

Protected Methods

	Name	Description
	DrawFrame (see page 1759)	This is DrawFrame, a member of class TStandardToolScrollBtn.

27.1.9.2.1 TStandardToolScrollBtn.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TStandardToolScrollBtn.

27.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	RegisterStandardMenus (see page 1760)	This is function StdActnMenus.RegisterStandardMenus.

27.2.1 StdActnMenus.RegisterStandardMenus Function

Pascal

```
procedure RegisterStandardMenus; deprecated;
```

C++

```
RegisterStandardMenus();
```

File

StdActnMenus

Description

This is function StdActnMenus.RegisterStandardMenus.

28 StdActns Namespace

This is namespace StdActns.

Topics

Name	Description
Classes (see page 1763)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 1947)	The following table lists structs, records, enums in this documentation.
Types (see page 1949)	The following table lists types in this documentation.

Classes

	Name	Description
	TBrowseForFolder (see page 1764)	This is class StdActns.TBrowseForFolder.
	TColorSelect (see page 1774)	TColorSelect is the standard action for displaying a color selection dialog.
	TCommonDialogAction (see page 1784)	TCommonDialogAction is the base class for action objects that display a dialog.
	TEditAction (see page 1791)	TEditAction is the base class for action objects that perform standard edits on an edit control.
	TEditCopy (see page 1795)	TEditCopy copies the selected text in a target edit control to the Windows clipboard.
	TEditCut (see page 1797)	TEditCut cuts the selected text in a target edit or memo control to the Windows clipboard.
	TEditDelete (see page 1799)	TEditDelete deletes the selected text in a target edit or memo control.
	TEditPaste (see page 1801)	TEditPaste pastes text from the clipboard into the active edit or memo control.
	TEditSelectAll (see page 1803)	TEditSelectAll selects all text in an active text control.
	TEditUndo (see page 1805)	TEditUndo backs out the last change in an edit control.
	TFileAction (see page 1807)	TFileAction is the base class for action objects that display a file selection dialog.
	TFileExit (see page 1810)	TFileExit is the standard action for shutting down an application.
	TFileOpen (see page 1817)	TFileOpen is the standard action for displaying a file open dialog.
	TFileOpenWith (see page 1829)	TFileOpenWith is the standard action for displaying the dialog that lets users choose what application to user for opening a file.
	TFilePageSetup (see page 1836)	TFilePageSetup is the standard action for displaying a page setup dialog.
	TFilePrintSetup (see page 1845)	TFilePrintSetup is the standard action for displaying a printer setup dialog.
	TFileSaveAs (see page 1855)	TFileSaveAs is the standard action for displaying a file save as dialog.
	TFontEdit (see page 1864)	TFontEdit is the standard action for displaying a font selection dialog.
	THelpAction (see page 1874)	THelpAction is the base class for action objects that interact with the help system.
	THelpContents (see page 1876)	THelpContents brings up the contents for the default help system.
	THelpContextAction (see page 1877)	THelpContextAction brings up the help topic for the active control.
	THelpOnHelp (see page 1879)	THelpOnHelp brings up a help topic on how to use Help.

	THelpTopicSearch (see page 1881)	THelpTopicSearch brings up the help index.
	THintAction (see page 1882)	THintAction is the action that executes when the user pauses the mouse over a control or menu item that has a hint.
	TPrintDlg (see page 1884)	TPrintDlg is the standard action for displaying a print dialog.
	TSearchAction (see page 1894)	TSearchAction is the base class for action objects that display a search or search and replace dialog.
	TSearchFind (see page 1899)	TSearchFind is the standard action for displaying a find dialog.
	TSearchFindFirst (see page 1909)	TSearchFindFirst is the standard action for displaying a find dialog that looks for the first occurrence of a string.
	TSearchFindNext (see page 1912)	TSearchFindNext is the standard action for locating the next instance of a string in an edit control.
	TSearchReplace (see page 1921)	TSearchReplace is the standard action for displaying a find-and-replace dialog.
	TWindowAction (see page 1932)	TWindowAction is the base class for action objects that work with MDI forms.
	TWindowArrange (see page 1936)	TWindowArrange arranges the icons of minimized MDI child forms.
	TWindowCascade (see page 1937)	TWindowCascade cascades the MDI child forms.
	TWindowClose (see page 1939)	TWindowClose closes the active MDI child form.
	TWindowMinimizeAll (see page 1941)	TWindowMinimizeAll minimizes all MDI child forms.
	TWindowTileHorizontal (see page 1943)	TWindowTileHorizontal arranges MDI child forms so that they are all the same size, tiled horizontally.
	TWindowTileVertical (see page 1944)	TWindowTileVertical arranges MDI child forms so that they are all the same size, tiled vertically.

Structs, Records, Enums

	Name	Description
	TBrowseForFolderOption (see page 1947)	TBrowseForFolderOption contains the options for creating a dialog box used when browsing for folders.

Types

Name	Description
TBrowseForFolderCallbackEvent (see page 1949)	This is type StdActns.TBrowseForFolderCallbackEvent.
TBrowseOptions (see page 1949)	TBrowseOptions is a set type of options used in customizing the browse dialog box to create.
TCommonDialogClass (see page 1950)	This is type StdActns.TCommonDialogClass.

28.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TBrowseForFolder (see page 1764)	This is class StdActns.TBrowseForFolder.
	TColorSelect (see page 1774)	TColorSelect is the standard action for displaying a color selection dialog.
	TCommonDialogAction (see page 1784)	TCommonDialogAction is the base class for action objects that display a dialog.
	TEditAction (see page 1791)	TEditAction is the base class for action objects that perform standard edits on an edit control.
	TEditCopy (see page 1795)	TEditCopy copies the selected text in a target edit control to the Windows clipboard.
	TEditCut (see page 1797)	TEditCut cuts the selected text in a target edit or memo control to the Windows clipboard.
	TEditDelete (see page 1799)	TEditDelete deletes the selected text in a target edit or memo control.
	TEditPaste (see page 1801)	TEditPaste pastes text from the clipboard into the active edit or memo control.
	TEditSelectAll (see page 1803)	TEditSelectAll selects all text in an active text control.
	TEditUndo (see page 1805)	TEditUndo backs out the last change in an edit control.
	TFileAction (see page 1807)	TFileAction is the base class for action objects that display a file selection dialog.
	TFileExit (see page 1810)	TFileExit is the standard action for shutting down an application.
	TFileOpen (see page 1817)	TFileOpen is the standard action for displaying a file open dialog.
	TFileOpenWith (see page 1829)	TFileOpenWith is the standard action for displaying the dialog that lets users choose what application to user for opening a file.
	TFilePageSetup (see page 1836)	TFilePageSetup is the standard action for displaying a page setup dialog.
	TFilePrintSetup (see page 1845)	TFilePrintSetup is the standard action for displaying a printer setup dialog.
	TFileSaveAs (see page 1855)	TFileSaveAs is the standard action for displaying a file save as dialog.
	TFontEdit (see page 1864)	TFontEdit is the standard action for displaying a font selection dialog.
	THelpAction (see page 1874)	THelpAction is the base class for action objects that interact with the help system.
	THelpContents (see page 1876)	THelpContents brings up the contents for the default help system.
	THelpContextAction (see page 1877)	THelpContextAction brings up the help topic for the active control.
	THelpOnHelp (see page 1879)	THelpOnHelp brings up a help topic on how to use Help.
	THelpTopicSearch (see page 1881)	THelpTopicSearch brings up the help index.
	THintAction (see page 1882)	THintAction is the action that executes when the user pauses the mouse over a control or menu item that has a hint.
	TPrintDlg (see page 1884)	TPrintDlg is the standard action for displaying a print dialog.
	TSearchAction (see page 1894)	TSearchAction is the base class for action objects that display a search or search and replace dialog.
	TSearchFind (see page 1899)	TSearchFind is the standard action for displaying a find dialog.
	TSearchFindFirst (see page 1909)	TSearchFindFirst is the standard action for displaying a find dialog that looks for the first occurrence of a string.
	TSearchFindNext (see page 1912)	TSearchFindNext is the standard action for locating the next instance of a string in an edit control.
	TSearchReplace (see page 1921)	TSearchReplace is the standard action for displaying a find-and-replace dialog.
	TWindowAction (see page 1932)	TWindowAction is the base class for action objects that work with MDI forms.
	TWindowArrange (see page 1936)	TWindowArrange arranges the icons of minimized MDI child forms.
	TWindowCascade (see page 1937)	TWindowCascade cascades the MDI child forms.
	TWindowClose (see page 1939)	TWindowClose closes the active MDI child form.
	TWindowMinimizeAll (see page 1941)	TWindowMinimizeAll minimizes all MDI child forms.
	TWindowTileHorizontal (see page 1943)	TWindowTileHorizontal arranges MDI child forms so that they are all the same size, tiled horizontally.
	TWindowTileVertical (see page 1944)	TWindowTileVertical arranges MDI child forms so that they are all the same size, tiled vertically.

28.1.1 TBrowseForFolder Class

Class Hierarchy

Pascal

```
TBrowseForFolder = class(TCommonDialogAction);
```

C++

```
class TBrowseForFolder : public TCommonDialogAction;
```

File

StdActns

Description

This is class StdActns.TBrowseForFolder.

28.1.1.1 TBrowseForFolder Members

The following tables list the members exposed by TBrowseForFolder.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCallback (see page 1765)	This is DoCallback, a member of class TBrowseForFolder.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	DoValidate (see page 1766)	This is DoValidate, a member of class TBrowseForFolder.
V	GetDialogClass (see page 1766)	This is GetDialogClass, a member of class TBrowseForFolder.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
V	Create (see page 1785)	Creates an instance of TCommonDialogAction.
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1766)	Executes the associated dialog and generates an OnAccept or OnCancel event.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.
	Folder (see page 1768)	This is Folder, a member of class TBrowseForFolder.

Published Events

	Name	Description
	BeforeExecute (see page 1772)	Occurs immediately before the dialog appears.

	OnAccept (see page 1772)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCallback (see page 1773)	This is OnCallback, a member of class TBrowseForFolder.
	OnCancel (see page 1773)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1774)	Occurs when the mouse pauses over a client control or menu item.
	OnValidate (see page 1774)	This is OnValidate, a member of class TBrowseForFolder.

Published Properties

	Name	Description
	BrowseOptions (see page 1767)	This is BrowseOptions, a member of class TBrowseForFolder.
	Caption (see page 1767)	Represents the caption of client controls and menu items.
	DialogCaption (see page 1768)	This is DialogCaption, a member of class TBrowseForFolder.
	Enabled (see page 1768)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1768)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1769)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1769)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1770)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1770)	Indicates the ImageIndex property for client controls and menu items.
	RootDir (see page 1770)	This is RootDir, a member of class TBrowseForFolder.
	SecondaryShortCuts (see page 1771)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1771)	Specifies the ShortCut property for client menu items.
	Visible (see page 1771)	Specifies the Visible property for client controls and menu items.

28.1.1.2 TBrowseForFolder Methods

The methods of the TBrowseForFolder class are listed here.

Protected Methods

	Name	Description
	DoCallback (see page 1765)	This is DoCallback, a member of class TBrowseForFolder.
	DoValidate (see page 1766)	This is DoValidate, a member of class TBrowseForFolder.
V	GetDialogClass (see page 1766)	This is GetDialogClass, a member of class TBrowseForFolder.

Public Methods

	Name	Description
V	ExecuteTarget (see page 1766)	Executes the associated dialog and generates an OnAccept or OnCancel event.

28.1.1.2.1 TBrowseForFolder.DoCallback Method

Pascal

```
function DoCallback(Wnd: HWND; uMsg: UINT; lParam: LPARAM; lpData: LPARAM): Integer;
```

C++

```
__fastcall int DoCallback(HWND Wnd, UINT uMsg, LPARAM lParam, LPARAM lpData);
```

Description

This is DoCallback, a member of class TBrowseForFolder.

28.1.1.2.2 TBrowseForFolder.DoValidate Method

Pascal

```
function DoValidate(Wnd: HWND; uMsg: UINT; lParam: LPARAM; lpData: LPARAM): Integer;
```

C++

```
__fastcall int DoValidate(HWND Wnd, UINT uMsg, LPARAM lParam, LPARAM lpData);
```

Description

This is DoValidate, a member of class TBrowseForFolder.

28.1.1.2.3 TBrowseForFolder.ExecuteTarget Method

Executes the associated dialog and generates an OnAccept or OnCancel event.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and

1. Generates a BeforeExecute event, so that the application can initialize the associated dialog according to current conditions.
2. Calls the Execute method of the dialog.
3. Generates an OnAccept event or an OnCancel event, depending on the value returned by the Execute method. You can write code to make use of the results from executing the dialog in these event handlers.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

BeforeExecute (see page 1790)

28.1.1.2.4 TBrowseForFolder.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TBrowseForFolder.

28.1.1.3 TBrowseForFolder Properties

The properties of the TBrowseForFolder class are listed here.

Public Properties

	Name	Description
	Folder (see page 1768)	This is Folder, a member of class TBrowseForFolder.

Published Properties

	Name	Description
	BrowseOptions (see page 1767)	This is BrowseOptions, a member of class TBrowseForFolder.
	Caption (see page 1767)	Represents the caption of client controls and menu items.
	DialogCaption (see page 1768)	This is DialogCaption, a member of class TBrowseForFolder.
	Enabled (see page 1768)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1768)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1769)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1769)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1770)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1770)	Indicates the ImageIndex property for client controls and menu items.
	RootDir (see page 1770)	This is RootDir, a member of class TBrowseForFolder.
	SecondaryShortCuts (see page 1771)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1771)	Specifies the ShortCut property for client menu items.
	Visible (see page 1771)	Specifies the Visible property for client controls and menu items.

28.1.1.3.1 TBrowseForFolder.BrowseOptions Property

Pascal

```
property BrowseOptions: TBrowseOptions;
```

C++

```
__property TBrowseOptions BrowseOptions;
```

Description

This is BrowseOptions, a member of class TBrowseForFolder.

28.1.1.3.2 TBrowseForFolder.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.1.3.3 TBrowseForFolder.DialogCaption Property

Pascal

```
property DialogCaption: string;
```

C++

```
__property UnicodeString DialogCaption;
```

Description

This is DialogCaption, a member of class TBrowseForFolder.

28.1.1.3.4 TBrowseForFolder.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.1.3.5 TBrowseForFolder.Folder Property

Pascal

```
property Folder: string;
```

C++

```
__property UnicodeString Folder;
```

Description

This is Folder, a member of class TBrowseForFolder.

28.1.1.3.6 TBrowseForFolder.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.1.3.7 TBrowseForFolder.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.1.3.8 TBrowseForFolder.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.1.3.9 TBrowseForFolder.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.1.3.10 TBrowseForFolder.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.1.3.11 TBrowseForFolder.RootDir Property

Pascal

```
property RootDir: string;
```

C++

```
__property UnicodeString RootDir;
```

Description

This is RootDir, a member of class TBrowseForFolder.

28.1.1.3.12 TBrowseForFolder.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.1.3.13 TBrowseForFolder.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.1.3.14 TBrowseForFolder.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.1.4 TBrowseForFolder Events

The events of the TBrowseForFolder class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1772)	Occurs immediately before the dialog appears.
	OnAccept (see page 1772)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCallback (see page 1773)	This is OnCallback, a member of class TBrowseForFolder.
	OnCancel (see page 1773)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1774)	Occurs when the mouse pauses over a client control or menu item.
	OnValidate (see page 1774)	This is OnValidate, a member of class TBrowseForFolder.

28.1.1.4.1 TBrowseForFolder.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.1.4.2 TBrowseForFolder.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.1.4.3 TBrowseForFolder.OnCallback Event

Pascal

```
property OnCallback: TBrowseForFolderCallbackEvent;
```

C++

```
__property TBrowseForFolderCallbackEvent OnCallback;
```

Description

This is OnCallback, a member of class TBrowseForFolder.

28.1.1.4.4 TBrowseForFolder.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.1.4.5 TBrowseForFolder.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.1.4.6 TBrowseForFolder.OnValidate Event

Pascal

```
property OnValidate: TBrowseForFolderCallbackEvent;
```

C++

```
__property TBrowseForFolderCallbackEvent OnValidate;
```

Description

This is OnValidate, a member of class TBrowseForFolder.

28.1.2 TColorSelect Class

TColorSelect is the standard action for displaying a color selection dialog.

Class Hierarchy

Pascal

```
TColorSelect = class(TCommonDialogAction);
```

C++

```
class TColorSelect : public TCommonDialogAction;
```

File

StdActns

Description

Add TColorSelect to an action list to add a modal color selection dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the color selection dialog when invoked. Use the OnAccept (see page 1781) event to respond after the user selects a color using the dialog or the OnCancel (see page 1782) event to respond if the user cancels from the dialog. In the event handler for these events, you can read the color from the dialog specified by the Dialog (see page 1777) property.

TColorDialog

28.1.2.1 TColorSelect Members

The following tables list the members exposed by TColorSelect.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
V	GetDialogClass (see page 1776)	This is GetDialogClass, a member of class TColorSelect.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
V	Create (see page 1785)	Creates an instance of TCommonDialogAction.
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1781)	Occurs immediately before the dialog appears.
	OnAccept (see page 1781)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1782)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1782)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1782)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1776)	Represents the caption of client controls and menu items.
R	Dialog (see page 1777)	Provides access the color selection dialog that the action executes.
	Enabled (see page 1777)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1777)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1778)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1778)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1779)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1779)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1780)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1780)	Specifies the ShortCut property for client menu items.

	Visible (see page 1780)	Specifies the Visible property for client controls and menu items.

28.1.2.2 TColorSelect Methods

The methods of the TColorSelect class are listed here.

Protected Methods

	Name	Description
V	GetDialogClass (see page 1776)	This is GetDialogClass, a member of class TColorSelect.

28.1.2.2.1 TColorSelect.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TColorSelect.

28.1.2.3 TColorSelect Properties

The properties of the TColorSelect class are listed here.

Published Properties

	Name	Description
	Caption (see page 1776)	Represents the caption of client controls and menu items.
R	Dialog (see page 1777)	Provides access the color selection dialog that the action executes.
	Enabled (see page 1777)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1777)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1778)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1778)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1779)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1779)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1780)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1780)	Specifies the ShortCut property for client menu items.
	Visible (see page 1780)	Specifies the Visible property for client controls and menu items.

28.1.2.3.1 TColorSelect.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and

menu items.

See Also

Caption

Caption

28.1.2.3.2 TColorSelect.Dialog Property

Provides access the color selection dialog that the action executes.

Pascal

```
property Dialog: TColorDialog;
```

C++

```
__property TColorDialog Dialog;
```

Description

Use Dialog to configure the color selection dialog before the action fires or to read the selected color after the action executes the dialog. For example, you can set the initially selected color in the dialog at design time using the Object Inspector or read the dialog's Color property in an OnAccept (see page 1781) event handler to make use of the selected color.

When using a color select action, you do not place a TColorDialog component on the form or data module at design time. Instead, you add the TColorSelect (see page 1774) to your action list and then use the Dialog property. The color selection dialog component is created by the TColorSelect (see page 1774) constructor.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Color

28.1.2.3.3 TColorSelect.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.2.3.4 TColorSelect.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.2.3.5 TColorSelect.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.2.3.6 TColorSelect.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.2.3.7 TColorSelect.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.2.3.8 TColorSelect.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.2.3.9 TColorSelect.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.2.3.10 TColorSelect.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.2.3.11 TColorSelect.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.2.4 TColorSelect Events

The events of the TColorSelect class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1781)	Occurs immediately before the dialog appears.
	OnAccept (see page 1781)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1782)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1782)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1782)	Occurs when the application is idle or when the action list updates.

28.1.2.4.1 TColorSelect.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.2.4.2 TColorSelect.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the

user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.2.4.3 TColorSelect.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.2.4.4 TColorSelect.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.2.4.5 TColorSelect.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
```

```
end;
```

UpdateAction

28.1.3 TCommonDialogAction Class

TCommonDialogAction is the base class for action objects that display a dialog.

Class Hierarchy

Pascal

```
TCommonDialogAction = class(TCustomAction);
```

C++

```
class TCommonDialogAction : public TCustomAction;
```

File

StdActns

Description

TCommonDialogAction implements the common behavior for actions that display a dialog when executed. Each descendant class represents a specific dialog. Do not use TCommonDialogAction directly in an application. Instead, use the specific TCommonDialogAction descendant that represents the type of dialog you want to execute. The various TCommonDialogAction descendants are listed in the See also list.

TCommonDialogAction objects do not require a specific type of control to be active: they handle any target. When executed, the dialog action displays its dialog, and then generates an OnAccept (see page 1790) or OnCancel (see page 1791) event, which you can use to process the results from the dialog.

When using TCommonDialogAction desendants, there is no need to place the dialog component in your form or data module. The action object creates its own dialog component.

28.1.3.1 TCommonDialogAction Members

The following tables list the members exposed by TCommonDialogAction.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Events

	Name	Description
	BeforeExecute (see page 1790)	Occurs immediately before the dialog appears.
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

28.1.3.2 TCommonDialogAction.Create Constructor

Creates an instance of TCommonDialogAction.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCommonDialogAction(TComponent * AOwner);
```

Description

Most applications do not need to call the TCommonDialogAction constructor because actions are added at design time to an action list or action manager.

The TCommonDialogAction constructor creates an instance of its associated dialog, which descendant classes make available through the Dialog property.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TCommonDialogAction

instance.

See Also

Owner

Actions

28.1.3.3 TCommonDialogAction.Destroy Destructor

Frees an instance of TCustomAction.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCommonDialogAction();
```

Description

Do not call the destructor directly in an application. Instead, call Free. Free ensures that the action is not nil before calling the destructor.

If the action is contained in an action list or action manager, Destroy removes the action from that list.

See Also

Create

Actions

28.1.3.4 TCommonDialogAction Fields

The fields of the TCommonDialogAction class are listed here.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

28.1.3.4.1 TCommonDialogAction.FDialog Field

Pascal

```
FDialog: TCommonDialog;
```

C++

```
TCommonDialog FDialog;
```

Description

This is FDialog, a member of class TCommonDialogAction.

28.1.3.5 TCommonDialogAction Methods

The methods of the TCommonDialogAction class are listed here.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

28.1.3.5.1 TCommonDialogAction.DoAccept Method

Pascal

```
procedure DoAccept; virtual;
```

C++

```
virtual __fastcall DoAccept();
```

Description

This is DoAccept, a member of class TCommonDialogAction.

28.1.3.5.2 TCommonDialogAction.DoCancel Method

Pascal

```
procedure DoCancel; virtual;
```

C++

```
virtual __fastcall DoCancel();
```

Description

This is DoCancel, a member of class TCommonDialogAction.

28.1.3.5.3 TCommonDialogAction.ExecuteTarget Method

Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and

1. Generates a BeforeExecute (see page 1790) event, so that the application can initialize the associated dialog according to current conditions.
2. Calls the Execute method of the dialog.
3. Generates an OnAccept (see page 1790) event or an OnCancel (see page 1791) event, depending on the value returned by the Execute method. You can write code to make use of the results from executing the dialog in these event handlers.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

BeforeExecute (see page 1790)

28.1.3.5.4 TCommonDialogAction.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; virtual;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TCommonDialogAction.

28.1.3.5.5 TCommonDialogAction.HandlesTarget Method

Indicates whether the action can execute its dialog.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method lets the action object indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

HandlesTarget always returns true, because the execution of the dialog does not depend on any target object.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

28.1.3.5.6 TCommonDialogAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

28.1.3.5.7 TCommonDialogAction.SetupDialog Method

Pascal

```
procedure SetupDialog; virtual;
```

C++

```
virtual __fastcall SetupDialog();
```

Description

This is SetupDialog, a member of class TCommonDialogAction.

28.1.3.6 TCommonDialogAction Properties

The properties of the TCommonDialogAction class are listed here.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

28.1.3.6.1 TCommonDialogAction.ExecuteResult Property

Indicates the result of executing the associated dialog.

Pascal

```
property ExecuteResult: Boolean;
```

C++

```
__property Boolean ExecuteResult;
```

Description

When the dialog action fires, it executes the dialog specified by the CommonDialog property and sets ExecuteResult the value returned by that dialog's Execute method. Thus, ExecuteResult is false if the dialog has not executed or the user canceled when

the dialog executed, and true if the user exited the dialog by clicking OK.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

28.1.3.7 TCommonDialogAction Events

The events of the TCommonDialogAction class are listed here.

Public Events

	Name	Description
	BeforeExecute (see page 1790)	Occurs immediately before the dialog appears.
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

28.1.3.7.1 TCommonDialogAction.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write (see page 3707) a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.3.7.2 TCommonDialogAction.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write (see page 3707) an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is

modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction (see page 1784) descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.3.7.3 TCommonDialogAction.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write (see page 3707) an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.4 TEditAction Class

TEditAction is the base class for action objects that perform standard edits on an edit control.

Class Hierarchy

Pascal

```
TEditAction = class(TAction);
```

C++

```
class TEditAction : public TAction;
```

File

StdActns

Description

TEditAction is the common base class for actions that work with edit controls. Each descendant class performs a specific type of edit on the target edit control. Do not use TEditAction directly in an application. Instead, use a TEditAction descendant that performs a specific function (for example, Cut, Copy (see page 3547), Paste, Delete (see page 3552), Select All, or Undo). The various TEditAction descendants are listed in the See also list.

See Also

TEditCut (see page 1797)

TEditDelete (see page 1799)

TEditPaste (see page 1801)

TEditSelectAll (see page 1803)

TEditUndo (see page 1805)

28.1.4.1 TEditAction Members

The following tables list the members exposed by TEditAction.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1794)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.4.2 TEditAction.Destroy Destructor

Frees an instance of TCustomAction.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEditAction();
```

Description

Do not call the destructor directly in an application. Instead, call Free. Free ensures that the action is not nil before calling the destructor.

If the action is contained in an action list or action manager, Destroy removes the action from that list.

See Also

Create

Actions

28.1.4.3 TEditAction Methods

The methods of the TEditAction class are listed here.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1794)	Enables or disables the action, depending on the currently active control in the form.

28.1.4.3.1 TEditAction.GetControl Method

Returns the target of the edit action.

Pascal

```
function GetControl(Target: TObject): TCustomEdit; virtual;
```

C++

```
virtual __fastcall TCustomEdit GetControl(TObject * Target);
```

Description

TEditAction (see page 1791) uses the protected GetControl method internally to obtain the target of the action. `Target` is the currently active object or the value of the `Control (see page 1795)` property. GetControl returns the target object as an edit control.

See Also

Notification (see page 1794)

28.1.4.3.2 TEditAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the `Target` parameter as a “target”. `Target` is the currently active object. HandlesTarget checks whether the `Target` is a TCustomEdit (see page 2345) or any subclass of

TCustomEdit (see page 2345). If the `Target` is nil (Delphi) or NULL (C++), HandlesTarget checks whether the Control (see page 1795) property of this action is a TCustomEdit (see page 2345) or any subclass of TCustomEdit (see page 2345). HandlesTarget returns True if there is an edit control to act as target, or False otherwise.

See Also

UpdateTarget (see page 1794)

28.1.4.3.3 TEditAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

28.1.4.3.4 TEditAction.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the potential target changes so that actions can update themselves accordingly. In TEditAction (see page 1791), UpdateTarget checks whether the current target object (specified by the `Target` parameter) is an edit control and that some of its text is selected (if the action function requires it). If so, UpdateTarget sets Enabled to True. If not, UpdateTarget sets Enabled to False.

See Also

HandlesTarget (see page 1793)

28.1.4.4 TEditAction Properties

The properties of the TEditAction class are listed here.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.4.4.1 TEditAction.Control Property

Provides access to the target of the action.

Pascal

```
property Control: TCustomEdit;
```

C++

```
__property TCustomEdit Control;
```

Description

Control is the edit control on which the action performs its function. Set the value of Control to limit the action so that it only operates on a specific edit control. If Control is unassigned, the action dynamically locates the target edit control when it executes.

See Also

GetControl (see page 1793)

28.1.5 TEditCopy Class

TEditCopy copies the selected text in a target edit control to the Windows clipboard.

Class Hierarchy

Pascal

```
TEditCopy = class(TEditAction);
```

C++

```
class TEditCopy : public TEditAction;
```

File

StdActns

Description

Add TEditCopy to an action list to allow users to copy selected text to the clipboard using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to copy the currently selected text in an active text control to the clipboard.

TEditCopy is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control or if that edit control does not have any text selected.

See Also

TEditCut (see page 1797)

TEditDelete (see page 1799)

TEditPaste (see page 1801)

TEditSelectAll (see page 1803)

TEditUndo (see page 1805)

TCustomEdit (see page 2345)

TRichEditBold

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.5.1 TEditCopy Members

The following tables list the members exposed by TEditCopy.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1796)	Copies selected text in the target control to the Windows clipboard.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1794)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.5.2 TEditCopy Methods

The methods of the TEditCopy class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1796)	Copies selected text in the target control to the Windows clipboard.

28.1.5.2.1 TEditCopy.ExecuteTarget Method

Copies selected text in the target control to the Windows clipboard.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for

example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is an edit control (TCustomEdit (see page 2345) descendant), and if so, calls its CopyToClipboard method, copying the selected text to the clipboard.

See Also

TCustomEdit (see page 2345)

CopyToClipboard (see page 2349)

28.1.6 TEditCut Class

TEditCut cuts the selected text in a target edit or memo control to the Windows clipboard.

Class Hierarchy

Pascal

```
TEditCut = class(TEditAction);
```

C++

```
class TEditCut : public TEditAction;
```

File

StdActns

Description

Add TEditCut to an action list to allow users to cut selected text to the clipboard using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to cut the currently selected text in an active text control to the clipboard.

TEditCut is designed to work with an edit control (TCustomEdit (see page 2345) or TCustomMemo (see page 2443) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control or if that edit control does not have a selection to cut.

See Also

TEditCopy (see page 1795)

TEditDelete (see page 1799)

TEditPaste (see page 1801)

TEditSelectAll (see page 1803)

TEditUndo (see page 1805)

TCustomEdit (see page 2345)

TRichEditBold

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.6.1 TEditCut Members

The following tables list the members exposed by TEditCut.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1798)	Cuts selected text in the target control to the Windows clipboard.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1794)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.6.2 TEditCut Methods

The methods of the TEditCut class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1798)	Cuts selected text in the target control to the Windows clipboard.

28.1.6.2.1 TEditCut.ExecuteTarget Method

Cuts selected text in the target control to the Windows clipboard.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is an edit control (TCustomEditControl descendant), and if so, calls its CutToClipboard method, cutting the selected text to the clipboard.

See Also

TCustomEdit (see page 2345)

CutToClipboard (see page 2352)

28.1.7 TEditDelete Class

TEditDelete deletes the selected text in a target edit or memo control.

Class Hierarchy

Pascal

```
TEditDelete = class(TEditAction);
```

C++

```
class TEditDelete : public TEditAction;
```

File

StdActns

Description

Add TEditDelete to an action list to let users delete selected text using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to delete the currently selected text in an active text control.

TEditDelete is designed to work with an edit control (TCustomEdit (see page 2345) or TCustomMemo (see page 2443) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control or if the active edit control does not have any selected text.

See Also

TEditCopy (see page 1795)

TEditCut (see page 1797)

TEditPaste (see page 1801)

TEditSelectAll (see page 1803)

TEditUndo (see page 1805)

TCustomEdit (see page 2345)

TCustomMemo (see page 2443)

TRichEditBold

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.7.1 TEditDelete Members

The following tables list the members exposed by TEditDelete.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.

	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1800)	Deletes selected text in the target control.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1800)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.7.2 TEditDelete Methods

The methods of the TEditDelete class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1800)	Deletes selected text in the target control.
	UpdateTarget (see page 1800)	Enables or disables the action, depending on the currently active control in the form.

28.1.7.2.1 TEditDelete.ExecuteTarget Method

Deletes selected text in the target control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a TCustomEdit (see page 2345) descendant, and if so, calls its ClearSelection method, deleting the selected text.

See Also

TCustomEdit (see page 2345)

ClearSelection (see page 2349)

28.1.7.2.2 TEditDelete.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TEditDelete (see page 1799), UpdateTarget checks whether the current target object (specified by the Target parameter) is an edit control that has some of its text selected. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

28.1.8 TEditPaste Class

TEditPaste pastes text from the clipboard into the active edit or memo control.

Class Hierarchy

Pascal

```
TEditPaste = class(TEditAction);
```

C++

```
class TEditPaste : public TEditAction;
```

File

StdActns

Description

Add TEditPaste to an action list to enable users to paste text from the clipboard using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to paste text from the clipboard into an active text control.

TEditPaste is designed to work with an edit control (TCustomEdit (see page 2345) or TCustomMemo (see page 2443) descendant) as a target. It automatically disables itself if the clipboard does not contain text.

See Also

TEditCopy (see page 1795)

TEditCut (see page 1797)

TEditDelete (see page 1799)

TEditSelectAll (see page 1803)

TEditUndo (see page 1805)

TRichEditBold

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.8.1 TEditPaste Members

The following tables list the members exposed by TEditPaste.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1802)	Pastes text from the clipboard into the target edit control.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1803)	Enables or disables the action, depending on the contents of the clipboard.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.8.2 TEditPaste Methods

The methods of the TEditPaste class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1802)	Pastes text from the clipboard into the target edit control.
	UpdateTarget (see page 1803)	Enables or disables the action, depending on the contents of the clipboard.

28.1.8.2.1 TEditPaste.ExecuteTarget Method

Pastes text from the clipboard into the target edit control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a TCustomEdit (see page 2345) descendant, and if so, calls its PasteFromClipboard method, pasting in any text on the clipboard.

See Also

TCustomEdit (see page 2345)

PasteFromClipboard (see page 2358)

28.1.8.2.2 TEditPaste.UpdateTarget Method

Enables or disables the action, depending on the contents of the clipboard.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In TEditPaste (see page 1801), UpdateTarget checks whether the clipboard contains text. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

28.1.9 TEditSelectAll Class

TEditSelectAll selects all text in an active text control.

Class Hierarchy

Pascal

```
TEditSelectAll = class(TEditAction);
```

C++

```
class TEditSelectAll : public TEditAction;
```

File

StdActns

Description

Add TEditSelectAll to an action list to allow users to select all the text in a text control using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to select all text in an active text control.

TEditSelectAll is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control or if the edit control does not have any text.

See Also

TEditCopy (see page 1795)

TEditCut (see page 1797)

TEditDelete (see page 1799)

TEditPaste (see page 1801)

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.9.1 TEditSelectAll Members

The following tables list the members exposed by TEditSelectAll.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1804)	Selects all text in the target edit control.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1805)	Enables or disables the action, depending on the contents of the target edit control.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.9.2 TEditSelectAll Methods

The methods of the TEditSelectAll class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1804)	Selects all text in the target edit control.
	UpdateTarget (see page 1805)	Enables or disables the action, depending on the contents of the target edit control.

28.1.9.2.1 TEditSelectAll.ExecuteTarget Method

Selects all text in the target edit control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a TCustomEdit (see page 2345) descendant, and if so, calls its SelectAll method, selecting all of its text.

See Also

TCustomEdit (see page 2345)

SelectAll (see page 2359)

28.1.9.2.2 TEditSelectAll.UpdateTarget Method

Enables or disables the action, depending on the contents of the target edit control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In TEditSelectAll (see page 1803), UpdateTarget checks whether Target is a text control that contains text. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

28.1.10 TEditUndo Class

TEditUndo backs out the last change in an edit control.

Class Hierarchy

Pascal

```
TEditUndo = class(TEditAction);
```

C++

```
class TEditUndo : public TEditAction;
```

File

StdActns

Description

Add TEditUndo to an action list to allow users to back out edits using menu items or toolbar buttons. Controls such as menu

items and tool buttons linked to this action cause the application to undo the last edit in an active text control.

TEditUndo is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control that can back out the last edit.

See Also

TEditCopy (see page 1795)

TEditCut (see page 1797)

TEditPaste (see page 1801)

TEditSelectAll (see page 1803)

TEditDelete (see page 1799)

TCustomEdit (see page 2345)

TRichEditBold

TRichEditItalic

TRichEditUnderline

TSearchReplace (see page 1921)

28.1.10.1 TEditUndo Members

The following tables list the members exposed by TEditUndo.

Protected Methods

	Name	Description
	GetControl (see page 1793)	Returns the target of the edit action.
	Notification (see page 1794)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Destroy (see page 1792)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1807)	Backs out the last edit from the target control.
	HandlesTarget (see page 1793)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1807)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	Control (see page 1795)	Provides access to the target of the action.

28.1.10.2 TEditUndo Methods

The methods of the TEditUndo class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1807)	Backs out the last edit from the target control.
	UpdateTarget (see page 1807)	Enables or disables the action, depending on the currently active control in the form.

28.1.10.2.1 TEditUndo.ExecuteTarget Method

Backs out the last edit from the target control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a TCustomEdit (see page 2345) descendant, and if so, calls its Undo method, backing out the last change.

See Also

TCustomEdit (see page 2345)

Undo (see page 2364)

28.1.10.2.2 TEditUndo.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In TEditUndo (see page 1805), UpdateTarget checks whether the current target object (specified by the Target parameter) is an edit control that is in a state where it can back out changes. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

CanUndo (see page 2367)

28.1.11 TFileAction Class

TFileAction is the base class for action objects that display a file selection dialog.

Class Hierarchy

Pascal

```
TFileAction = class(TCommonDialogAction);
```

C++

```
class TFileAction : public TCommonDialogAction;
```

File

StdActns

Description

TFileAction implements the FileName (see page 1809) property that is common to action objects that display a file selection object.

See Also

TFileOpen (see page 1817)

TFileSaveAs (see page 1855)

TOpenDialog

28.1.11.1 TFileAction Members

The following tables list the members exposed by TFileAction.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialog (see page 1809)	This is GetDialog, a member of class TFileAction.
	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Protected Properties

	Name	Description
	FileName (see page 1809)	Specifies the file name for the file selection dialog.

Public Events

	Name	Description
	BeforeExecute (see page 1790)	Occurs immediately before the dialog appears.
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.

	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

28.1.11.2 TFileAction Methods

The methods of the TFileAction class are listed here.

Protected Methods

	Name	Description
	GetDialog (see page 1809)	This is GetDialog, a member of class TFileAction.

28.1.11.2.1 TFileAction.GetDialog Method

Pascal

```
function GetDialog: TOpenDialog;
```

C++

```
__fastcall TOpenDialog GetDialog();
```

Description

This is GetDialog, a member of class TFileAction.

28.1.11.3 TFileAction Properties

The properties of the TFileAction class are listed here.

Protected Properties

	Name	Description
	FileName (see page 1809)	Specifies the file name for the file selection dialog.

28.1.11.3.1 TFileAction.FileName Property

Specifies the file name for the file selection dialog.

Pascal

```
property FileName: TFileName;
```

C++

```
__property TFileName FileName;
```

Description

Applications can't use the protected FileName property. To access the name of the file selected by the user, use the Dialog property of a TFileAction (see page 1807) descendant.

FileName is the same as the FileName property of the associated dialog.

See Also

FileName

OnAccept (see page 1790)

Dialog (see page 1821)

Dialog (see page 1858)

28.1.12 TFileExit Class

TFileExit is the standard action for shutting down an application.

Class Hierarchy

Pascal

```
TFileExit = class(TCustomAction);
```

C++

```
class TFileExit : public TCustomAction;
```

File

StdActns

Description

Add TFileExit to an action list to let users shut down the application using a menu or tool bar. Controls linked to this action cause the application to shut down by closing the main form.

See Also

TCustomForm

TApplication

28.1.12.1 TFileExit Members

The following tables list the members exposed by TFileExit.

Public Methods

	Name	Description
	ExecuteTarget (see page 1811)	Shuts down the main form of the application.
	HandlesTarget (see page 1811)	Indicates whether the action can execute.

Published Events

	Name	Description
	OnHint (see page 1816)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1816)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1812)	Represents the caption of client controls and menu items.
	Enabled (see page 1812)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1813)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1813)	Indicates the help keyword for client controls and menu items.

	HelpType (see page 1814)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1814)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1814)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1815)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1815)	Specifies the ShortCut property for client menu items.
	Visible (see page 1815)	Specifies the Visible property for client controls and menu items.

28.1.12.2 TFileExit Methods

The methods of the TFileExit class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1811)	Shuts down the main form of the application.
	HandlesTarget (see page 1811)	Indicates whether the action can execute.

28.1.12.2.1 TFileExit.ExecuteTarget Method

Shuts down the main form of the application.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and calls the Close (see page 3538) method of the application's main form. This causes the application to shut down.

See Also

MainForm

Close

28.1.12.2.2 TFileExit.HandlesTarget Method

Indicates whether the action can execute.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to

indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

HandlesTarget always returns true, because shutting down the application does not depend on any target object.

28.1.12.3 TFileExit Properties

The properties of the TFileExit class are listed here.

Published Properties

	Name	Description
	Caption (see page 1812)	Represents the caption of client controls and menu items.
	Enabled (see page 1812)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1813)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1813)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1814)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1814)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1814)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1815)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1815)	Specifies the ShortCut property for client menu items.
	Visible (see page 1815)	Specifies the Visible property for client controls and menu items.

28.1.12.3.1 TFileExit.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.12.3.2 TFileExit.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.12.3.3 TFileExit.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.12.3.4 TFileExit.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.12.3.5 TFileExit.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.12.3.6 TFileExit.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.12.3.7 TFileExit.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an

image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.12.3.8 TFileExit.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.12.3.9 TFileExit.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.12.3.10 TFileExit.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.12.4 TFileExit Events

The events of the TFileExit class are listed here.

Published Events

	Name	Description
	OnHint (see page 1816)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1816)	Occurs when the application is idle or when the action list updates.

28.1.12.4.1 TFileExit.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.12.4.2 TFileExit.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
```

```
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

28.1.13 TFileOpen Class

TFileOpen is the standard action for displaying a file open dialog.

Class Hierarchy

Pascal

```
TFileOpen = class(TFileAction);
```

C++

```
class TFileOpen : public TFileAction;
```

File

StdActns

Description

Add TFileOpen to an action list to add a common file open dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display a file open dialog when invoked. Use the OnAccept (see page 1826) event to respond after the user selects a file name in the file open dialog or the OnCancel (see page 1827) event to respond when the user cancels from the dialog. In the event handler for these events, you can read the file name from the dialog specified by the Dialog (see page 1821) property.

28.1.13.1 TFileOpen Members

The following tables list the members exposed by TFileOpen.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialog (see page 1809)	This is GetDialog, a member of class TFileAction.
	GetDialogClass (see page 1820)	This is GetDialogClass, a member of class TFileOpen.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Protected Properties

	Name	Description
	FileName (see page 1809)	Specifies the file name for the file selection dialog.

Public Methods

	Name	Description
	Create (see page 1819)	Creates an instance of TFileOpen (see page 1817).
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1820)	Executes the associated dialog and generates an OnAccept or OnCancel event.

V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1826)	Occurs immediately before the dialog appears.
	OnAccept (see page 1826)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1827)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1827)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1828)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1821)	Represents the caption of client controls and menu items.
R	Dialog (see page 1821)	Provides access the open dialog that the action executes.
	Enabled (see page 1822)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1822)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1823)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1823)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1824)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1824)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1824)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1825)	Specifies the ShortCut property for client menu items.
	UseDefaultApp (see page 1825)	Use the default application to open the file.
	Visible (see page 1825)	Specifies the Visible property for client controls and menu items.

28.1.13.2 TFileOpen.Create Constructor

Creates an instance of TFileOpen (see page 1817).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFileOpen(TComponent * AOwner);
```

Description

Most applications do not need to call the TFileOpen (see page 1817) constructor because actions are added at design time to an action manager or action list.

The TFileOpen (see page 1817) constructor creates an instance of its associated dialog and assigns that component as the value of the Dialog (see page 1821) property.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TFileOpen (see page 1817) instance.

See Also

Dialog (see page 1821)

Owner

28.1.13.3 TFileOpen Methods

The methods of the TFileOpen class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 1820)	This is GetDialogClass, a member of class TFileOpen.

Public Methods

	Name	Description
	ExecuteTarget (see page 1820)	Executes the associated dialog and generates an OnAccept or OnCancel event.

28.1.13.3.1 TFileOpen.ExecuteTarget Method

Executes the associated dialog and generates an OnAccept or OnCancel event.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and

1. Generates a BeforeExecute event, so that the application can initialize the associated dialog according to current conditions.
2. Calls the Execute method of the dialog.
3. Generates an OnAccept event or an OnCancel event, depending on the value returned by the Execute method. You can write code to make use of the results from executing the dialog in these event handlers.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

BeforeExecute (see page 1790)

28.1.13.3.2 TFileOpen.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TFileOpen.

28.1.13.4 TFileOpen Properties

The properties of the TFileOpen class are listed here.

Published Properties

	Name	Description
	Caption (see page 1821)	Represents the caption of client controls and menu items.
R	Dialog (see page 1821)	Provides access the open dialog that the action executes.
	Enabled (see page 1822)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1822)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1823)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1823)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1824)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1824)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1824)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1825)	Specifies the ShortCut property for client menu items.
	UseDefaultApp (see page 1825)	Use the default application to open the file.
	Visible (see page 1825)	Specifies the Visible property for client controls and menu items.

28.1.13.4.1 TFileOpen.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.13.4.2 TFileOpen.Dialog Property

Provides access the open dialog that the action executes.

Pascal

```
property Dialog: TOpenDialog;
```

C++

```
__property TOpenDialog Dialog;
```

Description

Use Dialog to configure the open dialog before the action fires. For example, you can set the open dialog's default extension or initially selected file at design time using the Object Inspector. From an OnAccept (see page 1826) event handler, use Dialog to read the selected file name.

When using a file open action, you do not place a TOpenDialog component on the form or data module at design time. Instead, you add the TFileOpen (see page 1817) action to your action list and then use the Dialog property. The open dialog component is created by the TFileOpen (see page 1817) constructor.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

FileName

28.1.13.4.3 TFileOpen.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.13.4.4 TFileOpen.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.13.4.5 TFileOpen.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.13.4.6 TFileOpen.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.13.4.7 TFileOpen.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.13.4.8 TFileOpen.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.13.4.9 TFileOpen.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.13.4.10 TFileOpen.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.13.4.11 TFileOpen.UseDefaultApp Property

Use the default application to open the file.

Pascal

```
property UseDefaultApp: Boolean;
```

C++

```
__property Boolean UseDefaultApp;
```

Description

When set to True, UseDefaultApp automatically uses the default application as specified in the registry to open the file. Otherwise, TFileOpen (see page 1817) displays the FileOpen (see page 4143) dialog. The default is False.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

FileName

28.1.13.4.12 TFileOpen.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.13.5 TFileOpen Events

The events of the TFileOpen class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1826)	Occurs immediately before the dialog appears.
	OnAccept (see page 1826)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1827)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1827)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1828)	Occurs when the application is idle or when the action list updates.

28.1.13.5.1 TFileOpen.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.13.5.2 TFileOpen.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.13.5.3 TFileOpen.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.13.5.4 TFileOpen.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.13.5.5 TFileOpen.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
```

```
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

28.1.14 TFileOpenWith Class

TFileOpenWith is the standard action for displaying the dialog that lets users choose what application to user for opening a file.

Class Hierarchy

Pascal

```
TFileOpenWith = class(TFileOpen);
```

C++

```
class TFileOpenWith : public TFileOpen;
```

File

StdActns

Description

Add TFileOpenWith to an action list to add the Open With dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the Open With dialog and then use the chosen application to open the file specified by the FileName (see page 1832) property. If the FileName (see page 1832) property was not previously set, TFileOpenWith first displays an Open dialog in which the user can select a file name before displaying the Open With dialog for the user to specify what application to use when opening that file.

Note: TFileOpenWith always displays the Open With dialog, even if the specified file already has an extension with a registered association. To let users open a file by letting Windows choose the application based on the extension (or bring up the Open With dialog automatically when there is no association for the extension), use the TFileRun action instead.

You do not need to do anything to launch the selected application. TFileOpenWith automatically opens the file using the application that the user selects.

Note: The Dialog (see page 1821) property of TFileOpenWith represents the Open dialog in which a user selects the file to open, not the Open With dialog in which they choose the application to user for opening that file. Similarly, the OnAccept (see page 1826) and OnCancel (see page 1827) events do not occur after the action displays the Open With dialog – rather, they occur after the Open dialog that appears when the FileName (see page 1832) property is not preset.

28.1.14.1 TFileOpenWith Members

The following tables list the members exposed by TFileOpenWith.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialog (see page 1809)	This is GetDialog, a member of class TFileAction.
V	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
V	GetDialogClass (see page 1820)	This is GetDialogClass, a member of class TFileOpen.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Events

	Name	Description
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Public Methods

	Name	Description
V	Create (see page 1785)	Creates an instance of TCommonDialogAction.
V	Create (see page 1819)	Creates an instance of TFileOpen (see page 1817).
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1831)	Displays the Open With dialog and then opens a file with the application the user selects.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	AfterOpen (see page 1834)	Occurs after an application completes opening an Open With dialog.
	BeforeExecute (see page 1834)	Occurs immediately before the dialog appears.
	OnAccept (see page 1826)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1827)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1827)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1835)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1821)	Represents the caption of client controls and menu items.
R	Dialog (see page 1821)	Provides access the open dialog that the action executes.

	Enabled (see page 1822)	Indicates whether client controls and menu items are enabled.
	FileName (see page 1832)	Specifies the file to be opened when the action executes.
	HelpContext (see page 1832)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1833)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1833)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1824)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1824)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1824)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1825)	Specifies the ShortCut property for client menu items.
	UseDefaultApp (see page 1825)	Use the default application to open the file.
	Visible (see page 1825)	Specifies the Visible property for client controls and menu items.

28.1.14.2 TFileOpenWith Methods

The methods of the TFileOpenWith class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1831)	Displays the Open With dialog and then opens a file with the application the user selects.

28.1.14.2.1 TFileOpenWith.ExecuteTarget Method

Displays the Open With dialog and then opens a file with the application the user selects.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and does the following:

1. If the FileName (see page 1832) property is not set, it displays the Open dialog (specified by the Dialog (see page 1821) property) to let the user select a file to open.
2. If it displays the Open dialog, it generates an OnAccept (see page 1826) or OnCancel (see page 1827) event, depending on whether the user exited the Open dialog by clicking OK or Cancel.
3. It displays the Open With dialog for the user to choose an application with which to view the file specified by FileName (see page 1832) or selected in the Open dialog.
4. It launches the selected application, displaying the specified File.

See Also

FileName (see page 1832)

Dialog (see page 1821)

OnAccept (see page 1790)

OnCancel (see page 1791)

28.1.14.3 TFileOpenWith Properties

The properties of the TFileOpenWith class are listed here.

Published Properties

	Name	Description
	FileName (see page 1832)	Specifies the file to be opened when the action executes.
	HelpContext (see page 1832)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1833)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1833)	Indicates the mechanism for client controls and menu items to use when invoking help.

28.1.14.3.1 TFileOpenWith.FileName Property

Specifies the file to be opened when the action executes.

Pascal

```
property FileName: TFileName;
```

C++

```
__property TFileName FileName;
```

Description

Set FileName to specify the file to open with the application that the user selects in the Open With dialog. If the FileName property is not set, then when the action executes, it displays an Open dialog (specified by the Dialog (see page 1821) property) in which the user can select a file before displaying the Open With dialog.

Note: When the action displays the Open dialog, it uses the selected file to set FileName. Thus, if you want to let the user select a file the next time the action executes, you must clear the FileName property in an OnAccept (see page 1826) event handler.

See Also

Dialog (see page 1821)

ExecuteTarget (see page 1831)

OnAccept (see page 1790)

28.1.14.3.2 TFileOpenWith.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated

action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.14.3.3 TFileOpenWith.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.14.3.4 TFileOpenWith.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

HelpType

HelpContext

HelpKeyword

28.1.14.4 TFileOpenWith Events

The events of the TFileOpenWith class are listed here.

Published Events

	Name	Description
	AfterOpen (see page 1834)	Occurs after an application completes opening an Open With dialog.
	BeforeExecute (see page 1834)	Occurs immediately before the dialog appears.
	OnUpdate (see page 1835)	Occurs when the application is idle or when the action list updates.

28.1.14.4.1 TFileOpenWith.AfterOpen Event

Occurs after an application completes opening an Open With dialog.

Pascal

```
property AfterOpen: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterOpen;
```

Description

Write (see page 3707) an AfterOpen event handler to take specific action immediately after an application opens the Open With dialog, but before the user responds to the dialog.

28.1.14.4.2 TFileOpenWith.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.14.4.3 TFileOpenWith.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
```

```
  Then set an object's (such as a button or menu item) Action
  to Action1.
  }
  procedure TMainForm.Action1Update(Sender: TObject);
  begin
    if ((Sender as TAction).Checked <> ToolBar1.Visible) then
      lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
      { Indicate whether ToolBar1 is currently visible }
      (Sender as TAction).Checked := ToolBar1.Visible;
  end;
```

28.1.15 TFilePageSetup Class

TFilePageSetup is the standard action for displaying a page setup dialog.

Class Hierarchy

Pascal

```
TFilePageSetup = class(TCommonDialogAction);
```

C++

```
class TFilePageSetup : public TCommonDialogAction;
```

File

StdActns

Description

Add TFilePageSetup to an action list to add a common page setup dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the page setup dialog when invoked. Because the page setup dialog automatically configures the pages as specified when the user clicks OK, there is usually no need to write an OnAccept (see page 1843) or OnCancel (see page 1843) event handler to continue processing after the dialog shuts down.

See Also

TPrinterSetupDialog

TPrintDlg (see page 1884)

28.1.15.1 TFilePageSetup Members

The following tables list the members exposed by TFilePageSetup.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.

	GetDialogClass (see page 1837)	This is GetDialogClass, a member of class TFilePageSetup.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1842)	Occurs immediately before the dialog appears.
	OnAccept (see page 1843)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1843)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1844)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1844)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1838)	Represents the caption of client controls and menu items.
	Dialog (see page 1838)	Provides access the page setup dialog that the action executes.
	Enabled (see page 1839)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1839)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1840)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1840)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1840)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1841)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1841)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1842)	Specifies the ShortCut property for client menu items.
	Visible (see page 1842)	Specifies the Visible property for client controls and menu items.

28.1.15.2 TFilePageSetup Methods

The methods of the TFilePageSetup class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 1837)	This is GetDialogClass, a member of class TFilePageSetup.

28.1.15.2.1 TFilePageSetup.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TFilePageSetup.

28.1.15.3 TFilePageSetup Properties

The properties of the TFilePageSetup class are listed here.

Published Properties

	Name	Description
	Caption (see page 1838)	Represents the caption of client controls and menu items.
R	Dialog (see page 1838)	Provides access the page setup dialog that the action executes.
	Enabled (see page 1839)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1839)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1840)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1840)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1840)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1841)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1841)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1842)	Specifies the ShortCut property for client menu items.
	Visible (see page 1842)	Specifies the Visible property for client controls and menu items.

28.1.15.3.1 TFilePageSetup.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.15.3.2 TFilePageSetup.Dialog Property

Provides access the page setup dialog that the action executes.

Pascal

```
property Dialog: TPageSetupDialog;
```

C++

```
__property TPageSetupDialog Dialog;
```

Description

When using a file page setup action, you do not place a TPageSetupDialog component on the form or data module at design time. Instead, you add the TFilePageSetup (see page 1836) action to your action list. If you want to configure the dialog, for example to assign a help context, you can access the dialog component using the Dialog property. The page setup dialog component is created by the TFilePageSetup (see page 1836) constructor.

See Also

Create (see page 1785)

28.1.15.3.3 TFilePageSetup.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.15.3.4 TFilePageSetup.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.15.3.5 TFilePageSetup.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

HelpKeyword

HelpContext

HelpType

28.1.15.3.6 TFilePageSetup.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.15.3.7 TFilePageSetup.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.15.3.8 TFilePageSetup.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.15.3.9 TFilePageSetup.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.15.3.10 TFilePageSetup.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.15.3.11 TFilePageSetup.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.15.4 TFilePageSetup Events

The events of the TFilePageSetup class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1842)	Occurs immediately before the dialog appears.
	OnAccept (see page 1843)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1843)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1844)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1844)	Occurs when the application is idle or when the action list updates.

28.1.15.4.1 TFilePageSetup.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.15.4.2 TFilePageSetup.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.15.4.3 TFilePageSetup.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.15.4.4 TFilePageSetup.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.15.4.5 TFilePageSetup.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
```

```
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

28.1.16 TFilePrintSetup Class

TFilePrintSetup is the standard action for displaying a printer setup dialog.

Class Hierarchy

Pascal

```
TFilePrintSetup = class(TCommonDialogAction);
```

C++

```
class TFilePrintSetup : public TCommonDialogAction;
```

File

StdActns

Description

Add TFilePrintSetup to an action list to add a common printer setup dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the printer setup dialog when invoked. Because the printer setup dialog automatically configures the printers as specified when the user clicks OK, there is usually no need to write an OnAccept (see page 1852) or OnCancel (see page 1853) event handler to continue processing after the dialog shuts down.

See Also

TPrinterSetupDialog

TPrintDlg (see page 1884)

28.1.16.1 TFilePrintSetup Members

The following tables list the members exposed by TFilePrintSetup.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1847)	This is GetDialogClass, a member of class TFilePrintSetup.
	Notification (see page 1789)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1852)	Occurs immediately before the dialog appears.
	OnAccept (see page 1852)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1853)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1853)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1854)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1848)	Represents the caption of client controls and menu items.
R	Dialog (see page 1848)	Provides access the printer setup dialog that the action executes.
	Enabled (see page 1848)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1849)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1849)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1850)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1850)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1850)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1851)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1851)	Specifies the ShortCut property for client menu items.
	Visible (see page 1851)	Specifies the Visible property for client controls and menu items.

28.1.16.2 TFilePrintSetup Methods

The methods of the TFilePrintSetup class are listed here.

Protected Methods

	Name	Description
V	GetDialogClass (see page 1847)	This is GetDialogClass, a member of class TFilePrintSetup.

28.1.16.2.1 TFilePrintSetup.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TFilePrintSetup.

28.1.16.3 TFilePrintSetup Properties

The properties of the TFilePrintSetup class are listed here.

Published Properties

	Name	Description
	Caption (see page 1848)	Represents the caption of client controls and menu items.
R	Dialog (see page 1848)	Provides access the printer setup dialog that the action executes.
	Enabled (see page 1848)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1849)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1849)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1850)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1850)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1850)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1851)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1851)	Specifies the ShortCut property for client menu items.

	Visible (see page 1851)	Specifies the Visible property for client controls and menu items.

28.1.16.3.1 TFilePrintSetup.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.16.3.2 TFilePrintSetup.Dialog Property

Provides access the printer setup dialog that the action executes.

Pascal

```
property Dialog: TPrinterSetupDialog;
```

C++

```
__property TPrinterSetupDialog Dialog;
```

Description

When using a file print setup action, you do not place a TPrinterSetupDialog component on the form or data module at design time. Instead, you add the TFilePrintSetup (see page 1845) action to your action list. If you want to configure the dialog, for example to assign a help context, you can access the dialog component using the Dialog property. The printer setup dialog component is created by the TFilePrintSetup (see page 1845) constructor.

See Also

Create (see page 1785)

28.1.16.3.3 TFilePrintSetup.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.16.3.4 TFilePrintSetup.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.16.3.5 TFilePrintSetup.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.16.3.6 TFilePrintSetup.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.16.3.7 TFilePrintSetup.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.16.3.8 TFilePrintSetup.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an

image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.16.3.9 TFilePrintSetup.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.16.3.10 TFilePrintSetup.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.16.3.11 TFilePrintSetup.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.16.4 TFilePrintSetup Events

The events of the TFilePrintSetup class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1852)	Occurs immediately before the dialog appears.
	OnAccept (see page 1852)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1853)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1853)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1854)	Occurs when the application is idle or when the action list updates.

28.1.16.4.1 TFilePrintSetup.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.16.4.2 TFilePrintSetup.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.16.4.3 TFilePrintSetup.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.16.4.4 TFilePrintSetup.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The

OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.16.4.5 TFilePrintSetup.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
```

```
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

28.1.17 TFileSaveAs Class

TFileSaveAs is the standard action for displaying a file save as dialog.

Class Hierarchy

Pascal

```
TFileSaveAs = class(TFileAction);
```

C++

```
class TFileSaveAs : public TFileAction;
```

File

StdActns

Description

Add TFileSaveAs to an action list to add a common file save dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display a file save dialog when invoked. Use the OnAccept (see page 1862) event to respond after the user selects a file name in the file save dialog or the OnCancel (see page 1862) event to respond when the user cancels from the dialog. In the event handler for these events, you can read the file name from the dialog specified by the Dialog (see page 1858) property.

TFileOpen (see page 1817)

TSaveDialog

TSavePicture

28.1.17.1 TFileSaveAs Members

The following tables list the members exposed by TFileSaveAs.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialog (see page 1809)	This is GetDialog, a member of class TFileAction.
V	GetDialogClass (see page 1857)	This is GetDialogClass, a member of class TFileSaveAs.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Protected Properties

	Name	Description
	FileName (see page 1809)	Specifies the file name for the file selection dialog.

Public Methods

	Name	Description
V	Create (see page 1856)	Creates an instance of TFileSaveAs (see page 1855).
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1861)	Occurs immediately before the dialog appears.
	OnAccept (see page 1862)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1862)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1863)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1863)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1858)	Represents the caption of client controls and menu items.
R	Dialog (see page 1858)	Provides access the save dialog that the action executes.
	Enabled (see page 1858)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1859)	Indicates the help context ID for client controls and menu items.
	Hint (see page 1859)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1860)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1860)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1860)	Specifies the ShortCut property for client menu items.
	Visible (see page 1861)	Specifies the Visible property for client controls and menu items.

28.1.17.2 TFileSaveAs.Create Constructor

Creates an instance of TFileSaveAs (see page 1855).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFileSaveAs(TComponent * AOwner);
```

Description

Most applications do not need to call the TFileSaveAs (see page 1855) constructor because actions are added at design time to an action manager or action list.

The TFileSaveAs (see page 1855) constructor creates an instance of its associated dialog and assigns that component as the value of the Dialog (see page 1858) property.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TFileSaveAs (see page 1855) instance.

See Also

Dialog (see page 1858)

Owner

28.1.17.3 TFileSaveAs Methods

The methods of the TFileSaveAs class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 1857)	This is GetDialogClass, a member of class TFileSaveAs.

28.1.17.3.1 TFileSaveAs.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TFileSaveAs.

28.1.17.4 TFileSaveAs Properties

The properties of the TFileSaveAs class are listed here.

Published Properties

	Name	Description
	Caption (see page 1858)	Represents the caption of client controls and menu items.
R	Dialog (see page 1858)	Provides access the save dialog that the action executes.
	Enabled (see page 1858)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1859)	Indicates the help context ID for client controls and menu items.
	Hint (see page 1859)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1860)	Indicates the ImageIndex property for client controls and menu items.

	SecondaryShortCuts (see page 1860)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1860)	Specifies the ShortCut property for client menu items.
	Visible (see page 1861)	Specifies the Visible property for client controls and menu items.

28.1.17.4.1 TFileSaveAs.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.17.4.2 TFileSaveAs.Dialog Property

Provides access the save dialog that the action executes.

Pascal

```
property Dialog: TSaveDialog;
```

C++

```
__property TSaveDialog Dialog;
```

Description

Use Dialog to configure the save as dialog before the action fires. For example, you can set the save as dialog's default extension at design time using the Object Inspector. Dialog is also useful for reading the selected file name from an OnAccept (see page 1862) event handler.

When using a file save as action, you do not place a TSaveDialog component on the form or data module at design time. Instead, you add the TFileSaveAs (see page 1855) to your action list and then use the Dialog property. The save dialog component is created by the TFileSaveAs (see page 1855) constructor.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

28.1.17.4.3 TFileSaveAs.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.17.4.4 TFileSaveAs.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

HelpType

HelpKeyword

28.1.17.4.5 TFileSaveAs.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.17.4.6 TFileSaveAs.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.17.4.7 TFileSaveAs.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.17.4.8 TFileSaveAs.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.17.4.9 TFileSaveAs.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.17.5 TFileSaveAs Events

The events of the TFileSaveAs class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1861)	Occurs immediately before the dialog appears.
	OnAccept (see page 1862)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1862)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1863)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1863)	Occurs when the application is idle or when the action list updates.

28.1.17.5.1 TFileSaveAs.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.17.5.2 TFileSaveAs.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.17.5.3 TFileSaveAs.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.17.5.4 TFileSaveAs.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.17.5.5 TFileSaveAs.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
```

```
    }
//    pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

28.1.18 TFontEdit Class

TFontEdit is the standard action for displaying a font selection dialog.

Class Hierarchy

Pascal

```
TFontEdit = class(TCommonDialogAction);
```

C++

```
class TFontEdit : public TCommonDialogAction;
```

File

StdActns

Description

Add TFontEdit to an action list to add a modal font selection dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display a font dialog when invoked. Use the OnAccept (see page 1871) event to respond after the user selects a font in the dialog or the OnCancel (see page 1872) event to respond when the user cancels from the dialog. In the event handler, you can read the selected font from the dialog specified by the Dialog (see page 1867) property.

See Also

TFontDialog

28.1.18.1 TFontEdit Members

The following tables list the members exposed by TFontEdit.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
V	GetDialogClass (see page 1866)	This is GetDialogClass, a member of class TFontEdit.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
V	Create (see page 1785)	Creates an instance of TCommonDialogAction.
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1871)	Occurs immediately before the dialog appears.
	OnAccept (see page 1871)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1872)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1872)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1872)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1866)	Represents the caption of client controls and menu items.
R	Dialog (see page 1867)	Provides access the font selection dialog that the action executes.
	Enabled (see page 1867)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1867)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1868)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1868)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1869)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1869)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1870)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1870)	Specifies the ShortCut property for client menu items.

	Visible (see page 1870)	Specifies the Visible property for client controls and menu items.

28.1.18.2 TFontEdit Methods

The methods of the TFontEdit class are listed here.

Protected Methods

	Name	Description
V	GetDialogClass (see page 1866)	This is GetDialogClass, a member of class TFontEdit.

28.1.18.2.1 TFontEdit.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TFontEdit.

28.1.18.3 TFontEdit Properties

The properties of the TFontEdit class are listed here.

Published Properties

	Name	Description
	Caption (see page 1866)	Represents the caption of client controls and menu items.
R	Dialog (see page 1867)	Provides access the font selection dialog that the action executes.
	Enabled (see page 1867)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1867)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1868)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1868)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1869)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1869)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1870)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1870)	Specifies the ShortCut property for client menu items.
	Visible (see page 1870)	Specifies the Visible property for client controls and menu items.

28.1.18.3.1 TFontEdit.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and

menu items.

See Also

Caption

Caption

28.1.18.3.2 TFontEdit.Dialog Property

Provides access the font selection dialog that the action executes.

Pascal

```
property Dialog: TFontDialog;
```

C++

```
__property TFontDialog Dialog;
```

Description

Use Dialog to configure the font selection dialog before the action fires or to read the selected font after the action executes the dialog. For example, you can set the font dialog's target device or limit the available font sizes at design time using the Object Inspector or read the Font property in an OnAccept (see page 1871) event handler to make use of the font that the user selects.

When using a font edit action, you do not place a TFontDialog component on the form or data module at design time. Instead, you add the TFontEdit (see page 1864) to your action list and then use the Dialog property. The font selection dialog component is created by the TFontEdit (see page 1864) constructor.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Font

28.1.18.3.3 TFontEdit.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.18.3.4 TFontEdit.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.18.3.5 TFontEdit.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.18.3.6 TFontEdit.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.18.3.7 TFontEdit.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.18.3.8 TFontEdit.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.18.3.9 TFontEdit.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.18.3.10 TFontEdit.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.18.3.11 TFontEdit.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.18.4 TFontEdit Events

The events of the TFontEdit class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1871)	Occurs immediately before the dialog appears.
	OnAccept (see page 1871)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1872)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1872)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1872)	Occurs when the application is idle or when the action list updates.

28.1.18.4.1 TFontEdit.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.18.4.2 TFontEdit.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the

user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.18.4.3 TFontEdit.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.18.4.4 TFontEdit.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.18.4.5 TFontEdit.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
```

```
end;
```

See Also

UpdateAction

28.1.19 THelpAction Class

THelpAction is the base class for action objects that interact with the help system.

Class Hierarchy

Pascal

```
THelpAction = class(TAction);
```

C++

```
class THelpAction : public TAction;
```

File

StdActns

Description

THelpAction implements the common behavior for actions that work the help system. Each descendant class performs a specific help function. Do not use THelpAction directly in an application. Instead, use a THelpAction descendant such as THelpContents (see page 1876), THelpContextAction (see page 1877), THelpOnHelp (see page 1879), or THelpTopicSearch (see page 1881).

THelpAction ensures that the action is enabled as long as there is an application object to pass commands on to a registered help system. THelpAction descendants override the ExecuteTarget method to execute their specific help command.

See Also

THelpContents (see page 1876)

THelpContextAction (see page 1877)

THelpOnHelp (see page 1879)

THelpTopicSearch (see page 1881)

TApplication

28.1.19.1 THelpAction Members

The following tables list the members exposed by THelpAction.

Public Methods

	Name	Description
	Create (see page 1875)	Creates and initializes a TAction object.
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1875)	Enables or disables the action, depending on the availability of the Application object.

28.1.19.2 THelpAction.Create Constructor

Creates and initializes a TAction object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall THelpAction(TComponent * AOwner);
```

Description

Applications do not usually create action objects explicitly. Actions are created automatically when you add them to an action manager or action list component at design time. When instantiating TAction at runtime, assign a TActionList or TActionManager component to the new action's ActionList property after calling Create.

See Also

ActionList

28.1.19.3 THelpAction Methods

The methods of the THelpAction class are listed here.

Public Methods

	Name	Description
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1875)	Enables or disables the action, depending on the availability of the Application object.

28.1.19.3.1 THelpAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

As implemented in THelpAction (see page 1874), HandlesTarget ignores the Target parameter and always returns true, because the help actions do not rely on a specific target object.

28.1.19.3.2 THelpAction.UpdateTarget Method

Enables or disables the action, depending on the availability of the Application object.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In THelpAction (see page 1874), UpdateTarget checks whether the global Application variable is assigned, because this object is required to pass help commands on to WinHelp HyperHelp. If Application is assigned, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

Application

28.1.20 THelpContents Class

THelpContents brings up the contents for the default help system.

Class Hierarchy

Pascal

```
THelpContents = class(THelpAction);
```

C++

```
class THelpContents : public THelpAction;
```

File

StdActns

Description

Add THelpContents to an action list to allow users to bring up the help contents by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to send the default help system a command to show the help contents.

On WinHelp, THelpContents displays the Help Topics dialog on the tab (Contents, Index or Find) that was last used.

See Also

THelpContextAction (see page 1877)

THelpOnHelp (see page 1879)

THelpTopicSearch (see page 1881)

28.1.20.1 THelpContents Members

The following tables list the members exposed by THelpContents.

Public Methods

	Name	Description
	Create (see page 1875)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1877)	Displays a dialog that lists the help topics.
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1875)	Enables or disables the action, depending on the availability of the Application object.

28.1.20.2 THelpContents Methods

The methods of the THelpContents class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1877)	Displays a dialog that lists the help topics.

28.1.20.2.1 THelpContents.ExecuteTarget Method

Displays a dialog that lists the help topics.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget calls the application's HelpCommand method, telling it to list the help topics.

28.1.21 THelpContextAction Class

THelpContextAction brings up the help topic for the active control.

Class Hierarchy

Pascal

```
THelpContextAction = class(THelpAction);
```

C++

```
class THelpContextAction : public THelpAction;
```

File

StdActns

Description

Add THelpContextAction to an action list to allow users to bring up the help for an active control. Controls such as menu items and tool buttons linked to this action cause the application to send the help engine a command to display the help topic specified by the active control's HelpContext property.

THelpTopicSearch (see page 1881)

THelpOnHelp (see page 1879)

TControl

TScreen

28.1.21.1 THelpContextAction Members

The following tables list the members exposed by THelpContextAction.

Public Methods

	Name	Description
	Create (see page 1875)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1878)	Displays the help topic associated with the active control's HelpContext property.
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1879)	Enables or disables the action, depending on whether there is an active object.

28.1.21.2 THelpContextAction Methods

The methods of the THelpContextAction class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1878)	Displays the help topic associated with the active control's HelpContext property.
	UpdateTarget (see page 1879)	Enables or disables the action, depending on whether there is an active object.

28.1.21.2.1 THelpContextAction.ExecuteTarget Method

Displays the help topic associated with the active control's HelpContext property.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget calls the application's HelpCommand method, telling it to display the topic specified by the active control's

HelpContext property. ExecuteTarget gets the active control from the global Screen object rather than using the Target parameter.

See Also

HelpCommand

ActiveControl

HelpContext

28.1.21.2.2 THelpContextAction.UpdateTarget Method

Enables or disables the action, depending on whether there is an active object.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In THelpContextAction (see page 1877), UpdateTarget checks whether the global Screen object's ActiveConrol property is assigned. If there is an active control, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

ActiveControl

28.1.22 THelpOnHelp Class

THelpOnHelp brings up a help topic on how to use Help.

Class Hierarchy

Pascal

```
THelpOnHelp = class(THelpAction);
```

C++

```
class THelpOnHelp : public THelpAction;
```

File

StdActns

Description

Add THelpOnHelp to an action list to allow users to bring up the help system that describes how to use help. Controls such as menu items and tool buttons linked to this action cause the application to send the default help system a command to display its help.

Note that on recent versions of Windows with a default help system of WinHelp, this brings up an HTML help file that does not describe the WinHelp system.

See Also

THelpContents (see page 1876)

THelpContextAction (see page 1877)

THelpTopicSearch (see page 1881)

28.1.22.1 THelpOnHelp Members

The following tables list the members exposed by THelpOnHelp.

Public Methods

	Name	Description
	Create (see page 1875)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1880)	Brings up the help system's help file.
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1875)	Enables or disables the action, depending on the availability of the Application object.

28.1.22.2 THelpOnHelp Methods

The methods of the THelpOnHelp class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1880)	Brings up the help system's help file.

28.1.22.2.1 THelpOnHelp.ExecuteTarget Method

Brings up the help system's help file.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget calls the application's HelpCommand method, telling it to display the Help system's own help file.

See Also

HelpCommand

28.1.23 THelpTopicSearch Class

THelpTopicSearch brings up the help index.

Class Hierarchy

Pascal

```
THelpTopicSearch = class(THelpAction);
```

C++

```
class THelpTopicSearch : public THelpAction;
```

File

StdActns

Description

Add THelpTopicSearch to an action list to allow users to bring up the help index. Controls such as menu items and tool buttons linked to this action cause the application to send the default help system a command to display the help index.

See Also

THelpContextAction (see page 1877)

THelpOnHelp (see page 1879)

28.1.23.1 THelpTopicSearch Members

The following tables list the members exposed by THelpTopicSearch.

Public Methods

	Name	Description
	Create (see page 1875)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1881)	Displays the Help Topics dialog with the index tab selected.
	HandlesTarget (see page 1875)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1875)	Enables or disables the action, depending on the availability of the Application object.

28.1.23.2 THelpTopicSearch Methods

The methods of the THelpTopicSearch class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1881)	Displays the Help Topics dialog with the index tab selected.

28.1.23.2.1 THelpTopicSearch.ExecuteTarget Method

Displays the Help Topics dialog with the index tab selected.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget calls the application's HelpCommand method, telling it to display the Help index.

28.1.24 THintAction Class

THintAction is the action that executes when the user pauses the mouse over a control or menu item that has a hint.

Class Hierarchy

Pascal

```
THintAction = class(TCustomAction);
```

C++

```
class THintAction : public TCustomAction;
```

File

StdActns

Description

Do not use THintAction in an action manager or action list the way you would use other predefined actions. THintAction is not intended to work with a client control. Rather, it is used by the application object.

When the user pauses the mouse over a control or menu item that defines its Hint (see page 1884) property, the application responds in one of two ways:

If the application has an OnHint event handler, it generates an OnHint event.

If there is no OnHint event handler, the application executes a THintAction object.

When THintAction executes, it calls the ExecuteAction method of potential target controls until a control is found to respond to the action. Some controls, such as TStatusBar, override the ExecuteAction method to respond to THintAction.

Component writers can override the ExecuteAction method of a new component to respond to THintAction by displaying hint messages. Such an ExecuteAction method might look like the following:

```
function TMyControl.ExecuteAction(Action: TBasicAction): Boolean;
var
  HintText: string;
begin
if Action is THintAction then
begin
    HintText := THintAction(Action).Hint;
    { do something to display the hint text }
    Result := True;
```

```
end
else Result := inherited ExecuteAction(Action);
end;
bool __fastcall TMyControl::ExecuteAction(TBasicAction *Action)
{
  THintAction *pHint = dynamic_cast<THintAction *>(Action);
if (pHint)
  {
    // do something to display pHint->Hint
returntrue;
  }
return TComponent::ExecuteAction(Action);
}
```

See Also

TControl

TMenuItem

TComponent

TApplication

28.1.24.1 THintAction Members

The following tables list the members exposed by THintAction.

Public Methods

	Name	Description
	Create (see page 1883)	Creates an instance of THintAction (see page 1882).

Published Properties

	Name	Description
	Hint (see page 1884)	Indicates the Help hint for client controls and menu items.

28.1.24.2 THintAction.Create Constructor

Creates an instance of THintAction (see page 1882).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall THintAction(TComponent * AOwner);
```

Description

Typically, you do not need to create THintAction (see page 1882) instances. THintAction (see page 1882) is created by the application object when it detects the need to display a hint.

You can, however, create a THintAction (see page 1882) object, set its Hint (see page 1884) property, and then call its Execute method to cause other controls in the application (such as status bars) to display a message for some application-generated condition (such as a status message).

AOwner is the component, typically the application object, that is responsible for freeing the THintAction (see page 1882) object.

See Also

Owner

Hint

Execute

28.1.24.3 THintAction Properties

The properties of the THintAction class are listed here.

Published Properties

	Name	Description
	Hint (see page 1884)	Indicates the Help hint for client controls and menu items.

28.1.24.3.1 THintAction.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.25 TPrintDlg Class

TPrintDlg is the standard action for displaying a print dialog.

Class Hierarchy

Pascal

```
TPrintDlg = class(TCommonDialogAction);
```

C++

```
class TPrintDlg : public TCommonDialogAction;
```

File

StdActns

Description

Add TPrintDlg to an action list to add a print dialog to your application. Controls such as menu items and tool buttons linked to

this action cause the application to display the print dialog (TPrintDialog) when invoked. Write (see page 3707) an OnAccept (see page 1891) event handler to perform the actual printing when the user clicks OK. You can read details about the user's selections in the dialog from the Dialog (see page 1887) property.

See Also

TPrintDialog

TFilePrintSetup (see page 1845)

28.1.25.1 TPrintDlg Members

The following tables list the members exposed by TPrintDlg.

Protected Fields

	Name	Description
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.

Protected Methods

	Name	Description
V	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
V	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
V	GetDialogClass (see page 1886)	This is GetDialogClass, a member of class TPrintDlg.
V	Notification (see page 1789)	Responds when components are created or destroyed.
V	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
V	Create (see page 1785)	Creates an instance of TCommonDialogAction.
V	Destroy (see page 1786)	Frees an instance of TCustomAction.
V	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
V	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.

Public Properties

	Name	Description
R	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1891)	Occurs immediately before the dialog appears.
	OnAccept (see page 1891)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1892)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1892)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1893)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1886)	Represents the caption of client controls and menu items.
R	Dialog (see page 1887)	Provides access the print dialog that the action executes.
	Enabled (see page 1887)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1888)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1888)	Indicates the help keyword for client controls and menu items.

	HelpType (see page 1889)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1889)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1889)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1890)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1890)	Specifies the ShortCut property for client menu items.
	Visible (see page 1890)	Specifies the Visible property for client controls and menu items.

28.1.25.2 TPrintDlg Methods

The methods of the TPrintDlg class are listed here.

Protected Methods

	Name	Description
V	GetDialogClass (see page 1886)	This is GetDialogClass, a member of class TPrintDlg.

28.1.25.2.1 TPrintDlg.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TPrintDlg.

28.1.25.3 TPrintDlg Properties

The properties of the TPrintDlg class are listed here.

Published Properties

	Name	Description
	Caption (see page 1886)	Represents the caption of client controls and menu items.
R	Dialog (see page 1887)	Provides access the print dialog that the action executes.
	Enabled (see page 1887)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1888)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1888)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1889)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1889)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1889)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1890)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1890)	Specifies the ShortCut property for client menu items.
	Visible (see page 1890)	Specifies the Visible property for client controls and menu items.

28.1.25.3.1 TPrintDlg.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.25.3.2 TPrintDlg.Dialog Property

Provides access the print dialog that the action executes.

Pascal

```
property Dialog: TPrintDialog;
```

C++

```
__property TPrintDialog Dialog;
```

Description

When using a print dialog action, you do not place a TPrintDialog component on the form or data module at design time. Instead, you add the TPrintDlg (see page 1884) action to your action list. If you want to configure the dialog, for example to set the Options that are available to users, you can access the dialog component using the Dialog property. From an OnAccept (see page 1891) event handler, use Dialog to read the choices that the user made in the print dialog and then perform the printing based on those choices.

The print dialog component is created by the TPrintDlg (see page 1884) constructor.

See Also

Create (see page 1785)

Options

OnAccept (see page 1790)

28.1.25.3.3 TPrintDlg.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.25.3.4 TPrintDlg.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.25.3.5 TPrintDlg.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.25.3.6 TPrintDlg.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.25.3.7 TPrintDlg.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.25.3.8 TPrintDlg.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.25.3.9 TPrintDlg.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.25.3.10 TPrintDlg.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.25.3.11 TPrintDlg.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.25.4 TPrintDlg Events

The events of the TPrintDlg class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1891)	Occurs immediately before the dialog appears.
	OnAccept (see page 1891)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1892)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1892)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1893)	Occurs when the application is idle or when the action list updates.

28.1.25.4.1 TPrintDlg.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.25.4.2 TPrintDlg.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.25.4.3 TPrintDlg.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.25.4.4 TPrintDlg.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.25.4.5 TPrintDlg.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
```

```
  Then set an object's (such as a button or menu item) Action
  to Action1.
  }
  procedure TMainForm.Action1Update(Sender: TObject);
  begin
    if ((Sender as TAction).Checked <> ToolBar1.Visible) then
      lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
      { Indicate whether ToolBar1 is currently visible }
      (Sender as TAction).Checked := ToolBar1.Visible;
  end;
```

28.1.26 TSearchAction Class

TSearchAction is the base class for action objects that display a search or search and replace dialog.

Class Hierarchy

Pascal

```
TSearchAction = class(TCommonDialogAction);
```

C++

```
class TSearchAction : public TCommonDialogAction;
```

File

StdActns

Description

TSearchAction implements the common behavior for actions that display a modeless dialog where the user can enter a search string for searching an edit control. Do not use TSearchAction directly in an application. Instead, use one of the TSearchAction descendants: TSearchFind (see page 1899) or TSearchFindFirst (see page 1909) for a simple locate dialog, TSearchReplace (see page 1921) for a locate-and-replace dialog.

TSearchAction descendants are designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. They automatically disable themselves if the active control in a form is not an edit control.

Unlike other dialog actions, search actions represent a modeless dialog. As a result, the OnAccept (see page 1790) event occurs not when the user exits the dialog, but when the dialog first appears or comes into focus. When the user directs the dialog to search for or replace a string, the search action automatically performs that search, selecting or replacing text in the target edit control.

TSearchFind (see page 1899)

TSearchReplace (see page 1921)

TSearchFindNext (see page 1912)

TCustomEdit (see page 2345)

TSearchFindFirst (see page 1909)

28.1.26.1 TSearchAction Members

The following tables list the members exposed by TSearchAction.

Protected Fields

	Name	Description
	FControl (see page 1896)	This is FControl, a member of class TSearchAction.
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.
	FFindFirst (see page 1897)	This is FFindFirst, a member of class TSearchAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
	Notification (see page 1898)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Events

	Name	Description
	BeforeExecute (see page 1790)	Occurs immediately before the dialog appears.
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Public Methods

	Name	Description
	Create (see page 1895)	Creates and initializes an instance of TSearchAction (see page 1894).
	Destroy (see page 1896)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1897)	Launches the associated dialog.
	HandlesTarget (see page 1898)	Indicates whether the action can execute its dialog.
	Search (see page 1898)	Selects the next occurrence of the search string in the target edit control.
	UpdateTarget (see page 1899)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

28.1.26.2 TSearchAction.Create Constructor

Creates and initializes an instance of TSearchAction (see page 1894).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSearchAction(TComponent * AOwner);
```

Description

Most applications do not need to call the TSearchAction (see page 1894) constructor because actions are added at design time to action lists or action managers.

The TSearchAction (see page 1894) constructor creates an instance of its associated dialog, which descendant classes surface as the Dialog property. It then assigns the Search (see page 1898) method as an event handler for the dialog's OnFind event, so that the action responds automatically when user's direct the dialog to search for a specified text string.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TSearchAction (see page 1894) instance.

See Also

Dialog (see page 1902)

Dialog (see page 1925)

Owner

Search (see page 1898)

OnFind

28.1.26.3 TSearchAction.Destroy Destructor

Frees an instance of TCustomAction.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSearchAction();
```

Description

Do not call the destructor directly in an application. Instead, call Free. Free ensures that the action is not nil before calling the destructor.

If the action is contained in an action list or action manager, Destroy removes the action from that list.

Create

Actions

28.1.26.4 TSearchAction Fields

The fields of the TSearchAction class are listed here.

Protected Fields

	Name	Description
	FControl (see page 1896)	This is FControl, a member of class TSearchAction.
	FFindFirst (see page 1897)	This is FFindFirst, a member of class TSearchAction.

28.1.26.4.1 TSearchAction.FControl Field

Pascal

```
FControl: TCustomEdit;
```

C++

```
TCustomEdit FControl;
```

Description

This is FControl, a member of class TSearchAction.

28.1.26.4.2 TSearchAction.FFindFirst Field

Pascal

```
FFindFirst: Boolean;
```

C++

```
Boolean FFindFirst;
```

Description

This is FFindFirst, a member of class TSearchAction.

28.1.26.5 TSearchAction Methods

The methods of the TSearchAction class are listed here.

Protected Methods

	Name	Description
	Notification (see page 1898)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	ExecuteTarget (see page 1897)	Launches the associated dialog.
	HandlesTarget (see page 1898)	Indicates whether the action can execute its dialog.
	Search (see page 1898)	Selects the next occurrence of the search string in the target edit control.
	UpdateTarget (see page 1899)	Enables or disables the action, depending on the currently active control in the form.

28.1.26.5.1 TSearchAction.ExecuteTarget Method

Launches the associated dialog.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget first launches its search or search and replace dialog. This is a modeless dialog, so the result of the dialog's Execute method simply indicates whether the dialog successfully appeared or was brought into focus. This result is set as the value of the ExecuteResult (see page 1789) property, and an OnAccept (see page 1790) or OnCancel (see page 1791) event occurs, depending on whether the dialog was brought into focus.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Execute

ExecuteResult (see page 1789)

28.1.26.5.2 TSearchAction.HandlesTarget Method

Indicates whether the action can execute its dialog.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method lets the action object indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

HandlesTarget returns true if the target is an edit control that has keyboard focus.

28.1.26.5.3 TSearchAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

28.1.26.5.4 TSearchAction.Search Method

Selects the next occurrence of the search string in the target edit control.

Pascal

```
procedure Search(Sender: TObject); virtual;
```

C++

```
virtual __fastcall Search(TObject * Sender);
```

Description

Most applications have no need to call the Search method: the TSearchAction (see page 1894) constructor automatically assigns Search as the OnFind event handler of its associated dialog. The dialog's OnFind event occurs when the user directs the dialog to find a specified string.

Search searches the target edit control for the string that is the FindText property of the search dialog, using the options specified by the dialog's Options property. If it finds the specified string, it selects it in the edit control. Otherwise, it displays a message to the user indicating that the string was not found.

Note: If the search action is an instance of TSearchFind (see page 1899), Search looks for the first occurrence of FindText after the current selection in the edit control. If the search action is an instance of TSearchFindFirst (see page 1909), Search looks for the first occurrence of FindText, regardless of the current selection.

OnFind

Options

FindText

28.1.26.5.5 TSearchAction.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TSearchAction (see page 1894), UpdateTarget checks whether the current target object (specified by the Target parameter) is an edit control. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

Enabled

28.1.27 TSearchFind Class

TSearchFind is the standard action for displaying a find dialog.

Class Hierarchy

Pascal

```
TSearchFind = class(TSearchAction);
```

C++

```
class TSearchFind : public TSearchAction;
```

File

StdActns

Description

Add TSearchFind to an action list to add a modeless find dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the find dialog or bring it to the fore.

TSearchFind is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control.

Search (see page 1898) actions represent a modeless dialog. As a result, the OnAccept (see page 1907) event occurs not when the user exits the dialog, but when the dialog first appears or comes into focus. When the user directs the dialog to search for a string, TSearchFind automatically performs that search, selecting the specified text in the target edit control.

TCustomEdit (see page 2345)

TSearchFindFirst (see page 1909)

28.1.27.1 TSearchFind Members

The following tables list the members exposed by TSearchFind.

Protected Fields

	Name	Description
	FControl (see page 1896)	This is FControl, a member of class TSearchAction.
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.
	FFindFirst (see page 1897)	This is FFindFirst, a member of class TSearchAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1901)	This is GetDialogClass, a member of class TSearchFind.
	Notification (see page 1789)	Responds when components are created or destroyed.
	Notification (see page 1898)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Create (see page 1895)	Creates and initializes an instance of TSearchAction (see page 1894).
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	Destroy (see page 1896)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	ExecuteTarget (see page 1897)	Launches the associated dialog.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.
	HandlesTarget (see page 1898)	Indicates whether the action can execute its dialog.

	Search (see page 1898)	Selects the next occurrence of the search string in the target edit control.
	UpdateTarget (see page 1899)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1906)	Occurs immediately before the dialog appears.
	OnAccept (see page 1907)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1907)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1908)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1908)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1902)	Represents the caption of client controls and menu items.
	Dialog (see page 1902)	Provides access the find dialog that the action executes.
	Enabled (see page 1903)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1903)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1903)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1904)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1904)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1905)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1905)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1905)	Specifies the ShortCut property for client menu items.
	Visible (see page 1906)	Specifies the Visible property for client controls and menu items.

28.1.27.2 TSearchFind Methods

The methods of the TSearchFind class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 1901)	This is GetDialogClass, a member of class TSearchFind.

28.1.27.2.1 TSearchFind.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TSearchFind.

28.1.27.3 TSearchFind Properties

The properties of the TSearchFind class are listed here.

Published Properties

	Name	Description
	Caption (see page 1902)	Represents the caption of client controls and menu items.
R	Dialog (see page 1902)	Provides access the find dialog that the action executes.
	Enabled (see page 1903)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1903)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1903)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1904)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1904)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1905)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1905)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1905)	Specifies the ShortCut property for client menu items.
	Visible (see page 1906)	Specifies the Visible property for client controls and menu items.

28.1.27.3.1 TSearchFind.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.27.3.2 TSearchFind.Dialog Property

Provides access the find dialog that the action executes.

Pascal

```
property Dialog: TFindDialog;
```

C++

```
__property TFindDialog Dialog;
```

Description

Use Dialog to configure the find dialog before the action fires or to close the modeless dialog programmatically. For example, you can set the find dialog's options at design time using the Object Inspector or call the dialog's CloseDialog method to close it.

When using a search-find action, you do not place a TFindDialog component on the form or data module at design time. Instead, you add the TSearchFind (see page 1899) action to your action list and then use the Dialog property. The find dialog

component is created by the TSearchFind (see page 1899) constructor.

See Also

ExecuteTarget (see page 1897)

CloseDialog

28.1.27.3.3 TSearchFind.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.27.3.4 TSearchFind.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.27.3.5 TSearchFind.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.27.3.6 TSearchFind.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.27.3.7 TSearchFind.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.27.3.8 TSearchFind.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.27.3.9 TSearchFind.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.27.3.10 TSearchFind.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.27.3.11 TSearchFind.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.27.4 TSearchFind Events

The events of the TSearchFind class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1906)	Occurs immediately before the dialog appears.
	OnAccept (see page 1907)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1907)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1908)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1908)	Occurs when the application is idle or when the action list updates.

28.1.27.4.1 TSearchFind.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.27.4.2 TSearchFind.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.27.4.3 TSearchFind.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel

occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.27.4.4 TSearchFind.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.27.4.5 TSearchFind.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
```

```
    // Indicate whether ToolBar1 is currently visible.
    TAction* pa = dynamic_cast<TAction*>(Sender);
    if (pa)
    {
      if (checked != ToolBar1->Visible)
      {
        lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
      }
      checked = ToolBar1->Visible;
    }
//    pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

28.1.28 TSearchFindFirst Class

TSearchFindFirst is the standard action for displaying a find dialog that looks for the first occurrence of a string.

Class Hierarchy

Pascal

```
TSearchFindFirst = class(TSearchFind);
```

C++

```
class TSearchFindFirst : public TSearchFind;
```

File

StdActns

Description

Add TSearchFindFirst to an action list to add a modeless find dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the find dialog or bring it to the fore.

TSearchFindFirst is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control.

Search (see page 1898) actions represent a modeless dialog. As a result, the OnAccept (see page 1907) event occurs not when the user exits the dialog, but when the dialog first appears or comes into focus. When the user directs the dialog to search for a string, TSearchFindFirst automatically performs that search, selecting the specified text in the target edit control. Unlike the TSearchFind (see page 1899) action, which locates the first occurrence of the search string following the cursor position in the edit control, TSearchFindFirst locates the first occurrence of the search string, regardless of the cursor position.

28.1.28.1 TSearchFindFirst Members

The following tables list the members exposed by TSearchFindFirst.

Protected Fields

	Name	Description
	FControl (see page 1896)	This is FControl, a member of class TSearchAction.
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.
	FFindFirst (see page 1897)	This is FFindFirst, a member of class TSearchAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1788)	This is GetDialogClass, a member of class TCommonDialogAction.
	GetDialogClass (see page 1901)	This is GetDialogClass, a member of class TSearchFind.
	Notification (see page 1789)	Responds when components are created or destroyed.
	Notification (see page 1898)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Events

	Name	Description
	BeforeExecute (see page 1790)	Occurs immediately before the dialog appears.
	OnAccept (see page 1790)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1791)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Public Methods

	Name	Description
	Create (see page 1911)	Creates and initializes an instance of TSearchFindFirst (see page 1909).

	Destroy (see page 1786)	Frees an instance of TCustomAction.
	Destroy (see page 1896)	Frees an instance of TCustomAction.
	ExecuteTarget (see page 1787)	Executes the associated dialog and generates an OnAccept (see page 1790) or OnCancel (see page 1791) event.
	ExecuteTarget (see page 1897)	Launches the associated dialog.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.
	HandlesTarget (see page 1898)	Indicates whether the action can execute its dialog.
	Search (see page 1898)	Selects the next occurrence of the search string in the target edit control.
	UpdateTarget (see page 1899)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1906)	Occurs immediately before the dialog appears.
	OnAccept (see page 1907)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1907)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1908)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1908)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1902)	Represents the caption of client controls and menu items.
	Dialog (see page 1902)	Provides access the find dialog that the action executes.
	Enabled (see page 1903)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1903)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1903)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1904)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1904)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1905)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1905)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1905)	Specifies the ShortCut property for client menu items.
	Visible (see page 1906)	Specifies the Visible property for client controls and menu items.

28.1.28.2 TSearchFindFirst.Create Constructor

Creates and initializes an instance of TSearchFindFirst (see page 1909).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSearchFindFirst(TComponent * AOwner);
```

Description

Most applications do not need to call the TSearchFindFirst (see page 1909) constructor because actions are added at design time to an action manager or action list.

The TSearchFindFirst (see page 1909) constructor creates an instance of its associated dialog and assigns that component as the value of the Dialog (see page 1902) property. It then assigns the Search (see page 1898) method as an event handler

for the dialog's OnFind event, so that the action responds automatically when user's direct the dialog to search for a specified text string.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TSearchFindFirst (see page 1909) instance.

See Also

Dialog (see page 1902)

Owner

Search (see page 1898)

OnFind

28.1.29 TSearchFindNext Class

TSearchFindNext is the standard action for locating the next instance of a string in an edit control.

Class Hierarchy

Pascal

```
TSearchFindNext = class(TCustomAction);
```

C++

```
class TSearchFindNext : public TCustomAction;
```

File

StdActns

Description

Add TSearchFindNext to an action list to add the ability to repeat a search initiated by a TSearchFind (see page 1899) or TSearchFindFirst (see page 1909) action. Controls such as menu items and tool buttons linked to this action cause the application to repeat the search initiated by the TSearchFind (see page 1899) action's dialog.

TSearchFindNext objects must be associated with a TSearchFind (see page 1899) action by setting the SearchFind (see page 1918) property.

See Also

TSearchFind (see page 1899)

TSearchFindFirst (see page 1909)

28.1.29.1 TSearchFindNext Members

The following tables list the members exposed by TSearchFindNext.

Public Methods

	Name	Description
	Create (see page 1913)	Creates an instance of TSearchFindNext (see page 1912).
	ExecuteTarget (see page 1914)	Searches the target edit control for the next instance of the search string.
	HandlesTarget (see page 1914)	Indicates whether the action can execute.

	UpdateTarget (see page 1915)	Enables or disables the action, depending on the currently active control in the form.

Published Events

	Name	Description
	OnHint (see page 1920)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1920)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1915)	Represents the caption of client controls and menu items.
	Enabled (see page 1916)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1916)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1917)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1917)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1917)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1918)	Indicates the ImageIndex property for client controls and menu items.
	SearchFind (see page 1918)	Associates the TSearchFindNext (see page 1912) action with a TSearchFind (see page 1899) action that initiates the search.
	SecondaryShortCuts (see page 1919)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1919)	Specifies the ShortCut property for client menu items.
	Visible (see page 1919)	Specifies the Visible property for client controls and menu items.

28.1.29.2 TSearchFindNext.Create Constructor

Creates an instance of TSearchFindNext (see page 1912).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSearchFindNext(TComponent * AOwner);
```

Description

Most applications do not need to call the TSearchFindNext (see page 1912) constructor because actions are added at design time to an action manager or action list.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TSearchFindNext (see page 1912) instance.

See Also

Owner

Actions

28.1.29.3 TSearchFindNext Methods

The methods of the TSearchFindNext class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1914)	Searches the target edit control for the next instance of the search string.
	HandlesTarget (see page 1914)	Indicates whether the action can execute.

	UpdateTarget (see page 1915)	Enables or disables the action, depending on the currently active control in the form.

28.1.29.3.1 TSearchFindNext.ExecuteTarget Method

Searches the target edit control for the next instance of the search string.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget calls the Search method of the TSearchFind (see page 1899) action specified by the SearchFind (see page 1918) property. This method ignores the Target parameter, and instead searches the edit control that was the target when SearchFind (see page 1918) first launched the search dialog. If another instance of the search dialog's current target string appears in the edit control, the next instance of the string is selected. Otherwise, a message dialog appears to inform the user that the string could not be found.

See Also

SearchFind (see page 1918)

Search (see page 1898)

28.1.29.3.2 TSearchFindNext.HandlesTarget Method

Indicates whether the action can execute.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a “target”.

Target is the currently active object.

HandlesTarget always ignores the Target parameter, and checks whether the associated TSearchFind (see page 1899) action is enabled, and if so, whether its associated dialog has a search string. If the action specified by SearchFind (see page 1918) is enabled, and the FindText property of its associated dialog has been set, then HandlesTarget returns true, because it can search for the FindText string in the TSearchFind (see page 1899) action's edit control.

See Also

SearchFind (see page 1918)

FindText

28.1.29.3.3 TSearchFindNext.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the potential target changes so that actions can update themselves accordingly.

In TSearchFindNext (see page 1912), UpdateTarget ignores the current target object (specified by the Target parameter). Instead, it checks the associated TSearchFind (see page 1899) action (the SearchFind (see page 1918) property), and sets Enabled (see page 1916) to true if the search dialog has already specified a search string. If SearchFind (see page 1918) is not set, or if there is no search string in its associated dialog, UpdateTarget sets Enabled (see page 1916) to false.

See Also

Enabled

SearchFind (see page 1918)

FindText

28.1.29.4 TSearchFindNext Properties

The properties of the TSearchFindNext class are listed here.

Published Properties

	Name	Description
	Caption (see page 1915)	Represents the caption of client controls and menu items.
	Enabled (see page 1916)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1916)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1917)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1917)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1917)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1918)	Indicates the ImageIndex property for client controls and menu items.
	SearchFind (see page 1918)	Associates the TSearchFindNext (see page 1912) action with a TSearchFind (see page 1899) action that initiates the search.
	SecondaryShortCuts (see page 1919)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1919)	Specifies the ShortCut property for client menu items.
	Visible (see page 1919)	Specifies the Visible property for client controls and menu items.

28.1.29.4.1 TSearchFindNext.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.29.4.2 TSearchFindNext.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.29.4.3 TSearchFindNext.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.29.4.4 TSearchFindNext.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.29.4.5 TSearchFindNext.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.29.4.6 TSearchFindNext.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.29.4.7 TSearchFindNext.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.29.4.8 TSearchFindNext.SearchFind Property

Associates the TSearchFindNext (see page 1912) action with a TSearchFind (see page 1899) action that initiates the search.

Pascal

```
property SearchFind: TSearchFind;
```

C++

```
__property TSearchFind SearchFind;
```

Description

SearchFind is the TSearchFind (see page 1899) action that displays the modeless search dialog whose current search should be repeated. If SearchFind is not set, then the TSearchFindNext (see page 1912) action remains disabled.

TSearchFindNext (see page 1912) uses the SearchFind property to obtain a search string from its associated dialog and to search its associated control.

See Also

ExecuteTarget (see page 1914)

Enabled

Search (see page 1898)

28.1.29.4.9 TSearchFindNext.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.29.4.10 TSearchFindNext.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.29.4.11 TSearchFindNext.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.29.5 TSearchFindNext Events

The events of the TSearchFindNext class are listed here.

Published Events

	Name	Description
	OnHint (see page 1920)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1920)	Occurs when the application is idle or when the action list updates.

28.1.29.5.1 TSearchFindNext.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.29.5.2 TSearchFindNext.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
```

```
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

28.1.30 TSearchReplace Class

TSearchReplace is the standard action for displaying a find-and-replace dialog.

Class Hierarchy

Pascal

```
TSearchReplace = class(TSearchAction);
```

C++

```
class TSearchReplace : public TSearchAction;
```

File

StdActns

Description

Add TSearchReplace to an action list to add a modeless find-and-replace dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the find-and-replace dialog or bring it to the fore.

TSearchReplace is designed to work with an edit control (TCustomEdit (see page 2345) descendant) as a target. It automatically disables itself if the active control in a form is not an edit control.

Search (see page 1898)/replace actions represent a modeless dialog. As a result, the OnAccept (see page 1930) event occurs not when the user exits the dialog, but when the dialog first appears or comes into focus. When the user directs the dialog to replace one or all instances of a string, TSearchReplace automatically performs the search and replaces the specified text in the target edit control.

See Also

TReplaceDialog

TSearchFind (see page 1899)

TCustomEdit (see page 2345)

TSearchFindFirst (see page 1909)

28.1.30.1 TSearchReplace Members

The following tables list the members exposed by TSearchReplace.

Protected Fields

	Name	Description
	FControl (see page 1896)	This is FControl, a member of class TSearchAction.
	FDialog (see page 1786)	This is FDialog, a member of class TCommonDialogAction.
	FFindFirst (see page 1897)	This is FFindFirst, a member of class TSearchAction.

Protected Methods

	Name	Description
	DoAccept (see page 1787)	This is DoAccept, a member of class TCommonDialogAction.
	DoCancel (see page 1787)	This is DoCancel, a member of class TCommonDialogAction.
	GetDialogClass (see page 1924)	This is GetDialogClass, a member of class TSearchReplace.
	Notification (see page 1789)	Responds when components are created or destroyed.
	Notification (see page 1898)	Responds when components are created or destroyed.
	SetupDialog (see page 1789)	This is SetupDialog, a member of class TCommonDialogAction.

Public Methods

	Name	Description
	Create (see page 1785)	Creates an instance of TCommonDialogAction.
	Create (see page 1895)	Creates and initializes an instance of TSearchAction (see page 1894).
	Destroy (see page 1786)	Frees an instance of TCustomAction.
	Destroy (see page 1896)	Frees an instance of TCustomAction.

	ExecuteTarget (see page 1923)	Launches the associated dialog and assigns an event handler to replace found text.
	HandlesTarget (see page 1788)	Indicates whether the action can execute its dialog.
	HandlesTarget (see page 1898)	Indicates whether the action can execute its dialog.
	Search (see page 1898)	Selects the next occurrence of the search string in the target edit control.
	UpdateTarget (see page 1899)	Enables or disables the action, depending on the currently active control in the form.

Public Properties

	Name	Description
	ExecuteResult (see page 1789)	Indicates the result of executing the associated dialog.

Published Events

	Name	Description
	BeforeExecute (see page 1929)	Occurs immediately before the dialog appears.
	OnAccept (see page 1930)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1930)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1930)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1931)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 1925)	Represents the caption of client controls and menu items.
	Dialog (see page 1925)	Provides access the find-and-replace dialog that the action executes.
	Enabled (see page 1925)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1926)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1926)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 1927)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1927)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1927)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1928)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1928)	Specifies the ShortCut property for client menu items.
	Visible (see page 1929)	Specifies the Visible property for client controls and menu items.

28.1.30.2 TSearchReplace Methods

The methods of the TSearchReplace class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 1924)	This is GetDialogClass, a member of class TSearchReplace.

Public Methods

	Name	Description
	ExecuteTarget (see page 1923)	Launches the associated dialog and assigns an event handler to replace found text.

28.1.30.2.1 TSearchReplace.ExecuteTarget Method

Launches the associated dialog and assigns an event handler to replace found text.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget first launches the search-and-replace dialog specified by Dialog (see page 1925). This is a modeless dialog, so the result of the dialog's Execute method simply indicates whether the dialog successfully appeared or was brought into focus. This result is set as the value of the ExecuteResult (see page 1789) property, and an OnAccept (see page 1930) event occurs if the dialog was brought into focus, or an OnCancel (see page 1930) event occurs if the dialog failed to appear.

Finally, ExecuteTarget sets the OnReplace event handler of the search-and-replace dialog to a private method that performs the replacement specified by the dialog.

See Also

OnAccept (see page 1790)

OnCancel (see page 1791)

Dialog (see page 1925)

Execute

ExecuteResult (see page 1789)

OnReplace

28.1.30.2.2 TSearchReplace.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TSearchReplace.

28.1.30.3 TSearchReplace Properties

The properties of the TSearchReplace class are listed here.

Published Properties

	Name	Description
	Caption (see page 1925)	Represents the caption of client controls and menu items.
R	Dialog (see page 1925)	Provides access the find-and-replace dialog that the action executes.
	Enabled (see page 1925)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 1926)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 1926)	Indicates the help keyword for client controls and menu items.

	HelpType (see page 1927)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 1927)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 1927)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 1928)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 1928)	Specifies the ShortCut property for client menu items.
	Visible (see page 1929)	Specifies the Visible property for client controls and menu items.

28.1.30.3.1 TSearchReplace.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption

28.1.30.3.2 TSearchReplace.Dialog Property

Provides access the find-and-replace dialog that the action executes.

Pascal

```
property Dialog: TReplaceDialog;
```

C++

```
__property TReplaceDialog Dialog;
```

Description

Use Dialog to configure the find-and-replace dialog before the action fires or to close the modeless dialog programmatically. For example, you can set the dialog's options at design time using the Object Inspector or call the dialog's CloseDialog method to shut down the modeless find-and-replace dialog.

When using a search/replace action, you do not place a TReplaceDialog component on the form or data module at design time. Instead, you add the TSearchReplace (see page 1921) action to your action list and then use the Dialog property. The TReplaceDialog component is created by the TSearchReplace (see page 1921) constructor.

See Also

ExecuteTarget (see page 1897)

CloseDialog

28.1.30.3.3 TSearchReplace.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled

28.1.30.3.4 TSearchReplace.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

28.1.30.3.5 TSearchReplace.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

28.1.30.3.6 TSearchReplace.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpContext

HelpKeyword

28.1.30.3.7 TSearchReplace.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint

28.1.30.3.8 TSearchReplace.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex

Images

28.1.30.3.9 TSearchReplace.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

28.1.30.3.10 TSearchReplace.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut

SecondaryShortCuts

28.1.30.3.11 TSearchReplace.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible

Visible

28.1.30.4 TSearchReplace Events

The events of the TSearchReplace class are listed here.

Published Events

	Name	Description
	BeforeExecute (see page 1929)	Occurs immediately before the dialog appears.
	OnAccept (see page 1930)	Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.
	OnCancel (see page 1930)	Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.
	OnHint (see page 1930)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 1931)	Occurs when the application is idle or when the action list updates.

28.1.30.4.1 TSearchReplace.BeforeExecute Event

Occurs immediately before the dialog appears.

Pascal

```
property BeforeExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeExecute;
```

Description

Write a BeforeExecute event handler to initialize the dialog immediately before it executes. When the action fires, it generates a BeforeExecute event, and then executes its associated dialog.

See Also

ExecuteTarget (see page 1787)

Execute

Handle

28.1.30.4.2 TSearchReplace.OnAccept Event

Occurs after the user exits a modal dialog by selecting “OK” or when a modeless dialog is successfully displayed.

Pascal

```
property OnAccept: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAccept;
```

Description

Write an OnAccept event handler to make use the dialog results after it executes. When the action fires, it executes its associated dialog. OnAccept occurs when the dialog component's Execute method returns true. Thus, if the dialog is modal, OnAccept occurs when the user closes the dialog by clicking the OK button. If the dialog is modeless, OnAccept occurs when the dialog first appears.

For modal dialogs, use the OnAccept event to read the user's selections from the dialog and act on them. TCommonDialogAction descendants introduce a Dialog property that the event handler can use to obtain information about the user's selections.

See Also

ExecuteResult (see page 1789)

OnCancel (see page 1791)

Execute

28.1.30.4.3 TSearchReplace.OnCancel Event

Occurs after the user exits a modal dialog by selecting “Cancel” or when a modeless dialog fails to come up.

Pascal

```
property OnCancel: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCancel;
```

Description

Write an OnCancel event handler to respond when the user cancels from the associated dialog. When the action fires, it executes its associated dialog. OnCancel occurs when the dialog component's Execute method returns false. Thus, if the dialog is modal, OnCancel occurs when the user closes the dialog by clicking the Cancel button. If the dialog is modeless, OnCancel occurs if the dialog fails to appear.

See Also

ExecuteResult (see page 1789)

OnAccept (see page 1790)

Execute

28.1.30.4.4 TSearchReplace.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

28.1.30.4.5 TSearchReplace.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

28.1.31 TWindowAction Class

TWindowAction is the base class for action objects that work with MDI forms.

Class Hierarchy

Pascal

```
TWindowAction = class(TAction);
```

C++

```
class TWindowAction : public TAction;
```

File

StdActns

Description

TWindowAction implements the common behavior for actions that work on MDI forms. Each descendant class performs a specific task, such as arranging, cascading, closing, tiling, or minimizing MDI child forms. Do not use TWindowAction directly in an application. Instead, use a TWindowAction descendant such as TWindowClose (see page 1939), TWindowCascade (see page 1937), TWindowMinimizeAll (see page 1941), TWindowArrange (see page 1936), TWindowTileHorizontal (see page 1943), or TWindowTileVertical (see page 1944).

TWindowAction ensures that the action is enabled as long as the target is an MDI parent form. TWindowAction descendants override the ExecuteTarget method to execute their specific function on the targets child forms.

See Also

TWindowArrange (see page 1936)

TWindowCascade (see page 1937)

TWindowClose (see page 1939)

TWindowMinimizeAll (see page 1941)

TWindowTileHorizontal (see page 1943)

TWindowTileVertical (see page 1944)

28.1.31.1 TWindowAction Members

The following tables list the members exposed by TWindowAction.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.31.2 TWindowAction.Create Constructor

Creates and initializes a TAction object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWindowAction(TComponent * AOwner);
```

Description

Applications do not usually create action objects explicitly. Actions are created automatically when you add them to an action manager or action list component at design time. When instantiating TAction at runtime, assign a TActionList or TActionManager component to the new action's ActionList property after calling Create.

See Also

ActionList

28.1.31.3 TWindowAction Methods

The methods of the TWindowAction class are listed here.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.

	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

28.1.31.3.1 TWindowAction.GetForm Method

Pascal

```
function GetForm(Target: TObject): TForm; virtual;
```

C++

```
virtual __fastcall TForm * GetForm(TObject * Target);
```

Description

This is GetForm, a member of class TWindowAction.

28.1.31.3.2 TWindowAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

As implemented in TWindowAction (see page 1932), HandlesTarget makes sure that the target is an MDI parent form. If the target is appropriate, HandlesTarget sets the Form (see page 1935) property.

See Also

Form (see page 1935)

FormStyle

28.1.31.3.3 TWindowAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

28.1.31.3.4 TWindowAction.UpdateTarget Method

Enables or disables the action, depending on whether the target form has MDI children.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In TWindowAction (see page 1932), UpdateTarget checks that the target object is an MDI parent form with an MDIChildCount property greater than 0. If so, UpdateTarget sets the Enabled property to true. Otherwise, it sets Enabled to false.

See Also

Enabled

MDIChildCount

28.1.31.4 TWindowAction Properties

The properties of the TWindowAction class are listed here.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.31.4.1 TWindowAction.Form Property

Provides access to the target of the action.

Pascal

```
property Form: TCustomForm;
```

C++

```
__property TCustomForm Form;
```

Description

Form is the MDI parent form on which the action performs its function.

28.1.32 TWindowArrange Class

TWindowArrange arranges the icons of minimized MDI child forms.

Class Hierarchy

Pascal

```
TWindowArrange = class(TWindowAction);
```

C++

```
class TWindowArrange : public TWindowAction;
```

File

StdActns

Description

Add TWindowArrange to an action list to allow users to arrange the icons that represent minimized MDI child forms. Controls such as menu items and tool buttons linked to this action cause the application to call the ArrangeIcons method of the MDI parent form.

TWindowArrange is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no MDI children.

See Also

TWindowClose (see page 1939)

TWindowCascade (see page 1937)

TWindowMinimizeAll (see page 1941)

TWindowTileHorizontal (see page 1943)

TWindowTileVertical (see page 1944)

TForm

28.1.32.1 TWindowArrange Members

The following tables list the members exposed by TWindowArrange.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1937)	Arranges the icons of minimized MDI child forms
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.32.2 TWindowArrange Methods

The methods of the TWindowArrange class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1937)	Arranges the icons of minimized MDI child forms

28.1.32.2.1 TWindowArrange.ExecuteTarget Method

Arranges the icons of minimized MDI child forms

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active form when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then calls that form's ArrangeIcons method to arrange the icons of minimized MDI children.

See Also

Form (see page 1935)

ArrangeIcons

28.1.33 TWindowCascade Class

TWindowCascade cascades the MDI child forms.

Class Hierarchy

Pascal

```
TWindowCascade = class(TWindowAction);
```

C++

```
class TWindowCascade : public TWindowAction;
```

File

StdActns

Description

Add TWindowCascade to an action list to allow users to arrange the MDI child forms in an overlapping cascade. Controls such as menu items and tool buttons linked to this action cause the application to call the Cascade method of the MDI parent form.

TWindowCascade is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no MDI children.

See Also

TWindowClose (see page 1939)

TWindowArrange (see page 1936)

TWindowMinimizeAll (see page 1941)

TWindowTileHorizontal (see page 1943)

TWindowTileVertical (see page 1944)

TForm

28.1.33.1 TWindowCascade Members

The following tables list the members exposed by TWindowCascade.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1938)	Arranges the MDI child forms in an overlapping cascade.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.33.2 TWindowCascade Methods

The methods of the TWindowCascade class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1938)	Arranges the MDI child forms in an overlapping cascade.

28.1.33.2.1 TWindowCascade.ExecuteTarget Method

Arranges the MDI child forms in an overlapping cascade.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active form when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then calls that form's Cascade method to arrange MDI child windows.

See Also

Form (see page 1935)

Cascade

28.1.34 TWindowClose Class

TWindowClose closes the active MDI child form.

Class Hierarchy

Pascal

```
TWindowClose = class(TWindowAction);
```

C++

```
class TWindowClose : public TWindowAction;
```

File

StdActns

Description

Add TWindowClose to an action list to allow users to close the active MDI child form. Controls such as menu items and tool buttons linked to this action cause the application to call the Close (see page 3538) method of the active MDI child.

TWindowClose is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no active MDI child.

See Also

TWindowArrange (see page 1936)

TWindowCascade (see page 1937)

TWindowMinimizeAll (see page 1941)

TWindowTileVertical (see page 1944)

TCustomForm

28.1.34.1 TWindowClose Members

The following tables list the members exposed by TWindowClose.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1940)	Closes the active MDI child.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1941)	Enables or disables the action, depending on whether the target form an active child.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.34.2 TWindowClose Methods

The methods of the TWindowClose class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1940)	Closes the active MDI child.
	UpdateTarget (see page 1941)	Enables or disables the action, depending on whether the target form an active child.

28.1.34.2.1 TWindowClose.ExecuteTarget Method

Closes the active MDI child.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then obtains a reference to the active MDI child by reading the form's ActiveMDIChild property. It calls this child form's Close (see page 3538) method to close the active child form.

See Also

Form (see page 1935)

ActiveMDIChild

Close

28.1.34.2.2 TWindowClose.UpdateTarget Method

Enables or disables the action, depending on whether the target form an active child.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically so that actions can update themselves according to current conditions.

In TWindowClose (see page 1939), UpdateTarget checks that the target object is an MDI parent form with a non-nil (Delphi) or NULL (C++) ActiveMDIChild property. If so, UpdateTarget sets the Enabled property to true. Otherwise, it sets Enabled to false.

See Also

Enabled

ActiveMDIChild

28.1.35 TWindowMinimizeAll Class

TWindowMinimizeAll minimizes all MDI child forms.

Class Hierarchy

Pascal

```
TWindowMinimizeAll = class(TWindowAction);
```

C++

```
class TWindowMinimizeAll : public TWindowAction;
```

File

StdActns

Description

Add TWindowMinimizeAll to an action list to allow users to minimize the MDI child forms in an MDI application. Controls such as menu items and tool buttons linked to this action cause the application to iterate through the MDI child forms, setting their WindowState to wsMinimized.

TWindowMinimizeAll is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no MDI children.

28.1.35.1 TWindowMinimizeAll Members

The following tables list the members exposed by TWindowMinimizeAll.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1942)	Minimizes all MDI child forms of the target MDI parent.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.35.2 TWindowMinimizeAll Methods

The methods of the TWindowMinimizeAll class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1942)	Minimizes all MDI child forms of the target MDI parent.

28.1.35.2.1 TWindowMinimizeAll.ExecuteTarget Method

Minimizes all MDI child forms of the target MDI parent.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active form when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then iterates through that form's MDI children, setting each child form's WindowState to wsMinimized.

WindowState

28.1.36 TWindowTileHorizontal Class

TWindowTileHorizontal arranges MDI child forms so that they are all the same size, tiled horizontally.

Class Hierarchy

Pascal

```
TWindowTileHorizontal = class(TWindowAction);
```

C++

```
class TWindowTileHorizontal : public TWindowAction;
```

File

StdActns

Description

Add TWindowTileHorizontal to an action list to allow users to tile the MDI child forms horizontally. Controls such as menu items and tool buttons linked to this action cause the MDI parent form to tile its children horizontally.

TWindowTileHorizontal is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no MDI children.

TCustomForm

28.1.36.1 TWindowTileHorizontal Members

The following tables list the members exposed by TWindowTileHorizontal.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1944)	Tiles the child forms of the target MDI parent horizontally.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.36.2 TWindowTileHorizontal Methods

The methods of the TWindowTileHorizontal class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1944)	Tiles the child forms of the target MDI parent horizontally.

28.1.36.2.1 TWindowTileHorizontal.ExecuteTarget Method

Tiles the child forms of the target MDI parent horizontally.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active form when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then instructs the form to tile its child forms horizontally.

Form (see page 1935)

MDIChildren

28.1.37 TWindowTileVertical Class

TWindowTileVertical arranges MDI child forms so that they are all the same size, tiled vertically.

Class Hierarchy

Pascal

```
TWindowTileVertical = class(TWindowAction);
```

C++

```
class TWindowTileVertical : public TWindowAction;
```

File

StdActns

Description

Add TWindowTileVertical to an action list to allow users to tile the MDI child forms vertically. Controls such as menu items and tool buttons linked to this action cause the MDI parent form to tile its children vertically.

TWindowTileVertical is designed to work with an MDI parent form as a target. It automatically disables itself if the active form is not an MDI parent or if it has no MDI children.

28.1.37.1 TWindowTileVertical Members

The following tables list the members exposed by TWindowTileVertical.

Protected Methods

	Name	Description
	GetForm (see page 1934)	This is GetForm, a member of class TWindowAction.
	Notification (see page 1934)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 1933)	Creates and initializes a TAction object.
	ExecuteTarget (see page 1946)	Tiles the child forms of the target MDI parent vertically.
	HandlesTarget (see page 1934)	Indicates whether the action can execute its function.
	UpdateTarget (see page 1935)	Enables or disables the action, depending on whether the target form has MDI children.

Public Properties

	Name	Description
	Form (see page 1935)	Provides access to the target of the action.

28.1.37.2 TWindowTileVertical Methods

The methods of the TWindowTileVertical class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 1946)	Tiles the child forms of the target MDI parent vertically.

28.1.37.2.1 TWindowTileVertical.ExecuteTarget Method

Tiles the child forms of the target MDI parent vertically.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active form when the action fires.

ExecuteTarget sets the Form (see page 1935) property to Target, which must be an MDI parent form. It then instructs the form to tile its child forms vertically.

28.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBrowseForFolderOption (see page 1947)	TBrowseForFolderOption contains the options for creating a dialog box used when browsing for folders.

28.2.1 StdActns.TBrowseForFolderOption Enumeration

TBrowseForFolderOption contains the options for creating a dialog box used when browsing for folders.

Pascal

```
TBrowseForFolderOption = (
  bifBrowseForComputer,
  bifBrowseForPrinter,
  bifBrowseIncludeFiles,
  bifBrowseIncludeURLS,
  bifDontGoBelowDomain,
  bifEditBox,
  bifNewDialogStyle,
  bifNoNewFolderButton,
  bifNoTranslateTargets,
  bifReturnFSAncestors,
  bifReturnOnlyFSDirs,
  bifShareable,
  bifStatusText,
  bifUAHint,
  bifUseNewUI,
  bifValidate
);
```

C++

```
enum TBrowseForFolderOption {
  bifBrowseForComputer,
  bifBrowseForPrinter,
  bifBrowseIncludeFiles,
  bifBrowseIncludeURLS,
  bifDontGoBelowDomain,
  bifEditBox,
  bifNewDialogStyle,
  bifNoNewFolderButton,
  bifNoTranslateTargets,
  bifReturnFSAncestors,
  bifReturnOnlyFSDirs,
  bifShareable,
  bifStatusText,
  bifUAHint,
  bifUseNewUI,
  bifValidate
};
```

File

StdActns

Description

TBrowseForFolderOption is an enumeration type containing the options that specify the type of dialog box used when browsing for folders.

The meaning of these options is given in the following table.

Option	Meaning
`bifBrowseForComputer`	Only allow computers to be returned. If anything else is selected, the **OK** button is disabled.
`bifBrowseForPrinter`	Only allow printers to be selected. If anything else is selected, the **OK** button is disabled.
`bifBrowseIncludeFiles`	The browse dialog box also displays files.
`bifBrowseIncludeURLS`	The browse dialog box also displays URL adresses. This automatically enables the options `bifBrowseIncludeFiles` and `bifUseNewUI`.
`bifDontGoBelowDomain`	Do not display network folders below the current domain level in the current tree view.
`bifEditBox`	Display an edit box containing the currently selected folder/file. This also allows typing the name of the folder/file to select.
`bifNewDialogStyle`	Use the new type of dialog, that is sizeable and includes a **Make a New (see page 3619) Folder** button. The dialog also allows dragging and dropping and using the context menu on either folders or files.
`bifNoNewFolderButton`	Hides the **Make New (see page 3619) Folder** button, when using the `bifNewDialogStyle` option.
`bifNoTranslateTargets`	If the selected folder/file is a shortuct, return the PIDL of the shortcut instead of its target.
`bifReturnFSAncestors`	Only allow file system ancestors to be returned. Ancestors are subfolders that live beneath the root of the namespace hierarchy. If the selected ancestor is not part of the file system, the **OK** button is disabled.
`bifReturnOnlyFSDirs`	Only allow file system directories to be returned. If anything else is selected, the **OK** button is disabled.
`bifShareable`	Shareable resources on remote systems are also displayed inside the browse dialog box. This automatically enables the option `bifNewDialogStyle`.
`bifStatusText`	Display a status message in the browse dialog box. The message is returned by the callback function. This option only works if the `bifNewDialogStyle` is disabled.
`bifUAHint`	Displays an usage hint instead of the edit box, when using the `bifNewDialogStyle` option
`bifUseNewUI`	Use the new user interface. This displays an edit box at the bottom of the dialog window, containing the name of the currently selected folder/file. The name of the folder/file to select can also be typed into this edit box.
`bifValidate`	Validates the name of the folder/file inserted into the edit box, when using the `bifEditBox` option. The validation triggers an event of type TBrowseForFolderCallbackEvent (see page 1949).

See Also

TBrowseForFolder (see page 1764)

28.3 Types

The following table lists types in this documentation.

Types

Name	Description
TBrowseForFolderCallbackEvent (see page 1949)	This is type StdActns.TBrowseForFolderCallbackEvent.
TBrowseOptions (see page 1949)	TBrowseOptions is a set type of options used in customizing the browse dialog box to create.
TCommonDialogClass (see page 1950)	This is type StdActns.TCommonDialogClass.

28.3.1 StdActns.TBrowseForFolderCallbackEvent Type

Pascal

```
TBrowseForFolderCallbackEvent = procedure (Sender: TBrowseForFolder; Wnd: HWND; uMsg: UINT;
lParam, lpData: LPARAM; var Result: Integer) of object;
```

C++

```
(Sender: TBrowseForFolder; Wnd: HWND; uMsg: UINT; lParam, lpData: LPARAM; var Result: Integer)
( TBrowseForFolderCallbackEvent)();
```

File

StdActns

Description

This is type StdActns.TBrowseForFolderCallbackEvent.

28.3.2 StdActns.TBrowseOptions Type

TBrowseOptions is a set type of options used in customizing the browse dialog box to create.

Pascal

```
TBrowseOptions = set of TBrowseForFolderOption;
```

C++

```
TBrowseForFolderOption TBrowseOptions;
```

File

StdActns

Description

TBrowseOptions is a set type, with elements of type TBrowseForFolderOption (see page 1947).

Each element included in a variable of type TBrowseOptions enables the corresponding option, when creating the browse dialog box.

The possible options are given in the following table.

Option	Meaning
bifBrowseForComputer	Only allow computers to be returned. If anything else is selected, the **OK** button is disabled.
bifBrowseForPrinter	Only allow printers to be selected. If anything else is selected, the **OK** button is disabled.
bifBrowseIncludeFiles	The browse dialog box also displays files.
bifBrowseIncludeURLS	The browse dialog box also displays URL adresses. This automatically enables the options bifBrowseIncludeFiles and bifUseNewUI.
bifDontGoBelowDomain	Do not display network folders below the current domain level in the current tree view.
bifEditBox	Display an edit box containing the currently selected folder/file. This also allows typing the name of the folder/file to select.
bifNewDialogStyle	Use the new type of dialog, that is sizeable and includes a **Make a New (see page 3619) Folder** button. The dialog also allows dragging and dropping and using the context menu on either folders or files.
bifNoNewFolderButton	Hides the **Make New (see page 3619) Folder** button, when using the bifNewDialogStyle option.
bifNoTranslateTargets	If the selected folder/file is a shortcut, return the PIDL of the shortcut instead of its target.
bifReturnFSAncestors	Only allow file system ancestors to be returned. Ancestors are subfolders that live beneath the root of the namespace hierarchy. If the selected ancestor is not part of the file system, the **OK** button is disabled.
bifReturnOnlyFSDirs	Only allow file system directories to be returned. If anything else is selected, the **OK** button is disabled.
bifShareable	Shareable resources on remote systems are also displayed inside the browse dialog box. This automatically enables the option bifNewDialogStyle.
bifStatusText	Display a status message in the browse dialog box. The message is returned by the callback function. This option only works if the bifNewDialogStyle is disabled.
bifUAHint	Displays an usage hint instead of the edit box, when using the bifNewDialogStyle option
bifUseNewUI	Use the new user interface. This displays an edit box at the bottom of the dialog window, containing the name of the currently selected folder/file. The name of the folder/file to select can also be typed into this edit box.
bifValidate	Validates the name of the folder/file inserted into the edit box, when using the bifEditBox option. The validation triggers an event of type TBrowseForFolderCallbackEvent (see page 1949).

SquareMetersPerSquareMile (see page 2031)	This is constant StdConvs.SquareMetersPerSquareMile.
SquareMetersPerSquareRod (see page 2031)	This is constant StdConvs.SquareMetersPerSquareRod.
SquareMetersPerSquareYard (see page 2032)	This is constant StdConvs.SquareMetersPerSquareYard.

Functions

	Name	Description
	CelsiusToFahrenheit (see page 1958)	Converts a temperature expressed in degrees Celsius to the corresponding temperature in degrees Fahrenheit.
	FahrenheitToCelsius (see page 1958)	Converts a temperature expressed in degrees Fahrenheit to the corresponding temperature in degrees Celsius.
	InitStdConvs (see page 1959)	Initialize (see page 3599) conversion variables for C++ program.

Variables

Name	Description
auAcres (see page 1962)	This is variable StdConvs.auAcres.
auAres (see page 1963)	This is variable StdConvs.auAres.
auCentares (see page 1963)	This is variable StdConvs.auCentares.
auHectares (see page 1963)	This is variable StdConvs.auHectares.
auSquareCentimeters (see page 1964)	This is variable StdConvs.auSquareCentimeters.
auSquareDecameters (see page 1964)	This is variable StdConvs.auSquareDecameters.

auSquareDecimeters (see page 1964)	This is variable StdConvs.auSquareDecimeters.
auSquareFeet (see page 1965)	This is variable StdConvs.auSquareFeet.
auSquareHectometers (see page 1965)	This is variable StdConvs.auSquareHectometers.
auSquareInches (see page 1965)	This is variable StdConvs.auSquareInches.
auSquareKilometers (see page 1966)	This is variable StdConvs.auSquareKilometers.
auSquareMeters (see page 1966)	This is variable StdConvs.auSquareMeters.
auSquareMiles (see page 1966)	This is variable StdConvs.auSquareMiles.
auSquareMillimeters (see page 1967)	This is variable StdConvs.auSquareMillimeters.
auSquareRods (see page 1967)	This is variable StdConvs.auSquareRods.
auSquareYards (see page 1967)	This is variable StdConvs.auSquareYards.
cbArea (see page 1968)	Represent units that measure cbArea.
cbDistance (see page 1968)	Represent units that measure cbDistance.
cbMass (see page 1969)	This is variable StdConvs.cbMass.
cbTemperature (see page 1969)	This is variable StdConvs.cbTemperature.
cbTime (see page 1969)	Represent units that measure cbTime.
cbVolume (see page 1970)	Represent units that measure volume.
duAngstroms (see page 1971)	This is variable StdConvs.duAngstroms.
duAstronomicalUnits (see page 1971)	This is variable StdConvs.duAstronomicalUnits.
duCentimeters (see page 1972)	This is variable StdConvs.duCentimeters.
duChains (see page 1972)	This is variable StdConvs.duChains.
duCubits (see page 1972)	This is variable StdConvs.duCubits.
duDecameters (see page 1973)	This is variable StdConvs.duDecameters.
duDecimeters (see page 1973)	This is variable StdConvs.duDecimeters.
duFathoms (see page 1973)	This is variable StdConvs.duFathoms.
duFeet (see page 1974)	This is variable StdConvs.duFeet.
duFurlongs (see page 1974)	This is variable StdConvs.duFurlongs.
duGigameters (see page 1974)	This is variable StdConvs.duGigameters.
duHands (see page 1975)	This is variable StdConvs.duHands.
duHectometers (see page 1975)	This is variable StdConvs.duHectometers.
duInches (see page 1975)	This is variable StdConvs.duInches.
duKilometers (see page 1976)	This is variable StdConvs.duKilometers.
duLightYears (see page 1976)	This is variable StdConvs.duLightYears.
duLinks (see page 1976)	This is variable StdConvs.duLinks.
duMegameters (see page 1977)	This is variable StdConvs.duMegameters.
duMeters (see page 1977)	This is variable StdConvs.duMeters.
duMicromicrons (see page 1977)	This is variable StdConvs.duMicromicrons.
duMicrons (see page 1978)	This is variable StdConvs.duMicrons.
duMiles (see page 1978)	This is variable StdConvs.duMiles.
duMillimeters (see page 1978)	This is variable StdConvs.duMillimeters.
duMillimicrons (see page 1979)	This is variable StdConvs.duMillimicrons.
duNauticalMiles (see page 1979)	This is variable StdConvs.duNauticalMiles.
duPaces (see page 1979)	This is variable StdConvs.duPaces.
duParsecs (see page 1980)	This is variable StdConvs.duParsecs.
duPicas (see page 1980)	This is variable StdConvs.duPicas.
duPoints (see page 1980)	This is variable StdConvs.duPoints.
duRods (see page 1981)	This is variable StdConvs.duRods.
duYards (see page 1981)	This is variable StdConvs.duYards.
muCentigrams (see page 1981)	This is variable StdConvs.muCentigrams.
muDecagrams (see page 1982)	This is variable StdConvs.muDecagrams.
muDecigrams (see page 1982)	This is variable StdConvs.muDecigrams.
muDrams (see page 1982)	This is variable StdConvs.muDrams.
muGrains (see page 1983)	This is variable StdConvs.muGrains.
muGrams (see page 1983)	This is variable StdConvs.muGrams.
muHectograms (see page 1983)	This is variable StdConvs.muHectograms.

muKilograms (see page 1984)	This is variable StdConvs.muKilograms.
muLongTons (see page 1984)	This is variable StdConvs.muLongTons.
muMetricTons (see page 1984)	This is variable StdConvs.muMetricTons.
muMicrograms (see page 1985)	This is variable StdConvs.muMicrograms.
muMilligrams (see page 1985)	This is variable StdConvs.muMilligrams.
muNanograms (see page 1985)	This is variable StdConvs.muNanograms.
muOunces (see page 1986)	This is variable StdConvs.muOunces.
muPounds (see page 1986)	This is variable StdConvs.muPounds.
muStones (see page 1986)	This is variable StdConvs.muStones.
muTons (see page 1987)	This is variable StdConvs.muTons.
tuCelsius (see page 1987)	This is variable StdConvs.tuCelsius.
tuCenturies (see page 1987)	This is variable StdConvs.tuCenturies.
tuDateTime (see page 1988)	This is variable StdConvs.tuDateTime.
tuDays (see page 1988)	This is variable StdConvs.tuDays.
tuDecades (see page 1988)	This is variable StdConvs.tuDecades.
tuFahrenheit (see page 1989)	This is variable StdConvs.tuFahrenheit.
tuFortnights (see page 1989)	This is variable StdConvs.tuFortnights.
tuHours (see page 1989)	This is variable StdConvs.tuHours.
tuJulianDate (see page 1990)	This is variable StdConvs.tuJulianDate.
tuKelvin (see page 1990)	This is variable StdConvs.tuKelvin.
tuMillennia (see page 1990)	This is variable StdConvs.tuMillennia.
tuMilliSeconds (see page 1991)	This is variable StdConvs.tuMilliSeconds.
tuMinutes (see page 1991)	This is variable StdConvs.tuMinutes.
tuModifiedJulianDate (see page 1991)	This is variable StdConvs.tuModifiedJulianDate.
tuMonths (see page 1992)	This is variable StdConvs.tuMonths.
tuRankine (see page 1992)	This is variable StdConvs.tuRankine.
tuReaumur (see page 1992)	This is variable StdConvs.tuReaumur.
tuSeconds (see page 1993)	This is variable StdConvs.tuSeconds.
tuWeeks (see page 1993)	This is variable StdConvs.tuWeeks.
tuYears (see page 1993)	This is variable StdConvs.tuYears.
vuAcreFeet (see page 1994)	This is variable StdConvs.vuAcreFeet.
vuAcreInches (see page 1994)	This is variable StdConvs.vuAcreInches.
vuCentiLiters (see page 1994)	This is variable StdConvs.vuCentiLiters.
vuCordFeet (see page 1995)	This is variable StdConvs.vuCordFeet.
vuCords (see page 1995)	This is variable StdConvs.vuCords.
vuCubicCentimeters (see page 1995)	This is variable StdConvs.vuCubicCentimeters.
vuCubicDecameters (see page 1996)	This is variable StdConvs.vuCubicDecameters.
vuCubicDecimeters (see page 1996)	This is variable StdConvs.vuCubicDecimeters.
vuCubicFeet (see page 1996)	This is variable StdConvs.vuCubicFeet.
vuCubicHectometers (see page 1997)	This is variable StdConvs.vuCubicHectometers.
vuCubicInches (see page 1997)	This is variable StdConvs.vuCubicInches.
vuCubicKilometers (see page 1997)	This is variable StdConvs.vuCubicKilometers.
vuCubicMeters (see page 1998)	This is variable StdConvs.vuCubicMeters.
vuCubicMiles (see page 1998)	This is variable StdConvs.vuCubicMiles.
vuCubicMillimeters (see page 1998)	This is variable StdConvs.vuCubicMillimeters.
vuCubicYards (see page 1999)	This is variable StdConvs.vuCubicYards.
vuDecaLiters (see page 1999)	This is variable StdConvs.vuDecaLiters.
vuDecasteres (see page 1999)	This is variable StdConvs.vuDecasteres.
vuDeciLiters (see page 2000)	This is variable StdConvs.vuDeciLiters.
vuDecisteres (see page 2000)	This is variable StdConvs.vuDecisteres.
vuDryBuckets (see page 2000)	This is variable StdConvs.vuDryBuckets.
vuDryBushels (see page 2001)	This is variable StdConvs.vuDryBushels.
vuDryGallons (see page 2001)	This is variable StdConvs.vuDryGallons.
vuDryPecks (see page 2001)	This is variable StdConvs.vuDryPecks.

vuDryPints (see page 2002)	This is variable StdConvs.vuDryPints.
vuDryQuarts (see page 2002)	This is variable StdConvs.vuDryQuarts.
vuFluidCups (see page 2002)	This is variable StdConvs.vuFluidCups.
vuFluidGallons (see page 2003)	This is variable StdConvs.vuFluidGallons.
vuFluidGills (see page 2003)	This is variable StdConvs.vuFluidGills.
vuFluidOunces (see page 2003)	This is variable StdConvs.vuFluidOunces.
vuFluidPints (see page 2004)	This is variable StdConvs.vuFluidPints.
vuFluidQuarts (see page 2004)	This is variable StdConvs.vuFluidQuarts.
vuFluidTablespoons (see page 2004)	This is variable StdConvs.vuFluidTablespoons.
vuFluidTeaspoons (see page 2005)	This is variable StdConvs.vuFluidTeaspoons.
vuHectoLiters (see page 2005)	This is variable StdConvs.vuHectoLiters.
vuKiloLiters (see page 2005)	This is variable StdConvs.vuKiloLiters.
vuLiters (see page 2006)	This is variable StdConvs.vuLiters.
vuMilliLiters (see page 2006)	This is variable StdConvs.vuMilliLiters.
vuSteres (see page 2006)	This is variable StdConvs.vuSteres.
vuUKBuckets (see page 2007)	This is variable StdConvs.vuUKBuckets.
vuUKBushels (see page 2007)	This is variable StdConvs.vuUKBushels.
vuUKGallons (see page 2007)	This is variable StdConvs.vuUKGallons.
vuUKGills (see page 2008)	This is variable StdConvs.vuUKGills.
vuUKOunces (see page 2008)	This is variable StdConvs.vuUKOunces.
vuUKPecks (see page 2008)	This is variable StdConvs.vuUKPecks.
vuUKPints (see page 2009)	This is variable StdConvs.vuUKPints.
vuUKPottles (see page 2009)	This is variable StdConvs.vuUKPottles.
vuUKQuarts (see page 2009)	This is variable StdConvs.vuUKQuarts.

29.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CelsiusToFahrenheit (see page 1958)	Converts a temperature expressed in degrees Celsius to the corresponding temperature in degrees Fahrenheit.
	FahrenheitToCelsius (see page 1958)	Converts a temperature expressed in degrees Fahrenheit to the corresponding temperature in degrees Celsius.
	InitStdConvs (see page 1959)	Initialize (see page 3599) conversion variables for C++ program.

29.1.1 StdConvs.CelsiusToFahrenheit Function

Converts a temperature expressed in degrees Celsius to the corresponding temperature in degrees Fahrenheit.

Pascal

```
function CelsiusToFahrenheit(const AValue: Double): Double;
```

C++

```
Double CelsiusToFahrenheit(const Double AValue);
```

File

StdConvs

Description

Call CelsiusToFahrenheit to convert the temperature specified by AValue, which is in degrees Celsius, to the corresponding temperature in degrees Fahrenheit.

See Also

FahrenheitToCelsius (see page 1958)

Convert

29.1.2 StdConvs.FahrenheitToCelsius Function

Converts a temperature expressed in degrees Fahrenheit to the corresponding temperature in degrees Celsius.

Pascal

```
function FahrenheitToCelsius(const AValue: Double): Double;
```

C++

```
Double FahrenheitToCelsius(const Double AValue);
```

File

StdConvs

Description

Call FahrenheitToCelsius to convert the temperature specified by AValue, which is in degrees Fahrenheit, to the corresponding temperature in degrees Celsius.

See Also

CelsiusToFahrenheit (see page 1958)

Convert

29.1.3 StdConvs.InitStdConvs Function

Initialize (see page 3599) conversion variables for C++ program.

Pascal

```
procedure InitStdConvs;
```

C++

```
InitStdConvs();
```

File

StdConvs

Description

Insert (see page 3601) InitStdConvs into a C++ program to ensure that StdConvs (see page 1953) global variables are properly initialized. InitStdConvs does nothing and does not need to be called. A reference to InitStdConvs in a C++ program guarantees that the linker will provide a call to the unit's initialization code, even if no other StdConvs (see page 1953) routines are present. This step is not necessary in Delphi code, which always calls the initialization code for referenced units.

FahrenheitToCelsius (see page 1958)

Convert

29.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
auAcres (see page 1962)	This is variable StdConvs.auAcres.
auAres (see page 1963)	This is variable StdConvs.auAres.
auCentares (see page 1963)	This is variable StdConvs.auCentares.
auHectares (see page 1963)	This is variable StdConvs.auHectares.
auSquareCentimeters (see page 1964)	This is variable StdConvs.auSquareCentimeters.
auSquareDecameters (see page 1964)	This is variable StdConvs.auSquareDecameters.
auSquareDecimeters (see page 1964)	This is variable StdConvs.auSquareDecimeters.
auSquareFeet (see page 1965)	This is variable StdConvs.auSquareFeet.
auSquareHectometers (see page 1965)	This is variable StdConvs.auSquareHectometers.
auSquareInches (see page 1965)	This is variable StdConvs.auSquareInches.
auSquareKilometers (see page 1966)	This is variable StdConvs.auSquareKilometers.
auSquareMeters (see page 1966)	This is variable StdConvs.auSquareMeters.
auSquareMiles (see page 1966)	This is variable StdConvs.auSquareMiles.
auSquareMillimeters (see page 1967)	This is variable StdConvs.auSquareMillimeters.
auSquareRods (see page 1967)	This is variable StdConvs.auSquareRods.
auSquareYards (see page 1967)	This is variable StdConvs.auSquareYards.
cbArea (see page 1968)	Represent units that measure cbArea.
cbDistance (see page 1968)	Represent units that measure cbDistance.
cbMass (see page 1969)	This is variable StdConvs.cbMass.
cbTemperature (see page 1969)	This is variable StdConvs.cbTemperature.
cbTime (see page 1969)	Represent units that measure cbTime.
cbVolume (see page 1970)	Represent units that measure volume.
duAngstroms (see page 1971)	This is variable StdConvs.duAngstroms.
duAstronomicalUnits (see page 1971)	This is variable StdConvs.duAstronomicalUnits.
duCentimeters (see page 1972)	This is variable StdConvs.duCentimeters.
duChains (see page 1972)	This is variable StdConvs.duChains.
duCubits (see page 1972)	This is variable StdConvs.duCubits.
duDecameters (see page 1973)	This is variable StdConvs.duDecameters.
duDecimeters (see page 1973)	This is variable StdConvs.duDecimeters.
duFathoms (see page 1973)	This is variable StdConvs.duFathoms.
duFeet (see page 1974)	This is variable StdConvs.duFeet.
duFurlongs (see page 1974)	This is variable StdConvs.duFurlongs.
duGigameters (see page 1974)	This is variable StdConvs.duGigameters.
duHands (see page 1975)	This is variable StdConvs.duHands.
duHectometers (see page 1975)	This is variable StdConvs.duHectometers.
duInches (see page 1975)	This is variable StdConvs.duInches.
duKilometers (see page 1976)	This is variable StdConvs.duKilometers.
duLightYears (see page 1976)	This is variable StdConvs.duLightYears.
duLinks (see page 1976)	This is variable StdConvs.duLinks.
duMegameters (see page 1977)	This is variable StdConvs.duMegameters.
duMeters (see page 1977)	This is variable StdConvs.duMeters.
duMicromicrons (see page 1977)	This is variable StdConvs.duMicromicrons.
duMicrons (see page 1978)	This is variable StdConvs.duMicrons.
duMiles (see page 1978)	This is variable StdConvs.duMiles.

duMillimeters (see page 1978)	This is variable StdConvs.duMillimeters.
duMillimicrons (see page 1979)	This is variable StdConvs.duMillimicrons.
duNauticalMiles (see page 1979)	This is variable StdConvs.duNauticalMiles.
duPaces (see page 1979)	This is variable StdConvs.duPaces.
duParsecs (see page 1980)	This is variable StdConvs.duParsecs.
duPicas (see page 1980)	This is variable StdConvs.duPicas.
duPoints (see page 1980)	This is variable StdConvs.duPoints.
duRods (see page 1981)	This is variable StdConvs.duRods.
duYards (see page 1981)	This is variable StdConvs.duYards.
muCentigrams (see page 1981)	This is variable StdConvs.muCentigrams.
muDecagrams (see page 1982)	This is variable StdConvs.muDecagrams.
muDecigrams (see page 1982)	This is variable StdConvs.muDecigrams.
muDrams (see page 1982)	This is variable StdConvs.muDrams.
muGrains (see page 1983)	This is variable StdConvs.muGrains.
muGrams (see page 1983)	This is variable StdConvs.muGrams.
muHectograms (see page 1983)	This is variable StdConvs.muHectograms.
muKilograms (see page 1984)	This is variable StdConvs.muKilograms.
muLongTons (see page 1984)	This is variable StdConvs.muLongTons.
muMetricTons (see page 1984)	This is variable StdConvs.muMetricTons.
muMicrograms (see page 1985)	This is variable StdConvs.muMicrograms.
muMilligrams (see page 1985)	This is variable StdConvs.muMilligrams.
muNanograms (see page 1985)	This is variable StdConvs.muNanograms.
muOunces (see page 1986)	This is variable StdConvs.muOunces.
muPounds (see page 1986)	This is variable StdConvs.muPounds.
muStones (see page 1986)	This is variable StdConvs.muStones.
muTons (see page 1987)	This is variable StdConvs.muTons.
tuCelsius (see page 1987)	This is variable StdConvs.tuCelsius.
tuCenturies (see page 1987)	This is variable StdConvs.tuCenturies.
tuDateTime (see page 1988)	This is variable StdConvs.tuDateTime.
tuDays (see page 1988)	This is variable StdConvs.tuDays.
tuDecades (see page 1988)	This is variable StdConvs.tuDecades.
tuFahrenheit (see page 1989)	This is variable StdConvs.tuFahrenheit.
tuFortnights (see page 1989)	This is variable StdConvs.tuFortnights.
tuHours (see page 1989)	This is variable StdConvs.tuHours.
tuJulianDate (see page 1990)	This is variable StdConvs.tuJulianDate.
tuKelvin (see page 1990)	This is variable StdConvs.tuKelvin.
tuMillennia (see page 1990)	This is variable StdConvs.tuMillennia.
tuMilliSeconds (see page 1991)	This is variable StdConvs.tuMilliSeconds.
tuMinutes (see page 1991)	This is variable StdConvs.tuMinutes.
tuModifiedJulianDate (see page 1991)	This is variable StdConvs.tuModifiedJulianDate.
tuMonths (see page 1992)	This is variable StdConvs.tuMonths.
tuRankine (see page 1992)	This is variable StdConvs.tuRankine.
tuReaumur (see page 1992)	This is variable StdConvs.tuReaumur.
tuSeconds (see page 1993)	This is variable StdConvs.tuSeconds.
tuWeeks (see page 1993)	This is variable StdConvs.tuWeeks.
tuYears (see page 1993)	This is variable StdConvs.tuYears.
vuAcreFeet (see page 1994)	This is variable StdConvs.vuAcreFeet.
vuAcreInches (see page 1994)	This is variable StdConvs.vuAcreInches.
vuCentiLiters (see page 1994)	This is variable StdConvs.vuCentiLiters.
vuCordFeet (see page 1995)	This is variable StdConvs.vuCordFeet.
vuCords (see page 1995)	This is variable StdConvs.vuCords.
vuCubicCentimeters (see page 1995)	This is variable StdConvs.vuCubicCentimeters.
vuCubicDecameters (see page 1996)	This is variable StdConvs.vuCubicDecameters.
vuCubicDecimeters (see page 1996)	This is variable StdConvs.vuCubicDecimeters.

vuCubicFeet (see page 1996)	This is variable StdConvs.vuCubicFeet.
vuCubicHectometers (see page 1997)	This is variable StdConvs.vuCubicHectometers.
vuCubicInches (see page 1997)	This is variable StdConvs.vuCubicInches.
vuCubicKilometers (see page 1997)	This is variable StdConvs.vuCubicKilometers.
vuCubicMeters (see page 1998)	This is variable StdConvs.vuCubicMeters.
vuCubicMiles (see page 1998)	This is variable StdConvs.vuCubicMiles.
vuCubicMillimeters (see page 1998)	This is variable StdConvs.vuCubicMillimeters.
vuCubicYards (see page 1999)	This is variable StdConvs.vuCubicYards.
vuDecaLiters (see page 1999)	This is variable StdConvs.vuDecaLiters.
vuDecasteres (see page 1999)	This is variable StdConvs.vuDecasteres.
vuDeciLiters (see page 2000)	This is variable StdConvs.vuDeciLiters.
vuDecisteres (see page 2000)	This is variable StdConvs.vuDecisteres.
vuDryBuckets (see page 2000)	This is variable StdConvs.vuDryBuckets.
vuDryBushels (see page 2001)	This is variable StdConvs.vuDryBushels.
vuDryGallons (see page 2001)	This is variable StdConvs.vuDryGallons.
vuDryPecks (see page 2001)	This is variable StdConvs.vuDryPecks.
vuDryPints (see page 2002)	This is variable StdConvs.vuDryPints.
vuDryQuarts (see page 2002)	This is variable StdConvs.vuDryQuarts.
vuFluidCups (see page 2002)	This is variable StdConvs.vuFluidCups.
vuFluidGallons (see page 2003)	This is variable StdConvs.vuFluidGallons.
vuFluidGills (see page 2003)	This is variable StdConvs.vuFluidGills.
vuFluidOunces (see page 2003)	This is variable StdConvs.vuFluidOunces.
vuFluidPints (see page 2004)	This is variable StdConvs.vuFluidPints.
vuFluidQuarts (see page 2004)	This is variable StdConvs.vuFluidQuarts.
vuFluidTablespoons (see page 2004)	This is variable StdConvs.vuFluidTablespoons.
vuFluidTeaspoons (see page 2005)	This is variable StdConvs.vuFluidTeaspoons.
vuHectoLiters (see page 2005)	This is variable StdConvs.vuHectoLiters.
vuKiloLiters (see page 2005)	This is variable StdConvs.vuKiloLiters.
vuLiters (see page 2006)	This is variable StdConvs.vuLiters.
vuMilliLiters (see page 2006)	This is variable StdConvs.vuMilliLiters.
vuSteres (see page 2006)	This is variable StdConvs.vuSteres.
vuUKBuckets (see page 2007)	This is variable StdConvs.vuUKBuckets.
vuUKBushels (see page 2007)	This is variable StdConvs.vuUKBushels.
vuUKGallons (see page 2007)	This is variable StdConvs.vuUKGallons.
vuUKGills (see page 2008)	This is variable StdConvs.vuUKGills.
vuUKOunces (see page 2008)	This is variable StdConvs.vuUKOunces.
vuUKPecks (see page 2008)	This is variable StdConvs.vuUKPecks.
vuUKPints (see page 2009)	This is variable StdConvs.vuUKPints.
vuUKPottles (see page 2009)	This is variable StdConvs.vuUKPottles.
vuUKQuarts (see page 2009)	This is variable StdConvs.vuUKQuarts.

29.2.1 StdConvs.auAcres Variable

Pascal

```
auAcres: TConvType;
```

C++

```
TConvType auAcres;
```

File

StdConvs

Description

This is variable StdConvs.auAcres.

29.2.2 StdConvs.auAres Variable

Pascal

```
auAres: TConvType;
```

C++

```
TConvType auAres;
```

File

StdConvs

Description

This is variable StdConvs.auAres.

29.2.3 StdConvs.auCentares Variable

Pascal

```
auCentares: TConvType;
```

C++

```
TConvType auCentares;
```

File

StdConvs

Description

This is variable StdConvs.auCentares.

29.2.4 StdConvs.auHectares Variable

Pascal

```
auHectares: TConvType;
```

C++

```
TConvType auHectares;
```

File

StdConvs

Description

This is variable StdConvs.auHectares.

29.2.5 StdConvs.auSquareCentimeters Variable

Pascal

```
auSquareCentimeters: TConvType;
```

C++

```
TConvType auSquareCentimeters;
```

File

StdConvs

Description

This is variable StdConvs.auSquareCentimeters.

29.2.6 StdConvs.auSquareDecameters Variable

Pascal

```
auSquareDecameters: TConvType;
```

C++

```
TConvType auSquareDecameters;
```

File

StdConvs

Description

This is variable StdConvs.auSquareDecameters.

29.2.7 StdConvs.auSquareDecimeters Variable

Pascal

```
auSquareDecimeters: TConvType;
```

C++

```
TConvType auSquareDecimeters;
```

File

StdConvs

Description

This is variable StdConvs.auSquareDecimeters.

29.2.8 StdConvs.auSquareFeet Variable

Pascal

```
auSquareFeet: TConvType;
```

C++

```
TConvType auSquareFeet;
```

File

StdConvs

Description

This is variable StdConvs.auSquareFeet.

29.2.9 StdConvs.auSquareHectometers Variable

Pascal

```
auSquareHectometers: TConvType;
```

C++

```
TConvType auSquareHectometers;
```

File

StdConvs

Description

This is variable StdConvs.auSquareHectometers.

29.2.10 StdConvs.auSquareInches Variable

Pascal

```
auSquareInches: TConvType;
```

C++

```
TConvType auSquareInches;
```

File

StdConvs

Description

This is variable StdConvs.auSquareInches.

29.2.11 StdConvs.auSquareKilometers Variable

Pascal

```
auSquareKilometers: TConvType;
```

C++

```
TConvType auSquareKilometers;
```

File

StdConvs

Description

This is variable StdConvs.auSquareKilometers.

29.2.12 StdConvs.auSquareMeters Variable

Pascal

```
auSquareMeters: TConvType;
```

C++

```
TConvType auSquareMeters;
```

File

StdConvs

Description

This is variable StdConvs.auSquareMeters.

29.2.13 StdConvs.auSquareMiles Variable

Pascal

```
auSquareMiles: TConvType;
```

C++

```
TConvType auSquareMiles;
```

File

StdConvs

Description

This is variable StdConvs.auSquareMiles.

29.2.14 StdConvs.auSquareMillimeters Variable

Pascal

```
auSquareMillimeters: TConvType;
```

C++

```
TConvType auSquareMillimeters;
```

File

StdConvs

Description

This is variable StdConvs.auSquareMillimeters.

29.2.15 StdConvs.auSquareRods Variable

Pascal

```
auSquareRods: TConvType;
```

C++

```
TConvType auSquareRods;
```

File

StdConvs

Description

This is variable StdConvs.auSquareRods.

29.2.16 StdConvs.auSquareYards Variable

Pascal

```
auSquareYards: TConvType;
```

C++

```
TConvType auSquareYards;
```

File

StdConvs

Description

This is variable StdConvs.auSquareYards.

29.2.17 StdConvs.cbArea Variable

Represent units that measure cbArea.

Pascal

```
cbArea: TConvFamily;
```

C++

```
TConvFamily cbArea;
```

File

StdConvs

Description

Use the cbArea unit variables as parameters to the Convert function to convert an cbArea measurement to a different set of units. The StdConvs (see page 1953) unit registers these cbArea measurement units in the cbArea family and assigns the resulting TConvType values to these global variables.

Note: To initialize these variables in C++ programs, use the InitStdConvs (see page 1959) procedure.

Convert

RegisterConversionType

InitStdConvs (see page 1959)

TConvType

29.2.18 StdConvs.cbDistance Variable

Represent units that measure cbDistance.

Pascal

```
cbDistance: TConvFamily;
```

C++

```
TConvFamily cbDistance;
```

File

StdConvs

Description

Use the cbDistance unit variables as parameters to the Convert function to convert a cbDistance measurement to a different set of units. The StdConvs (see page 1953) unit registers these cbDistance measurement units in the cbDistance family and assigns the resulting TConvType values to these global variables.

Note: The cbDistance units vary greatly in scale. If you are converting between cbDistances that are all at one extreme (for example between parsecs and light years or between angstroms and microns), you may want to register your own conversion family (for example astronomical distances or microscopic distances) so that the conversions can be made with greater precision.

Note: To initialize these variables in C++ programs, use the InitStdConvs (see page 1959) procedure.

29.2.19 StdConvs.cbMass Variable

Pascal

```
cbMass: TConvFamily;
```

C++

```
TConvFamily cbMass;
```

File

StdConvs

Description

This is variable StdConvs.cbMass.

29.2.20 StdConvs.cbTemperature Variable

Pascal

```
cbTemperature: TConvFamily;
```

C++

```
TConvFamily cbTemperature;
```

File

StdConvs

Description

This is variable StdConvs.cbTemperature.

29.2.21 StdConvs.cbTime Variable

Represent units that measure cbTime.

Pascal

```
cbTime: TConvFamily;
```

C++

```
TConvFamily cbTime;
```

File

StdConvs

Description

Use the cbTime unit variables as parameters to the Convert function to convert a cbTime measurement to a different set of units. The StdConvs (see page 1953) unit registers these cbTime measurement units in the cbTime family and assigns the resulting TConvType values to these global variables.

Note: Conversions involving tuMonths (see page 1992), tuYears (see page 1993), tuDecades (see page 1988), tuCenturies (see page 1987), and tuMillennia (see page 1990) are approximations, due to the fact that not all months nor all years are the same length. If you are only using units that are multiples of years, you may want to register your own conversion family that uses years as a base unit so that conversions are more accurate.

Note: To initialize these variables in C++ programs, use the InitStdConvs (see page 1959) procedure.

FahrenheitToCelsius (see page 1958)

CelsiusToFahrenheit (see page 1958)

InitStdConvs (see page 1959)

TConvType

29.2.22 StdConvs.cbVolume Variable

Represent units that measure volume.

Pascal

```
cbVolume: TConvFamily;
```

C++

```
TConvFamily cbVolume;
```

File

StdConvs

Description

Use the cbVolume unit variables as parameters to the Convert function to convert a cbVolume measurement to a different set of units. The StdConvs (see page 1953) unit registers these cbVolume measurement units in the cbVolume family and assigns the resulting TConvType values to these global variables.

The interpretation of cbVolume measurements (ounces, gills, pints, quarts, gallons, pecks, bushels, and buckets) varies, depending on whether you are using American or British Imperial measurements. The vuFluidOunces (see page 2003), vuFluidGills (see page 2003), vuFluidPints (see page 2004), vuFluidQuarts (see page 2004), vuFluidGallons (see page 2003), vuDryPecks (see page 2001), vuDryBushels (see page 2001), and vuDryBuckets (see page 2000) variables refer

to the American units, while the vuUKOunces (see page 2008), vuUKGills (see page 2008), vuUKPints (see page 2009), vuUKQuarts (see page 2009), vuUKGallons (see page 2007), vuUKPecks (see page 2008), vuUKBushels (see page 2007), and vuUKBuckets (see page 2007) variables refer to the British Imperial units. Similarly, certain American dry measurements have the same names as American fluid cbVolume measurements (dry pints, dry quarts, and dry gallons), and are distinguished by using the variables vuDryPints (see page 2002), vuDryQuarts (see page 2002), and vuDryGallons (see page 2001).

Note: To initialize these variables in C++ programs, use the InitStdConvs (see page 1959) procedure.

```

C++

```
TConvType duMillimicrons;
```

File

StdConvs

Description

This is variable StdConvs.duMillimicrons.

29.2.47 StdConvs.duNauticalMiles Variable

Pascal

```
duNauticalMiles: TConvType;
```

C++

```
TConvType duNauticalMiles;
```

File

StdConvs

Description

This is variable StdConvs.duNauticalMiles.

29.2.48 StdConvs.duPaces Variable

Pascal

```
duPaces: TConvType;
```

C++

```
TConvType duPaces;
```

File

StdConvs

Description

This is variable StdConvs.duPaces.

29.2.49 StdConvs.duParsecs Variable

Pascal

```
duParsecs: TConvType;
```

C++

```
TConvType duParsecs;
```

File

StdConvs

Description

This is variable StdConvs.duParsecs.

29.2.50 StdConvs.duPicas Variable

Pascal

```
duPicas: TConvType;
```

C++

```
TConvType duPicas;
```

File

StdConvs

Description

This is variable StdConvs.duPicas.

29.2.51 StdConvs.duPoints Variable

Pascal

```
duPoints: TConvType;
```

C++

```
TConvType duPoints;
```

File

StdConvs

Description

This is variable StdConvs.duPoints.

29.2.52 StdConvs.duRods Variable

Pascal

```
duRods: TConvType;
```

C++

```
TConvType duRods;
```

File

StdConvs

Description

This is variable StdConvs.duRods.

29.2.53 StdConvs.duYards Variable

Pascal

```
duYards: TConvType;
```

C++

```
TConvType duYards;
```

File

StdConvs

Description

This is variable StdConvs.duYards.

29.2.54 StdConvs.muCentigrams Variable

Pascal

```
muCentigrams: TConvType;
```

C++

```
TConvType muCentigrams;
```

File

StdConvs

Description

This is variable StdConvs.muCentigrams.

29.2.55 StdConvs.muDecagrams Variable

Pascal

```
muDecagrams: TConvType;
```

C++

```
TConvType muDecagrams;
```

File

StdConvs

Description

This is variable StdConvs.muDecagrams.

29.2.56 StdConvs.muDecigrams Variable

Pascal

```
muDecigrams: TConvType;
```

C++

```
TConvType muDecigrams;
```

File

StdConvs

Description

This is variable StdConvs.muDecigrams.

29.2.57 StdConvs.muDrams Variable

Pascal

```
muDrams: TConvType;
```

C++

```
TConvType muDrams;
```

File

StdConvs

Description

This is variable StdConvs.muDrams.

29.2.58 StdConvs.muGrains Variable

Pascal

```
muGrains: TConvType;
```

C++

```
TConvType muGrains;
```

File

StdConvs

Description

This is variable StdConvs.muGrains.

29.2.59 StdConvs.muGrams Variable

Pascal

```
muGrams: TConvType;
```

C++

```
TConvType muGrams;
```

File

StdConvs

Description

This is variable StdConvs.muGrams.

29.2.60 StdConvs.muHectograms Variable

Pascal

```
muHectograms: TConvType;
```

C++

```
TConvType muHectograms;
```

File

StdConvs

Description

This is variable StdConvs.muHectograms.

29.2.61 StdConvs.muKilograms Variable

Pascal

```
muKilograms: TConvType;
```

C++

```
TConvType muKilograms;
```

File

StdConvs

Description

This is variable StdConvs.muKilograms.

29.2.62 StdConvs.muLongTons Variable

Pascal

```
muLongTons: TConvType;
```

C++

```
TConvType muLongTons;
```

File

StdConvs

Description

This is variable StdConvs.muLongTons.

29.2.63 StdConvs.muMetricTons Variable

Pascal

```
muMetricTons: TConvType;
```

C++

```
TConvType muMetricTons;
```

File

StdConvs

Description

This is variable StdConvs.muMetricTons.

29.2.64 StdConvs.muMicrograms Variable

Pascal

```
muMicrograms: TConvType;
```

C++

```
TConvType muMicrograms;
```

File

StdConvs

Description

This is variable StdConvs.muMicrograms.

29.2.65 StdConvs.muMilligrams Variable

Pascal

```
muMilligrams: TConvType;
```

C++

```
TConvType muMilligrams;
```

File

StdConvs

Description

This is variable StdConvs.muMilligrams.

29.2.66 StdConvs.muNanograms Variable

Pascal

```
muNanograms: TConvType;
```

C++

```
TConvType muNanograms;
```

File

StdConvs

Description

This is variable StdConvs.muNanograms.

29.2.67 StdConvs.muOunces Variable

Pascal

```
muOunces: TConvType;
```

C++

```
TConvType muOunces;
```

File

StdConvs

Description

This is variable StdConvs.muOunces.

29.2.68 StdConvs.muPounds Variable

Pascal

```
muPounds: TConvType;
```

C++

```
TConvType muPounds;
```

File

StdConvs

Description

This is variable StdConvs.muPounds.

29.2.69 StdConvs.muStones Variable

Pascal

```
muStones: TConvType;
```

C++

```
TConvType muStones;
```

File

StdConvs

Description

This is variable StdConvs.muStones.

29.2.70 StdConvs.muTons Variable

Pascal

```
muTons: TConvType;
```

C++

```
TConvType muTons;
```

File

StdConvs

Description

This is variable StdConvs.muTons.

29.2.71 StdConvs.tuCelsius Variable

Pascal

```
tuCelsius: TConvType;
```

C++

```
TConvType tuCelsius;
```

File

StdConvs

Description

This is variable StdConvs.tuCelsius.

29.2.72 StdConvs.tuCenturies Variable

Pascal

```
tuCenturies: TConvType;
```

C++

```
TConvType tuCenturies;
```

File

StdConvs

Description

This is variable StdConvs.tuCenturies.

29.2.73 StdConvs.tuDateTime Variable

Pascal

```

Pascal

```
tuMillennia: TConvType;
```

C++

```
TConvType tuMillennia;
```

File

StdConvs

Description

This is variable StdConvs.tuMillennia.

29.2.82 StdConvs.tuMilliSeconds Variable

Pascal

```
tuMilliSeconds: TConvType;
```

C++

```
TConvType tuMilliSeconds;
```

File

StdConvs

Description

This is variable StdConvs.tuMilliSeconds.

29.2.83 StdConvs.tuMinutes Variable

Pascal

```
tuMinutes: TConvType;
```

C++

```
TConvType tuMinutes;
```

File

StdConvs

Description

This is variable StdConvs.tuMinutes.

29.2.84 StdConvs.tuModifiedJulianDate Variable

Pascal

```
tuModifiedJulianDate: TConvType;
```

C++

```
TConvType tuModifiedJulianDate;
```

File

StdConvs

Description

This is variable StdConvs.tuModifiedJulianDate.

29.2.85 StdConvs.tuMonths Variable

Pascal

```
tuMonths: TConvType;
```

C++

```
TConvType tuMonths;
```

File

StdConvs

Description

This is variable StdConvs.tuMonths.

29.2.86 StdConvs.tuRankine Variable

Pascal

```
tuRankine: TConvType;
```

C++

```
TConvType tuRankine;
```

File

StdConvs

Description

This is variable StdConvs.tuRankine.

29.2.87 StdConvs.tuReaumur Variable

Pascal

```
tuReaumur: TConvType;
```

C++

```
TConvType tuReaumur;
```

File

StdConvs

Description

This is variable StdConvs.tuReaumur.

29.2.88 StdConvs.tuSeconds Variable

```
tuSeconds: TConvType;
```

C++

```
TConvType tuSeconds;
```

File

StdConvs

Description

This is variable StdConvs.tuSeconds.

29.2.89 StdConvs.tuWeeks Variable

Pascal

```
tuWeeks: TConvType;
```

C++

```
TConvType tuWeeks;
```

File

StdConvs

Description

This is variable StdConvs.tuWeeks.

29.2.90 StdConvs.tuYears Variable

Pascal

```
tuYears: TConvType;
```

C++

```
TConvType tuYears;
```

File

StdConvs

Description

This is variable StdConvs.tuYears.

29.2.91 StdConvs.vuAcreFeet Variable

Pascal

```
vuAcreFeet: TConvType;
```

C++

```
TConvType vuAcreFeet;
```

File

StdConvs

Description

This is variable StdConvs.vuAcreFeet.

29.2.92 StdConvs.vuAcreInches Variable

Pascal

```
vuAcreInches: TConvType;
```

C++

```
TConvType vuAcreInches;
```

File

StdConvs

Description

This is variable StdConvs.vuAcreInches.

29.2.93 StdConvs.vuCentiLiters Variable

Pascal

```
vuCentiLiters: TConvType;
```

C++

```
TConvType vuCentiLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuCentiLiters.

29.2.94 StdConvs.vuCordFeet Variable

Pascal

```
vuCordFeet: TConvType;
```

C++

```
TConvType vuCordFeet;
```

File

StdConvs

Description

This is variable StdConvs.vuCordFeet.

29.2.95 StdConvs.vuCords Variable

Pascal

```
vuCords: TConvType;
```

C++

```
TConvType vuCords;
```

File

StdConvs

Description

This is variable StdConvs.vuCords.

29.2.96 StdConvs.vuCubicCentimeters Variable

Pascal

```
vuCubicCentimeters: TConvType;
```

C++

```
TConvType vuCubicCentimeters;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicCentimeters.

29.2.97 StdConvs.vuCubicDecameters Variable

Pascal

```
vuCubicDecameters: TConvType;
```

C++

```
TConvType vuCubicDecameters;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicDecameters.

29.2.98 StdConvs.vuCubicDecimeters Variable

Pascal

```
vuCubicDecimeters: TConvType;
```

C++

```
TConvType vuCubicDecimeters;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicDecimeters.

29.2.99 StdConvs.vuCubicFeet Variable

Pascal

```
vuCubicFeet: TConvType;
```

C++

```
TConvType vuCubicFeet;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicFeet.

29.2.100 StdConvs.vuCubicHectometers Variable

Pascal

```
vuCubicHectometers: TConvType;
```

C++

```
TConvType vuCubicHectometers;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicHectometers.

29.2.101 StdConvs.vuCubicInches Variable

Pascal

```
vuCubicInches: TConvType;
```

C++

```
TConvType vuCubicInches;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicInches.

29.2.102 StdConvs.vuCubicKilometers Variable

Pascal

```
vuCubicKilometers: TConvType;
```

C++

```
TConvType vuCubicKilometers;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicKilometers.

29.2.103 StdConvs.vuCubicMeters Variable

Pascal

```
vuCubicMeters: TConvType;
```

C++

```
TConvType vuCubicMeters;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicMeters.

29.2.104 StdConvs.vuCubicMiles Variable

Pascal

```
vuCubicMiles: TConvType;
```

C++

```
TConvType vuCubicMiles;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicMiles.

29.2.105 StdConvs.vuCubicMillimeters Variable

Pascal

```
vuCubicMillimeters: TConvType;
```

C++

```
TConvType vuCubicMillimeters;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicMillimeters.

29.2.106 StdConvs.vuCubicYards Variable

Pascal

```
vuCubicYards: TConvType;
```

C++

```
TConvType vuCubicYards;
```

File

StdConvs

Description

This is variable StdConvs.vuCubicYards.

29.2.107 StdConvs.vuDecaLiters Variable

Pascal

```
vuDecaLiters: TConvType;
```

C++

```
TConvType vuDecaLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuDecaLiters.

29.2.108 StdConvs.vuDecasteres Variable

Pascal

```
vuDecasteres: TConvType;
```

C++

```
TConvType vuDecasteres;
```

File

StdConvs

Description

This is variable StdConvs.vuDecasteres.

29.2.109 StdConvs.vuDeciLiters Variable

Pascal

```
vuDeciLiters: TConvType;
```

C++

```
TConvType vuDeciLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuDeciLiters.

29.2.110 StdConvs.vuDecisteres Variable

Pascal

```
vuDecisteres: TConvType;
```

C++

```
TConvType vuDecisteres;
```

File

StdConvs

Description

This is variable StdConvs.vuDecisteres.

29.2.111 StdConvs.vuDryBuckets Variable

Pascal

```
vuDryBuckets: TConvType;
```

C++

```
TConvType vuDryBuckets;
```

File

StdConvs

Description

This is variable StdConvs.vuDryBuckets.

29.2.112 StdConvs.vuDryBushels Variable

Pascal

```
vuDryBushels: TConvType;
```

C++

```
TConvType vuDryBushels;
```

File

StdConvs

Description

This is variable StdConvs.vuDryBushels.

29.2.113 StdConvs.vuDryGallons Variable

Pascal

```
vuDryGallons: TConvType;
```

C++

```
TConvType vuDryGallons;
```

File

StdConvs

Description

This is variable StdConvs.vuDryGallons.

29.2.114 StdConvs.vuDryPecks Variable

Pascal

```
vuDryPecks: TConvType;
```

C++

```
TConvType vuDryPecks;
```

File

StdConvs

Description

This is variable StdConvs.vuDryPecks.

29.2.115 StdConvs.vuDryPints Variable

Pascal

```
vuDryPints: TConvType;
```

C++

```
TConvType vuDryPints;
```

File

StdConvs

Description

This is variable StdConvs.vuDryPints.

29.2.116 StdConvs.vuDryQuarts Variable

Pascal

```
vuDryQuarts: TConvType;
```

C++

```
TConvType vuDryQuarts;
```

File

StdConvs

Description

This is variable StdConvs.vuDryQuarts.

29.2.117 StdConvs.vuFluidCups Variable

Pascal

```
vuFluidCups: TConvType;
```

C++

```
TConvType vuFluidCups;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidCups.

29.2.118 StdConvs.vuFluidGallons Variable

Pascal

```
vuFluidGallons: TConvType;
```

C++

```
TConvType vuFluidGallons;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidGallons.

29.2.119 StdConvs.vuFluidGills Variable

Pascal

```
vuFluidGills: TConvType;
```

C++

```
TConvType vuFluidGills;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidGills.

29.2.120 StdConvs.vuFluidOunces Variable

Pascal

```
vuFluidOunces: TConvType;
```

C++

```
TConvType vuFluidOunces;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidOunces.

29.2.121 StdConvs.vuFluidPints Variable

Pascal

```
vuFluidPints: TConvType;
```

C++

```
TConvType vuFluidPints;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidPints.

29.2.122 StdConvs.vuFluidQuarts Variable

Pascal

```
vuFluidQuarts: TConvType;
```

C++

```
TConvType vuFluidQuarts;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidQuarts.

29.2.123 StdConvs.vuFluidTablespoons Variable

Pascal

```
vuFluidTablespoons: TConvType;
```

C++

```
TConvType vuFluidTablespoons;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidTablespoons.

29.2.124 StdConvs.vuFluidTeaspoons Variable

Pascal

```
vuFluidTeaspoons: TConvType;
```

C++

```
TConvType vuFluidTeaspoons;
```

File

StdConvs

Description

This is variable StdConvs.vuFluidTeaspoons.

29.2.125 StdConvs.vuHectoLiters Variable

Pascal

```
vuHectoLiters: TConvType;
```

C++

```
TConvType vuHectoLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuHectoLiters.

29.2.126 StdConvs.vuKiloLiters Variable

Pascal

```
vuKiloLiters: TConvType;
```

C++

```
TConvType vuKiloLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuKiloLiters.

29.2.127 StdConvs.vuLiters Variable

Pascal

```
vuLiters: TConvType;
```

C++

```
TConvType vuLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuLiters.

29.2.128 StdConvs.vuMilliLiters Variable

Pascal

```
vuMilliLiters: TConvType;
```

C++

```
TConvType vuMilliLiters;
```

File

StdConvs

Description

This is variable StdConvs.vuMilliLiters.

29.2.129 StdConvs.vuSteres Variable

Pascal

```
vuSteres: TConvType;
```

C++

```
TConvType vuSteres;
```

File

StdConvs

Description

This is variable StdConvs.vuSteres.

29.2.130 StdConvs.vuUKBuckets Variable

Pascal

```
vuUKBuckets: TConvType;
```

C++

```
TConvType vuUKBuckets;
```

File

StdConvs

Description

This is variable StdConvs.vuUKBuckets.

29.2.131 StdConvs.vuUKBushels Variable

Pascal

```
vuUKBushels: TConvType;
```

C++

```
TConvType vuUKBushels;
```

File

StdConvs

Description

This is variable StdConvs.vuUKBushels.

29.2.132 StdConvs.vuUKGallons Variable

Pascal

```
vuUKGallons: TConvType;
```

C++

```
TConvType vuUKGallons;
```

File

StdConvs

Description

This is variable StdConvs.vuUKGallons.

29.2.133 StdConvs.vuUKGills Variable

Pascal

```
vuUKGills: TConvType;
```

C++

```
TConvType vuUKGills;
```

File

StdConvs

Description

This is variable StdConvs.vuUKGills.

29.2.134 StdConvs.vuUKOunces Variable

Pascal

```
vuUKOunces: TConvType;
```

C++

```
TConvType vuUKOunces;
```

File

StdConvs

Description

This is variable StdConvs.vuUKOunces.

29.2.135 StdConvs.vuUKPecks Variable

Pascal

```
vuUKPecks: TConvType;
```

C++

```
TConvType vuUKPecks;
```

File

StdConvs

Description

This is variable StdConvs.vuUKPecks.

29.2.136 StdConvs.vuUKPints Variable

Pascal

```
vuUKPints: TConvType;
```

C++

```
TConvType vuUKPints;
```

File

StdConvs

Description

This is variable StdConvs.vuUKPints.

29.2.137 StdConvs.vuUKPottles Variable

Pascal

```
vuUKPottles: TConvType;
```

C++

```
TConvType vuUKPottles;
```

File

StdConvs

Description

This is variable StdConvs.vuUKPottles.

29.2.138 StdConvs.vuUKQuarts Variable

Pascal

```
vuUKQuarts: TConvType;
```

C++

```
TConvType vuUKQuarts;
```

File

StdConvs

Description

This is variable StdConvs.vuUKQuarts.

29.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CubicMetersPerAcreFoot (see page 2011)	This is constant StdConvs.CubicMetersPerAcreFoot.
CubicMetersPerAcreInch (see page 2011)	This is constant StdConvs.CubicMetersPerAcreInch.
CubicMetersPerCord (see page 2012)	This is constant StdConvs.CubicMetersPerCord.
CubicMetersPerCordFoot (see page 2012)	This is constant StdConvs.CubicMetersPerCordFoot.
CubicMetersPerCubicFoot (see page 2012)	This is constant StdConvs.CubicMetersPerCubicFoot.
CubicMetersPerCubicInch (see page 2013)	This is constant StdConvs.CubicMetersPerCubicInch.
CubicMetersPerCubicMile (see page 2013)	This is constant StdConvs.CubicMetersPerCubicMile.
CubicMetersPerCubicYard (see page 2013)	This is constant StdConvs.CubicMetersPerCubicYard.
CubicMetersPerUKBucket (see page 2014)	This is constant StdConvs.CubicMetersPerUKBucket.
CubicMetersPerUKBushel (see page 2014)	This is constant StdConvs.CubicMetersPerUKBushel.
CubicMetersPerUKGallon (see page 2014)	This is constant StdConvs.CubicMetersPerUKGallon.
CubicMetersPerUKGill (see page 2015)	This is constant StdConvs.CubicMetersPerUKGill.
CubicMetersPerUKOunce (see page 2015)	This is constant StdConvs.CubicMetersPerUKOunce.
CubicMetersPerUKPeck (see page 2015)	This is constant StdConvs.CubicMetersPerUKPeck.
CubicMetersPerUKPint (see page 2016)	This is constant StdConvs.CubicMetersPerUKPint.
CubicMetersPerUKPottle (see page 2016)	This is constant StdConvs.CubicMetersPerUKPottle.
CubicMetersPerUKQuart (see page 2016)	This is constant StdConvs.CubicMetersPerUKQuart.
CubicMetersPerUSDryBucket (see page 2017)	This is constant StdConvs.CubicMetersPerUSDryBucket.
CubicMetersPerUSDryBushel (see page 2017)	This is constant StdConvs.CubicMetersPerUSDryBushel.
CubicMetersPerUSDryGallon (see page 2017)	This is constant StdConvs.CubicMetersPerUSDryGallon.
CubicMetersPerUSDryPeck (see page 2018)	This is constant StdConvs.CubicMetersPerUSDryPeck.
CubicMetersPerUSDryPint (see page 2018)	This is constant StdConvs.CubicMetersPerUSDryPint.
CubicMetersPerUSDryQuart (see page 2018)	This is constant StdConvs.CubicMetersPerUSDryQuart.
CubicMetersPerUSFluidCup (see page 2019)	This is constant StdConvs.CubicMetersPerUSFluidCup.
CubicMetersPerUSFluidGallon (see page 2019)	This is constant StdConvs.CubicMetersPerUSFluidGallon.
CubicMetersPerUSFluidGill (see page 2019)	This is constant StdConvs.CubicMetersPerUSFluidGill.
CubicMetersPerUSFluidOunce (see page 2020)	This is constant StdConvs.CubicMetersPerUSFluidOunce.
CubicMetersPerUSFluidPint (see page 2020)	This is constant StdConvs.CubicMetersPerUSFluidPint.
CubicMetersPerUSFluidQuart (see page 2020)	This is constant StdConvs.CubicMetersPerUSFluidQuart.
CubicMetersPerUSFluidTablespoon (see page 2021)	This is constant StdConvs.CubicMetersPerUSFluidTablespoon.
CubicMetersPerUSFluidTeaspoon (see page 2021)	This is constant StdConvs.CubicMetersPerUSFluidTeaspoon.
GramsPerDrams (see page 2021)	This is constant StdConvs.GramsPerDrams.
GramsPerGrains (see page 2022)	This is constant StdConvs.GramsPerGrains.
GramsPerLongTons (see page 2022)	This is constant StdConvs.GramsPerLongTons.
GramsPerOunces (see page 2022)	This is constant StdConvs.GramsPerOunces.
GramsPerPound (see page 2023)	This is constant StdConvs.GramsPerPound.
GramsPerStones (see page 2023)	This is constant StdConvs.GramsPerStones.
GramsPerTons (see page 2023)	This is constant StdConvs.GramsPerTons.
MetersPerAstronomicalUnit (see page 2024)	This is constant StdConvs.MetersPerAstronomicalUnit.
MetersPerChain (see page 2024)	This is constant StdConvs.MetersPerChain.
MetersPerCubit (see page 2024)	This is constant StdConvs.MetersPerCubit.
MetersPerFathom (see page 2025)	This is constant StdConvs.MetersPerFathom.
MetersPerFoot (see page 2025)	This is constant StdConvs.MetersPerFoot.
MetersPerFurlong (see page 2025)	This is constant StdConvs.MetersPerFurlong.

MetersPerHand (see page 2026)	This is constant StdConvs.MetersPerHand.
MetersPerInch (see page 2026)	This is constant StdConvs.MetersPerInch.
MetersPerLightSecond (see page 2026)	This is constant StdConvs.MetersPerLightSecond.
MetersPerLightYear (see page 2027)	This is constant StdConvs.MetersPerLightYear.
MetersPerLink (see page 2027)	This is constant StdConvs.MetersPerLink.
MetersPerMile (see page 2027)	This is constant StdConvs.MetersPerMile.
MetersPerNauticalMiles (see page 2028)	This is constant StdConvs.MetersPerNauticalMiles.
MetersPerPace (see page 2028)	This is constant StdConvs.MetersPerPace.
MetersPerParsec (see page 2028)	This is constant StdConvs.MetersPerParsec.
MetersPerPica (see page 2029)	This is constant StdConvs.MetersPerPica.
MetersPerPoint (see page 2029)	This is constant StdConvs.MetersPerPoint.
MetersPerRod (see page 2029)	This is constant StdConvs.MetersPerRod.
MetersPerYard (see page 2030)	This is constant StdConvs.MetersPerYard.
SquareMetersPerAcre (see page 2030)	This is constant StdConvs.SquareMetersPerAcre.
SquareMetersPerSquareFoot (see page 2030)	This is constant StdConvs.SquareMetersPerSquareFoot.
SquareMetersPerSquareInch (see page 2031)	This is constant StdConvs.SquareMetersPerSquareInch.
SquareMetersPerSquareMile (see page 2031)	This is constant StdConvs.SquareMetersPerSquareMile.
SquareMetersPerSquareRod (see page 2031)	This is constant StdConvs.SquareMetersPerSquareRod.
SquareMetersPerSquareYard (see page 2032)	This is constant StdConvs.SquareMetersPerSquareYard.

29.3.1 StdConvs.CubicMetersPerAcreFoot Constant

Pascal

```
CubicMetersPerAcreFoot = SquareMetersPerAcre * MetersPerFoot;
```

C++

```
CubicMetersPerAcreFoot = SquareMetersPerAcre * MetersPerFoot;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerAcreFoot.

29.3.2 StdConvs.CubicMetersPerAcreInch Constant

Pascal

```
CubicMetersPerAcreInch = SquareMetersPerAcre * MetersPerInch;
```

C++

```
CubicMetersPerAcreInch = SquareMetersPerAcre * MetersPerInch;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerAcreInch.

29.3.3 StdConvs.CubicMetersPerCord Constant

Pascal

```
CubicMetersPerCord = CubicMetersPerCubicFoot * 128;
```

C++

```
CubicMetersPerCord = CubicMetersPerCubicFoot * 128;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCord.

29.3.4 StdConvs.CubicMetersPerCordFoot Constant

Pascal

```
CubicMetersPerCordFoot = CubicMetersPerCubicFoot * 16;
```

C++

```
CubicMetersPerCordFoot = CubicMetersPerCubicFoot * 16;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCordFoot.

29.3.5 StdConvs.CubicMetersPerCubicFoot Constant

Pascal

```
CubicMetersPerCubicFoot = MetersPerFoot * MetersPerFoot * MetersPerFoot;
```

C++

```
CubicMetersPerCubicFoot = MetersPerFoot * MetersPerFoot * MetersPerFoot;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCubicFoot.

29.3.6 StdConvs.CubicMetersPerCubicInch Constant

Pascal

```
CubicMetersPerCubicInch = MetersPerInch * MetersPerInch * MetersPerInch;
```

C++

```
CubicMetersPerCubicInch = MetersPerInch * MetersPerInch * MetersPerInch;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCubicInch.

29.3.7 StdConvs.CubicMetersPerCubicMile Constant

Pascal

```
CubicMetersPerCubicMile = MetersPerMile * MetersPerMile * MetersPerMile;
```

C++

```
CubicMetersPerCubicMile = MetersPerMile * MetersPerMile * MetersPerMile;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCubicMile.

29.3.8 StdConvs.CubicMetersPerCubicYard Constant

Pascal

```
CubicMetersPerCubicYard = MetersPerYard * MetersPerYard * MetersPerYard;
```

C++

```
CubicMetersPerCubicYard = MetersPerYard * MetersPerYard * MetersPerYard;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerCubicYard.

29.3.9 StdConvs.CubicMetersPerUKBucket Constant

Pascal

```
CubicMetersPerUKBucket = CubicMetersPerUKPeck * 2;
```

C++

```
CubicMetersPerUKBucket = CubicMetersPerUKPeck * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKBucket.

29.3.10 StdConvs.CubicMetersPerUKBushel Constant

Pascal

```
CubicMetersPerUKBushel = CubicMetersPerUKBucket * 2;
```

C++

```
CubicMetersPerUKBushel = CubicMetersPerUKBucket * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKBushel.

29.3.11 StdConvs.CubicMetersPerUKGallon Constant

Pascal

```
CubicMetersPerUKGallon = 0.00454609;
```

C++

```
CubicMetersPerUKGallon = 0.00454609;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKGallon.

29.3.12 StdConvs.CubicMetersPerUKGill Constant

Pascal

```
CubicMetersPerUKGill = CubicMetersPerUKPint / 4;
```

C++

```
CubicMetersPerUKGill = CubicMetersPerUKPint / 4;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKGill.

29.3.13 StdConvs.CubicMetersPerUKOunce Constant

Pascal

```
CubicMetersPerUKOunce = CubicMetersPerUKPint / 20;
```

C++

```
CubicMetersPerUKOunce = CubicMetersPerUKPint / 20;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKOunce.

29.3.14 StdConvs.CubicMetersPerUKPeck Constant

Pascal

```
CubicMetersPerUKPeck = CubicMetersPerUKGallon * 2;
```

C++

```
CubicMetersPerUKPeck = CubicMetersPerUKGallon * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKPeck.

29.3.15 StdConvs.CubicMetersPerUKPint Constant

Pascal

```
CubicMetersPerUKPint = CubicMetersPerUKQuart / 2;
```

C++

```
CubicMetersPerUKPint = CubicMetersPerUKQuart / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKPint.

29.3.16 StdConvs.CubicMetersPerUKPottle Constant

Pascal

```
CubicMetersPerUKPottle = CubicMetersPerUKGallon / 2;
```

C++

```
CubicMetersPerUKPottle = CubicMetersPerUKGallon / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKPottle.

29.3.17 StdConvs.CubicMetersPerUKQuart Constant

Pascal

```
CubicMetersPerUKQuart = CubicMetersPerUKPottle / 2;
```

C++

```
CubicMetersPerUKQuart = CubicMetersPerUKPottle / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUKQuart.

29.3.18 StdConvs.CubicMetersPerUSDryBucket Constant

Pascal

```
CubicMetersPerUSDryBucket = CubicMetersPerUSDryPeck * 2;
```

C++

```
CubicMetersPerUSDryBucket = CubicMetersPerUSDryPeck * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryBucket.

29.3.19 StdConvs.CubicMetersPerUSDryBushel Constant

Pascal

```
CubicMetersPerUSDryBushel = CubicMetersPerUSDryBucket * 2;
```

C++

```
CubicMetersPerUSDryBushel = CubicMetersPerUSDryBucket * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryBushel.

29.3.20 StdConvs.CubicMetersPerUSDryGallon Constant

Pascal

```
CubicMetersPerUSDryGallon = CubicMetersPerCubicInch * 268.8025;
```

C++

```
CubicMetersPerUSDryGallon = CubicMetersPerCubicInch * 268.8025;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryGallon.

29.3.21 StdConvs.CubicMetersPerUSDryPeck Constant

Pascal

```
CubicMetersPerUSDryPeck = CubicMetersPerUSDryGallon * 2;
```

C++

```
CubicMetersPerUSDryPeck = CubicMetersPerUSDryGallon * 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryPeck.

29.3.22 StdConvs.CubicMetersPerUSDryPint Constant

Pascal

```
CubicMetersPerUSDryPint = CubicMetersPerUSDryQuart / 2;
```

C++

```
CubicMetersPerUSDryPint = CubicMetersPerUSDryQuart / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryPint.

29.3.23 StdConvs.CubicMetersPerUSDryQuart Constant

Pascal

```
CubicMetersPerUSDryQuart = CubicMetersPerUSDryGallon / 4;
```

C++

```
CubicMetersPerUSDryQuart = CubicMetersPerUSDryGallon / 4;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSDryQuart.

29.3.24 StdConvs.CubicMetersPerUSFluidCup Constant

Pascal

```
CubicMetersPerUSFluidCup = CubicMetersPerUSFluidPint / 2;
```

C++

```
CubicMetersPerUSFluidCup = CubicMetersPerUSFluidPint / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidCup.

29.3.25 StdConvs.CubicMetersPerUSFluidGallon Constant

Pascal

```
CubicMetersPerUSFluidGallon = CubicMetersPerCubicInch * 231;
```

C++

```
CubicMetersPerUSFluidGallon = CubicMetersPerCubicInch * 231;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidGallon.

29.3.26 StdConvs.CubicMetersPerUSFluidGill Constant

Pascal

```
CubicMetersPerUSFluidGill = CubicMetersPerUSFluidCup / 2;
```

C++

```
CubicMetersPerUSFluidGill = CubicMetersPerUSFluidCup / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidGill.

29.3.27 StdConvs.CubicMetersPerUSFluidOunce Constant

Pascal

```
CubicMetersPerUSFluidOunce = CubicMetersPerUSFluidCup / 8;
```

C++

```
CubicMetersPerUSFluidOunce = CubicMetersPerUSFluidCup / 8;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidOunce.

29.3.28 StdConvs.CubicMetersPerUSFluidPint Constant

Pascal

```
CubicMetersPerUSFluidPint = CubicMetersPerUSFluidQuart / 2;
```

C++

```
CubicMetersPerUSFluidPint = CubicMetersPerUSFluidQuart / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidPint.

29.3.29 StdConvs.CubicMetersPerUSFluidQuart Constant

Pascal

```
CubicMetersPerUSFluidQuart = CubicMetersPerUSFluidGallon / 4;
```

C++

```
CubicMetersPerUSFluidQuart = CubicMetersPerUSFluidGallon / 4;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidQuart.

29.3.30 StdConvs.CubicMetersPerUSFluidTablespoon Constant

Pascal

```
CubicMetersPerUSFluidTablespoon = CubicMetersPerUSFluidOunce / 2;
```

C++

```
CubicMetersPerUSFluidTablespoon = CubicMetersPerUSFluidOunce / 2;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidTablespoon.

29.3.31 StdConvs.CubicMetersPerUSFluidTeaspoon Constant

Pascal

```
CubicMetersPerUSFluidTeaspoon = CubicMetersPerUSFluidOunce / 6;
```

C++

```
CubicMetersPerUSFluidTeaspoon = CubicMetersPerUSFluidOunce / 6;
```

File

StdConvs

Description

This is constant StdConvs.CubicMetersPerUSFluidTeaspoon.

29.3.32 StdConvs.GramsPerDrams Constant

Pascal

```
GramsPerDrams = GramsPerPound / 256;
```

C++

```
GramsPerDrams = GramsPerPound / 256;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerDrams.

29.3.33 StdConvs.GramsPerGrains Constant

Pascal

```
GramsPerGrains = GramsPerPound / 7000;
```

C++

```
GramsPerGrains = GramsPerPound / 7000;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerGrains.

29.3.34 StdConvs.GramsPerLongTons Constant

Pascal

```
GramsPerLongTons = GramsPerPound * 2240;
```

C++

```
GramsPerLongTons = GramsPerPound * 2240;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerLongTons.

29.3.35 StdConvs.GramsPerOunces Constant

Pascal

```
GramsPerOunces = GramsPerPound / 16;
```

C++

```
GramsPerOunces = GramsPerPound / 16;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerOunces.

29.3.36 StdConvs.GramsPerPound Constant

Pascal

```
GramsPerPound = 453.59237;
```

C++

```
GramsPerPound = 453.59237;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerPound.

29.3.37 StdConvs.GramsPerStones Constant

Pascal

```
GramsPerStones = GramsPerPound * 14;
```

C++

```
GramsPerStones = GramsPerPound * 14;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerStones.

29.3.38 StdConvs.GramsPerTons Constant

Pascal

```
GramsPerTons = GramsPerPound * 2000;
```

C++

```
GramsPerTons = GramsPerPound * 2000;
```

File

StdConvs

Description

This is constant StdConvs.GramsPerTons.

29.3.39 StdConvs.MetersPerAstronomicalUnit Constant

Pascal

```
MetersPerAstronomicalUnit = 1.49598E11;
```

C++

```
MetersPerAstronomicalUnit = 1.49598E11;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerAstronomicalUnit.

29.3.40 StdConvs.MetersPerChain Constant

Pascal

```
MetersPerChain = MetersPerRod * 4;
```

C++

```
MetersPerChain = MetersPerRod * 4;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerChain.

29.3.41 StdConvs.MetersPerCubit Constant

Pascal

```
MetersPerCubit = 0.4572;
```

C++

```
MetersPerCubit = 0.4572;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerCubit.

29.3.42 StdConvs.MetersPerFathom Constant

Pascal

```
MetersPerFathom = MetersPerFoot * 6;
```

C++

```
MetersPerFathom = MetersPerFoot * 6;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerFathom.

29.3.43 StdConvs.MetersPerFoot Constant

Pascal

```
MetersPerFoot = MetersPerInch * 12;
```

C++

```
MetersPerFoot = MetersPerInch * 12;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerFoot.

29.3.44 StdConvs.MetersPerFurlong Constant

Pascal

```
MetersPerFurlong = MetersPerYard * 220;
```

C++

```
MetersPerFurlong = MetersPerYard * 220;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerFurlong.

29.3.45 StdConvs.MetersPerHand Constant

Pascal

```
MetersPerHand = MetersPerInch * 4;
```

C++

```
MetersPerHand = MetersPerInch * 4;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerHand.

29.3.46 StdConvs.MetersPerInch Constant

Pascal

```
MetersPerInch = 0.0254;
```

C++

```
MetersPerInch = 0.0254;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerInch.

29.3.47 StdConvs.MetersPerLightSecond Constant

Pascal

```
MetersPerLightSecond = 2.99792458E8;
```

C++

```
MetersPerLightSecond = 2.99792458E8;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerLightSecond.

29.3.48 StdConvs.MetersPerLightYear Constant

Pascal

```
MetersPerLightYear = MetersPerLightSecond * 31556925.9747;
```

C++

```
MetersPerLightYear = MetersPerLightSecond * 31556925.9747;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerLightYear.

29.3.49 StdConvs.MetersPerLink Constant

Pascal

```
MetersPerLink = MetersPerChain / 100;
```

C++

```
MetersPerLink = MetersPerChain / 100;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerLink.

29.3.50 StdConvs.MetersPerMile Constant

Pascal

```
MetersPerMile = MetersPerFoot * 5280;
```

C++

```
MetersPerMile = MetersPerFoot * 5280;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerMile.

29.3.51 StdConvs.MetersPerNauticalMiles Constant

Pascal

```
MetersPerNauticalMiles = 1852;
```

C++

```
MetersPerNauticalMiles = 1852;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerNauticalMiles.

29.3.52 StdConvs.MetersPerPace Constant

Pascal

```
MetersPerPace = MetersPerInch * 30;
```

C++

```
MetersPerPace = MetersPerInch * 30;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerPace.

29.3.53 StdConvs.MetersPerParsec Constant

Pascal

```
MetersPerParsec = MetersPerAstronomicalUnit * 206264.806247096;
```

C++

```
MetersPerParsec = MetersPerAstronomicalUnit * 206264.806247096;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerParsec.

29.3.54 StdConvs.MetersPerPica Constant

Pascal

```
MetersPerPica = MetersPerPoint * 12;
```

C++

```
MetersPerPica = MetersPerPoint * 12;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerPica.

29.3.55 StdConvs.MetersPerPoint Constant

Pascal

```
MetersPerPoint = MetersPerInch * 0.013837;
```

C++

```
MetersPerPoint = MetersPerInch * 0.013837;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerPoint.

29.3.56 StdConvs.MetersPerRod Constant

Pascal

```
MetersPerRod = MetersPerFoot * 16.5;
```

C++

```
MetersPerRod = MetersPerFoot * 16.5;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerRod.

29.3.57 StdConvs.MetersPerYard Constant

Pascal

```
MetersPerYard = MetersPerFoot * 3;
```

C++

```
MetersPerYard = MetersPerFoot * 3;
```

File

StdConvs

Description

This is constant StdConvs.MetersPerYard.

29.3.58 StdConvs.SquareMetersPerAcre Constant

Pascal

```
SquareMetersPerAcre = SquareMetersPerSquareYard * 4840;
```

C++

```
SquareMetersPerAcre = SquareMetersPerSquareYard * 4840;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerAcre.

29.3.59 StdConvs.SquareMetersPerSquareFoot Constant

Pascal

```
SquareMetersPerSquareFoot = MetersPerFoot * MetersPerFoot;
```

C++

```
SquareMetersPerSquareFoot = MetersPerFoot * MetersPerFoot;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerSquareFoot.

29.3.60 StdConvs.SquareMetersPerSquareInch Constant

Pascal

```
SquareMetersPerSquareInch = MetersPerInch * MetersPerInch;
```

C++

```
SquareMetersPerSquareInch = MetersPerInch * MetersPerInch;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerSquareInch.

29.3.61 StdConvs.SquareMetersPerSquareMile Constant

Pascal

```
SquareMetersPerSquareMile = MetersPerMile * MetersPerMile;
```

C++

```
SquareMetersPerSquareMile = MetersPerMile * MetersPerMile;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerSquareMile.

29.3.62 StdConvs.SquareMetersPerSquareRod Constant

Pascal

```
SquareMetersPerSquareRod = MetersPerRod * MetersPerRod;
```

C++

```
SquareMetersPerSquareRod = MetersPerRod * MetersPerRod;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerSquareRod.

29.3.63 StdConvs.SquareMetersPerSquareYard Constant

Pascal

```
SquareMetersPerSquareYard = MetersPerYard * MetersPerYard;
```

C++

```
SquareMetersPerSquareYard = MetersPerYard * MetersPerYard;
```

File

StdConvs

Description

This is constant StdConvs.SquareMetersPerSquareYard.

30 StdCtrls Namespace

This is namespace StdCtrls.

Topics

Name	Description
Classes (see page 2035)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 2999)	The following table lists structs, records, enums in this documentation.
Types (see page 3008)	The following table lists types in this documentation.

Classes

	Name	Description
	TButton (see page 2035)	TButton is a push button control.
	TButtonActionLink (see page 2106)	TButtonActionLink is an action link designed specifically for button control clients.
	TButtonControl (see page 2109)	TButtonControl is the base class for objects that represent Windows button controls.
	TCheckBox (see page 2116)	TCheckBox represents a check box that can be on (checked) or off (unchecked)
	TComboBox (see page 2184)	TComboBox combines an edit box with a scrollable list.
	TCustomButton (see page 2259)	Base class for a push button control.
	TCustomCheckBox (see page 2276)	TCustomCheckBox is the ancestor of all check-box components.
	TCustomCombo (see page 2283)	TCustomCombo is the base class for all combo boxes.
	TCustomComboBox (see page 2322)	TCustomComboBox is the base class for combobox components.
	TCustomComboBoxStrings (see page 2339)	TCustomComboBoxStrings represents the strings in the drop-down list of a combo box.
	TCustomEdit (see page 2345)	TCustomEdit is the base class from which all edit-box and memo controls are derived.
	TCustomGroupBox (see page 2381)	TCustomGroupBox is the base class for all group-box components.
	TCustomLabel (see page 2384)	TCustomLabel is the base class for non-windowed controls that display text on a form.
	TCustomListBox (see page 2398)	TCustomListBox is the base class for listbox objects that are wrappers for list box controls.
	TCustomMemo (see page 2443)	TCustomMemo is the base type for memo components, which are multiline edit boxes, including TMemo (see page 2737) and TDBMemo.
	TCustomStaticText (see page 2457)	TCustomStaticText is the base class for TStaticText (see page 2945).
	TEdit (see page 2463)	TEdit is a wrapper for a Windows single-line edit control.
	TGroupBox (see page 2535)	TGroupBox represents a Windows group box.
	TImageMargins (see page 2602)	Margins of image on button.
	TLabel (see page 2607)	TLabel is a nonwindowed control that displays text on a form.
	TListBox (see page 2657)	TListBox displays a collection of items in a scrollable list.

	TMemo (see page 2737)	TMemo is a wrapper for a Windows multiline edit control.
	TPushButtonActionLink (see page 2811)	TPushButtonActionLink is an action link designed specifically for button control clients.
	TRadioButton (see page 2813)	TRadioButton is a wrapper for a system radio button.
	TScrollBar (see page 2881)	TScrollBar is a Windows scroll bar, which is used to scroll the contents of a window, form, or control.
	TStaticText (see page 2945)	TStaticText is a windowed control that displays text on a form.

Structs, Records, Enums

	Name	Description
	TCheckBoxState (see page 2999)	TCheckBoxState indicates the state of a check box control.
	TComboBoxStyle (see page 3000)	TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls unit.
	TEditCharCase (see page 3000)	TEditCharCase indicates how a control forces the case of characters, if at all.
	TEllipsisPosition (see page 3001)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	TImageAlignment (see page 3002)	Alignment of image on TButton (see page 2035).
	TListBoxStyle (see page 3003)	TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.
	TScrollCode (see page 3004)	TScrollCode indicates what action the user performed on a scroll bar.
	TScrollStyle (see page 3005)	Identifies a set of scrollbars by their orientation.
	TSelection (see page 3006)	TSelection definese the start and position of a selection.
	TStaticBorderStyle (see page 3006)	TStaticBorderStyle determines the appearance of the border on a static text control.
	TTextLayout (see page 3007)	TTextLayout indicates where text appears within the client area of a control.

Types

Name	Description
TButtonActionLinkClass (see page 3008)	TButtonActionLinkClass defines the metaclass for TButtonActionLink (see page 2106).
TCustomComboBoxStringsClass (see page 3008)	TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 2339).
TDrawItemEvent (see page 3009)	TDrawItemEvent is the type of an OnDrawItem event handler.
TFNDrawText (see page 3010)	TFNDrawText represents the procedure type for the events that specify the details of the Text property of a control.
TLBFindDataEvent (see page 3010)	TLBFindDataEvent is the type of the list box OnDataFind event handler.
TLBGetDataEvent (see page 3011)	TLBGetDataEvent is the type of the list box OnData event handler.
TLBGetDataObjectEvent (see page 3011)	TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.
TMeasureItemEvent (see page 3012)	TMeasureItemEvent is the type for the OnMeasureItem event handler.
TOwnerDrawState (see page 3012)	Indicates state information that can influence how an item is drawn.
TPushButtonActionLinkClass (see page 3013)	TPushButtonActionLinkClass defines the metaclass for TPushButtonActionLink (see page 2811).
TScrollEvent (see page 3013)	TScrollEvent is the type of an OnScroll event handler.

30.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TButton (see page 2035)	TButton is a push button control.
	TButtonActionLink (see page 2106)	TButtonActionLink is an action link designed specifically for button control clients.
	TButtonControl (see page 2109)	TButtonControl is the base class for objects that represent Windows button controls.
	TCheckBox (see page 2116)	TCheckBox represents a check box that can be on (checked) or off (unchecked)
	TComboBox (see page 2184)	TComboBox combines an edit box with a scrollable list.
	TCustomButton (see page 2259)	Base class for a push button control.
	TCustomCheckBox (see page 2276)	TCustomCheckBox is the ancestor of all check-box components.
	TCustomCombo (see page 2283)	TCustomCombo is the base class for all combo boxes.
	TCustomComboBox (see page 2322)	TCustomComboBox is the base class for combobox components.
	TCustomComboBoxStrings (see page 2339)	TCustomComboBoxStrings represents the strings in the drop-down list of a combo box.
	TCustomEdit (see page 2345)	TCustomEdit is the base class from which all edit-box and memo controls are derived.
	TCustomGroupBox (see page 2381)	TCustomGroupBox is the base class for all group-box components.
	TCustomLabel (see page 2384)	TCustomLabel is the base class for non-windowed controls that display text on a form.
	TCustomListBox (see page 2398)	TCustomListBox is the base class for listbox objects that are wrappers for list box controls.
	TCustomMemo (see page 2443)	TCustomMemo is the base type for memo components, which are multiline edit boxes, including TMemo (see page 2737) and TDBMemo.
	TCustomStaticText (see page 2457)	TCustomStaticText is the base class for TStaticText (see page 2945).
	TEdit (see page 2463)	TEdit is a wrapper for a Windows single-line edit control.
	TGroupBox (see page 2535)	TGroupBox represents a Windows group box.
	TImageMargins (see page 2602)	Margins of image on button.
	TLabel (see page 2607)	TLabel is a nonwindowed control that displays text on a form.
	TListBox (see page 2657)	TListBox displays a collection of items in a scrollable list.
	TMemo (see page 2737)	TMemo is a wrapper for a Windows multiline edit control.
	TPushButtonActionLink (see page 2811)	TPushButtonActionLink is an action link designed specifically for button control clients.
	TRadioButton (see page 2813)	TRadioButton is a wrapper for a system radio button.
	TScrollBar (see page 2881)	TScrollBar is a Windows scroll bar, which is used to scroll the contents of a window, form, or control.
	TStaticText (see page 2945)	TStaticText is a windowed control that displays text on a form.

30.1.1 TButton Class

TButton is a push button control.

Class Hierarchy

Pascal

```
TButton = class(TCustomButton);
```

C++

```
class TButton : public TCustomButton;
```

File

StdCtrls

Description

Use TButton to put a standard push button on a form. TButton introduces several properties to control its behavior in a dialog box setting. Users choose button controls to initiate actions.

To use a button that displays a bitmap instead of a label, use TBitBtn. To use a button that can remain in a depressed position, use TSpeedButton.

Note: Since the TButton caption is always centered, changing the BiDi alignment has no effect.

See Also

TBitBtn

TCustomButton (see page 2259)

Buttons and Similar Controls

30.1.1.1 TButton Members

The following tables list the members exposed by TButton.

Enumerations

	Name	Description
	TButtonStyle (see page 2261)	Style (see page 2275) of TButton (see page 2035).

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	ActionChange (see page 2262)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2111)	Initializes a window-creation parameter data structure.
	CreateParams (see page 2263)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 2264)	Creates the underlying window.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetActionLinkClass (see page 2264)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2112)	Returns whether the button control is checked.
	Loaded (see page 2264)	Initializes the control after it is loaded from a stream.
	Notification (see page 2265)	Responds to notifications that components are being created or destroyed.
	SetButtonStyle (see page 2265)	Sets the Style (see page 2275) property for a button.
	SetChecked (see page 2112)	Sets the Checked (see page 2113) property.
	UpdateImageList (see page 2266)	Rebuilds the image list associated with the button.
	UpdateImages (see page 2266)	Updates the image list associated with the button.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	Checked (see page 2113)	Specifies whether the button control is checked.

	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.

Public Methods

	Name	Description
	Click (see page 2263)	Simulates a mouse click, as if the user had clicked the button.
	Create (see page 2110)	Creates a button control.
	Create (see page 2260)	Creates and initializes a button instance.
	Destroy (see page 2261)	Destroys an instance of TWinControl.
	UseRightToLeftAlignment (see page 2266)	Specifies whether the control's alignment is in a right-to-left mode.

Published Events

	Name	Description
	OnClick (see page 2073)	Occurs when the user clicks the control.
	OnContextPopup (see page 2075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2076)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2079)	Occurs when the user drags an object over a control.
	OnDropDownClick (see page 2082)	Down arrow part of Vista style split button is clicked.
	OnEndDock (see page 2082)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2083)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2084)	Occurs when a control receives the input focus.
	OnExit (see page 2086)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2090)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2094)	Occurs when a key is pressed.
	OnKeyUp (see page 2095)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2096)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2097)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2100)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2100)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2100)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2103)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2105)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2105)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Action (see page 2039)	Designates the action associated with the control.
	Align (see page 2040)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2044)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2044)	Specifies the bi-directional mode for the control.
	Cancel (see page 2045)	Determines whether the button's OnClick event handler executes when the Escape key is pressed.
	Caption (see page 2045)	Specifies a text string that identifies the control to the user.
	CommandLinkHint (see page 2048)	Text displayed as hint below button caption for Command Link.
	Constraints (see page 2048)	Specifies the size constraints for the control.
	Default (see page 2049)	Determines whether the button's OnClick event handler executes when the Enter key is pressed.
	DisabledImageIndex (see page 2050)	Image index for disabled button state.
	DoubleBuffered (see page 2050)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

	DragCursor (see page 2052)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2052)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2053)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownMenu (see page 2054)	Split button drop down menu.
	ElevationRequired (see page 2055)	Put shield icon on button indicating elevated access rights required.
	Enabled (see page 2055)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2056)	Controls the attributes of text written on or in the control.
	HotImageIndex (see page 2057)	Image index for hot button state.
	ImageAlignment (see page 2057)	Alignment of image on button.
	ImageIndex (see page 2058)	Image index for normal button state.
	ImageMargins (see page 2058)	Margins of image on button.
	Images (see page 2059)	List of images for a button.
	ModalResult (see page 2059)	Determines whether and how the button closes its (modal) parent form.
	ParentBiDiMode (see page 2060)	Specifies whether the control uses its parent's BiDiMode.
	ParentDoubleBuffered (see page 2060)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2061)	Determines where a control looks for its font information.
	ParentShowHint (see page 2061)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2062)	Identifies the pop-up menu associated with the control.
	PressedImageIndex (see page 2067)	Image index for pressed button state.
	SelectedImageIndex (see page 2067)	Image index for selected button state.
	ShowHint (see page 2068)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 2069)	Style of a button.
	TabOrder (see page 2069)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2070)	Determines if the user can tab to a control.
	Visible (see page 2070)	Determines whether the component appears onscreen.
	WordWrap (see page 2072)	Specifies whether the button text wraps to fit the width of the control.

30.1.1.2 TButton Properties

The properties of the TButton class are listed here.

Published Properties

	Name	Description
	Action (see page 2039)	Designates the action associated with the control.
	Align (see page 2040)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2044)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2044)	Specifies the bi-directional mode for the control.
	Cancel (see page 2045)	Determines whether the button's OnClick event handler executes when the Escape key is pressed.
	Caption (see page 2045)	Specifies a text string that identifies the control to the user.
	CommandLinkHint (see page 2048)	Text displayed as hint below button caption for Command Link.
	Constraints (see page 2048)	Specifies the size constraints for the control.
	Default (see page 2049)	Determines whether the button's OnClick event handler executes when the Enter key is pressed.
	DisabledImageIndex (see page 2050)	Image index for disabled button state.
	DoubleBuffered (see page 2050)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2052)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2052)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2053)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownMenu (see page 2054)	Split button drop down menu.

	ElevationRequired (see page 2055)	Put shield icon on button indicating elevated access rights required.
	Enabled (see page 2055)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2056)	Controls the attributes of text written on or in the control.
	HotImageIndex (see page 2057)	Image index for hot button state.
	ImageAlignment (see page 2057)	Alignment of image on button.
	ImageIndex (see page 2058)	Image index for normal button state.
	ImageMargins (see page 2058)	Margins of image on button.
	Images (see page 2059)	List of images for a button.
	ModalResult (see page 2059)	Determines whether and how the button closes its (modal) parent form.
	ParentBiDiMode (see page 2060)	Specifies whether the control uses its parent's BiDiMode.
	ParentDoubleBuffered (see page 2060)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2061)	Determines where a control looks for its font information.
	ParentShowHint (see page 2061)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2062)	Identifies the pop-up menu associated with the control.
	PressedImageIndex (see page 2067)	Image index for pressed button state.
	SelectedImageIndex (see page 2067)	Image index for selected button state.
	ShowHint (see page 2068)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 2069)	Style of a button.
	TabOrder (see page 2069)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2070)	Determines if the user can tab to a control.
	Visible (see page 2070)	Determines whether the component appears onscreen.
	WordWrap (see page 2072)	Specifies whether the button text wraps to fit the width of the control.

30.1.1.2.1 TButton.Action Property

Designates the action associated with the control.

Pascal

```
property Action;
```

C++

```
__property Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

C++ Examples:

```
/*
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
*/
void __fastcall TForm1::ChangeColor(TObject *Sender)
{
  // randomly change the color of the form
  Color = Random(0xFFFF);
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // allocate memory for the Action property
  Action = new TBasicAction(this);

  // set the OnExecute event handler
  Action->OnExecute = ChangeColor;

  // initialize the random number generator
  Randomize();
}
```

Delphi Examples:

```
{
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
}
procedure TForm1.ChangeColor(Sender: TObject);
begin
  { randomly change the color of the form }
  Color := Random($FFFF);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { allocate memory for the Action property }
  Action := TBasicAction.Create(Self);

  { set the OnExecute event handler }
  Action.OnExecute := ChangeColor;

  { initialize the random number generator }
  Randomize;
end;
```

30.1.1.2.2 TButton.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the

edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
```

```
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
```

```
  }

  var

Parent

Anchors

30.1.1.2.3 TButton.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.1.2.4 TButton.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.1.2.5 TButton.Cancel Property

Determines whether the button's OnClick event handler executes when the Escape key is pressed.

Pascal

```
property Cancel: Boolean;
```

C++

```
__property Boolean Cancel;
```

Description

If Cancel is true, the button's OnClick event handler executes when the user presses Esc. Although an application can have more than one Cancel button, the form calls the OnClick event handler only for the first visible button in the tab order.

Default (see page 2268)

OnClick

30.1.1.2.6 TButton.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
```

```
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin

    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.1.2.7 TButton.CommandLinkHint Property

Text displayed as hint below button caption for Command Link.

Pascal

```
property CommandLinkHint: string;
```

C++

```
__property UnicodeString CommandLinkHint;
```

Description

CommandLinkHint is the text displayed as a hint below the button caption when the Style property is **bsCommandLink** to specify a Command Link button.

This is available on Windows Vista only.

30.1.1.2.8 TButton.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

30.1.1.2.9 TButton.Default Property

Determines whether the button's OnClick event handler executes when the Enter key is pressed.

Pascal

```
property Default: Boolean;
```

C++

```
__property Boolean Default;
```

Description

If Default is true, the button's OnClick event handler executes when the user presses Enter.

Although an application can have more than one Default button, the form calls the OnClick event handler only for the first visible button in the tab order. Moreover, any button that has focus becomes the Default button temporarily; hence, if the user selects another button before pressing Enter, the selected button's OnClick event handler executes instead.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
```

```
end;
```

Cancel (see page 2267)

OnClick

30.1.1.2.10 TButton.DisabledImageIndex Property

Image index for disabled button state.

Pascal

```
property DisabledImageIndex: TImageIndex;
```

C++

```
__property TImageIndex DisabledImageIndex;
```

Description

DisabledImageIndex is an image index into the Images property for the disabled button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

See Also

TCustomImageList

HotImageIndex (see page 2270)

Images (see page 2272)

PressedImageIndex (see page 2274)

SelectedImageIndex (see page 2274)

30.1.1.2.11 TButton.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
```

```
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

30.1.1.2.12 TButton.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.1.2.13 TButton.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.1.2.14 TButton.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
```

```
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

30.1.1.2.15 TButton.DropDownMenu Property

Split button drop down menu.

Pascal

```
property DropDownMenu: TPopupMenu;
```

C++

```
__property TPopupMenu DropDownMenu;
```

Description

When the Style property is **bsSplitButton**, the button is a Vista style split button with a drop down menu. DropDownMenu specifies the drop down menu for the down arrow button part. The OnDropDownClick event also occurs when the down arrow button part is clicked.

This is available on Windows Vista only.

30.1.1.2.16 TButton.ElevationRequired Property

Put shield icon on button indicating elevated access rights required.

Pascal

```
property ElevationRequired: Boolean;
```

C++

```
__property Boolean ElevationRequired;
```

Description

When ElevationRequired is true, the button has a shield icon, indicating that elevated access rights are required. Vista UI guidelines specify that when there is a button that performs an operation requiring elevated access rights, it should have this shield icon.

This icon overrides any of the properties specifying a button image for various button states, as in ImageIndex.

This is available on Windows Vista only.

See Also

ImageIndex (see page 2271)

Images (see page 2272)

30.1.1.2.17 TButton.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.1.2.18 TButton.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

30.1.1.2.19 TButton.HotImageIndex Property

Image index for hot button state.

Pascal

```
property HotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex HotImageIndex;
```

Description

HotImageIndex is an image index into the Images property for the hot button state, i.e., the cursor hovering over the button. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

30.1.1.2.20 TButton.ImageAlignment Property

Alignment of image on button.

Pascal

```
property ImageAlignment: TImageAlignment;
```

C++

```
__property TImageAlignment ImageAlignment;
```

Description

TImageAlignment indicates the alignment of an image on a button. It is a TImageAlignment type.

See Also

ImageMargins (see page 2272)

Images (see page 2272)

TImageAlignment (see page 3002)

30.1.1.2.21 TButton.ImageIndex Property

Image index for normal button state.

Pascal

```
property ImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ImageIndex;
```

Description

ImageIndex is an image index into the Images property for the normal button state. If the index value is -1, no image is used.

In Vista, a standard green arrow is used when the index is -1 and the Style property is **bsCommandLink** for a Command Link button.

This is available only on Windows XP and Vista.

30.1.1.2.22 TButton.ImageMargins Property

Margins of image on button.

Pascal

```
property ImageMargins: TImageMargins;
```

C++

```
__property TImageMargins ImageMargins;
```

Description

A button image may be positioned using margins. ImageMargins holds aTImageMargins object containing the margins of an image on a button. The TImageMargins.OnChange event is triggered when a margin changes.

See Also

ImageAlignment (see page 2271)

TImageMargins (see page 2602)

Images (see page 2272)

OnChange (see page 2607)

30.1.1.2.23 TButton.Images Property

List of images for a button.

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

Images is a TCustomImageList object listing the various images that can be placed on a button.

The button's image depends on the button state. These images are determined by the value of the image state properties that index ImageIndex: DisabledImageIndex, HotImageIndex, ImageIndex, PressedImageIndex, and SelectedImageIndex. When the ImageIndex index is -1, it generally means that no image is used for the normal state. For the other state image indexes, -1 means to use the same image as the normal state.

The ImageMargins and ImageAlignment properties orient the image inside the button. The image is not sized to fit the button, and the button is not stretched.

This is available only on Windows XP and Vista.

30.1.1.2.24 TButton.ModalResult Property

Determines whether and how the button closes its (modal) parent form.

Pascal

```
property ModalResult: TModalResult;
```

C++

```
__property TModalResult ModalResult;
```

Description

Setting the button component's ModalResult property is an easy way to make clicking the button close a modal form. When a button is clicked, the ModalResult property of its parent form is set to the same value as the button's ModalResult property.

For example, if a dialog box has OK and Cancel buttons, their ModalResult properties could be set at design time to mrOk and mrCancel, respectively. At runtime, clicking the OK button then changes the dialog's ModalResult property to mrOk, and clicking the Cancel button changes the dialog's ModalResult property to mrCancel. Unless further processing is required, no OnClick event handlers are required for the buttons.

The following constants are of TModalResult type and defined for the ModalResult property:

Constant	Value	Meaning
mrNone	0	None. Used as a default value before the user exits.
mrOk	idOK	The user exited with OK button.
mrCancel	idCancel	The user exited with the CANCEL button.
mrAbort	idAbort	The user exited with the ABORT button.
mrRetry	idRetry	The user exited with the RETRY button.
mrIgnore	idIgnore	The user exited with the IGNORE button.
mrYes	idYes	The user exited with the YES button.
mrNo	idNo	The user exited with the NO button.
mrAll	mrNo + 1	The user exited with the ALL button.
mrNoToAll	mrAll + 1	The user exited with the NO TO ALL button.
mrYesToAll	mrNoToAll + 1	The user exited with the YES TO ALL button.
mrClose	mrYesToAll + 1	The user exited with the CLOSE button.

TModalResult

30.1.1.2.25 TButton.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.1.2.26 TButton.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.1.2.27 TButton.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

30.1.1.2.28 TButton.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.1.2.29 TButton.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
```

```
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
```

```
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type
  TForm1 = class(TForm)

30.1.1.2.30 TButton.PressedImageIndex Property

Image index for pressed button state.

Pascal

```
property PressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex PressedImageIndex;
```

Description

PressedImageIndex is an image index into the Images property for the pressed button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

30.1.1.2.31 TButton.SelectedImageIndex Property

Image index for selected button state.

Pascal

```
property SelectedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex SelectedImageIndex;
```

Description

SelectedImageIndex is an image index into the Images property for the selected button state. If the index value is -1, the same image is used as in the normal button state.

This is available only on Windows XP and Vista.

30.1.1.2.32 TButton.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
```

```
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.1.2.33 TButton.Style Property

Style of a button.

Pascal

```
property Style: TButtonStyle;
```

C++

```
__property TButtonStyle Style;
```

Description

Style indicates a button's style, which is a TButtonStyle type.

See Also

TButtonStyle (see page 2261)

30.1.1.2.34 TButton.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.1.2.35 TButton.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.1.2.36 TButton.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

30.1.1.2.37 TButton.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

30.1.1.3 TButton Events

The events of the TButton class are listed here.

Published Events

	Name	Description
	OnClick (see page 2073)	Occurs when the user clicks the control.
	OnContextPopup (see page 2075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2076)	Occurs when the user drops an object being dragged.

	OnDragOver (see page 2079)	Occurs when the user drags an object over a control.
	OnDropDownClick (see page 2082)	Down arrow part of Vista style split button is clicked.
	OnEndDock (see page 2082)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2083)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2084)	Occurs when a control receives the input focus.
	OnExit (see page 2086)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2090)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2094)	Occurs when a key is pressed.
	OnKeyUp (see page 2095)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2096)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2097)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2100)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2100)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2100)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2103)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2105)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2105)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.1.3.1 TButton.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
```

```
      end;
    end;

30.1.1.3.2 TButton.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup

30.1.1.3.3 TButton.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
```

```
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{

30.1.1.3.4 TButton.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/

30.1.1.3.5 TButton.OnDropDownClick Event

Down arrow part of Vista style split button is clicked.

Pascal

```
property OnDropDownClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDownClick;
```

Description

OnDropDownClick occurs when the down arrow part of a Vista style split button is clicked. This only applies when the button's Style property is **bsSplitButton**.

This is available on Windows Vista only.

30.1.1.3.6 TButton.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock;
```

C++

```
__property OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

30.1.1.3.7 TButton.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

30.1.1.3.8 TButton.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;

30.1.1.3.9 TButton.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/

ActiveControl

30.1.1.3.10 TButton.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;

KeyPreview

OnKeyPress

OnKeyUp

30.1.1.3.11 TButton.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{

which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
```

```
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

KeyPreview

30.1.1.3.12 TButton.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*

OnKeyDown

OnKeyPress

30.1.1.3.13 TButton.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.1.3.14 TButton.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

30.1.1.3.15 TButton.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.1.3.16 TButton.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.1.3.17 TButton.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
```

```
  status bar.  (Set the Width of the status panels to 150
  before running this example).  When the user presses a mouse
  button, moves the mouse, and releases the mouse button, a
  rectangle is drawn on the form. When the mouse button is
  released, the rectangle appears on the form's canvas. Its
  top-left and bottom-right corners are defined by the
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  }
  procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

MouseCapture

30.1.1.3.18 TButton.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
```

```
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

30.1.1.3.19 TButton.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

30.1.1.3.20 TButton.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.2 TButtonActionLink Class

TButtonActionLink is an action link designed specifically for button control clients.

Class Hierarchy

Pascal

```
TButtonActionLink = class(TWinControlActionLink);
```

C++

```
class TButtonActionLink : public TWinControlActionLink;
```

File

StdCtrls

Description

TButtonActionLink is designed to specifically link actions to button control clients. TButtonActionLink overrides methods to determine whether the action and client are linked, and to ensure that action events are appropriate for properties of button control clients.

TButtonActionLink inherits, from its ancestors, support for linking actions with the properties of components, generic controls, and windowed controls. TButtonActionLink adds support for linking the checked property to the appropriate property of a button

control.

30.1.2.1 TButtonActionLink Members

The following tables list the members exposed by TButtonActionLink.

Protected Fields

	Name	Description
	FClient (see page 2107)	Specifies a client control.

Protected Methods

	Name	Description
	AssignClient (see page 2108)	Assigns a client button that is linked to the associated action.
	IsCheckedLinked (see page 2108)	Indicates whether the checked state for the action and the client are linked.
	SetChecked (see page 2108)	Sets the checked state of a button control if the client is linked to the action for this property.

30.1.2.2 TButtonActionLink Fields

The fields of the TButtonActionLink class are listed here.

Protected Fields

	Name	Description
	FClient (see page 2107)	Specifies a client control.

30.1.2.2.1 TButtonActionLink.FClient Field

Specifies a client control.

Pascal

```
FClient: TButtonControl;
```

C++

```
TButtonControl FClient;
```

Description

FClient is a protected field that specifies a client control.

See Also

AssignClient

30.1.2.3 TButtonActionLink Methods

The methods of the TButtonActionLink class are listed here.

Protected Methods

	Name	Description
	AssignClient (see page 2108)	Assigns a client button that is linked to the associated action.
	IsCheckedLinked (see page 2108)	Indicates whether the checked state for the action and the client are linked.
	SetChecked (see page 2108)	Sets the checked state of a button control if the client is linked to the action for this property.

30.1.2.3.1 TButtonActionLink.AssignClient Method

Assigns a client button that is linked to the associated action.

Pascal

```
procedure AssignClient(AClient: TObject); override;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

TButtonActionLink (see page 2106) overrides AssignClient to ensure that the client for the action is a button control.

See Also

Action

30.1.2.3.2 TButtonActionLink.IsCheckedLinked Method

Indicates whether the checked state for the action and the client are linked.

Pascal

```
function IsCheckedLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCheckedLinked();
```

Description

IsCheckedLinked indicates whether the Checked property is linked to the appropriate client property. IsCheckedLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Checked

Checked (see page 2113)

SetChecked (see page 2108)

30.1.2.3.3 TButtonActionLink.SetChecked Method

Sets the checked state of a button control if the client is linked to the action for this property.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked sets the checked state of a button control, and is called only if the client is linked for this property. Value specifies whether the checked state should be set.

See Also

Checked

Checked (see page 2113)

IsCheckedLinked (see page 2108)

30.1.3 TButtonControl Class

TButtonControl is the base class for objects that represent Windows button controls.

Class Hierarchy

Pascal

```
TButtonControl = class(TWinControl);
```

C++

```
class TButtonControl : public TWinControl;
```

File

StdCtrls

Description

TButtonControl encapsulates behavior common to button controls, check boxes, and radio buttons. Use TButtonControl as a base class when defining a button that is a wrapper for a Windows button. Do not create instances of TButtonControl directly in an application. Instead, use a descendant of TButtonControl to put a push button, check box, or radio button on a form.

Note: Some buttons, such as TSpeedButton, are not wrappers for Windows buttons. These controls do not descend from TButtonControl.

TButton (see page 2035)

TCustomCheckBox (see page 2276)

TRadioButton (see page 2813)

TSpeedButton

30.1.3.1 TButtonControl Members

The following tables list the members exposed by TButtonControl.

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2111)	Initializes a window-creation parameter data structure.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2112)	Returns whether the button control is checked.
	SetChecked (see page 2112)	Sets the Checked (see page 2113) property.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	Checked (see page 2113)	Specifies whether the button control is checked.
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.

	WordWrap (see page 2115)	Specifies whether the button text wraps to fit the width of the control.

Public Methods

	Name	Description
	Create (see page 2110)	Creates a button control.

30.1.3.2 TButtonControl.Create Constructor

Creates a button control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TButtonControl(TComponent * AOwner);
```

Description

AOwner is the component that is responsible for freeing the button. It becomes the value of the Owner property.

30.1.3.3 TButtonControl Methods

The methods of the TButtonControl class are listed here.

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	CreateParams (see page 2111)	Initializes a window-creation parameter data structure.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2112)	Returns whether the button control is checked.
	SetChecked (see page 2112)	Sets the Checked (see page 2113) property.
	WndProc (see page 2112)	Handles Windows messages.

30.1.3.3.1 TButtonControl.ActionChange Method

Updates the button control to reflect changes in its associated action.

Pascal

```
procedure ActionChange(Sender: TObject; CheckDefaults: Boolean); override;
```

C++

```
virtual __fastcall ActionChange(TObject * Sender, Boolean CheckDefaults);
```

Description

ActionChange is called automatically when the associated action changes. It updates the button control to reflect the action's current Checked (see page 2113) state. Then it calls the inherited method, which checks the associated properties for that client type.

The Sender parameter is the associated action. The CheckDefaults parameter specifies whether properties and event handlers should be changed if they differ from the default values. When CheckDefaults is true, properties and event handlers are only changed when the current values are the default values (that is, when the values have not been previously changed). When CheckDefaults is false, properties and event handlers are changed, regardless of their current values.

See Also

TCustomAction

30.1.3.3.2 TButtonControl.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

30.1.3.3.3 TButtonControl.GetActionLinkClass Method

Returns the appropriate action link class that is associated with button controls.

Pascal

```
function GetActionLinkClass: TControlActionLinkClass; override;
```

C++

```
virtual __fastcall TControlActionLinkClass GetActionLinkClass();
```

Description

GetActionLinkClass is used to get the appropriate class type for the action link used with button controls. GetActionLinkClass is used internally to create action link objects for clients when a button control has an associated action. The action link is used to link the action to the button control client. Each Action link class type is designed to link specific actions to clients based upon the types of properties the client supports. For button controls, GetActionLinkClass returns the TButtonActionLink (see page 2106) class type.

See Also

TButtonActionLink (see page 2106)

30.1.3.3.4 TButtonControl.GetChecked Method

Returns whether the button control is checked.

Pascal

```
function GetChecked: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetChecked();
```

Description

GetChecked is the read implementation of the Checked (see page 2113) property.

See Also

Checked (see page 2113)

30.1.3.3.5 TButtonControl.SetChecked Method

Sets the Checked (see page 2113) property.

Pascal

```
procedure SetChecked(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked is the write implementer for the Checked (see page 2113) property.

See Also

Checked (see page 2113)

30.1.3.3.6 TButtonControl.WndProc Method

Handles Windows messages.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc enables button objects to receive input focus when WM_LBUTTONDOWN and WM_LBUTTONDBLCLK messages occur.

See Also

WndProc

30.1.3.4 TButtonControl Properties

The properties of the TButtonControl class are listed here.

Protected Properties

	Name	Description
	Checked (see page 2113)	Specifies whether the button control is checked.
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.
	WordWrap (see page 2115)	Specifies whether the button text wraps to fit the width of the control.

30.1.3.4.1 TButtonControl.Checked Property

Specifies whether the button control is checked.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Use Checked to determine whether a button control is checked.

C++ Examples:

```
/*
This example requires a PageControl with no pages created,
and a TCheckBox. During the form create, a series of tabs
will be created on the Page Control that exceed the Page
Control's width.  When the Check Box control is clicked, the
setting of the MultiLine property is toggled, alternately
stacking the tabs vertically, or along a single line
horizontally.
*/

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->MultiLine = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->Caption = "Stack Tabs?";
  for (int i = 0; i < 20; i++)
  {
    TTabSheet *pPage = new TTabSheet(PageControl1); // PageControl1 is the parent, so it will
clean up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
  }
}
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This example requires a PageControl with no pages created,
and a TCheckBox. During the form create, a series of tabs
will be created on the Page Control that exceed the Page
Control's width.  When the Check Box control is clicked, the
setting of the MultiLine property is toggled, alternately
stacking the tabs vertically, or along a single line
horizontally.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.MultiLine := CheckBox1.Checked;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Checkbox1.Caption := 'Stack Tabs?';
  for i := 0 to 20 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'Tab #' + IntToStr(i);
    end;
end;
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
```

```
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

30.1.3.4.2 TButtonControl.ClicksDisabled Property

Specifies whether the button control accepts mouse clicks.

Pascal

```
property ClicksDisabled: Boolean;
```

C++

```
__property Boolean ClicksDisabled;
```

Description

Use ClicksDisabled to determine whether a button control accepts mouse clicks. If ClicksDisabled is true, the button control doesn't accept mouse clicks. Otherwise, the button control accepts mouse clicks.

See Also

WndProc

30.1.3.4.3 TButtonControl.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

30.1.4 TCheckBox Class

TCheckBox represents a check box that can be on (checked) or off (unchecked)

Class Hierarchy

Pascal

```
TCheckBox = class(TCustomCheckBox);
```

C++

```
class TCheckBox : public TCustomCheckBox;
```

File

StdCtrls

Description

A TCheckBox component presents an option for the user. The user can check the box to select the option, or uncheck it to deselect the option.

Check Boxes

30.1.4.1 TCheckBox Members

The following tables list the members exposed by TCheckBox.

Protected Methods

	Name	Description
	ActionChange (see page 2110)	Updates the button control to reflect changes in its associated action.
	Click (see page 2278)	Click generates an OnClick event.
	CreateParams (see page 2111)	Initializes a window-creation parameter data structure.
	CreateParams (see page 2278)	Initializes a window-creation parameter record.
	CreateWnd (see page 2279)	Creates a Windows control corresponding to the check box.
	GetActionLinkClass (see page 2111)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 2112)	Returns whether the button control is checked.
	GetChecked (see page 2279)	Returns the value of the Checked (see page 2113) property.
	SetChecked (see page 2112)	Sets the Checked (see page 2113) property.
	SetChecked (see page 2280)	Sets the value of the Checked (see page 2113) property.
	Toggle (see page 2280)	Changes the state of the check box.
	WndProc (see page 2112)	Handles Windows messages.

Protected Properties

	Name	Description
	ClicksDisabled (see page 2115)	Specifies whether the button control accepts mouse clicks.

Public Methods

	Name	Description
	Create (see page 2110)	Creates a button control.
	Create (see page 2277)	Creates and initializes a TCustomCheckBox (see page 2276) instance.
	GetControlsAlignment (see page 2279)	Returns the alignment of the check box caption.

Published Events

	Name	Description
	OnClick (see page 2151)	Occurs when the user clicks the control.
	OnContextPopup (see page 2153)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2154)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2157)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2160)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2160)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2161)	Occurs when a control receives the input focus.
	OnExit (see page 2164)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2168)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2171)	Occurs when a key is pressed.
	OnKeyUp (see page 2172)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2174)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2175)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2177)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2178)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2178)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2180)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2182)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2183)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Action (see page 2119)	Designates the action associated with the control.
	Align (see page 2120)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2123)	Determines whether the check box label aligns to the left or to the right of the tick box.
	AllowGrayed (see page 2124)	Determines whether check box can be in a "grayed" state.
	Anchors (see page 2124)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2125)	Specifies the bi-directional mode for the control.
	Caption (see page 2126)	Specifies a text string that identifies the control to the user.
	Checked (see page 2128)	Specifies whether the button control is checked.
	Color (see page 2130)	Specifies the background color of the control.
	Constraints (see page 2131)	Specifies the size constraints for the control.
	Ctl3D (see page 2132)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2132)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2134)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2134)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2135)	Determines how the control initiates drag-and-drop or drag-and-dock operations.

	Enabled (see page 2136)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2137)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2138)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2138)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2139)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2139)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2139)	Determines where a control looks for its font information.
	ParentShowHint (see page 2140)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2140)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2145)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	State (see page 2147)	Indicates whether the check box is selected, deselected, or grayed.
	TabOrder (see page 2148)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2148)	Determines if the user can tab to a control.
	Visible (see page 2149)	Determines whether the component appears onscreen.
	WordWrap (see page 2150)	Specifies whether the button text wraps to fit the width of the control.

30.1.4.2 TCheckBox Properties

The properties of the TCheckBox class are listed here.

Published Properties

	Name	Description
	Action (see page 2119)	Designates the action associated with the control.
	Align (see page 2120)	Determines how the control aligns within its container (parent control).
	Alignment (see page 2123)	Determines whether the check box label aligns to the left or to the right of the tick box.
	AllowGrayed (see page 2124)	Determines whether check box can be in a "grayed" state.
	Anchors (see page 2124)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 2125)	Specifies the bi-directional mode for the control.
	Caption (see page 2126)	Specifies a text string that identifies the control to the user.
	Checked (see page 2128)	Specifies whether the button control is checked.
	Color (see page 2130)	Specifies the background color of the control.
	Constraints (see page 2131)	Specifies the size constraints for the control.
	Ctl3D (see page 2132)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2132)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2134)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2134)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2135)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2136)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2137)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 2138)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2138)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2139)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2139)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2139)	Determines where a control looks for its font information.
	ParentShowHint (see page 2140)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2140)	Identifies the pop-up menu associated with the control.

	ShowHint (see page 2145)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	State (see page 2147)	Indicates whether the check box is selected, deselected, or grayed.
	TabOrder (see page 2148)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2148)	Determines if the user can tab to a control.
	Visible (see page 2149)	Determines whether the component appears onscreen.
	WordWrap (see page 2150)	Specifies whether the button text wraps to fit the width of the control.

30.1.4.2.1 TCheckBox.Action Property

Designates the action associated with the control.

Pascal

```
property Action;
```

C++

```
__property Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

C++ Examples:

```
/*
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
*/
void __fastcall TForm1::ChangeColor(TObject *Sender)
{
  // randomly change the color of the form
  Color = Random(0xFFFF);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // allocate memory for the Action property
  Action = new TBasicAction(this);

  // set the OnExecute event handler
  Action->OnExecute = ChangeColor;

  // initialize the random number generator
  Randomize();
}
```

Delphi Examples:

```
{
This example shows that OnClick is the default event of a form.
When the form is created, the OnExecute event of its Action property
is initialized to some user-defined procedure, which randomly changes
the color of the form.
}
procedure TForm1.ChangeColor(Sender: TObject);
```

```
begin
  { randomly change the color of the form }
  Color := Random($FFFF);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { allocate memory for the Action property }
  Action := TBasicAction.Create(Self);

  { set the OnExecute event handler }
  Action.OnExecute := ChangeColor;

  { initialize the random number generator }
  Randomize;
end;
```

30.1.4.2.2 TCheckBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
```

```
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
    }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
```

```
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

Anchors

30.1.4.2.3 TCheckBox.Alignment Property

Determines whether the check box label aligns to the left or to the right of the tick box.

Pascal

```
property Alignment: TLeftRight;
```

C++

```
__property TLeftRight Alignment;
```

Description

The Alignment property determines the position of the label, relative to the tick box. The TLeftRight alignment type may have one of the following values.

Value	Meaning
taLeftJustify	The label is aligned to the left of the control and the tick box is aligned to the right of the control.
taRightJustify	This is the default value. The label is aligned to the right of the control and the tick box is aligned to the left of the control.

See Also

TLeftRight

30.1.4.2.4 TCheckBox.AllowGrayed Property

Determines whether check box can be in a "grayed" state.

Pascal

```
property AllowGrayed: Boolean;
```

C++

```
__property Boolean AllowGrayed;
```

Description

If AllowGrayed is set to true, the check box has three possible states: checked, unchecked, and grayed. If AllowGrayed is set to false, the check box has only two possible states: checked and unchecked.

C++ Examples:

```
/*
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->AllowGrayed = true;
  CheckBox1->State = cbChecked;
}
```

Delphi Examples:

```
{
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  CheckBox1.AllowGrayed := True;
  CheckBox1.State := cbChecked;
end;
```

See Also

Checked (see page 2113)

State (see page 2282)

30.1.4.2.5 TCheckBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.4.2.6 TCheckBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.4.2.7 TCheckBox.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>
```

```
void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
```

```
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

30.1.4.2.8 TCheckBox.Checked Property

Specifies whether the button control is checked.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Use Checked to determine whether a button control is checked.

C++ Examples:

```
/*
This example requires a PageControl with no pages created,
and a TCheckBox. During the form create, a series of tabs
will be created on the Page Control that exceed the Page
Control's width.  When the Check Box control is clicked, the
setting of the MultiLine property is toggled, alternately
stacking the tabs vertically, or along a single line
horizontally.
```

```
*/

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->MultiLine = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->Caption = "Stack Tabs?";
  for (int i = 0; i < 20; i++)
  {
    TTabSheet *pPage = new TTabSheet(PageControl1); // PageControl1 is the parent, so it will
clean up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
  }
}
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This example requires a PageControl with no pages created,
and a TCheckBox. During the form create, a series of tabs
will be created on the Page Control that exceed the Page
Control's width.  When the Check Box control is clicked, the
setting of the MultiLine property is toggled, alternately
stacking the tabs vertically, or along a single line
horizontally.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.MultiLine := CheckBox1.Checked;
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  i: Integer;
begin
  Checkbox1.Caption := 'Stack Tabs?';
  for i := 0 to 20 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'Tab #' + IntToStr(i);
    end;
end;
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

WndProc

30.1.4.2.9 TCheckBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

30.1.4.2.10 TCheckBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict,

the response of the control to resize attempts is not well-defined.

OnCanResize

30.1.4.2.11 TCheckBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

30.1.4.2.12 TCheckBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to

false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
```

```
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

30.1.4.2.13 TCheckBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

30.1.4.2.14 TCheckBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.4.2.15 TCheckBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;

30.1.4.2.16 TCheckBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled

controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

30.1.4.2.17 TCheckBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
```

```
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

30.1.4.2.18 TCheckBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

30.1.4.2.19 TCheckBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example,

if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

30.1.4.2.20 TCheckBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

30.1.4.2.21 TCheckBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

30.1.4.2.22 TCheckBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

30.1.4.2.23 TCheckBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

30.1.4.2.24 TCheckBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
```

```
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

30.1.4.2.25 TCheckBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
```

```
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

30.1.4.2.26 TCheckBox.State Property

Indicates whether the check box is selected, deselected, or grayed.

Pascal

```
property State: TCheckBoxState;
```

C++

```
__property TCheckBoxState State;
```

Description

Use State to determine whether the check box is checked (cbChecked), unchecked (cbUnchecked), or grayed (cbGrayed).

C++ Examples:

```
/*
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CheckBox1->AllowGrayed = true;
  CheckBox1->State = cbChecked;
}
```

Delphi Examples:

```
{
This example uses a check box on a form. When the
application runs, the check box is initially checked. When
the user clicks it, the check box is unchecked. Clicking it
again grays the check box.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  CheckBox1.AllowGrayed := True;
  CheckBox1.State := cbChecked;
end;
```

Checked (see page 2113)

30.1.4.2.27 TCheckBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

30.1.4.2.28 TCheckBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

30.1.4.2.29 TCheckBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
```

```
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

30.1.4.2.30 TCheckBox.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

30.1.4.3 TCheckBox Events

The events of the TCheckBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 2151)	Occurs when the user clicks the control.
	OnContextPopup (see page 2153)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 2154)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2157)	Occurs when the user drags an object over a control.
	OnEndDock (see page 2160)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2160)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2161)	Occurs when a control receives the input focus.
	OnExit (see page 2164)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2168)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2171)	Occurs when a key is pressed.
	OnKeyUp (see page 2172)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2174)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2175)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2177)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2178)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2178)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2180)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2182)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2183)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

30.1.4.3.1 TCheckBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).

- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

30.1.4.3.2 TCheckBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

AutoPopup

30.1.4.3.3 TCheckBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))

TDragObject

30.1.4.3.4 TCheckBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
```

```
  control was successfully dropped into and accepted by a
  another control.
  */
  void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
       int Y)
  {
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }

DragKind

30.1.4.3.7 TCheckBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter

event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{

Using a Single Navigator for Multiple Datasets

30.1.4.3.8 TCheckBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
  hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((netmask1 < 0) Or (netmask1 > 255) Or
      (netmask2 < 0) Or (netmask2 > 255) Or
      (hostmask1 < 0) Or (hostmask1 > 255) Or
      (hostmask2 < 0) Or (hostmask2 > 255)) then
    raise EArgumentException.Create('Not a valid subnet mask.');

  // compute the subnet address using bit-wise AND
  sub_net1 := net1 And netmask1;
  sub_net2 := net2 And netmask2;
  sub_host1 := host1 And hostmask1;
  sub_host2 := host2 And hostmask2;

  // display the subnet address
  MaskEdit3.Text :=
    IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
    IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;
```

```
procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

ActiveControl

30.1.4.3.9 TCheckBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {

OnKeyPress

OnKeyUp

30.1.4.3.10 TCheckBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

30.1.4.3.12 TCheckBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no

control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

30.1.4.3.13 TCheckBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
```

```
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  */
  int StartX, StartY; // Declare at the top of the form's unit
  // Use this code as the OnMouseDown event handler of the form:
  void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

30.1.4.3.14 TCheckBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

30.1.4.3.15 TCheckBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

30.1.4.3.16 TCheckBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

}
```

```
// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
```

```
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

MouseCapture

30.1.4.3.17 TCheckBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

30.1.4.3.18 TCheckBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

DragKind

OnDragOver

OnDockDrop

30.1.4.3.19 TCheckBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

30.1.5 TComboBox Class

TComboBox combines an edit box with a scrollable list.

Class Hierarchy

Pascal

```
TComboBox = class(TCustomComboBox);
```

C++

```
class TComboBox : public TCustomComboBox;
```

File

StdCtrls

Description

A TComboBox component is an edit box with a scrollable drop-down list attached to it. Users can select an item from the list or type directly into the edit box.

Note: The width of the button in a TComboBox is equal to the width that Windows uses for scrollbars. This width depends on the color scheme that the user has chosen (by right-clicking the desktop, selecting Properties, and choosing Appearance). On Windows XP, the user can specifically change the width of the scrollbar by clicking the Advanced button and selecting scrollbar as the Item. If you carefully size your combo box so all the text is visible, then a user running under a different color scheme may find that the text is obscured by the button. One solution is to set the scrollbar wide when developing the application. Most color schemes use a scrollbar that is at most 21 pixels wide.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
```

```
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

Combo Boxes

List Controls

30.1.5.1 TComboBox Members

The following tables list the members exposed by TComboBox.

Protected Fields

	Name	Description
	FDefEditProc (see page 2286)	Represents the address of the edit box procedure assigned by Windows.
	FDefListProc (see page 2287)	Represents the address of the list box procedure assigned by Windows.
	FDropHandle (see page 2287)	Represents the window handle for the entire combo box.
	FDroppingDown (see page 2287)	Specifies whether the list box is dropping down.
	FEditHandle (see page 2288)	Represents the window handle for the edit portion of the combo box.
	FEditInstance (see page 2288)	Represents the address of an internal routine associated with the edit control.
	FFocusChanged (see page 2288)	Specifies whether the combo box changed its focus state.
	FIsFocused (see page 2288)	Specifies whether the combo box is focused.
	FListHandle (see page 2289)	Represents the window handle for the list of items in the combo box.
	FListInstance (see page 2289)	Represents the address of an internal routine associated with the list box.
	FSaveIndex (see page 2289)	Represents the index of an item from the combo box.

Protected Methods

	Name	Description
V	AdjustDropDown (see page 2292)	Adjusts the size and position of the drop down list.
	Change (see page 2292)	Generates an OnChange (see page 2318) event.
	CloseUp (see page 2293)	Generates an OnCloseUp (see page 2320) event.
V	ComboWndProc (see page 2294)	Responds to Windows messages sent to the edit control or drop-down list.
V	CreateParams (see page 2326)	Initializes the window-creation parameter record.
V	CreateWnd (see page 2295)	Creates the Windows control that represents the combo box.
V	CreateWnd (see page 2327)	Creates the Windows control that represents the combo box.
V	DestroyWindowHandle (see page 2296)	Destroys all of the windows controls that implement the combo box.
V	DestroyWnd (see page 2327)	Destroys the Windows control that represents the combo box.
V	DoSetTextHint (see page 2328)	Sets the value of TextHint (see page 2337).
V	DrawItem (see page 2328)	Generates an OnDrawItem (see page 2338) event.
	DropDown (see page 2296)	Generates an OnDropDown (see page 2320) event.
V	EditWndProc (see page 2296)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	GetDroppedDown (see page 2297)	Returns the value of the DroppedDown (see page 2306) property.
A	GetItemCount (see page 2298)	Returns the value of the ItemCount (see page 2307) property.
V	GetItemCount (see page 2328)	Returns the number of items in the Items (see page 2308) property list.
A	GetItemHt (see page 2298)	Returns the value of the ItemHeight (see page 2307) property.
V	GetItemHt (see page 2329)	Returns the value of the ItemHeight (see page 2307) property.
V	GetItemIndex (see page 2298)	Returns the value of the ItemIndex property.
A	GetItemsClass (see page 2299)	Indicates the class that implements the Items (see page 2308) property.
V	GetItemsClass (see page 2329)	Returns the class used to implement the Items (see page 2308) property.
	GetSelLength (see page 2299)	Returns the value of the SelLength (see page 2311) property.
	GetSelStart (see page 2299)	Returns the value of the SelStart (see page 2314) property.
	GetSelText (see page 2329)	Returns the value of the SelText (see page 2335) property.
V	KeyPress (see page 2329)	Responds to WM_CHAR messages sent to the combo box.
	ListWndProc (see page 2300)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
V	Loaded (see page 2300)	Initializes the combo box after its form is loaded into memory.
V	MeasureItem (see page 2330)	Generates an OnMeasureItem (see page 2338) event.
	Select (see page 2301)	Generates an OnSelect (see page 2322) event.
	SelectItem (see page 2330)	Selects a specified item from the drop-down list.
V	SetDropDownCount (see page 2301)	Sets the value of the DropDownCount (see page 2306) property.
	SetDroppedDown (see page 2302)	Sets the value of the DroppedDown (see page 2306) property.
V	SetItemHeight (see page 2302)	Sets the value of the ItemHeight (see page 2307) property.
V	SetItemIndex (see page 2302)	Sets the value of the ItemIndex property.
V	SetItems (see page 2303)	Sets the value of the Items (see page 2308) property.
	SetMaxLength (see page 2303)	Sets the value of the MaxLength (see page 2310) property.

	SetSelLength (see page 2303)	Sets the value of the SelLength (see page 2311) property.
	SetSelStart (see page 2304)	Sets the value of the SelStart (see page 2314) property.
V	SetStyle (see page 2331)	Sets the Style (see page 2337) property.
V	WndProc (see page 2304)	Processes messages received by the combo box.
V	WndProc (see page 2331)	Processes messages received by the combo box.

Protected Properties

	Name	Description
R	EditHandle (see page 2307)	Returns the window handle for the edit portion of the combo box.
R	ItemCount (see page 2307)	Specifies the number of items in the drop-down list.
R	ListHandle (see page 2310)	Provides access to the window handle of the list of items in the combo box.

Public Methods

	Name	Description
V	AddItem (see page 2291)	Adds an item to the drop-down list of items.
V	Clear (see page 2293)	Deletes all text from the edit box and all items from the Items (see page 2308) list.
V	ClearSelection (see page 2293)	Deselects any selected items in the drop-down list.
V	CopySelection (see page 2294)	Copies the selected item in the drop-down list to another list control.
V	Create (see page 2285)	Creates and initializes a TCustomCombo (see page 2283) instance.
V	Create (see page 2325)	Creates and initializes a TCustomComboBox (see page 2322) instance.
V	DeleteSelected (see page 2295)	Deletes the selected item from the drop-down list.
V	Destroy (see page 2286)	Destroys the combo box and frees its memory.
V	Destroy (see page 2326)	Destroys the combo box and frees its memory.
V	Focused (see page 2297)	Indicates whether the combo box has input focus.
V	GetCount (see page 2297)	Returns the value of the ItemCount (see page 2307) property.
V	SelectAll (see page 2301)	Selects the entire block of text in the edit box.

Public Properties

	Name	Description
R	Canvas (see page 2305)	Provides access to the drawing surface of the combo box.
	DroppedDown (see page 2306)	Indicates whether the drop-down list is currently displayed.
	SelLength (see page 2311)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 2314)	Specifies the position of the first selected character in the edit portion of the combo box.
	SelText (see page 2335)	Represents the selected text in the edit region.

Published Events

	Name	Description
	OnChange (see page 2228)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 2230)	Occurs when the user clicks the control.
	OnCloseUp (see page 2232)	Occurs when the drop-down list closes up due to some user action.
	OnContextPopup (see page 2233)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 2233)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2234)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2237)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2240)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnDropDown (see page 2240)	Occurs when the user opens the drop-down list.
	OnEndDock (see page 2242)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2242)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2243)	Occurs when a control receives the input focus.
	OnExit (see page 2246)	Occurs when the input focus shifts away from one control to another.

	OnKeyDown (see page 2250)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2253)	Occurs when a key is pressed.
	OnKeyUp (see page 2254)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2256)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnMouseEnter (see page 2257)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2257)	Occurs when the user moves the mouse outside of a control.
	OnSelect (see page 2257)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 2257)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2258)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2190)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2193)	Specifies how the control is anchored to its parent.
	AutoCloseUp (see page 2194)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2194)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2195)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2195)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 2195)	Specifies which edges of the control are beveled.
	BevelInner (see page 2196)	Specifies the cut of the inner bevel.
	BevelKind (see page 2196)	Specifies the control's bevel style.
	BevelOuter (see page 2197)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2197)	Specifies the bi-directional mode for the control.
	CharCase (see page 2197)	Determines the case of the text in the combo box.
	Color (see page 2198)	Specifies the background color of the control.
	Constraints (see page 2199)	Specifies the size constraints for the control.
	Ctl3D (see page 2199)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2200)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2202)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2202)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2202)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownCount (see page 2204)	Specifies the maximum number of items displayed in the drop-down list.
	Enabled (see page 2204)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2205)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2206)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2206)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ItemHeight (see page 2207)	Specifies the height, in pixels, of the items in the drop-down list.
	ItemIndex (see page 2208)	Specifies the index of the selected item.
	Items (see page 2210)	Provides access to the list of items (strings) in the list portion of the combo box.
	MaxLength (see page 2212)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentBiDiMode (see page 2212)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2213)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2213)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 2214)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2214)	Determines where a control looks for its font information.
	ParentShowHint (see page 2214)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2215)	Identifies the pop-up menu associated with the control.

	ShowHint (see page 2220)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2221)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 2223)	Determines the display style of the combo box.
	TabOrder (see page 2223)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2224)	Determines if the user can tab to a control.
	Text (see page 2224)	Contains a text string associated with the control.
	TextHint (see page 2226)	Specifies the text that is displayed as a text watermark in the edit box of the combo box control.
	Visible (see page 2226)	Determines whether the component appears onscreen.

30.1.5.2 TComboBox Properties

The properties of the TComboBox class are listed here.

Published Properties

	Name	Description
	Align (see page 2190)	Determines how the control aligns within its container (parent control).
	Anchors (see page 2193)	Specifies how the control is anchored to its parent.
	AutoCloseUp (see page 2194)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoComplete (see page 2194)	Positions to matching list items as you type.
	AutoCompleteDelay (see page 2195)	Specifies the delay between a key press and an attempt to autocomplete the field.
	AutoDropDown (see page 2195)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 2195)	Specifies which edges of the control are beveled.
	BevelInner (see page 2196)	Specifies the cut of the inner bevel.
	BevelKind (see page 2196)	Specifies the control's bevel style.
	BevelOuter (see page 2197)	Specifies the cut of the outer bevel.
	BiDiMode (see page 2197)	Specifies the bi-directional mode for the control.
	CharCase (see page 2197)	Determines the case of the text in the combo box.
	Color (see page 2198)	Specifies the background color of the control.
	Constraints (see page 2199)	Specifies the size constraints for the control.
	Ctl3D (see page 2199)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 2200)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 2202)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2202)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2202)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownCount (see page 2204)	Specifies the maximum number of items displayed in the drop-down list.
	Enabled (see page 2204)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2205)	Controls the attributes of text written on or in the control.
	ImeMode (see page 2206)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2206)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ItemHeight (see page 2207)	Specifies the height, in pixels, of the items in the drop-down list.
	ItemIndex (see page 2208)	Specifies the index of the selected item.
	Items (see page 2210)	Provides access to the list of items (strings) in the list portion of the combo box.
	MaxLength (see page 2212)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	ParentBiDiMode (see page 2212)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2213)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2213)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 2214)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 2214)	Determines where a control looks for its font information.
	ParentShowHint (see page 2214)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2215)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2220)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2221)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 2223)	Determines the display style of the combo box.
	TabOrder (see page 2223)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2224)	Determines if the user can tab to a control.
	Text (see page 2224)	Contains a text string associated with the control.
	TextHint (see page 2226)	Specifies the text that is displayed as a text watermark in the edit box of the combo box control.
	Visible (see page 2226)	Determines whether the component appears onscreen.

30.1.5.2.1 TComboBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
```

```
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
    }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form

Parent

Anchors

30.1.5.2.2 TComboBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control

has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

30.1.5.2.3 TComboBox.AutoCloseUp Property

Specifies whether the drop-down closes up automatically when the user selects an item.

Pascal

```
property AutoCloseUp: Boolean;
```

C++

```
__property Boolean AutoCloseUp;
```

Description

When AutoCloseUp is true, the drop-down closes up automatically when the user selects an item.

See Also

AutoDropDown (see page 2334)

30.1.5.2.4 TComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, sometimes saving you keystrokes.

As you type, the ItemIndex (see page 2208) property is updated with the list entry that matches the characters you have entered. As you type, different list enrties may match, and ItemIndex (see page 2208) is changed accordingly.

There is a delay of AutoCompleteDelay (see page 2195) milliseconds between the characters typed and the autocomplete operation.

See Also

AutoCompleteDelay (see page 2195)

30.1.5.2.5 TComboBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 2194) is true.

See Also

AutoComplete (see page 2194)

30.1.5.2.6 TComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown: Boolean;
```

C++

```
__property Boolean AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

AutoComplete (see page 2332)

OnDropDown (see page 2320)

DroppedDown (see page 2306)

30.1.5.2.7 TComboBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

30.1.5.2.8 TComboBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

30.1.5.2.9 TComboBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

30.1.5.2.10 TComboBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

30.1.5.2.11 TComboBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

30.1.5.2.12 TComboBox.CharCase Property

Determines the case of the text in the combo box.

Pascal

```
property CharCase: TEditCharCase;
```

C++

```
__property TEditCharCase CharCase;
```

Description

Use CharCase to force the contents of the combo box into upper or lower case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types into the combo box. Changing the CharCase property changes the actual text, not just its appearance; case information is lost and cannot be recaptured by changing CharCase back to ecNormal.

Text

30.1.5.2.13 TComboBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

30.1.5.2.14 TComboBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

30.1.5.2.15 TComboBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

30.1.5.2.16 TComboBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
```

```
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;

30.1.5.2.17 TComboBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

Cursor

DragKind

DragMode

30.1.5.2.18 TComboBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

30.1.5.2.19 TComboBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

Arranging the Order of Persistent Columns

30.1.5.2.20 TComboBox.DropDownCount Property

Specifies the maximum number of items displayed in the drop-down list.

Pascal

```
property DropDownCount: Integer;
```

C++

```
__property int DropDownCount;
```

Description

By default, the drop-down list is long enough to contain eight items without requiring the user to scroll to see them all. To make the drop-down list smaller or larger, specify a number larger or smaller than eight as the DropDownCount value.

If the DropDownCount value is larger than the number of items in the Items property, the drop-down list will be just large enough to hold all the possible choices and no more. If the DropDownCount value is smaller then the number of item in the Items property, the drop down list will display a scroll bar.

ItemCount (see page 2307)

30.1.5.2.21 TComboBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.
