Use AdminEnabled to indicate whether this application implements the WSDL administrator. When AdminEnabled is true, pointing a Web browser at the URL that addresses this application using the path info specified by WebDispatch (see page 7288) launches a Web page that includes a button for the WSDL administrator. The WSDL administrator can then adjust the published WSDL documents to indicate an address other than the one where this application is installed as the location or locations where the Web Services are deployed.

When AdminEnabled is false, the URL that includes WebDispatch (see page 7288) publishes a list of WSDL documents but does not provide access to the WSDL administrator.

Tip: You can set AdminEnabled to true, update the URLs in the resulting WSDL documents, and then rebuild your application, setting AdminEnabled to false. The WSDL administrator stores your changes in a .ini file so that they appear in the list of WSDL documents even after you have changed AdminEnabled.

See Also

WebDispatch (see page 7288)

TargetNamespace (see page 7288)

Generating WSDL Documents for a Web Service Application

77.1.1.5.2 TWSDLHTMLPublish.PublishOptions Property

Controls the definitions TWSDLHTMLPublish (see page 7280) creates when it generates its WSDL documents.

Pascal

```
property PublishOptions: TSOAPPublishOptions;
```

C++

```
__property TSOAPPublishOptions PublishOptions;
```

Description

PublishOptions is a set of flags that customize the generated WSDL document.

See Also

TargetNamespace (see page 7288)

77.1.1.5.3 TWSDLHTMLPublish.TargetNamespace Property

Specifies the target namespace URL of the WSDL document.

Pascal

```
property TargetNamespace: InvString;
```

C++

```
__property InvString TargetNamespace;
```

Description

Use TargetNamespace to specify a namespace for the WSDL documents this component publishes. This is the namespace URL that the WSDL document uses for the definitions it publishes.

See Also

AdminEnabled (see page 7287)

77.1.1.5.4 TWSDLHTMLPublish.WebDispatch Property

Lets the Web dispatcher identify what HTTP messages should return a list of WSDL documents.

Pascal

```
property WebDispatch: TWebDispatch;
```

C++

```
__property TWebDispatch WebDispatch;
```

Description

Use WebDispatch to specify the messages to which TWSDLHTMLPublish (see page 7280) responds by providing a list of WSDL documents. These documents describe the Web Services that this application knows about, based on the registered interfaces, remotable classes, and remotable types. If this application registers but does not implement the invokable interface, you should also enable the WSDL administrator and use the WSDL administrator to indicate where the application that implements the Web Services is deployed.

The TWebDispatch object that implements WebDispatch includes properties that let you specify the path portion of URLs to which this component responds with an HTML page that publishes WSDL documents describing the Web Service. It also specifies the values allowed in the MESSAGE header. By default, WebDispatch identifies any URL whose path portion begins with the string “wsdl”.

Note: You can't use WebDispatch to disable the TWSDLHTMLPublish (see page 7280) object's ability to publish WSDL documents describing the Web Services. Setting its Enabled property to false does nothing.

RemTypeRegistry

77.1.1.6 TWSDLHTMLPublish Events

The events of the TWSDLHTMLPublish class are listed here.

Published Events

	Name	Description
	OnAfterPublishingWSDL (see page 7289)	Occurs after the publisher generates a WSDL document for the Web Service application.
	OnBeforePublishingTypes (see page 7290)	Occurs before the publisher starts adding type definitions to the WSDL document.
	OnBeforePublishingWSDL (see page 7290)	Occurs before the publisher generates its WSDL document.
	OnPublishingType (see page 7290)	Occurs before the publisher generates the schema for a given type.

77.1.1.6.1 TWSDLHTMLPublish.OnAfterPublishingWSDL Event

Occurs after the publisher generates a WSDL document for the Web Service application.

Pascal

```
property OnAfterPublishingWSDL: TAfterPublishingWSDLEvent;
```

C++

```
__property TAfterPublishingWSDLEvent OnAfterPublishingWSDL;
```

Description

Use OnAfterPublishingWSDL to perform special actions after the publisher has generated a WSDL document. For example, you can use this event to cache the generated WSDL document and then re-use the cached document in an OnBeforePublishingWSDL (see page 7290) event rather than requiring the publisher to generate a new document for every WSDL request it receives.

See Also

OnBeforePublishingWSDL (see page 7290)

77.1.1.6.2 TWSDLHTMLPublish.OnBeforePublishingTypes Event

Occurs before the publisher starts adding type definitions to the WSDL document.

Pascal

```
property OnBeforePublishingTypes: TBeforePublishingTypesEvent;
```

C++

```
__property TBeforePublishingTypesEvent OnBeforePublishingTypes;
```

Description

Use OnBeforePublishingTypes to add your own type definitions to the WSDL document before the publisher adds definitions for the types that the invokable interfaces use and types that are registered with the remotable type registry. If the OnBeforePublishingTypes event handler adds a schema definition for a type, the publisher uses that definition rather than generating its own version.

See Also

OnBeforePublishingWSDL (see page 7290)

OnPublishingType (see page 7290)

77.1.1.6.3 TWSDLHTMLPublish.OnBeforePublishingWSDL Event

Occurs before the publisher generates its WSDL document.

Pascal

```
property OnBeforePublishingWSDL: TBeforePublishingWSDLEvent;
```

C++

```
__property TBeforePublishingWSDLEvent OnBeforePublishingWSDL;
```

Description

Use OnBeforePublishingWSDL to provide your own WSDL document rather than letting the publisher generate one dynamically. For example, the event handler can supply a cached version of the WSDL document that you saved previously from an OnAfterPublishingWSDL (see page 7289) event handler.

See Also

OnAfterPublishingWSDL (see page 7289)

OnBeforePublishingTypes (see page 7290)

77.1.1.6.4 TWSDLHTMLPublish.OnPublishingType Event

Occurs before the publisher generates the schema for a given type.

Pascal

```
property OnPublishingType: TPublishingTypeEvent;
```

C++

```
__property TPublishingTypeEvent OnPublishingType;
```

Description

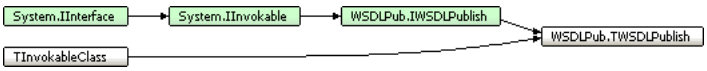
Use OnPublishingType to perform specific actions immediately before the publisher adds a type definition to the emerging WSDL document.

See Also

OnBeforePublishingTypes (see page 7290)

77.1.2 TWSDLPublish Class

Class Hierarchy



Pascal

```
TWSDLPublish = class(TInvokableClass, IWSDLPublish);
```

C++

```
class TWSDLPublish : public TInvokableClass, public IWSDLPublish;
```

File

WSDLPub

Description

This is class WSDLPub.TWSDLPublish.

77.1.2.1 TWSDLPublish Members

The following tables list the members exposed by TWSDLPublish.

Public Events

	Name	Description
	OnAfterPublishingWSDL (see page 7294)	This is OnAfterPublishingWSDL, a member of class TWSDLPublish.
	OnBeforePublishingTypes (see page 7294)	This is OnBeforePublishingTypes, a member of class TWSDLPublish.
	OnBeforePublishingWSDL (see page 7294)	This is OnBeforePublishingWSDL, a member of class TWSDLPublish.
	OnPublishingType (see page 7294)	This is OnPublishingType, a member of class TWSDLPublish.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	GetPortTypeEntries (see page 7292)	This is GetPortTypeEntries, a member of class TWSDLPublish.
	GetPortTypeList (see page 7292)	This is GetPortTypeList, a member of class TWSDLPublish.
	GetTypeSystemsList (see page 7292)	This is GetTypeSystemsList, a member of class TWSDLPublish.
	GetWSDLForPortType (see page 7293)	This is GetWSDLForPortType, a member of class TWSDLPublish.
	GetXSDForTypeSystem (see page 7293)	This is GetXSDForTypeSystem, a member of class TWSDLPublish.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

Public Properties

	Name	Description
	TargetNamespace (see page 7293)	This is TargetNamespace, a member of class TWSDLPublish.

77.1.2.2 TWSDLPublish Methods

The methods of the TWSDLPublish class are listed here.

Public Methods

	Name	Description
	GetPortTypeEntries (see page 7292)	This is GetPortTypeEntries, a member of class TWSDLPublish.
	GetPortTypeList (see page 7292)	This is GetPortTypeList, a member of class TWSDLPublish.
	GetTypeSystemsList (see page 7292)	This is GetTypeSystemsList, a member of class TWSDLPublish.
	GetWSDLForPortType (see page 7293)	This is GetWSDLForPortType, a member of class TWSDLPublish.
	GetXSDForTypeSystem (see page 7293)	This is GetXSDForTypeSystem, a member of class TWSDLPublish.

77.1.2.2.1 TWSDLPublish.GetPortTypeEntries Method

Pascal

```
procedure GetPortTypeEntries(var Entries: TInvRegIntfEntryArray);
```

C++

```
__fastcall GetPortTypeEntries(TInvRegIntfEntryArray Entries);
```

Description

This is GetPortTypeEntries, a member of class TWSDLPublish.

77.1.2.2.2 TWSDLPublish.GetPortTypeList Method

Pascal

```
function GetPortTypeList: InvStringDynArray; stdcall;
```

C++

```
__fastcall __stdcall InvStringDynArray GetPortTypeList();
```

Description

This is GetPortTypeList, a member of class TWSDLPublish.

77.1.2.2.3 TWSDLPublish.GetTypeSystemsList Method

Pascal

```
function GetTypeSystemsList: InvStringDynArray; stdcall;
```

C++

```
__fastcall __stdcall InvStringDynArray GetTypeSystemsList();
```

Description

This is GetTypeSystemsList, a member of class TWSDLPublish.

77.1.2.2.4 TWSDLPublish.GetWSDLForPortType Method

Pascal

```
function GetWSDLForPortType(const PortType: InvString): InvString; stdcall;
```

C++

```
__fastcall __stdcall InvString GetWSDLForPortType(const InvString PortType);
```

Description

This is GetWSDLForPortType, a member of class TWSDLPublish.

77.1.2.2.5 TWSDLPublish.GetXSDForTypeSystem Method

Pascal

```
function GetXSDForTypeSystem(const TypeSystem: InvString): InvString; stdcall;
```

C++

```
__fastcall __stdcall InvString GetXSDForTypeSystem(const InvString TypeSystem);
```

Description

This is GetXSDForTypeSystem, a member of class TWSDLPublish.

77.1.2.3 TWSDLPublish Properties

The properties of the TWSDLPublish class are listed here.

Public Properties

	Name	Description
	TargetNamespace (see page 7293)	This is TargetNamespace, a member of class TWSDLPublish.

77.1.2.3.1 TWSDLPublish.TargetNamespace Property

Pascal

```
property TargetNamespace: InvString;
```

C++

```
__property InvString TargetNamespace;
```

Description

This is TargetNamespace, a member of class TWSDLPublish.

77.1.2.4 TWSDLPublish Events

The events of the TWSDLPublish class are listed here.

Public Events

	Name	Description
	OnAfterPublishingWSDL (see page 7294)	This is OnAfterPublishingWSDL, a member of class TWSDLPublish.
	OnBeforePublishingTypes (see page 7294)	This is OnBeforePublishingTypes, a member of class TWSDLPublish.
	OnBeforePublishingWSDL (see page 7294)	This is OnBeforePublishingWSDL, a member of class TWSDLPublish.

	OnPublishingType (see page 7294)	This is OnPublishingType, a member of class TWSDLPublish.

77.1.2.4.1 TWSDLPublish.OnAfterPublishingWSDL Event

Pascal

```
property OnAfterPublishingWSDL: TAfterPublishingWSDLEvent;
```

C++

```
__property TAfterPublishingWSDLEvent OnAfterPublishingWSDL;
```

Description

This is OnAfterPublishingWSDL, a member of class TWSDLPublish.

77.1.2.4.2 TWSDLPublish.OnBeforePublishingTypes Event

Pascal

```
property OnBeforePublishingTypes: TBeforePublishingTypesEvent;
```

C++

```
__property TBeforePublishingTypesEvent OnBeforePublishingTypes;
```

Description

This is OnBeforePublishingTypes, a member of class TWSDLPublish.

77.1.2.4.3 TWSDLPublish.OnBeforePublishingWSDL Event

Pascal

```
property OnBeforePublishingWSDL: TBeforePublishingWSDLEvent;
```

C++

```
__property TBeforePublishingWSDLEvent OnBeforePublishingWSDL;
```

Description

This is OnBeforePublishingWSDL, a member of class TWSDLPublish.

77.1.2.4.4 TWSDLPublish.OnPublishingType Event

Pascal

```
property OnPublishingType: TPublishingTypeEvent;
```

C++

```
__property TPublishingTypeEvent OnPublishingType;
```

Description

This is OnPublishingType, a member of class TWSDLPublish.

77.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IWSDLPublish (see page 7295)	This is class WSDLPub.IWSDLPublish.

77.2.1 IWSDLPublish Interface

Class Hierarchy

Pascal

```
IWSDLPublish = interface(IInvokable);
```

C++

```
__interface IWSDLPublish : public IInvokable;
```

File

WSDLPub

Description

This is class WSDLPub.IWSDLPublish.

77.2.1.1 IWSDLPublish Members

The following tables list the members exposed by IWSDLPublish.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	GetPortTypeList (see page 7296)	This is GetPortTypeList, a member of class IWSDLPublish.
	GetTypeSystemsList (see page 7296)	This is GetTypeSystemsList, a member of class IWSDLPublish.
	GetWSDLForPortType (see page 7296)	This is GetWSDLForPortType, a member of class IWSDLPublish.
	GetXSDForTypeSystem (see page 7296)	This is GetXSDForTypeSystem, a member of class IWSDLPublish.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

77.2.1.2 IWSDLPublish Methods

The methods of the IWSDLPublish class are listed here.

Public Methods

	Name	Description
	GetPortTypeList (see page 7296)	This is GetPortTypeList, a member of class IWSDLPublish.
	GetTypeSystemsList (see page 7296)	This is GetTypeSystemsList, a member of class IWSDLPublish.
	GetWSDLForPortType (see page 7296)	This is GetWSDLForPortType, a member of class IWSDLPublish.
	GetXSDForTypeSystem (see page 7296)	This is GetXSDForTypeSystem, a member of class IWSDLPublish.

77.2.1.2.1 IWSDLPublish.GetPortTypeList Method

Pascal

```
function GetPortTypeList: InvStringDynArray; stdcall;
```

C++

```
__fastcall __stdcall InvStringDynArray GetPortTypeList();
```

Description

This is GetPortTypeList, a member of class IWSDLPublish.

77.2.1.2.2 IWSDLPublish.GetTypeSystemsList Method

Pascal

```
function GetTypeSystemsList: InvStringDynArray; stdcall;
```

C++

```
__fastcall __stdcall InvStringDynArray GetTypeSystemsList();
```

Description

This is GetTypeSystemsList, a member of class IWSDLPublish.

77.2.1.2.3 IWSDLPublish.GetWSDLForPortType Method

Pascal

```
function GetWSDLForPortType(const PortType: InvString): InvString; stdcall;
```

C++

```
__fastcall __stdcall InvString GetWSDLForPortType(const InvString PortType);
```

Description

This is GetWSDLForPortType, a member of class IWSDLPublish.

77.2.1.2.4 IWSDLPublish.GetXSDForTypeSystem Method

Pascal

```
function GetXSDForTypeSystem(const TypeSystem: InvString): InvString; stdcall;
```

C++

```
__fastcall __stdcall InvString GetXSDForTypeSystem(const InvString TypeSystem);
```

Description

This is GetXSDForTypeSystem, a member of class IWSDLPublish.

77.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	WSDLPubFactory (see page 7297)	This is function WSDLPub.WSDLPubFactory.

77.3.1 WSDLPub.WSDLPubFactory Function

Pascal

```
procedure WSDLPubFactory(out obj: TObject);
```

C++

```
WSDLPubFactory(TObject * obj);
```

File

WSDLPub

Description

This is function WSDLPub.WSDLPubFactory.

77.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	SOAPPublishOptions (see page 7298)	SOAPPublishOptions and TSOAPPublishOptions (see page 7299) are flags that customize the definitions the TWSDLHTMLPublish (see page 7280) creates for a Web Service.

77.4.1 WSDLPub.SOAPPublishOptions Enumeration

SOAPPublishOptions and TSOAPPublishOptions (see page 7299) are flags that customize the definitions the TWSDLHTMLPublish (see page 7280) creates for a Web Service.

Pascal

```
SOAPPublishOptions = (
  poDefault,
  poPublishLocationAsSecure,
  poUTF8ContentType
);
```

C++

```
enum SOAPPublishOptions {
  poDefault,
  poPublishLocationAsSecure,
  poUTF8ContentType
};
```

File

WSDLPub

Description

TSOAPPublishOptions (see page 7299) is a set of SOAPPublishOptions values. SOAPPublishOptions values are flags that configure the definitions that TWSDLHTMLPublish (see page 7280) creates when describing a Web Service. The following table lists the possible values:

Value	Meaning
poDefault	Use the default options when generating WSDL documents.
poPublishLocationAsSecure	Add a property that indicates the Web Service is on a secure server. Clients should use https rather than http.

77.5 Types

The following table lists types in this documentation.

Types

Name	Description
TBeforePublishingWSDLEvent (see page 7299)	TBeforePublishingWSDLEvent is the type of the OnBeforePublishingWSDL event of TWSDLHTMLPublish (see page 7280).
TSOAPPublishOptions (see page 7299)	This is type WSDLPub.TSOAPPublishOptions.

77.5.1 WSDLPub.TBeforePublishingWSDLEvent Type

TBeforePublishingWSDLEvent is the type of the OnBeforePublishingWSDL event of TWSDLHTMLPublish (see page 7280).

Pascal

```
TBeforePublishingWSDLEvent = procedure (const IntfName: InvString; var WSDL: InvString; var
Handled: Boolean) of object;
```

C++

```
(const IntfName: InvString; var WSDL: InvString; var Handled: Boolean) (
TBeforePublishingWSDLEvent)();
```

File

WSDLPub

Description

TBeforePublishingWSDLEvent is the type of the OnBeforePublishingWSDL event handler, which allows an application to generate the content of a WSDL document on behalf of the WSDL publisher.

IntfName is the name of the invokable interface for which to generate a WSDL description.

WSDL returns a string of XML that makes up the content of the WSDL document that describes the specified interface.

Handled returns true if the event handler generates and returns a value for WSDL. If Handled returns true, the publisher uses the value of WSDL rather than generating its own WSDL document. If Handled returns false, the publisher generates a WSDL document for the interface and all types that it uses.

See Also

Procedural types

Creating events

77.5.2 WSDLPub.TSOAPPublishOptions Type

Pascal

```
TSOAPPublishOptions = set of SOAPPublishOptions;
```

C++

```
SOAPPublishOptions TSOAPPublishOptions;
```

File

WSDLPub

Description

This is type WSDLPub.TSOAPPublishOptions.

78 XMLBrokr Namespace

This is namespace XMLBrokr.

Topics

Name	Description
Classes (see page 7303)	The following table lists classes in this documentation.
Interfaces (see page 7337)	The following table lists interfaces in this documentation.
Functions (see page 7339)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 7340)	The following table lists structs, records, enums in this documentation.
Types (see page 7341)	The following table lists types in this documentation.
Constants (see page 7343)	The following table lists constants in this documentation.

Classes

	Name	Description
	TXMLBroker (see page 7303)	TXMLBroker fetches XML data packets from an application server and applies XML updates to the application server.
	TXMLParams (see page 7333)	TXMLParams manages a list of parameters for an XML broker.

Constants

Name	Description
sPostDelta (see page 7343)	This is constant XMLBrokr.sPostDelta.
sProducer (see page 7343)	This is constant XMLBrokr.sProducer.
sRedirect (see page 7343)	This is constant XMLBrokr.sRedirect.

Functions

	Name	Description
	FormatXML (see page 7339)	This is function XMLBrokr.FormatXML.

Interfaces

	Name	Description
	INotifyConnectionChange (see page 7337)	This is class XMLBrokr.INotifyConnectionChange.

Structs, Records, Enums

	Name	Description
	TXMLOption (see page 7340)	TXMLOptions (see page 7342) is a set of flags that indicates how database information should be formatted in an XML data packet.

Types

Name	Description
TGetErrorResponseEvent (see page 7341)	This is type XMLBrokr.TGetErrorResponseEvent.
TGetResponseEvent (see page 7341)	This is type XMLBrokr.TGetResponseEvent.
TRequestRecordsEvent (see page 7342)	This is type XMLBrokr.TRequestRecordsEvent.
TRequestUpdateEvent (see page 7342)	This is type XMLBrokr.TRequestUpdateEvent.
TXMLOptions (see page 7342)	This is type XMLBrokr.TXMLOptions.

78.1 Classes

The following table lists classes in this documentation.

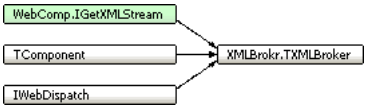
Classes

	Name	Description
	TXMLBroker (see page 7303)	TXMLBroker fetches XML data packets from an application server and applies XML updates to the application server.
	TXMLParams (see page 7333)	TXMLParams manages a list of parameters for an XML broker.

78.1.1 TXMLBroker Class

TXMLBroker fetches XML data packets from an application server and applies XML updates to the application server.

Class Hierarchy



Pascal

```
TXMLBroker = class(TComponent, IWebDispatch, IGetXMLStream);
```

C++

```
class TXMLBroker : public TComponent, public IWebDispatch, public IGetXMLStream;
```

File

XMLBrokr

Description

Use TXMLBroker in an application that is simultaneously the client of a multi-tiered database application and a Web server application. This class serves two major functions:

It fetches XML data packets from a provider using the IAppServer interface.

It receives HTTP messages from Web browsers that contain XML delta packets and applies them to the application server.

Add a TXMLBroker object to a Web module to make database information supplied by a provider on the application server available as XML. An InternetExpress page producer (TInetXPageProducer) in the same Web module uses this XML to build HTML pages that represent that database information.

The XML broker automatically registers itself with the Web module (or Web dispatcher) as an auto-dispatching object. This means that the Web module or Web dispatcher forwards all incoming HTTP messages directed to the XML broker without requiring the use of Web action items.

These incoming messages are assumed to be update messages created by the browser in response to HTML generated by a TApplyUpdatesButton component. The XML broker automatically applies the delta packet (the content of the HTTP request message) to the application server, and passes any update errors to a separate content producer, which can generate a response message.

78.1.1.1 TXMLBroker Members

The following tables list the members exposed by TXMLBroker.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 7308)	This is AS_ApplyUpdates, a member of class TXMLBroker.
	AS_FetchParams (see page 7309)	This is AS_FetchParams, a member of class TXMLBroker.
	AS_GetRecords (see page 7309)	This is AS_GetRecords, a member of class TXMLBroker.
	CheckInactive (see page 7309)	This is CheckInactive, a member of class TXMLBroker.
	DispatchEnabled (see page 7309)	
	DispatchMask (see page 7309)	
	DispatchMethodType (see page 7310)	
	DispatchRequest (see page 7310)	
	GetAppServer (see page 7310)	This is GetAppServer, a member of class TXMLBroker.
	GetConnected (see page 7311)	This is GetConnected, a member of class TXMLBroker.
	GetErrorResponse (see page 7312)	This is GetErrorResponse, a member of class TXMLBroker.
	GetHasAppServer (see page 7312)	This is GetHasAppServer, a member of class TXMLBroker.
	GetNotify (see page 7312)	This is GetNotify, a member of class TXMLBroker.
	GetNotifyCount (see page 7313)	This is GetNotifyCount, a member of class TXMLBroker.
	GetProducerName (see page 7313)	This is GetProducerName, a member of class TXMLBroker.
	GetRedirect (see page 7313)	This is GetRedirect, a member of class TXMLBroker.
	GetResponse (see page 7313)	This is GetResponse, a member of class TXMLBroker.
	GetXMLStream (see page 7314)	This is GetXMLStream, a member of class TXMLBroker.
V	Notification (see page 7316)	Forwards notification messages to all owned components.
	SendConnectEvent (see page 7319)	This is SendConnectEvent, a member of class TXMLBroker.
	SetAppServer (see page 7319)	This is SetAppServer, a member of class TXMLBroker.
	SetConnected (see page 7319)	This is SetConnected, a member of class TXMLBroker.
	SetParams (see page 7319)	This is SetParams, a member of class TXMLBroker.
	SetProviderName (see page 7320)	This is SetProviderName, a member of class TXMLBroker.
	SetReconcileProducer (see page 7320)	This is SetReconcileProducer, a member of class TXMLBroker.
	SetRemoteServer (see page 7321)	This is SetRemoteServer, a member of class TXMLBroker.
	SetWebDispatch (see page 7321)	This is SetWebDispatch, a member of class TXMLBroker.

Public Methods

	Name	Description
	AddNotify (see page 7307)	Adds an object to the Notify (see page 7325) property list.
	ApplyXMLUpdates (see page 7308)	Sends an XML delta packet of updated, inserted, and deleted records to the provider on the application server for writing to the database.
V	Create (see page 7305)	Creates a new TXMLBroker (see page 7303) object.
V	Destroy (see page 7306)	Frees the memory associated with the TXMLBroker (see page 7303) object.
V	FetchParams (see page 7310)	Retrieves parameter values from the application server.
	GetDelta (see page 7311)	Extracts an XML delta packet from an HTTP request message.

	GetErrorCount (see page 7311)	Returns the number of errors in the delta packet returned by GetErrors (see page 7312).
	GetErrors (see page 7312)	Returns the XML delta packet (if any) that describes the errors that occurred when applying updates.
	GetXMLRecords (see page 7314)	Retrieves an XML data packet from the application server.
	HTMLSubmitFormName (see page 7315)	Returns the name of the HTML form that submits updates to the XML broker.
	MasterRowSetVarName (see page 7315)	Returns the name of the javascript variable for the XML broker's dataset.
	RemoveNotify (see page 7316)	Removes an object to the Notify (see page 7325) property list.
V	RequestRecords (see page 7316)	Returns an XML data packet from the application server.
V	RequestUpdate (see page 7317)	Responds to an HTTP update request.
	RowSetVarName (see page 7318)	Returns the name of the javascript variable for the XML broker's dataset.
	SetProvider (see page 7320)	Associates the XML broker with a provider in the same process space.
	SubmitFormVarName (see page 7321)	Returns the name of the variable that refers to the HTML form named by HTMLSubmitFormName (see page 7315).

Public Properties

	Name	Description
	AppServer (see page 7322)	Provides access to the interface the XML broker uses to communicate with the application server.
R	HasAppServer (see page 7323)	Indicates whether the XML broker has an IAppServer interface for communicating with its provider.
R	Notify (see page 7325)	Lists the objects that are notified when any properties affecting the XML broker's connection to its provider change.
R	NotifyCount (see page 7325)	Indicates the number of objects in the Notify (see page 7325) property list.

Published Events

	Name	Description
	AfterDispatch (see page 7329)	Occurs after the XML broker generates the content of a response message.
	BeforeDispatch (see page 7330)	Occurs when the XML broker receives an HTTP request message.
	OnGetErrorResponse (see page 7330)	Occurs when there are errors applying updates to the application server.
	OnGetResponse (see page 7331)	Occurs when there are no errors applying updates to the application server.
	OnRequestRecords (see page 7332)	Occurs when the XML broker needs to fetch a data packet from its associated provider.
	OnRequestUpdate (see page 7332)	Occurs immediately before the XML broker applies updates to the application server.

Published Properties

	Name	Description
	Connected (see page 7322)	Determines whether the XML broker has an active connection to the provider that supplies its data and applies its updates.
	MaxErrors (see page 7323)	Specifies the maximum number of update errors allowed before aborting an update operations.
	MaxRecords (see page 7324)	Specifies the maximum number of records that can appear in XML data packets.
	Params (see page 7325)	Contains parameter values that are sent to or retrieved from the application server.
	ProviderName (see page 7326)	Specifies the name of a registered provider from the application server.
	ReconcileProducer (see page 7327)	Specifies the producer that generates response message content when an update generates errors.
	RemoteServer (see page 7328)	Specifies the connection component that this XML broker uses to connect to an application server.
	WebDispatch (see page 7328)	Lets the Web dispatcher identify what HTTP messages should be forwarded to the XML broker.

78.1.1.2 TXMLBroker.Create Constructor

Creates a new TXMLBroker (see page 7303) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXMLBroker(TComponent * AOwner);
```

Description

Most applications do not need to call the XML broker constructor. Typically the XML broker is added to a Web module at design time, so that the constructor is called automatically.

The Owner parameter specifies the component (usually the Web module) that is responsible for freeing the XML broker.

See Also

Owner

78.1.1.3 TXMLBroker.Destroy Destructor

Frees the memory associated with the TXMLBroker (see page 7303) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLBroker();
```

Description

Do not call Destroy directly. Instead,call Free, which verifies that the XML broker is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

78.1.1.4 TXMLBroker Methods

The methods of the TXMLBroker class are listed here.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 7308)	This is AS_ApplyUpdates, a member of class TXMLBroker.
	AS_FetchParams (see page 7309)	This is AS_FetchParams, a member of class TXMLBroker.
	AS_GetRecords (see page 7309)	This is AS_GetRecords, a member of class TXMLBroker.
	CheckInactive (see page 7309)	This is CheckInactive, a member of class TXMLBroker.
	DispatchEnabled (see page 7309)	
	DispatchMask (see page 7309)	
	DispatchMethodType (see page 7310)	
	DispatchRequest (see page 7310)	
	GetAppServer (see page 7310)	This is GetAppServer, a member of class TXMLBroker.
	GetConnected (see page 7311)	This is GetConnected, a member of class TXMLBroker.
	GetErrorResponse (see page 7312)	This is GetErrorResponse, a member of class TXMLBroker.
	GetHasAppServer (see page 7312)	This is GetHasAppServer, a member of class TXMLBroker.
	GetNotify (see page 7312)	This is GetNotify, a member of class TXMLBroker.
	GetNotifyCount (see page 7313)	This is GetNotifyCount, a member of class TXMLBroker.
	GetProducerName (see page 7313)	This is GetProducerName, a member of class TXMLBroker.

	GetRedirect (see page 7313)	This is GetRedirect, a member of class TXMLBroker.
	GetResponse (see page 7313)	This is GetResponse, a member of class TXMLBroker.
	GetXMLStream (see page 7314)	This is GetXMLStream, a member of class TXMLBroker.
	Notification (see page 7316)	Forwards notification messages to all owned components.
	SendConnectEvent (see page 7319)	This is SendConnectEvent, a member of class TXMLBroker.
	SetAppServer (see page 7319)	This is SetAppServer, a member of class TXMLBroker.
	SetConnected (see page 7319)	This is SetConnected, a member of class TXMLBroker.
	SetParams (see page 7319)	This is SetParams, a member of class TXMLBroker.
	SetProviderName (see page 7320)	This is SetProviderName, a member of class TXMLBroker.
	SetReconcileProducer (see page 7320)	This is SetReconcileProducer, a member of class TXMLBroker.
	SetRemoteServer (see page 7321)	This is SetRemoteServer, a member of class TXMLBroker.
	SetWebDispatch (see page 7321)	This is SetWebDispatch, a member of class TXMLBroker.

Public Methods

	Name	Description
	AddNotify (see page 7307)	Adds an object to the Notify (see page 7325) property list.
	ApplyXMLUpdates (see page 7308)	Sends an XML delta packet of updated, inserted, and deleted records to the provider on the application server for writing to the database.
	FetchParams (see page 7310)	Retrieves parameter values from the application server.
	GetDelta (see page 7311)	Extracts an XML delta packet from an HTTP request message.
	GetErrorCount (see page 7311)	Returns the number of errors in the delta packet returned by GetErrors (see page 7312).
	GetErrors (see page 7312)	Returns the XML delta packet (if any) that describes the errors that occurred when applying updates.
	GetXMLRecords (see page 7314)	Retrieves an XML data packet from the application server.
	HTMLSubmitFormName (see page 7315)	Returns the name of the HTML form that submits updates to the XML broker.
	MasterRowSetVarName (see page 7315)	Returns the name of the javascript variable for the XML broker's dataset.
	RemoveNotify (see page 7316)	Removes an object to the Notify (see page 7325) property list.
	RequestRecords (see page 7316)	Returns an XML data packet from the application server.
	RequestUpdate (see page 7317)	Responds to an HTTP update request.
	RowSetVarName (see page 7318)	Returns the name of the javascript variable for the XML broker's dataset.
	SetProvider (see page 7320)	Associates the XML broker with a provider in the same process space.
	SubmitFormVarName (see page 7321)	Returns the name of the variable that refers to the HTML form named by HTMLSubmitFormName (see page 7315).

78.1.1.4.1 TXMLBroker.AddNotify Method

Adds an object to the Notify (see page 7325) property list.

Pascal

```
procedure AddNotify(ANotify: TObject);
```

C++

```
__fastcall AddNotify(TObject * ANotify);
```

Description

Call AddNotify to add an object to the list maintained by the Notify (see page 7325) property. Each object in this list is notified every time a property that affects the metadata of the XML broker's data packets changes. These include changes to the RemoteServer (see page 7328), AppServer (see page 7322), and ProviderName (see page 7326) properties.

ANotify specifies the object that wants to be notified of property changes. This object must support the INotifyConnectionChange (see page 7337) interface, which the XML broker uses to notify it of changes.

See Also

NotifyCount (see page 7325)

Notify (see page 7325)

RemoveNotify (see page 7316)

RemoteServer (see page 7328)

AppServer (see page 7322)

ProviderName (see page 7326)

78.1.1.4.2 TXMLBroker.ApplyXMLUpdates Method

Sends an XML delta packet of updated, inserted, and deleted records to the provider on the application server for writing to the database.

Pascal

```
function ApplyXMLUpdates(const Delta: string; out ErrorCount: Integer): string;
```

C++

```
__fastcall UnicodeString ApplyXMLUpdates(const UnicodeString Delta, int ErrorCount);
```

Description

Call ApplyXMLUpdates to send the updates in the XML delta packet specified by Delta to the application server. ApplyXMLUpdates is used internally (by the RequestUpdate (see page 7317) method) to apply updates in an XML delta packet and retrieve a delta packet containing any failed updates.

Delta is the XML delta packet that contains the insertions, deletions and modifications from a Web browser. Typically, it is retrieved from an HTTP request message using the GetDelta (see page 7311) method.

ErrorCount returns the number of errors encountered on the application server before it terminated the update operation. If ErrorCount is 0, all updates were applied successfully. ErrorCount can not exceed the value of MaxErrors (see page 7323).

ApplyXMLUpdates returns an XML delta packet containing all updates that were not successfully applied. If ErrorCount is 0, this is an empty string.

See Also

RequestUpdate (see page 7317)

AS_ApplyUpdates

MaxErrors (see page 7323)

GetDelta (see page 7311)

78.1.1.4.3 TXMLBroker.AS_ApplyUpdates Method

Pascal

```
function AS_ApplyUpdates(Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer):
OleVariant;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(OleVariant Delta, int MaxErrors, int ErrorCount);
```

Description

This is AS_ApplyUpdates, a member of class TXMLBroker.

78.1.1.4.4 TXMLBroker.AS_FetchParams Method

Pascal

```
procedure AS_FetchParams;
```

C++

```
__fastcall AS_FetchParams();
```

Description

This is AS_FetchParams, a member of class TXMLBroker.

78.1.1.4.5 TXMLBroker.AS_GetRecords Method

Pascal

```
function AS_GetRecords(Count: Integer; out RecsOut: Integer; Options: Integer; const
CommandText: WideString; Params: OleVariant; var OwnerData: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant AS_GetRecords(int Count, int RecsOut, int Options, const BSTR
CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

This is AS_GetRecords, a member of class TXMLBroker.

78.1.1.4.6 TXMLBroker.CheckInactive Method

Pascal

```
procedure CheckInactive;
```

C++

```
__fastcall CheckInactive();
```

Description

This is CheckInactive, a member of class TXMLBroker.

78.1.1.4.7 TXMLBroker.DispatchEnabled Method

Pascal

```
function DispatchEnabled: Boolean;
```

C++

```
__fastcall Boolean DispatchEnabled();
```

See Also

Enabled

78.1.1.4.8 TXMLBroker.DispatchMask Method

Pascal

```
function DispatchMask: TMask;
```

C++

```
__fastcall TMask DispatchMask();
```

See Also

Mask

78.1.1.4.9 TXMLBroker.DispatchMethodType Method

Pascal

```
function DispatchMethodType: TMethodType;
```

C++

```
__fastcall TMethodType DispatchMethodType();
```

See Also

MethodType

78.1.1.4.10 TXMLBroker.DispatchRequest Method

Pascal

```
function DispatchRequest(Sender: TObject; Request: TWebRequest; Response: TWebResponse):
Boolean;
```

C++

```
__fastcall Boolean DispatchRequest(TObject * Sender, TWebRequest Request, TWebResponse
Response);
```

78.1.1.4.11 TXMLBroker.FetchParams Method

Retrieves parameter values from the application server.

Pascal

```
procedure FetchParams; virtual;
```

C++

```
virtual __fastcall FetchParams();
```

Description

Call FetchParams to initialize the Params (see page 7325) property with the current parameter values on the application server. FetchParams does nothing unless the provider component on the application server can supply parameter values.

Warning: if the XML broker uses a stateless application server, other clients can change the values returned by FetchParams at any time.

See Also

RowRequest

Params (see page 7325)

78.1.1.4.12 TXMLBroker.GetAppServer Method

Pascal

```
function GetAppServer: IAppServer;
```

C++

```
__fastcall IAppServer GetAppServer();
```

Description

This is GetAppServer, a member of class TXMLBroker.

78.1.1.4.13 TXMLBroker.GetConnected Method

Pascal

```
function GetConnected: Boolean;
```

C++

```
__fastcall Boolean GetConnected();
```

Description

This is GetConnected, a member of class TXMLBroker.

78.1.1.4.14 TXMLBroker.GetDelta Method

Extracts an XML delta packet from an HTTP request message.

Pascal

```
function GetDelta(Request: TWebRequest): string;
```

C++

```
__fastcall UnicodeString GetDelta(TWebRequest Request);
```

Description

Call GetDelta to obtain the XML delta packet contained in the content of the request message specified by Request. This value can be used to apply the updates from the request message by calling ApplyXMLUpdates (see page 7308).

See Also

ApplyXMLUpdates (see page 7308)

78.1.1.4.15 TXMLBroker.GetErrorCount Method

Returns the number of errors in the delta packet returned by GetErrors (see page 7312).

Pascal

```
function GetErrorCount: Integer;
```

C++

```
__fastcall int GetErrorCount();
```

Description

Call GetErrorCount to determine the number errors included in the XML delta packet that the application server returns when an update operation causes errors.

See Also

OnGetErrorResponse (see page 7330)

ApplyXMLUpdates (see page 7308)

GetErrors (see page 7312)

78.1.1.4.16 TXMLBroker.GetErrorResponse Method

Pascal

```
function GetErrorResponse(ErrorCount: Integer; XMLErrors: string; Request: TWebRequest;
Response: TWebResponse): Boolean;
```

C++

```
__fastcall Boolean GetErrorResponse(int ErrorCount, UnicodeString XMLErrors, TWebRequest
Request, TWebResponse Response);
```

Description

This is GetErrorResponse, a member of class TXMLBroker.

78.1.1.4.17 TXMLBroker.GetErrors Method

Returns the XML delta packet (if any) that describes the errors that occurred when applying updates.

Pascal

```
function GetErrors: string;
```

C++

```
__fastcall UnicodeString GetErrors();
```

Description

Call GetErrors to obtain the XML delta packet returned by the application server when an update operation included some errors.

Note: See the template err.html (included in the WebMidas directory) for one possible use for the XML delta packet of errors. In err.html, the string returned by GetErrors should replace the <#XMLEMBED_VAR_ERR> tag.

See Also

OnGetErrorResponse (see page 7330)

ApplyXMLUpdates (see page 7308)

GetErrorCount (see page 7311)

78.1.1.4.18 TXMLBroker.GetHasAppServer Method

Pascal

```
function GetHasAppServer: Boolean;
```

C++

```
__fastcall Boolean GetHasAppServer();
```

Description

This is GetHasAppServer, a member of class TXMLBroker.

78.1.1.4.19 TXMLBroker.GetNotify Method

Pascal

```
function GetNotify(Index: Integer): TObject;
```

C++

```
__fastcall TObject * GetNotify(int Index);
```

Description

This is GetNotify, a member of class TXMLBroker.

78.1.1.4.20 TXMLBroker.GetNotifyCount Method

Pascal

```
function GetNotifyCount: Integer;
```

C++

```
__fastcall int GetNotifyCount();
```

Description

This is GetNotifyCount, a member of class TXMLBroker.

78.1.1.4.21 TXMLBroker.GetProducerName Method

Pascal

```
function GetProducerName(Request: TWebRequest): string;
```

C++

```
__fastcall UnicodeString GetProducerName(TWebRequest Request);
```

Description

This is GetProducerName, a member of class TXMLBroker.

78.1.1.4.22 TXMLBroker.GetRedirect Method

Pascal

```
function GetRedirect(Request: TWebRequest): string;
```

C++

```
__fastcall UnicodeString GetRedirect(TWebRequest Request);
```

Description

This is GetRedirect, a member of class TXMLBroker.

78.1.1.4.23 TXMLBroker.GetResponse Method

Pascal

```
function GetResponse(Request: TWebRequest; Response: TWebResponse): Boolean;
```

C++

```
__fastcall Boolean GetResponse(TWebRequest Request, TWebResponse Response);
```

Description

This is GetResponse, a member of class TXMLBroker.

78.1.1.4.24 TXMLBroker.GetXMLRecords Method

Retrieves an XML data packet from the application server.

Pascal

```
function GetXMLRecords(var RecsOut: Integer; var OwnerData: OleVariant; XMLOptions:
TXMLOptions): string;
```

C++

```
__fastcall UnicodeString GetXMLRecords(int RecsOut, OleVariant OwnerData, TXMLOptions
XMLOptions);
```

Description

Call GetXMLRecords to obtain the XML data packet from the application server. GetXMLRecords calls the interface specified by AppServer (see page 7322), requesting an XML data packet with at most MaxRecords (see page 7324) records. It returns the resulting XML data packet in a form that is ready for insertion into an HTML document.

RecsOut returns the number of records in the XML data packet.

On entry, OwnerData contains an application-defined value that is passed to the provider's BeforeGetRecords event handler. OwnerData returns an application-defined value that is set by the provider's AfterGetRecords event handler. Typically, this parameter is used to transmit persistent state information to and from a stateless application server.

XMLOptions is a set of flags that indicate how the broker should format the XML data packet after it is retrieved from the application server.

GetXMLRecords returns the formatted XML data packet.

Note: Unlike the RequestRecords (see page 7316) method, GetXMLRecords bypasses the OnRequestRecords (see page 7332) event.

See Also

RequestRecords (see page 7316)

AS_GetRecords

MaxRecords (see page 7324)

AppServer (see page 7322)

BeforeGetRecords

AfterGetRecords

Using an XML Broker

78.1.1.4.25 TXMLBroker.GetXMLStream Method

Pascal

```
function GetXMLStream(var Owned: Boolean): TStream;
```

C++

```
__fastcall TStream GetXMLStream(Boolean Owned);
```

Description

This is GetXMLStream, a member of class TXMLBroker.

78.1.1.4.26 TXMLBroker.HTMLSubmitFormName Method

Returns the name of the HTML form that submits updates to the XML broker.

Pascal

```
function HTMLSubmitFormName: string;
```

C++

```
__fastcall UnicodeString HTMLSubmitFormName();
```

Description

When the InternetExpress page producer assembles an HTML document that uses the XML data packets managed by the XML broker, it declares an HTML form that submits the updates to the XML broker. HTMLSubmitFormName is the name of that HTML form.

The HTML form named by this return value sends the HTTP request messages containing an XML delta packet of updates to be applied.

See Also

SubmitFormVarName (see page 7321)

Content

78.1.1.4.27 TXMLBroker.MasterRowSetVarName Method

Returns the name of the javascript variable for the XML broker's dataset.

Pascal

```
function MasterRowSetVarName(Path: TStrings): string;
```

C++

```
__fastcall UnicodeString MasterRowSetVarName(TStrings Path);
```

Description

When the InternetExpress page producer assembles an HTML document that uses the XML data packets managed by the XML broker, it declares a javascript variable of type RowSet for the javascript object that represents the XML broker's dataset. When the variable is first declared, the InternetExpress page producer calls MasterRowSetVarName.

Path is a set of variable names for all the master datasets for which the XML broker's dataset is a detail set. These names come from previous calls to the MasterRowSetVarName method of their XML brokers. The last string in Path refers to the XML broker's dataset itself.

MasterRowSetVarName returns the name of the XML broker, qualified by all strings in Path except for the last one, which is assumed to refer to the XML broker's dataset. Thus, to change the name of the generated variable for an XML broker's dataset, change the Name property of the XML broker.

Note: To retrieve the name of the XML broker preceded by all the datasets in Path, use the RowSetVarName (see page 7318) method instead.

See Also

Name

Content

RowSetVarName (see page 7318)

78.1.1.4.28 TXMLBroker.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

78.1.1.4.29 TXMLBroker.RemoveNotify Method

Removes an object to the Notify (see page 7325) property list.

Pascal

```
procedure RemoveNotify(ANotify: TObject);
```

C++

```
__fastcall RemoveNotify(TObject * ANotify);
```

Description

Call RemoveNotify to remove an object from the list maintained by the Notify (see page 7325) property. Each object in this list is notified every time a property that affects the metadata of the XML broker's data packets changes.

See Also

NotifyCount (see page 7325)

Notify (see page 7325)

AddNotify (see page 7307)

78.1.1.4.30 TXMLBroker.RequestRecords Method

Returns an XML data packet from the application server.

Pascal

```
function RequestRecords(Sender: TObject; Request: TWebRequest; out RecCount: Integer; var
OwnerData: OleVariant; XMLOptions: TXMLOptions): string; virtual;
```

C++

```
virtual __fastcall UnicodeString RequestRecords(TObject * Sender, TWebRequest Request, int
RecCount, OleVariant OwnerData, TXMLOptions XMLOptions);
```

Description

Call RequestRecords to obtain a current XML data packet, while first allowing the OnRequestRecords (see page 7332) event handler to customize it. After generating the OnRequestRecords (see page 7332) event, RequestRecords fetches the XML data packet by calling GetXMLRecords (see page 7314), unless the event handler supplies the XML data packet first.

Sender is the object that is requesting the XML data packet (usually an InternetExpress page producer).

Request describes an HTTP request message that originated the need for an XML data packet. Typically, this is a request message for which the InternetExpress page producer is creating a response.

RecCount returns the number of records in the XML data packet.

On entry, OwnerData contains an application-defined value that is passed to the OnRequestRecords (see page 7332) event handler, and then forwarded (with any changes provided by the event handler) to the provider's BeforeGetRecords event handler. OwnerData returns an application-defined value that is set by the provider's AfterGetRecords event handler. Typically, this parameter is used to transmit persistent state information to and from a stateless application server.

XMLOptions is a set of flags indicating how the XML broker should format the XML data packet that the application server or OnRequestRecords (see page 7332) event handler supplies.

RequestRecords returns the XML data packet.

OnRequestRecords (see page 7332)

AppServer (see page 7322)

BeforeGetRecords

AfterGetRecords

Using an XML Broker

78.1.1.4.31 TXMLBroker.RequestUpdate Method

Responds to an HTTP update request.

Pascal

```
function RequestUpdate(Sender: TObject; Request: TWebRequest; Response: TWebResponse):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean RequestUpdate(TObject * Sender, TWebRequest Request, TWebResponse
Response);
```

Description

Call RequestUpdate when using a Web action item to respond to update requests from a Web browser. When using a Web

action item to respond to update requests, instead of letting the XML broker receive the update requests directly, you should set the Enabled property of the WebDispatch (see page 7328) to false.

RequestUpdate generates an OnRequestUpdate (see page 7332) event, to allow the event handler to apply the updates in the HTTP request message and generate a response. If the OnRequestUpdate (see page 7332) event handler does not handle the message, RequestUpdate applies the updates using the ApplyXMLUpdates (see page 7308) method. Finally, if there are no update errors, RequestUpdate generates an OnGetResponse (see page 7331) event. If there were update errors, RequestResponse generates an OnGetErrorResponse (see page 7330) event and (if the event handler does not generate a response) assigns the content of ReconcileProducer (see page 7327) to the response message. If there are update errors and the response is not completed by an event handler or the ReconcileProducer (see page 7327), the XML broker raises an exception.

Sender is the object that received the request message.

Request describes an HTTP request message that contains the updates that need to be applied.

Response is the emerging response object that should be completed by RequestUpdate so that the XML broker can send it back to the Web browser.

RequestUpdate returns true if the response message is ready to send back to the Web browser, false if it still needs more processing.

Enabled

78.1.1.4.32 TXMLBroker.RowSetVarName Method

Returns the name of the javascript variable for the XML broker's dataset.

Pascal

```
function RowSetVarName(Path: TStrings): string;
```

C++

```
__fastcall UnicodeString RowSetVarName(TStrings Path);
```

Description

When the InternetExpress page producer assembles an HTML document that uses the XML data packets managed by the XML broker, it declares a javascript variable of type RowSet for the javascript object that represents the XML broker's dataset. When the InternetExpress page producer needs to determine whether a RowSet variable was already declared, it looks up the variable name by calling RowSetVarName.

Path is a set of variable names for all the master datasets for which the XML broker's dataset is a detail set.

RowSetVarName returns the name of the XML broker, qualified by all strings in Path.

Note: Variable names are assigned for an XML broker's dataset using the MasterRowSetVarName (see page 7315) method.

MasterRowSetVarName (see page 7315)

78.1.1.4.33 TXMLBroker.SendConnectEvent Method

Pascal

```
procedure SendConnectEvent(Connecting: Boolean);
```

C++

```
__fastcall SendConnectEvent(Boolean Connecting);
```

Description

This is SendConnectEvent, a member of class TXMLBroker.

78.1.1.4.34 TXMLBroker.SetAppServer Method

Pascal

```
procedure SetAppServer(Value: IAppServer);
```

C++

```
__fastcall SetAppServer(IAppServer Value);
```

Description

This is SetAppServer, a member of class TXMLBroker.

78.1.1.4.35 TXMLBroker.SetConnected Method

Pascal

```
procedure SetConnected(Value: Boolean);
```

C++

```
__fastcall SetConnected(Boolean Value);
```

Description

This is SetConnected, a member of class TXMLBroker.

78.1.1.4.36 TXMLBroker.SetParams Method

Pascal

```
procedure SetParams(const Value: TXMLParams);
```

C++

```
__fastcall SetParams(const TXMLParams Value);
```

Description

This is SetParams, a member of class TXMLBroker.

78.1.1.4.37 TXMLBroker.SetProvider Method

Associates the XML broker with a provider in the same process space.

Pascal

```
procedure SetProvider(Provider: TComponent);
```

C++

```
__fastcall SetProvider(TComponent * Provider);
```

Description

Use SetProvider to specify a local provider component that provides data to and applies updates from the XML broker. The XML broker communicates with this provider using the IAppServer interface specified by the AppServer (see page 7322) property.

Do not use SetProvider for remote providers on an application server. If the provider is not in the same process space as the XML broker, use the ProviderName (see page 7326) property.

The Provider parameter must be a descendant of TCustomProvider. Otherwise, SetProvider raises an exception.

See Also

AppServer (see page 7322)

ProviderName (see page 7326)

TDataSetProvider

TCustomProvider

78.1.1.4.38 TXMLBroker.SetProviderName Method

Pascal

```
procedure SetProviderName(const Value: string);
```

C++

```
__fastcall SetProviderName(const UnicodeString Value);
```

Description

This is SetProviderName, a member of class TXMLBroker.

78.1.1.4.39 TXMLBroker.SetReconcileProducer Method

Pascal

```
procedure SetReconcileProducer(const Value: TCustomContentProducer);
```

C++

```
__fastcall SetReconcileProducer(const TCustomContentProducer Value);
```

Description

This is SetReconcileProducer, a member of class TXMLBroker.

78.1.1.4.40 TXMLBroker.SetRemoteServer Method

Pascal

```
procedure SetRemoteServer(Value: TCustomRemoteServer);
```

C++

```
__fastcall SetRemoteServer(TCustomRemoteServer Value);
```

Description

This is SetRemoteServer, a member of class TXMLBroker.

78.1.1.4.41 TXMLBroker.SetWebDispatch Method

Pascal

```
procedure SetWebDispatch(const Value: TWebDispatch);
```

C++

```
__fastcall SetWebDispatch(const TWebDispatch Value);
```

Description

This is SetWebDispatch, a member of class TXMLBroker.

78.1.1.4.42 TXMLBroker.SubmitFormVarName Method

Returns the name of the variable that refers to the HTML form named by HTMLSubmitFormName (see page 7315).

Pascal

```
function SubmitFormVarName: string;
```

C++

```
__fastcall UnicodeString SubmitFormVarName();
```

Description

When the InternetExpress page producer assembles an HTML document that uses the XML data packets managed by the XML broker, it declares an HTML form that submits the updates to the XML broker. In addition, it declares a variable that refers to that form. SubmitFormVarName is the name of that variable.

See Also

HTMLSubmitFormName (see page 7315)

Content

78.1.1.5 TXMLBroker Properties

The properties of the TXMLBroker class are listed here.

Public Properties

	Name	Description
	AppServer (see page 7322)	Provides access to the interface the XML broker uses to communicate with the application server.
R	HasAppServer (see page 7323)	Indicates whether the XML broker has an IAppServer interface for communicating with its provider.

	Notify (see page 7325)	Lists the objects that are notified when any properties affecting the XML broker's connection to its provider change.
	NotifyCount (see page 7325)	Indicates the number of objects in the Notify (see page 7325) property list.

Published Properties

	Name	Description
	Connected (see page 7322)	Determines whether the XML broker has an active connection to the provider that supplies its data and applies its updates.
	MaxErrors (see page 7323)	Specifies the maximum number of update errors allowed before aborting an update operations.
	MaxRecords (see page 7324)	Specifies the maximum number of records that can appear in XML data packets.
	Params (see page 7325)	Contains parameter values that are sent to or retrieved from the application server.
	ProviderName (see page 7326)	Specifies the name of a registered provider from the application server.
	ReconcileProducer (see page 7327)	Specifies the producer that generates response message content when an update generates errors.
	RemoteServer (see page 7328)	Specifies the connection component that this XML broker uses to connect to an application server.
	WebDispatch (see page 7328)	Lets the Web dispatcher identify what HTTP messages should be forwarded to the XML broker.

78.1.1.5.1 TXMLBroker.AppServer Property

Provides access to the interface the XML broker uses to communicate with the application server.

Pascal

```
property AppServer: IAppServer;
```

C++

```
__property IAppServer AppServer;
```

Description

Use AppServer to communicate with the providers that supply data to and resolve updates for the XML broker. If the providers are on a remote application server, AppServer has the same value as the AppServer property of the connection component. If the XML broker uses a provider in the same process space, AppServer is the interface to an internally created object that dispatches IAppServer calls to the local provider.

Applications don't need to work directly with the IAppServer interface. The properties and methods of the XML broker are automatically translated into IAppServer calls as needed.

See Also

HasAppServer (see page 7323)

AppServer

SetProvider (see page 7320)

78.1.1.5.2 TXMLBroker.Connected Property

Determines whether the XML broker has an active connection to the provider that supplies its data and applies its updates.

Pascal

```
property Connected: Boolean;
```

C++

```
__property Boolean Connected;
```

Description

Use Connected to determine whether the XML broker can supply XML data packets and apply updates. If the XML broker uses a provider on an application server, setting Connected to true sets the Connected property of the connection component to true. If the XML broker uses a local provider component, setting Connected to true causes the XML broker to generate an internal object that communicates with the provider using the IAppServer interface. Thus, the value of Connected indicates whether an IAppServer interface is available for communicating with a provider, and so the value of Connected is the same as the value of HasAppServer (see page 7323).

You can't set Connected to true unless the XML broker has a provider to which it can connect. Trying to set Connected to true before the ProviderName (see page 7326) property is set or a local provider is assigned using the SetProvider (see page 7320) method causes the XML broker to raise an exception.

Note: In the Web Page editor, default fields or parameter values may not appear if the associated XML broker is not connected.

See Also

HasAppServer (see page 7323)

AppServer (see page 7322)

Connected

TDataSetProvider

ProviderName (see page 7326)

SetProvider (see page 7320)

78.1.1.5.3 TXMLBroker.HasAppServer Property

Indicates whether the XML broker has an IAppServer interface for communicating with its provider.

Pascal

```
property HasAppServer: Boolean;
```

C++

```
__property Boolean HasAppServer;
```

Description

Read (see page 3634) HasAppServer to determine whether the XML broker can get its data from an IAppServer interface. When HasAppServer is true, the XML broker can interact with its provider through the IAppServer interface.

Use HasAppServer to check whether the XML broker is connected rather than reading the AppServer (see page 7322) property. Reading AppServer (see page 7322) causes the XML broker to obtain an IAppServer interface if it does not already have one.

See Also

IAppServer

AppServer (see page 7322)

Connected (see page 7322)

78.1.1.5.4 TXMLBroker.MaxErrors Property

Specifies the maximum number of update errors allowed before aborting an update operations.

Pascal

```
property MaxErrors: Integer;
```

C++

```
__property int MaxErrors;
```

Description

Set MaxErrors to indicate the maximum number of errors that the associated provider should allow before prematurely stopping an update operation. Set MaxErrors to –1 to indicate that there is no limit to the number of errors.

See Also

AS_ApplyUpdates

ReconcileProducer (see page 7327)

ApplyXMLUpdates (see page 7308)

78.1.1.5.5 TXMLBroker.MaxRecords Property

Specifies the maximum number of records that can appear in XML data packets.

Pascal

```
property MaxRecords: Integer;
```

C++

```
__property int MaxRecords;
```

Description

Set MaxRecords to limit the size of XML data packets retrieved from the associated provider.

When MaxRecords is –1, XML data packets contain all the records in the provider's dataset.

When MaxRecords is 0, XML data packets contain only metadata.

When MaxRecords is greater than 0, XML data packets contain up to MaxRecords records, depending on the number of records in the provider's dataset.

Tip: Because an InternetExpress application sends the entire data packet to client applications, it is important to limit the size of data packets. Otherwise, the time to download web pages containing data packets can be prohibitively long.

Note: When limiting the number of records that appear in data packets, you may need to fetch several data packets before all data is returned. Because InternetExpress applications are always stateless, you will need to supply information about what record should start the next data packet as the OwnerData parameter of GetXMLRecords (see page 7314) or RequestRecords (see page 7316). You can use a query form to obtain information about the last record seen by a particular Web client.

AS_GetRecords

GetXMLRecords (see page 7314)

RequestRecords (see page 7316)

TQueryForm

Using an XML Broker

78.1.1.5.6 TXMLBroker.Notify Property

Lists the objects that are notified when any properties affecting the XML broker's connection to its provider change.

Pascal

```
property Notify [Index: Integer]: TObject;
```

C++

```
__property TObject * Notify[int Index];
```

Description

Read (see page 3634) Notify to access the objects that respond when the XML broker's connection to its provider changes. These objects are sent a notification when the ProviderName (see page 7326), AppServer (see page 7322), or RemoteServer (see page 7328) property changes.

Most applications do not need to use the Notify property. It allows the Web page editor to remain synchronized with property changes made at design time.

See Also

NotifyCount (see page 7325)

AddNotify (see page 7307)

RemoveNotify (see page 7316)

RemoteServer (see page 7328)

AppServer (see page 7322)

ProviderName (see page 7326)

78.1.1.5.7 TXMLBroker.NotifyCount Property

Indicates the number of objects in the Notify (see page 7325) property list.

Pascal

```
property NotifyCount: Integer;
```

C++

```
__property int NotifyCount;
```

Description

NotifyCount specifies the number of objects listed in the Notify (see page 7325) property.

See Also

Notify (see page 7325)

AddNotify (see page 7307)

RemoveNotify (see page 7316)

78.1.1.5.8 TXMLBroker.Params Property

Contains parameter values that are sent to or retrieved from the application server.

Pascal

```
property Params: TXMLParams;
```

C++

```
__property TXMLParams Params;
```

Description

Use Params to specify parameter values that should be passed to a source dataset on the application server. These parameter values are used in one of two ways:

If the associated provider represents a query or stored procedure, they supply parameter values that the application server uses when executing the query or stored procedure.

If the associated provider represents a table, they limit the records that are sent in data packets so that they only include records where each field with the same name as a parameter has the same value as the parameter.

After the application specifies parameters (at design time or runtime), they are sent to the application server automatically when the XML broker fetches data.

To send parameter values to a query or stored procedure, add a parameter object (TParam) to Params for every parameter on the query or stored procedure for which you want to supply a value. Assign each parameter object the same Name, DataType, and ParamType as the corresponding parameter on the query or stored procedure. These values are automatically encoded and sent to the application server when the XML broker fetches data.

To send parameter values to a table, add a parameter object for each field in the table that is used to limit the values sent in data packets. Assign each parameter object the same Name and DataType as the corresponding field component on the table. These parameter values are automatically sent when the client dataset fetches data, and the records returned in data packets from the application server only contain records that match the assigned value on the corresponding fields.

Tip: You can assign parameter values from the content fields supplied to a request message by TSubmitQueryButton using the AssignStrings method of Params.

Note: To initialize Params so that it reflects the parameters of a query or stored procedure on an application server, call the FetchParams (see page 7310) method.

Params

Params

FetchParams (see page 7310)

TSubmitQueryButton

AssignStrings (see page 7335)

Using an XML Broker

78.1.1.5.9 TXMLBroker.ProviderName Property

Specifies the name of a registered provider from the application server.

Pascal

```
property ProviderName: string;
```

C++

```
__property UnicodeString ProviderName;
```

Description

Use ProviderName to specify the provider with which to communicate on the server (or in the same Web module). This property is passed as a parameter to IAppServer interface calls when the XML broker fetches data or applies updates. If an application server contains multiple provider objects, an XML broker can set ProviderName to any of them once the connection component establishes a connection to the application server.

ProviderName can be set from a drop-down in the Object Inspector once the RemoteServer (see page 7328) property is set.

Note: ProviderName can also be used to link the XML broker to a provider in the same process space, as long as the provider component has the same Owner as the XML broker. If the local provider component has a different Owner, use the SetProvider (see page 7320) method instead.

See Also

RemoteServer (see page 7328)

TDataSetProvider

IAppServer

SetProvider (see page 7320)

Using an XML Broker

78.1.1.5.10 TXMLBroker.ReconcileProducer Property

Specifies the producer that generates response message content when an update generates errors.

Pascal

```
property ReconcileProducer: TCustomContentProducer;
```

C++

```
__property TCustomContentProducer ReconcileProducer;
```

Description

Use ReconcileProducer to specify the component that generates the content of response messages to update requests when the update operation generated errors.

When the XML broker applies updates, the application server returns a delta packet containing all records that could not be updated because of errors. The XML broker can attempt to respond to those errors or generate its own response message using the OnGetErrorResponse (see page 7330) event. However, unless the OnGetErrorResponse (see page 7330) event handler generates an HTML document to be sent in the response message and indicates that the update is completely handled, the XML broker must still generate a response to the update operation. To do so, it calls the Content method of the ReconcileProducer to generate the content of the response message.

Tip: The Reconcile producer will probably need information about the update errors that the application server returned. You can provide it with this information either by initializing the Reconcile producer in an OnGetErrorResponse (see page 7330) event handler or by having the Reconcile producer call the GetErrors (see page 7312) method.

Note: If there is no ReconcileProducer assigned and an update generates errors, the XML broker raises an exception unless the OnGetErrorResponse (see page 7330) event handler generates a response message.

Tip: The InetXCustom demo contains a TReconcilePageProducer component that you can use as the value of the ReconcileProducer property or as the basis of your own reconcile producer.

See Also

MaxErrors (see page 7323)

OnGetErrorResponse (see page 7330)

ApplyXMLUpdates (see page 7308)

GetErrors (see page 7312)

Using an XML Broker

78.1.1.5.11 TXMLBroker.RemoteServer Property

Specifies the connection component that this XML broker uses to connect to an application server.

Pascal

```
property RemoteServer: TCustomRemoteServer;
```

C++

```
__property TCustomRemoteServer RemoteServer;
```

Description

Use RemoteServer to specify the connection component that establishes a connection to the remote application server. The connection component obtains an IAppServer interface for data exchange and maintains the interface of the remote data module on the application server.

If a Web application uses more than connection component, the application can change which connection an XML broker uses by changing the value for this property.

ProviderName (see page 7326)

TSocketConnection (see page 221)

TDCOMConnection

TWebConnection (see page 254)

AppServer

IAppServer

Using an XML Broker

78.1.1.5.12 TXMLBroker.WebDispatch Property

Lets the Web dispatcher identify what HTTP messages should be forwarded to the XML broker.

Pascal

```
property WebDispatch: TWebDispatch;
```

C++

```
__property TWebDispatch WebDispatch;
```

Description

Use WebDispatch to specify the HTTP messages to which the XML broker responds. Typically, these originate from a button added to HTML forms by TApplyUpdatesButton.

The TWebDispatch object that implements WebDispatch includes properties that let you specify the path portion of URLs to which the XML broker responds, as well as the types of messages it accepts (typically post messages). You can also use this property to disable the XML broker so that the Web dispatcher does not send it any HTTP messages. When the XML broker is disabled in this way, it can still provide XML data packets to an InternetExpress page producer, but any update messages must be handled by a Web action item.

Using an XML Broker

78.1.1.6 TXMLBroker Events

The events of the TXMLBroker class are listed here.

Published Events

	Name	Description
	AfterDispatch (see page 7329)	Occurs after the XML broker generates the content of a response message.
	BeforeDispatch (see page 7330)	Occurs when the XML broker receives an HTTP request message.
	OnGetErrorResponse (see page 7330)	Occurs when there are errors applying updates to the application server.
	OnGetResponse (see page 7331)	Occurs when there are no errors applying updates to the application server.
	OnRequestRecords (see page 7332)	Occurs when the XML broker needs to fetch a data packet from its associated provider.
	OnRequestUpdate (see page 7332)	Occurs immediately before the XML broker applies updates to the application server.

78.1.1.6.1 TXMLBroker.AfterDispatch Event

Occurs after the XML broker generates the content of a response message.

Pascal

```
property AfterDispatch: THTTPMethodEvent;
```

C++

```
__property THTTPMethodEvent AfterDispatch;
```

Description

Write (see page 3707) an AfterDispatch event handler to perform any final actions before sending a response back to the Web browser that sent the XML broker an update message. Usually by the time AfterDispatch occurs, the XML broker has already applied the updates and generated the response message (using the ReconcileProducer (see page 7327) or one of the events that occurs when the XML broker receives an update request).

See Also

WebDispatch (see page 7328)

BeforeDispatch (see page 7330)

OnRequestUpdate (see page 7332)

OnGetResponse (see page 7331)

OnGetErrorResponse (see page 7330)

ReconcileProducer (see page 7327)

Using an XML Broker

78.1.1.6.2 TXMLBroker.BeforeDispatch Event

Occurs when the XML broker receives an HTTP request message.

Pascal

```
property BeforeDispatch: THTTPMethodEvent;
```

C++

```
__property THTTPMethodEvent BeforeDispatch;
```

Description

Write (see page 3707) a BeforeDispatch event handler to initialize the response to an update request or to handle any messages sent to the XML broker that are not update requests. If the event handler completely handles the request, filling out the response object so that it is ready to send, it should set the Handled parameter to true, thereby preventing the XML broker from applying the updates.

Unless the BeforeDispatch event handler sets the Handled parameter to true, the XML broker receives an OnRequestUpdate (see page 7332) event after the BeforeDispatch event handler exits. After the OnRequestUpdate (see page 7332) event, the XML broker applies the updates to the application server and generates the contents of the response based on whether there were any update errors. Finally, the XML broker receives an AfterDispatch (see page 7329) event where it can perform any final changes to the response message before it is sent back to the Web browser.

If the BeforeDispatch event handler sets the Handled parameter to true, the XML broker receives an AfterDispatch (see page 7329) event, but does not attempt to apply updates from the request message or receive any of the events that accompany that process.

See Also

WebDispatch (see page 7328)

AfterDispatch (see page 7329)

OnRequestUpdate (see page 7332)

Using an XML Broker

78.1.1.6.3 TXMLBroker.OnGetErrorResponse Event

Occurs when there are errors applying updates to the application server.

Pascal

```
property OnGetErrorResponse: TGetErrorResponseEvent;
```

C++

```
__property TGetErrorResponseEvent OnGetErrorResponse;
```

Description

Write (see page 3707) an OnGetErrorResponse event handler to generate the response message after an update request

encountered errors or to initialize a ReconcileProducer (see page 7327) before it generates the response.

The Sender parameter is the XML broker that applied updates to the application server and received back a delta packet of update errors.

ErrorCount is the number of update errors found by the application server before it halted the update operation.

XMLErrors is a string of XML returned by the application server. It is a delta packet containing all the updates that could not be applied.

Request is the original request message that contains the delta packet of updates from the Web browser.

Response is the emerging response message that will be sent to the Web browser in response to the update request. Fill in the properties of this object to generate a response (such as an error message or a reconcile form) that indicates the errors in XMLErrors.

Handled indicates whether the event handler completed filling out Response. Set Handled to true if the event handler completes the response for the Web browser. Leave Handled as false if ReconcileProducer (see page 7327) should generate the content of Response.

Note: If the OnGetErrorResponse event handler does not set Handled to true and there is no ReconcileProducer (see page 7327), the XML broker raises an exception.

See Also

MaxErrors (see page 7323)

ReconcileProducer (see page 7327)

OnGetResponse (see page 7331)

ApplyXMLUpdates (see page 7308)

Using an XML Broker

78.1.1.6.4 TXMLBroker.OnGetResponse Event

Occurs when there are no errors applying updates to the application server.

Pascal

```
property OnGetResponse: TGetResponseEvent;
```

C++

```
__property TGetResponseEvent OnGetResponse;
```

Description

Write (see page 3707) an OnGetResponse event handler to edit the response message after an update request is successfully applied.

The Sender parameter is the XML broker that applied updates to the application server with no errors.

Request is the original request message that contains the delta packet of updates from the Web browser.

Response is the emerging response message that will be sent to the Web browser in response to the update request. Fill in the properties of this object to generate a response (such as refreshing the data).

Handled indicates whether the event handler completed filling out Response. Set Handled to true if the event handler completes the response for the Web browser. Leave Handled as false if the XML broker should send a redirect response that sends the browser back to the page that generated the update request.

See Also

OnGetErrorResponse (see page 7330)

ApplyXMLUpdates (see page 7308)

Using an XML Broker

78.1.1.6.5 TXMLBroker.OnRequestRecords Event

Occurs when the XML broker needs to fetch a data packet from its associated provider.

Pascal

```
property OnRequestRecords: TRequestRecordsEvent;
```

C++

```
__property TRequestRecordsEvent OnRequestRecords;
```

Description

Write (see page 3707) an OnRequestRecords event handler to provide an alternate mechanism for providing XML data packets or to perform other actions whenever the XML broker needs to fetch an XML data packet. For example, the OnRequestRecords event handler might call GetXMLRecords (see page 7314) to fetch an XML data packet from the application server and then edit its contents.

OnRequestRecords occurs when the InternetExpress page producer requests an XML data packet (usually in response to a request message) or when the application calls the XML broker's RequestRecords (see page 7316) method.

The Sender parameter is the object that originates the request (usually an InternetExpress page producer).

Request is the request message that prompted the request for an XML data packet. This value may be nil (Delphi) or NULL (C++) if the request did not arise from a page producer or if the page producer is not processing a request message.

OwnerData contains an application-defined variant that is sent to the provider's BeforeGetRecords event handler. The InternetExpress page producer that is requesting records or the caller of RequestRecords (see page 7316) may initialize this value. OwnerData can be used to pass persistent state information to a stateless application server (for example, the first record that should appear in the data packet when MaxRecords (see page 7324) is greater than 0).

Records optionally returns an XML data packet as a string. If Records is an empty string on exit from the event handler, the XML broker automatically fetches the XML data packet from its associated provider. Otherwise, the XML broker uses the value of Records as the new XML data packet.

See Also

RequestRecords (see page 7316)

GetXMLRecords (see page 7314)

GetXMLData

BeforeGetRecords

MaxRecords (see page 7324)

Using an XML Broker

78.1.1.6.6 TXMLBroker.OnRequestUpdate Event

Occurs immediately before the XML broker applies updates to the application server.

Pascal

```
property OnRequestUpdate: TRequestUpdateEvent;
```

C++

```
__property TRequestUpdateEvent OnRequestUpdate;
```

Description

Write (see page 3707) an OnRequestUpdate event handler to provide an alternate mechanism for applying updates to the application server. For example, the OnRequestUpdate event handler might call GetDelta (see page 7311) to extract the delta packet from the request message and then preprocess the XML string before applying the updates with a call to ApplyXMLUpdates (see page 7308).

OnRequestUpdate occurs immediately after the BeforeDispatch (see page 7330) event or when the application calls the XML broker's RequestUpdate (see page 7317) method.

The Sender parameter is the object that received the update request (the XML broker or a Web action item).

Request is the request message that contains the updates to be applied. The XML delta packet can be extracted from this request object using the GetDelta (see page 7311) method.

Response is the emerging response message that will be sent back to the Web browser that generated the update request. The event handler can set properties on this response object to partially or completely specify the message will be returned to the Web browser.

Handled indicates whether the event handler applied the updates. If Handled is true on exit from the event handler, the XML broker does not apply the updates, does not receive an OnGetResponse (see page 7331) or OnGetErrorResponse (see page 7330) event, and does not call on the ReconcileProducer (see page 7327) to generate a response message. (It does still receive an AfterDispatch (see page 7329) event). If Handled is false on exit from the event handler, the XML broker proceeds to apply the updates contained in the request message and receives all the associated events.

Note: If the event handler applies the updates, it must also generate the response message.

Using an XML Broker

78.1.2 TXMLParams Class

TXMLParams manages a list of parameters for an XML broker.

Class Hierarchy

Pascal

```
TXMLParams = class(TParams);
```

C++

```
class TXMLParams : public TParams;
```

File

XMLBrokr

Description

XML brokers use TXMLParams to manage a list of parameters that it passes to a provider on the application server. These parameters supply values to a query or stored procedure on the application server, or limit the records provided from a table on the application server.

Use the properties and methods of TXMLParams to:

Access a specific parameter.

Add or delete parameters from the list.

Get or set the values of individual parameters.

Assign parameter values from a list such as the one supplied in a request message from a Web browser.

Compare parameters.

Iterate through all parameters.

Copy (see page 3547) a set of parameters to another parameter list.

See Also

TParam

TXMLBroker (see page 7303)

78.1.2.1 TXMLParams Members

The following tables list the members exposed by TXMLParams.

Protected Methods

	Name	Description
	AssignTo (see page 7335)	Copies the properties of an object to a destination object.

Public Methods

	Name	Description
	AssignStrings (see page 7335)	Assigns values to the parameters from a list of name/value pairs.

78.1.2.2 TXMLParams Methods

The methods of the TXMLParams class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 7335)	Copies the properties of an object to a destination object.

Public Methods

	Name	Description
	AssignStrings (see page 7335)	Assigns values to the parameters from a list of name/value pairs.

78.1.2.2.1 TXMLParams.AssignStrings Method

Assigns values to the parameters from a list of name/value pairs.

Pascal

```
procedure AssignStrings(Value: TStrings);
```

C++

```
__fastcall AssignStrings(TStrings Value);
```

Description

Use AssignStrings to update the values of the parameters in the Items list to match the values in the list specified by Value. For each string in Value of the form Name=Value, AssignStrings locates the parameter (if any) that has the same name as the name portion of the string. It then assigns the Value portion of the string as the parameter's value.

AssignStrings makes it very convenient to assign parameter values that are received as the content of a request message. In particular, TSubmitQueryButton generates an HTML control that sends the values in an HTML query form to the Web application. If the query form displays parameter values that should be sent to a provider on the application server, you can call AssignStrings with the ContentFields property of that Web request message.

TSubmitQueryButton

78.1.2.2.2 TXMLParams.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

78.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	INotifyConnectionChange (see page 7337)	This is class XMLBrokr.INotifyConnectionChange.

78.2.1 INotifyConnectionChange Interface

Class Hierarchy

Pascal

```
INotifyConnectionChange = interface;
```

C++

```
__interface INotifyConnectionChange;
```

File

XMLBrokr

Description

This is class XMLBrokr.INotifyConnectionChange.

78.2.1.1 INotifyConnectionChange Members

The following tables list the members exposed by INotifyConnectionChange.

Public Methods

	Name	Description
	ConnectionChange (see page 7338)	This is ConnectionChange, a member of class INotifyConnectionChange.

78.2.1.2 INotifyConnectionChange Methods

The methods of the INotifyConnectionChange class are listed here.

Public Methods

	Name	Description
	ConnectionChange (see page 7338)	This is ConnectionChange, a member of class INotifyConnectionChange.

78.2.1.2.1 INotifyConnectionChange.ConnectionChange Method

Pascal

```
procedure ConnectionChange(Sender: TComponent; Connected: Boolean);
```

C++

```
__fastcall ConnectionChange(TComponent * Sender, Boolean Connected);
```

Description

This is ConnectionChange, a member of class INotifyConnectionChange.

78.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FormatXML (see page 7339)	This is function XMLBrokr.FormatXML.

78.3.1 XMLBrokr.FormatXML Function

Pascal

```
function FormatXML(const Value: string; XMLOptions: TXMLOptions): string;
```

C++

```
UnicodeString FormatXML(const UnicodeString Value, TXMLOptions XMLOptions);
```

File

XMLBrokr

Description

This is function XMLBrokr.FormatXML.

78.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TXMLOption (see page 7340)	TXMLOptions (see page 7342) is a set of flags that indicates how database information should be formatted in an XML data packet.

78.4.1 XMLBrokr.TXMLOption Enumeration

TXMLOptions (see page 7342) is a set of flags that indicates how database information should be formatted in an XML data packet.

Pascal

```
TXMLOption = (
  xoQuote
);
```

C++

```
enum TXMLOption {
  xoQuote
};
```

File

XMLBrokr

Description

TXMLOption is the type for flags that influence how an XML broker formats the XML string that an application server provides. After the XML broker fetches data from an application server, it reformats the data using a set of TXMLOption flags.

TXMLOptions (see page 7342) is a set of zero or more TXMLOption flags.

The following table lists the TXMLOption flags:

Value	Meaning
xoQuote	The XML string is divided into readable lines, each of which is enclosed in quotation marks.

78.5 Types

The following table lists types in this documentation.

Types

Name	Description
TGetErrorResponseEvent (see page 7341)	This is type XMLBrokr.TGetErrorResponseEvent.
TGetResponseEvent (see page 7341)	This is type XMLBrokr.TGetResponseEvent.
TRequestRecordsEvent (see page 7342)	This is type XMLBrokr.TRequestRecordsEvent.
TRequestUpdateEvent (see page 7342)	This is type XMLBrokr.TRequestUpdateEvent.
TXMLOptions (see page 7342)	This is type XMLBrokr.TXMLOptions.

78.5.1 XMLBrokr.TGetErrorResponseEvent Type

Pascal

```
TGetErrorResponseEvent = procedure (Sender: TObject; ErrorCount: Integer; XMLErrors: string;
Request: TWebRequest; Response: TWebResponse; var Handled: Boolean) of object;
```

C++

```
(Sender: TObject; ErrorCount: Integer; XMLErrors: string; Request: TWebRequest; Response:
TWebResponse; var Handled: Boolean) ( TGetErrorResponseEvent)();
```

File

XMLBrokr

Description

This is type XMLBrokr.TGetErrorResponseEvent.

78.5.2 XMLBrokr.TGetResponseEvent Type

Pascal

```
TGetResponseEvent = procedure (Sender: TObject;Request: TWebRequest; Response: TWebResponse;
var Handled: Boolean) of object;
```

C++

```
(Sender: TObject;Request: TWebRequest; Response: TWebResponse; var Handled: Boolean) (
TGetResponseEvent)();
```

File

XMLBrokr

Description

This is type XMLBrokr.TGetResponseEvent.

78.5.3 XMLBrokr.TRequestRecordsEvent Type

Pascal

```
TRequestRecordsEvent = procedure (Sender: TObject; Request: TWebRequest; out RecCount:
Integer; var OwnerData: OleVariant; var Records: string) of object;
```

C++

```
(Sender: TObject; Request: TWebRequest; out RecCount: Integer; var OwnerData: OleVariant; var
Records: string) ( TRequestRecordsEvent)();
```

File

XMLBrokr

Description

This is type XMLBrokr.TRequestRecordsEvent.

78.5.4 XMLBrokr.TRequestUpdateEvent Type

Pascal

```
TRequestUpdateEvent = procedure (Sender: TObject; Request: TWebRequest; Response:
TWebResponse; var Handled: Boolean) of object;
```

C++

```
(Sender: TObject; Request: TWebRequest; Response: TWebResponse; var Handled: Boolean) (
TRequestUpdateEvent)();
```

File

XMLBrokr

Description

This is type XMLBrokr.TRequestUpdateEvent.

78.5.5 XMLBrokr.TXMLOptions Type

Pascal

```
TXMLOptions = set of TXMLOption;
```

C++

```
TXMLOption TXMLOptions;
```

File

XMLBrokr

Description

This is type XMLBrokr.TXMLOptions.

78.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
sPostDelta (see page 7343)	This is constant XMLBrokr.sPostDelta.
sProducer (see page 7343)	This is constant XMLBrokr.sProducer.
sRedirect (see page 7343)	This is constant XMLBrokr.sRedirect.

78.6.1 XMLBrokr.sPostDelta Constant

Pascal

```
sPostDelta = 'postdelta';
```

C++

```
sPostDelta = 'postdelta';
```

File

XMLBrokr

Description

This is constant XMLBrokr.sPostDelta.

78.6.2 XMLBrokr.sProducer Constant

Pascal

```
sProducer = 'PRODUCER';
```

C++

```
sProducer = 'PRODUCER';
```

File

XMLBrokr

Description

This is constant XMLBrokr.sProducer.

78.6.3 XMLBrokr.sRedirect Constant

Pascal

```
sRedirect = 'REDIRECT';
```

C++

```
sRedirect = 'REDIRECT';
```

File

XMLBrokr

Description

This is constant XMLBrokr.sRedirect.

79 XMLDoc Namespace

This is namespace XMLDoc.

Topics

Name	Description
Classes (see page 7347)	The following table lists classes in this documentation.
Interfaces (see page 7478)	The following table lists interfaces in this documentation.
Functions (see page 7488)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 7494)	The following table lists structs, records, enums in this documentation.
Types (see page 7498)	The following table lists types in this documentation.
Variables (see page 7502)	The following table lists variables in this documentation.

Classes

	Name	Description
	TXMLDocument (see page 7347)	TXMLDocument represents an XML (see page 7392) document.
	TXMLNode (see page 7396)	TXMLNode represents a node in an XML document.
	TXMLNodeCollection (see page 7444)	TXMLNodeCollection represents a node in an XML document whose children are instances of the same repeating element.
	TXMLNodeList (see page 7460)	TXMLNodeList represents a set of nodes in an XML document.

Functions

	Name	Description
	CheckEncoding (see page 7488)	This is function XMLDoc.CheckEncoding.
	CreateDOMNode (see page 7488)	Creates a new DOM node and returns its interface.
	DetectCharEncoding (see page 7489)	This is function XMLDoc.DetectCharEncoding.
	FormatXMLData (see page 7490)	Formats a string of XML so that it is more readable.
	LoadXMLData (see page 7490)	Creates and returns the interface of an XML document object, given a string of XML.
	LoadXMLData (see page 7490)	Creates and returns the interface of an XML document object, given a string of XML.
	LoadXMLDocument (see page 7491)	Returns the interface for an XML document given the name of an XML file.
	NewXMLDocument (see page 7491)	Returns the interface for a new, empty XML document.
	XMLDocError (see page 7492)	Raises an EXMLDocError (see page 7639) exception.
	XMLDocError (see page 7492)	Raises an EXMLDocError (see page 7639) exception.
	XMLStringToUnicodeString (see page 7492)	This is function XMLDoc.XMLStringToUnicodeString.
	XMLStringToWideString (see page 7492)	This is function XMLDoc.XMLStringToWideString.

Interfaces

	Name	Description
	IXMLDocumentAccess (see page 7478)	This is class XMLDoc.IXMLDocumentAccess.
	IXMLNodeAccess (see page 7480)	This is class XMLDoc.IXMLNodeAccess.

Structs, Records, Enums

	Name	Description
	TNodeChange (see page 7494)	TNodeChange indicates the type of change made to a node in an XML document.
	TNodeClassInfo (see page 7495)	TNodeClassInfo and TNodeClassArray (see page 7499) represent information about the classes that implement XML node interfaces.
	TNodeListOperation (see page 7495)	TNodeListOperation indicates what type of change is about to occur using an IXMLNodeList (see page 7703) interface.
	TXMLDocumentSource (see page 7496)	This is record XMLDoc.TXMLDocumentSource.
	TXMLPrologItem (see page 7497)	This is record XMLDoc.TXMLPrologItem.

Types

Name	Description
TNodeChangeEvent (see page 7498)	TNodeChangeEvent is the type for event handlers that respond when XML nodes are changed.
TNodeClassArray (see page 7499)	This is type XMLDoc.TNodeClassArray.
TNodeListNotification (see page 7499)	TNodeListNotification is the type of the callback the TXMLNodeList (see page 7460) calls when it adds, deletes, or creates XML nodes.
TXMLNodeArray (see page 7500)	TXMLNodeArray is a dynamic array of TXMLNode (see page 7396) objects.
TXMLNodeClass (see page 7501)	TXMLNodeClass is a class reference to a TXMLNode (see page 7396) descendant.
TXMLNodeCollectionClass (see page 7501)	TXMLNodeCollectionClass is a class reference to a TXMLNodeCollection (see page 7444) descendant.

Variables

Name	Description
UseXSDBooleanStrings (see page 7502)	This is variable XMLDoc.UseXSDBooleanStrings.

79.1 Classes

The following table lists classes in this documentation.

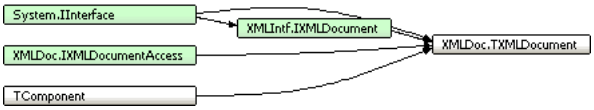
Classes

	Name	Description
	TXMLDocument (see page 7347)	TXMLDocument represents an XML (see page 7392) document.
	TXMLNode (see page 7396)	TXMLNode represents a node in an XML document.
	TXMLNodeCollection (see page 7444)	TXMLNodeCollection represents a node in an XML document whose children are instances of the same repeating element.
	TXMLNodeList (see page 7460)	TXMLNodeList represents a set of nodes in an XML document.

79.1.1 TXMLDocument Class

TXMLDocument represents an XML (see page 7392) document.

Class Hierarchy



Pascal

```
TXMLDocument = class(TComponent, IInterface, IXMLDocument, IXMLDocumentAccess);
```

C++

```
class TXMLDocument : public TComponent, public IInterface, public IXMLDocument, public
IXMLDocumentAccess;
```

File

XMLDoc

Description

Use TXMLDocument to represent an XML (see page 7392) document. TXMLDocument can read an existing XML (see page 7392) document from a file, it can be associated with an in-memory string that is the contents of an XML (see page 7392) document, or it can create a new, empty XML (see page 7392) document.

You can use TXMLDocument directly to load an XML (see page 7392) document, read and edit it, and save any changes. You can also use TXMLDocument to access the objects generated by the XML (see page 7392) Data Binding wizard.

TXMLDocument uses an external DOM (Document Object Model) parser to analyze the XML (see page 7392) document. This parser is usually assigned by specifying the DOMVendor (see page 7386) property.

When you set the Active (see page 7381) property to true, TXMLDocument uses the DOM parser to parse the XML (see page 7392) document so that you can examine or modify it. In particular, the DocumentElement (see page 7383) property provides an interface to the root node of the document. You can use that interface to access its child nodes and to add or delete child nodes.

TXMLDocument implements the IXMLDocument (see page 7640) interface. Applications obtain this interface from TXMLDocument or from the nodes in the document.

When TXMLDocument is created without an Owner, it behaves like an interfaced object. That is, when all references to its interface are released, the TXMLDocument instance is automatically freed. When TXMLDocument is created with an Owner, however, it behaves like any other component, and is freed by its Owner. When you add a TXMLDocument component from the component palette to a form or data module, it is automatically created with an Owner. When the TXMLDocument component is created using the global LoadXMLDocument (see page 7491) function (or by a function that the XML (see page 7392) Data Binding wizard generates to return the root node of the document), the function creates a TXMLDocument instance without an Owner.

Using TXMLDocument

Using Code That the XML Data Binding Wizard Generates

79.1.1.1 TXMLDocument Members

The following tables list the members exposed by TXMLDocument.

Protected Methods

	Name	Description
	_AddRef (see page 7354)	Called when an application uses a component interface.
	_Release (see page 7354)	Called when an application releases a component interface.
	AssignParseOptions (see page 7356)	This is AssignParseOptions, a member of class TXMLDocument.
	CheckActive (see page 7356)	This is CheckActive, a member of class TXMLDocument.
	CheckAutoSave (see page 7356)	This is CheckAutoSave, a member of class TXMLDocument.
	CheckDOM (see page 7356)	This is CheckDOM, a member of class TXMLDocument.
V	DefineProperties (see page 7358)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoAfterClose (see page 7359)	This is DoAfterClose, a member of class TXMLDocument.
	DoAfterOpen (see page 7359)	This is DoAfterOpen, a member of class TXMLDocument.
	DoBeforeClose (see page 7359)	This is DoBeforeClose, a member of class TXMLDocument.
	DoBeforeOpen (see page 7360)	This is DoBeforeOpen, a member of class TXMLDocument.
	DoNodeChange (see page 7360)	This is DoNodeChange, a member of class TXMLDocument.
V	GetActive (see page 7360)	Returns the value of the Active property.
	GetAsyncLoadState (see page 7361)	Returns the value of the AsyncLoadState property.
V	GetChildNodeClass (see page 7361)	This is GetChildNodeClass, a member of class TXMLDocument.
	GetChildNodes (see page 7361)	Returns the value of the ChildNodes property.
	GetDocumentElement (see page 7362)	Returns the value of the DocumentElement property.
	GetDocumentNode (see page 7362)	Returns the value of the Node property.
	GetDocumentObject (see page 7363)	This is GetDocumentObject, a member of class TXMLDocument.
	GetDOMDocument (see page 7363)	Returns the value of the DOMDocument property.
	GetDOMPersist (see page 7363)	This is GetDOMPersist, a member of class TXMLDocument.
	GetEncoding (see page 7363)	Returns the value of the Encoding property.
	GetFileName (see page 7364)	Returns the value of the FileName property.
	GetModified (see page 7364)	Returns the value of the Modified property.
	GetNodeIndentStr (see page 7364)	Returns the value of the NodeIndentStr property.
	GetOptions (see page 7365)	Returns the value of the Options property.
	GetParseOptions (see page 7365)	Returns the value of the ParseOptions property.

	GetPrologNode (see page 7365)	This is GetPrologNode, a member of class TXMLDocument.
	GetPrologValue (see page 7366)	This is GetPrologValue, a member of class TXMLDocument.
	GetSchemaRef (see page 7366)	Returns the value of the SchemaRef property.
	GetStandAlone (see page 7366)	Returns the value of the StandAlone property.
	GetVersion (see page 7366)	Returns the value of the Version property.
	GetXML (see page 7367)	Returns the value of the XML property.
	InternalSetPrologValue (see page 7367)	This is InternalSetPrologValue, a member of class TXMLDocument.
	LoadData (see page 7368)	This is LoadData, a member of class TXMLDocument.
V	Loaded (see page 7368)	Initializes the component after the form file has been read into memory.
	ReadDOMVendor (see page 7371)	This is ReadDOMVendor, a member of class TXMLDocument.
	ReleaseDoc (see page 7372)	This is ReleaseDoc, a member of class TXMLDocument.
	SaveToUTF8String (see page 7374)	This is SaveToUTF8String, a member of class TXMLDocument.
	SaveToXMLStrings (see page 7375)	Saves the XML (see page 7392) document to an internal string list.
V	SetActive (see page 7375)	Sets the value of the Active property.
	SetDocumentElement (see page 7375)	Sets the value of the DocumentElement property.
	SetDOMDocument (see page 7376)	Sets the value of the DOMDocument property.
	SetEncoding (see page 7376)	Sets the value of the Encoding property.
	SetFileName (see page 7376)	Sets the value of the FileName property.
	SetModified (see page 7377)	This is SetModified, a member of class TXMLDocument.
	SetNodeIndentStr (see page 7377)	Sets the value of the NodeIndentStr property.
	SetOnAsyncLoad (see page 7377)	Supplies an event handler that responds when the AsyncLoadState property changes.
	SetOptions (see page 7378)	Sets the value of the Options property.
	SetParseOptions (see page 7378)	Sets the value of the ParseOptions property.
	SetPrologValue (see page 7378)	This is SetPrologValue, a member of class TXMLDocument.
	SetStandAlone (see page 7378)	Sets the value of the StandAlone property.
	SetVersion (see page 7379)	Sets the value of the Version property.
	SetXML (see page 7379)	Sets the value of the XML property.
	SetXMLStrings (see page 7379)	This is SetXMLStrings, a member of class TXMLDocument.
	WriteDOMVendor (see page 7380)	This is WriteDOMVendor, a member of class TXMLDocument.
	XMLStringsChanging (see page 7380)	This is XMLStringsChanging, a member of class TXMLDocument.

Protected Properties

	Name	Description
R	DocBindingInfo (see page 7383)	This is DocBindingInfo, a member of class TXMLDocument.
	DocSource (see page 7383)	This is DocSource, a member of class TXMLDocument.
R	DOMParseOptions (see page 7385)	This is DOMParseOptions, a member of class TXMLDocument.
R	DOMPersist (see page 7386)	This is DOMPersist, a member of class TXMLDocument.
	PrefixID (see page 7391)	This is PrefixID, a member of class TXMLDocument.

Public Methods

	Name	Description
	AddChild (see page 7354)	This is the overview for the AddChild method overload.
	AddChild (see page 7643)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 7355)	Responds after the last constructor has executed.
	Create (see page 7351)	This is the overview for the Create constructor overload.
	CreateElement (see page 7357)	Creates a new element node that is associated with this document.
	CreateNode (see page 7357)	Creates a new node that is associated with this document.
V	Destroy (see page 7352)	Disposes of a TXMLDocument (see page 7347) object.
	GeneratePrefix (see page 7360)	Generates a unique namespace prefix that can be used for a node in the document.
	GetDocBinding (see page 7362)	Replaces the document element with an instance of a specified implementation class.
	IsEmptyDoc (see page 7367)	Indicates whether the TXMLDocument (see page 7347) instance represents an empty document.
	LoadFromFile (see page 7368)	Loads an XML (see page 7392) document and activates it.

	LoadFromStream (see page 7369)	Loads an XML (see page 7392) document from a stream and activates it.
	LoadFromXML (see page 7370)	This is the overview for the LoadFromXML method overload.
	LoadFromXML (see page 7653)	This is the overview for the LoadFromXML method overload.
V	NewInstance (see page 7370)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	Refresh (see page 7371)	Updates the parsed XML (see page 7392) document to reflect external changes.
	RegisterDocBinding (see page 7372)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7372)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7373)	Saves the XML (see page 7392) document to disk.
	SaveToStream (see page 7373)	Saves the XML (see page 7392) document to a stream.
	SaveToXML (see page 7374)	This is the overview for the SaveToXML method overload.
	SaveToXML (see page 7656)	This is the overview for the SaveToXML method overload.

Public Properties

	Name	Description
R	AsyncLoadState (see page 7382)	Indicates the state of the DOM parser when it parses the XML (see page 7392) document asynchronously.
R	ChildNodes (see page 7383)	Lists all of the child nodes of the document.
	DocumentElement (see page 7383)	Provides access to the root node of the XML (see page 7392) document.
R	DocumentObject (see page 7479)	This is DocumentObject, a member of class IXMLDocumentAccess.
	DOMDocument (see page 7384)	Provides access to the DOM interface for the parsed XML (see page 7392) document.
	DOMImplementation (see page 7385)	Provides access to the DOM interface for document-independent functions.
	Encoding (see page 7386)	Indicates the character set that the XML (see page 7392) document uses to encode characters.
R	Modified (see page 7387)	Indicates whether the XML (see page 7392) document has been modified.
R	Node (see page 7388)	Provides access to the document node for the XML (see page 7392) document.
	NSPrefixBase (see page 7389)	Specifies the base string for automatically-generated namespace prefixes.
R	SchemaRef (see page 7391)	Returns the name of the schema associated with this XML (see page 7392) document.
	StandAlone (see page 7391)	Indicates whether the XML (see page 7392) document includes any external markup declarations.
	Version (see page 7391)	Indicates the XML (see page 7392) version that the document uses.

Published Events

	Name	Description
	AfterClose (see page 7393)	Occurs after the XML (see page 7392) document is closed.
	AfterNodeChange (see page 7393)	Occurs after a change is made to one of the nodes in the document.
	AfterOpen (see page 7394)	Occurs immediately after the XML (see page 7392) document is opened.
	BeforeClose (see page 7394)	Occurs immediately before the XML (see page 7392) document is closed.
	BeforeNodeChange (see page 7394)	Occurs before a change is made to one of the nodes in the document.
	BeforeOpen (see page 7395)	Occurs immediately before the XML (see page 7392) document is opened.
	OnAsyncLoad (see page 7395)	Occurs at various stages during the asynchronous parsing of an XML (see page 7392) document.

Published Properties

	Name	Description
	Active (see page 7381)	Specifies whether the XML (see page 7392) document has been parsed so that the DOM interfaces are available to examine or change its contents.
	DOMVendor (see page 7386)	Specifies the DOM implementation to use for parsing and manipulating the XML (see page 7392) document.
	FileName (see page 7387)	Specifies the file name for the XML (see page 7392) document associated with this TXMLDocument (see page 7347) object.
	NodeIndentStr (see page 7388)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7392) text.

	Options (see page 7389)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7390)	Specifies implementation-specific options that are followed when parsing the XML (see page 7392) document.
	XML (see page 7392)	Specifies the content of the XML document associated with this TXMLDocument (see page 7347) object.

79.1.1.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TXMLDocument.Create (DOMString) (see page 7351)	Instantiates a TXMLDocument (see page 7347) object.
	TXMLDocument.Create (TComponent) (see page 7351)	Instantiates a TXMLDocument (see page 7347) object.

79.1.1.2.1 TXMLDocument.Create Constructor (DOMString)

Instantiates a TXMLDocument (see page 7347) object.

Pascal

```
constructor Create(AOwner: TComponent); override; overload;
constructor Create(const AFileName: DOMString); overload; reintroduce;
```

C++

```
virtual __fastcall TXMLDocument(TComponent * AOwner);
__fastcall TXMLDocument(const DOMString AFileName);
```

Description

Call Create to instantiate a TXMLDocument (see page 7347) component at runtime. You do not need to explicitly create TXMLDocument (see page 7347) components that are added to forms or data modules at design time: they are created automatically.

AFileName specifies the file that the new TXMLDocument (see page 7347) instance represents.

AOwner is another component that is responsible for freeing the TXMLDocument (see page 7347) instance. It becomes the value of the Owner property.

TXMLDocument (see page 7347) components that are created at runtime without an owner are freed automatically when all references to their IXMLDocument (see page 7640) interface are released. This differs from TXMLDocument (see page 7347) components added to a form or data module at design time or those created with an owner. When added to a form or data module at design time, the object is explicitly freed by its Owner (the form or data module).

See Also

FileName (see page 7387)

IXMLDocument (see page 7640)

Owner

79.1.1.3 TXMLDocument.Destroy Destructor

Disposes of a TXMLDocument (see page 7347) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLDocument();
```

Description

It is not necessary to explicitly free a TXMLDocument (see page 7347) component. If the component is created with an Owner, that Owner handles the task of freeing the document. If the component is created without an Owner, it is freed automatically when the reference count on its IXMLDocument (see page 7640) interface drops to zero.

See Also

Create (see page 7351)

79.1.1.4 TXMLDocument Methods

The methods of the TXMLDocument class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 7354)	Called when an application uses a component interface.
	_Release (see page 7354)	Called when an application releases a component interface.
	AssignParseOptions (see page 7356)	This is AssignParseOptions, a member of class TXMLDocument.
	CheckActive (see page 7356)	This is CheckActive, a member of class TXMLDocument.
	CheckAutoSave (see page 7356)	This is CheckAutoSave, a member of class TXMLDocument.
	CheckDOM (see page 7356)	This is CheckDOM, a member of class TXMLDocument.
V	DefineProperties (see page 7358)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoAfterClose (see page 7359)	This is DoAfterClose, a member of class TXMLDocument.
	DoAfterOpen (see page 7359)	This is DoAfterOpen, a member of class TXMLDocument.
	DoBeforeClose (see page 7359)	This is DoBeforeClose, a member of class TXMLDocument.
	DoBeforeOpen (see page 7360)	This is DoBeforeOpen, a member of class TXMLDocument.
	DoNodeChange (see page 7360)	This is DoNodeChange, a member of class TXMLDocument.
V	GetActive (see page 7360)	Returns the value of the Active property.
	GetAsyncLoadState (see page 7361)	Returns the value of the AsyncLoadState property.
V	GetChildNodeClass (see page 7361)	This is GetChildNodeClass, a member of class TXMLDocument.
	GetChildNodes (see page 7361)	Returns the value of the ChildNodes property.
	GetDocumentElement (see page 7362)	Returns the value of the DocumentElement property.
	GetDocumentNode (see page 7362)	Returns the value of the Node property.
	GetDocumentObject (see page 7363)	This is GetDocumentObject, a member of class TXMLDocument.
	GetDOMDocument (see page 7363)	Returns the value of the DOMDocument property.
	GetDOMPersist (see page 7363)	This is GetDOMPersist, a member of class TXMLDocument.
	GetEncoding (see page 7363)	Returns the value of the Encoding property.
	GetFileName (see page 7364)	Returns the value of the FileName property.
	GetModified (see page 7364)	Returns the value of the Modified property.
	GetNodeIndentStr (see page 7364)	Returns the value of the NodeIndentStr property.
	GetOptions (see page 7365)	Returns the value of the Options property.
	GetParseOptions (see page 7365)	Returns the value of the ParseOptions property.

	GetPrologNode (see page 7365)	This is GetPrologNode, a member of class TXMLDocument.
	GetPrologValue (see page 7366)	This is GetPrologValue, a member of class TXMLDocument.
	GetSchemaRef (see page 7366)	Returns the value of the SchemaRef property.
	GetStandAlone (see page 7366)	Returns the value of the StandAlone property.
	GetVersion (see page 7366)	Returns the value of the Version property.
	GetXML (see page 7367)	Returns the value of the XML property.
	InternalSetPrologValue (see page 7367)	This is InternalSetPrologValue, a member of class TXMLDocument.
	LoadData (see page 7368)	This is LoadData, a member of class TXMLDocument.
V	Loaded (see page 7368)	Initializes the component after the form file has been read into memory.
	ReadDOMVendor (see page 7371)	This is ReadDOMVendor, a member of class TXMLDocument.
	ReleaseDoc (see page 7372)	This is ReleaseDoc, a member of class TXMLDocument.
	SaveToUTF8String (see page 7374)	This is SaveToUTF8String, a member of class TXMLDocument.
	SaveToXMLStrings (see page 7375)	Saves the XML (see page 7392) document to an internal string list.
V	SetActive (see page 7375)	Sets the value of the Active property.
	SetDocumentElement (see page 7375)	Sets the value of the DocumentElement property.
	SetDOMDocument (see page 7376)	Sets the value of the DOMDocument property.
	SetEncoding (see page 7376)	Sets the value of the Encoding property.
	SetFileName (see page 7376)	Sets the value of the FileName property.
	SetModified (see page 7377)	This is SetModified, a member of class TXMLDocument.
	SetNodeIndentStr (see page 7377)	Sets the value of the NodeIndentStr property.
	SetOnAsyncLoad (see page 7377)	Supplies an event handler that responds when the AsyncLoadState property changes.
	SetOptions (see page 7378)	Sets the value of the Options property.
	SetParseOptions (see page 7378)	Sets the value of the ParseOptions property.
	SetPrologValue (see page 7378)	This is SetPrologValue, a member of class TXMLDocument.
	SetStandAlone (see page 7378)	Sets the value of the StandAlone property.
	SetVersion (see page 7379)	Sets the value of the Version property.
	SetXML (see page 7379)	Sets the value of the XML property.
	SetXMLStrings (see page 7379)	This is SetXMLStrings, a member of class TXMLDocument.
	WriteDOMVendor (see page 7380)	This is WriteDOMVendor, a member of class TXMLDocument.
	XMLStringsChanging (see page 7380)	This is XMLStringsChanging, a member of class TXMLDocument.

Public Methods

	Name	Description
	AddChild (see page 7354)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 7355)	Responds after the last constructor has executed.
	CreateElement (see page 7357)	Creates a new element node that is associated with this document.
	CreateNode (see page 7357)	Creates a new node that is associated with this document.
	GeneratePrefix (see page 7360)	Generates a unique namespace prefix that can be used for a node in the document.
	GetDocBinding (see page 7362)	Replaces the document element with an instance of a specified implementation class.
	IsEmptyDoc (see page 7367)	Indicates whether the TXMLDocument (see page 7347) instance represents an empty document.
	LoadFromFile (see page 7368)	Loads an XML (see page 7392) document and activates it.
	LoadFromStream (see page 7369)	Loads an XML (see page 7392) document from a stream and activates it.
	LoadFromXML (see page 7370)	This is the overview for the LoadFromXML method overload.
V	NewInstance (see page 7370)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Refresh (see page 7371)	Updates the parsed XML (see page 7392) document to reflect external changes.
	RegisterDocBinding (see page 7372)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7372)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7373)	Saves the XML (see page 7392) document to disk.
	SaveToStream (see page 7373)	Saves the XML (see page 7392) document to a stream.
	SaveToXML (see page 7374)	This is the overview for the SaveToXML method overload.

79.1.1.4.1 TXMLDocument._AddRef Method

Called when an application uses a component interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef is a basic implementation of the IInterface method, _AddRef.

Note: If the component is a wrapper for a COM object, __AddRef calls the _AddRef method of that COM object, and returns the resulting reference count.

In all other cases, __AddRef simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __AddRef to implement reference counting.

See Also

QueryInterface

_Release

_AddRef (see page 3503)

79.1.1.4.2 TXMLDocument._Release Method

Called when an application releases a component interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release is a basic implementation of the IInterface method, _Release.

__Release returns the resulting value of the reference count for the component's interface.

Note:

In all other cases, __Release simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __Release to implement reference counting.

See Also

QueryInterface

_AddRef

79.1.1.4.3 AddChild Method

This is the overview for the AddChild method overload.

Overload List

	Name	Description
	TXMLDocument.AddChild (DOMString) (see page 7355)	Creates and adds a node to the child nodes of this document.
	TXMLDocument.AddChild (DOMString, DOMString) (see page 7355)	Creates and adds a node to the child nodes of this document.

79.1.1.4.3.1 TXMLDocument.AddChild Method (DOMString)

Creates and adds a node to the child nodes of this document.

Pascal

```
function AddChild(const TagName: DOMString): IXMLNode; overload;
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode AddChild(const DOMString TagName);
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI);
```

Description

Call AddChild to add a new child element node to the document itself. The new node is added to the end of the list maintained by the ChildNodes (see page 7383) property.

TagName is the tag name for the new element node.

NamespaceURI identifies the namespace, if any, that includes the new node's definition.

AddChild returns the interface for the newly created node.

Note: Do not call AddChild to add a child to the document element of this document. When adding data to the XML (see page 7392) document, use the AddChild method of the document element or of the node in the hierarchy that should be the parent of the new node.

See Also

AddChild (see page 7672)

CreateNode (see page 7357)

CreateElement (see page 7357)

ChildNodes (see page 7383)

DocumentElement (see page 7383)

79.1.1.4.4 TXMLDocument.AfterConstruction Method

Responds after the last constructor has executed.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly

in your applications.

The System::TObject::AfterConstruction method implemented in System::TObject does nothing. Override this method when creating a class that takes some action after the object is created. For example, TCustomForm overrides System::TObject::AfterConstruction to generate an OnCreate event.

See Also

System::TObject::BeforeDestruction (see page 3358)

OnCreate

System::TObject::Create (see page 3355)

79.1.1.4.5 TXMLDocument.AssignParseOptions Method

Pascal

```
procedure AssignParseOptions;
```

C++

```
__fastcall AssignParseOptions();
```

Description

This is AssignParseOptions, a member of class TXMLDocument.

79.1.1.4.6 TXMLDocument.CheckActive Method

Pascal

```
procedure CheckActive;
```

C++

```
__fastcall CheckActive();
```

Description

This is CheckActive, a member of class TXMLDocument.

79.1.1.4.7 TXMLDocument.CheckAutoSave Method

Pascal

```
procedure CheckAutoSave; dynamic;
```

C++

```
__fastcall CheckAutoSave();
```

Description

This is CheckAutoSave, a member of class TXMLDocument.

79.1.1.4.8 TXMLDocument.CheckDOM Method

Pascal

```
procedure CheckDOM; dynamic;
```

C++

```
__fastcall CheckDOM();
```

Description

This is CheckDOM, a member of class TXMLDocument.

79.1.1.4.9 TXMLDocument.CreateElement Method

Creates a new element node that is associated with this document.

Pascal

```
function CreateElement(const TagOrData: DOMString; const NamespaceURI: DOMString): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateElement(const DOMString TagOrData, const DOMString NamespaceURI);
```

Description

Call CreateElement to create a new generic element node. The resulting node does not have a parent, but can be added to the ChildNodes (see page 7383) list of any node in the document (including this document's ChildNodes (see page 7383) property). It can also be assigned to the DocumentElement (see page 7383) property to replace the entire data hierarchy of this document.

TagOrData provides the tag name of the newly created node.

NamespaceURI identifies the namespace that includes the new node's definition.

CreateElement returns the interface for the new node.

Note: To add a node as the child of another node in this document, it is simpler to call that node's AddChild (see page 7355) method.

See Also

AddChild (see page 7672)

ChildNodes (see page 7383)

DocumentElement (see page 7383)

AddChild (see page 7355)

CreateNode (see page 7357)

79.1.1.4.10 TXMLDocument.CreateNode Method

Creates a new node that is associated with this document.

Pascal

```
function CreateNode(const NameOrData: DOMString; NodeType: TNodeType = ntElement; const
AddlData: DOMString = ''): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateNode(const DOMString NameOrData, TNodeType NodeType = ntElement,
const DOMString AddlData = '');
```

Description

Call CreateNode to create a new generic XML (see page 7392) node. The resulting node does not have a parent, but can be added to the ChildNodes (see page 7383) or AttributeNodes list of any node in the document (including this document's ChildNodes (see page 7383) property). It can also be assigned to the DocumentElement (see page 7383) property to replace the entire data hierarchy of this document.

NameOrData provides the tag name or value of the newly created node. Its interpretation depends on the type of node created, as indicated in the following table:

NodeType	NameOrData
ntElement	The tag name.
ntAttribute	The attribute name.
ntText	The value of the node.
ntCData	The value of the CDATA section.
ntEntityRef	The name of the referenced entity.
ntProcessingInstr	The target of the processing instruction.
ntComment	The value (text) of the comment.
ntDocFragment	Not used.
ntElement	The namespace URI that qualifies the tag name.
ntAttribute	The namespace URI that qualifies the attribute name.
ntProcessingInstr	The content of the processing instruction, except for the target.

NodeType indicates the type of node to create. It can only be one of the types listed in the previous table.

The meaning of AddlData depends on the node type, as indicated in the following table:

NodeType	AddlData
ntElement	The namespace URI that qualifies the tag name.
ntAttribute	The namespace URI that qualifies the attribute name.
ntProcessingInstr	The content of the processing instruction, except for the target.

CreateNode returns the interface for the new node.

Note: To add a node as the child of another node in this document, it is simpler to call that node's AddChild (see page 7355) method.

See Also

AddChild (see page 7672)

ChildNodes (see page 7383)

AttributeNodes (see page 7438)

DocumentElement (see page 7383)

AddChild (see page 7355)

CreateElement (see page 7357)

CreateDOMNode (see page 7488)

79.1.1.4.11 TXMLDocument.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent overrides the DefineProperties method defined in TPersistent to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

Ancestor

DefineBinaryProperty

DefineProperties

DefineProperty

79.1.1.4.12 TXMLDocument.DoAfterClose Method

Pascal

```
procedure DoAfterClose; dynamic;
```

C++

```
__fastcall DoAfterClose();
```

Description

This is DoAfterClose, a member of class TXMLDocument.

79.1.1.4.13 TXMLDocument.DoAfterOpen Method

Pascal

```
procedure DoAfterOpen; dynamic;
```

C++

```
__fastcall DoAfterOpen();
```

Description

This is DoAfterOpen, a member of class TXMLDocument.

79.1.1.4.14 TXMLDocument.DoBeforeClose Method

Pascal

```
procedure DoBeforeClose; dynamic;
```

C++

```
__fastcall DoBeforeClose();
```

Description

This is DoBeforeClose, a member of class TXMLDocument.

79.1.1.4.15 TXMLDocument.DoBeforeOpen Method

Pascal

```
procedure DoBeforeOpen; dynamic;
```

C++

```
__fastcall DoBeforeOpen();
```

Description

This is DoBeforeOpen, a member of class TXMLDocument.

79.1.1.4.16 TXMLDocument.DoNodeChange Method

Pascal

```
procedure DoNodeChange(const Node: IXMLNode; ChangeType: TNodeChange; BeforeOperation:
Boolean);
```

C++

```
__fastcall DoNodeChange(const IXMLNode Node, TNodeChange ChangeType, Boolean BeforeOperation);
```

Description

This is DoNodeChange, a member of class TXMLDocument.

79.1.1.4.17 TXMLDocument.GeneratePrefix Method

Generates a unique namespace prefix that can be used for a node in the document.

Pascal

```
function GeneratePrefix(const Node: IXMLNode): DOMString;
```

C++

```
__fastcall DOMString GeneratePrefix(const IXMLNode Node);
```

Description

Call GeneratePrefix to generate a new namespace prefix that is not already used in the document to represent a namespace URI. GeneratePrefix uses the NSPrefixBase (see page 7389) property to generate a unique string to act as a namespace prefix. This unique string consists of NSPrefixBase (see page 7389) followed by a number that ensures uniqueness. Thus, for example, if NSPrefixBase (see page 7389) is 'NS', automatically-generated namespace prefixes have the form 'NS1', 'NS2', and so on.

Node (see page 7388) is the interface for the node which will use the newly-generated namespace prefix.

The generated namespace prefixes are only unique within a single document. If two document components have the same value for NSPrefixBase (see page 7389), they will generate the same namespace prefixes.

See Also

NSPrefixBase (see page 7389)

79.1.1.4.18 TXMLDocument.GetActive Method

Returns the value of the Active property.

Pascal

```
function GetActive: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetActive();
```

Description

GetActive is the read implementation of the Active property.

See Also

Active (see page 7661)

79.1.1.4.19 TXMLDocument.GetAsyncLoadState Method

Returns the value of the AsyncLoadState property.

Pascal

```
function GetAsyncLoadState: Integer;
```

C++

```
__fastcall int GetAsyncLoadState();
```

Description

GetAsyncLoadState is the read implementation of the AsyncLoadState property.

See Also

AsyncLoadState (see page 7662)

79.1.1.4.20 TXMLDocument.GetChildNodeClass Method

Pascal

```
function GetChildNodeClass(const Node: IDOMNode): TXMLNodeClass; virtual;
```

C++

```
virtual __fastcall TXMLNodeClass GetChildNodeClass(const IDOMNode Node);
```

Description

This is GetChildNodeClass, a member of class TXMLDocument.

79.1.1.4.21 TXMLDocument.GetChildNodes Method

Returns the value of the ChildNodes property.

Pascal

```
function GetChildNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetChildNodes();
```

Description

GetChildNodes is the read implementation of the ChildNodes property.

See Also

ChildNodes (see page 7663)

79.1.1.4.22 TXMLDocument.GetDocBinding Method

Replaces the document element with an instance of a specified implementation class.

Pascal

```
function GetDocBinding(const TagName: DOMString; DocNodeClass: TClass; NamespaceURI: DOMString
= ''): IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocBinding(const DOMString TagName, TClass DocNodeClass, DOMString
NamespaceURI = '');
```

Description

Call GetDocBinding to specify the implementation class and tag name for the document element. After replacing the specified node with an instance of the specified class, GetDocBinding returns the interface of the document element.

TagName is the tag name of the child node to be replaced. Typically, this identifies the document element.

DocNodeClass is the implementation class to use for all child nodes with the specified tag name.

NamespaceURI is the URI of the namespace in which TagName is defined.

See Also

DocumentElement (see page 7383)

RegisterDocBinding (see page 7372)

ChildNodes (see page 7383)

79.1.1.4.23 TXMLDocument.GetDocumentElement Method

Returns the value of the DocumentElement property.

Pascal

```
function GetDocumentElement: IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocumentElement();
```

Description

GetDocumentElement is the read implementation of the DocumentElement property.

See Also

DocumentElement (see page 7663)

79.1.1.4.24 TXMLDocument.GetDocumentNode Method

Returns the value of the Node property.

Pascal

```
function GetDocumentNode: IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocumentNode();
```

Description

GetDocumentNode is the read implementation of the Node property.

See Also

Node (see page 7665)

79.1.1.4.25 TXMLDocument.GetDocumentObject Method

Pascal

```
function GetDocumentObject: TXMLDocument;
```

C++

```
__fastcall TXMLDocument GetDocumentObject();
```

Description

This is GetDocumentObject, a member of class TXMLDocument.

79.1.1.4.26 TXMLDocument.GetDOMDocument Method

Returns the value of the DOMDocument property.

Pascal

```
function GetDOMDocument: IDOMDocument;
```

C++

```
__fastcall IDOMDocument GetDOMDocument();
```

Description

GetDOMDocument is the read implementation of the DOMDocument property.

See Also

DOMDocument (see page 7663)

79.1.1.4.27 TXMLDocument.GetDOMPersist Method

Pascal

```
function GetDOMPersist: IDOMPersist;
```

C++

```
__fastcall IDOMPersist GetDOMPersist();
```

Description

This is GetDOMPersist, a member of class TXMLDocument.

79.1.1.4.28 TXMLDocument.GetEncoding Method

Returns the value of the Encoding property.

Pascal

```
function GetEncoding: DOMString;
```

C++

```
__fastcall DOMString GetEncoding();
```

Description

GetEncoding is the read implementation of the Encoding property.

See Also

Encoding (see page 7664)

79.1.1.4.29 TXMLDocument.GetFileName Method

Returns the value of the FileName property.

Pascal

```
function GetFileName: DOMString;
```

C++

```
__fastcall DOMString GetFileName();
```

Description

GetFileName is the read implementation of the FileName property.

See Also

FileName (see page 7664)

79.1.1.4.30 TXMLDocument.GetModified Method

Returns the value of the Modified property.

Pascal

```
function GetModified: Boolean;
```

C++

```
__fastcall Boolean GetModified();
```

Description

GetModified is the read implementation of the Modified property.

See Also

Modified (see page 7665)

79.1.1.4.31 TXMLDocument.GetNodeIndentStr Method

Returns the value of the NodeIndentStr property.

Pascal

```
function GetNodeIndentStr: DOMString;
```

C++

```
__fastcall DOMString GetNodeIndentStr();
```

Description

GetNodeIndentStr is the read implementation of the NodeIndentStr property.

See Also

NodeIndentStr (see page 7666)

79.1.1.4.32 TXMLDocument.GetOptions Method

Returns the value of the Options property.

Pascal

```
function GetOptions: TXMLDocOptions;
```

C++

```
__fastcall TXMLDocOptions GetOptions();
```

Description

GetOptions is the read implementation of the Options property.

See Also

Options (see page 7666)

79.1.1.4.33 TXMLDocument.GetParseOptions Method

Returns the value of the ParseOptions property.

Pascal

```
function GetParseOptions: TParseOptions;
```

C++

```
__fastcall TParseOptions GetParseOptions();
```

Description

GetParseOptions is the read implementation of the ParseOptions property.

See Also

ParseOptions (see page 7667)

79.1.1.4.34 TXMLDocument.GetPrologNode Method

Pascal

```
function GetPrologNode: IXMLNode;
```

C++

```
__fastcall IXMLNode GetPrologNode();
```

Description

This is GetPrologNode, a member of class TXMLDocument.

79.1.1.4.35 TXMLDocument.GetPrologValue Method

Pascal

```
function GetPrologValue(PrologItem: TXMLPrologItem; const Default: DOMString = ''): DOMString;
```

C++

```
__fastcall DOMString GetPrologValue(TXMLPrologItem PrologItem, const DOMString Default = '');
```

Description

This is GetPrologValue, a member of class TXMLDocument.

79.1.1.4.36 TXMLDocument.GetSchemaRef Method

Returns the value of the SchemaRef property.

Pascal

```
function GetSchemaRef: DOMString;
```

C++

```
__fastcall DOMString GetSchemaRef();
```

Description

GetSchemaRef is the read implementation of the SchemaRef property.

See Also

SchemaRef (see page 7667)

79.1.1.4.37 TXMLDocument.GetStandAlone Method

Returns the value of the StandAlone property.

Pascal

```
function GetStandAlone: DOMString;
```

C++

```
__fastcall DOMString GetStandAlone();
```

Description

GetStandAlone is the read implementation of the StandAlone property.

See Also

StandAlone (see page 7668)

79.1.1.4.38 TXMLDocument.GetVersion Method

Returns the value of the Version property.

Pascal

```
function GetVersion: DOMString;
```

C++

```
__fastcall DOMString GetVersion();
```

Description

GetVersion is the read implementation of the Version property.

See Also

Version (see page 7668)

79.1.1.4.39 TXMLDocument.GetXML Method

Returns the value of the XML property.

Pascal

```
function GetXML: TStrings;
```

C++

```
__fastcall TStrings GetXML();
```

Description

GetXML is the read implementation of the XML property.

See Also

XML (see page 7668)

79.1.1.4.40 TXMLDocument.InternalSetPrologValue Method

Pascal

```
function InternalSetPrologValue(const PrologNode: IXMLNode; const Value: Variant; PrologItem:
TXMLPrologItem): string;
```

C++

```
__fastcall UnicodeString InternalSetPrologValue(const IXMLNode PrologNode, const Variant
Value, TXMLPrologItem PrologItem);
```

Description

This is InternalSetPrologValue, a member of class TXMLDocument.

79.1.1.4.41 TXMLDocument.IsEmptyDoc Method

Indicates whether the TXMLDocument (see page 7347) instance represents an empty document.

Pascal

```
function IsEmptyDoc: Boolean;
```

C++

```
__fastcall Boolean IsEmptyDoc();
```

Description

Call IsEmptyDoc to determine whether the TXMLDocument (see page 7347) instance represents an empty document. IsEmptyDoc returns true if the DOMDocument (see page 7384) property is not set (for example, if there is no DOM implementation) or if this object represents a document with no child nodes.

See Also

XML (see page 7392)

ChildNodes (see page 7383)

DOMDocument (see page 7384)

79.1.1.4.42 TXMLDocument.LoadData Method

Pascal

```
procedure LoadData; dynamic;
```

C++

```
__fastcall LoadData();
```

Description

This is LoadData, a member of class TXMLDocument.

79.1.1.4.43 TXMLDocument.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling pointers can be used after being streamed in.

As implemented in TComponent, Loaded clears the csLoading flag in the ComponentState property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

See Also

ComponentState

Create

TReader

79.1.1.4.44 TXMLDocument.LoadFromFile Method

Loads an XML (see page 7392) document and activates it.

Pascal

```
procedure LoadFromFile(const AFileName: DOMString = '');
```

C++

```
__fastcall LoadFromFile(const DOMString AFileName = '');
```

Description

Call LoadFromFile to load the XML (see page 7392) document specified by AFileName and set the Active (see page 7381) property to true so that you can examine or modify the document.

AFileName is the name of the XML (see page 7392) document to load from disk. If AFileName is an empty string, TXMLDocument (see page 7347) uses the value of the FileName (see page 7387) property. If AFileName is not an empty string, TXMLDocument (see page 7347) changes the FileName (see page 7387) property to AFileName.

Once you have loaded an XML (see page 7392) document, any changes you make to the document are not saved back to disk until you call the SaveToFile (see page 7373) method.

See Also

SaveToFile (see page 7373)

FileName (see page 7387)

Active (see page 7381)

Refresh (see page 7371)

LoadFromXML (see page 7370)

LoadFromStream (see page 7369)

79.1.1.4.45 TXMLDocument.LoadFromStream Method

Loads an XML (see page 7392) document from a stream and activates it.

Pascal

```
procedure LoadFromStream(const Stream: TStream; EncodingType: TXMLEncodingType = xetUnknown);
```

C++

```
__fastcall LoadFromStream(const TStream Stream, TXMLEncodingType EncodingType = xetUnknown);
```

Description

Call LoadFromStream to load the XML (see page 7392) document from a stream.

Stream is a stream object that can be used to read the string of XML (see page 7392) that makes up the document.

EncodingType indicates the character set that is used for Stream. If EncodingType is xetUnknown (the default), LoadFromStream attempts to infer the encoding type from the XML (see page 7392) encoding declaration at the beginning of the document.

After loading the document from Stream, LoadFromStream sets the Active (see page 7381) property to true.

See Also

SaveToStream (see page 7373)

LoadFromFile (see page 7368)

Active (see page 7381)

LoadFromXML (see page 7370)

79.1.1.4.46 LoadFromXML Method

This is the overview for the LoadFromXML method overload.

Overload List

	Name	Description
	TXMLDocument.LoadFromXML (AnsiString) (see page 7370)	Loads a string representation of an XML (see page 7392) document and activates it.
	TXMLDocument.LoadFromXML (DOMString) (see page 7370)	Loads a string representation of an XML (see page 7392) document and activates it.

79.1.1.4.46.1 TXMLDocument.LoadFromXML Method (AnsiString)

Loads a string representation of an XML (see page 7392) document and activates it.

Pascal

```
procedure LoadFromXML(const XML: AnsiString); overload;
procedure LoadFromXML(const XML: DOMString); overload;
```

C++

```
__fastcall LoadFromXML(const AnsiString XML);
__fastcall LoadFromXML(const DOMString XML);
```

Description

Call LoadFromXML to assign a string as the value of the XML (see page 7392) document. Unlike the XML (see page 7392) property, which lets you assign XML (see page 7392) on a line-by-line basis, LoadFromXML treats the text of the XML (see page 7392) document as a whole.

The XML (see page 7392) parameter is a string containing the text of an XML (see page 7392) document. It should represent the XML (see page 7392) text encoded using UTF-8, Unicode, or UTF-16.

After assigning the XML (see page 7392) property as the contents of the document, LoadFromXML sets the Active (see page 7381) property to true.

See Also

SaveToXML (see page 7374)

LoadFromFile (see page 7368)

Active (see page 7381)

LoadFromStream (see page 7369)

XML (see page 7392)

79.1.1.4.47 TXMLDocument.NewInstance Method

Allocates memory for an instance of an object type and returns a pointer to that new instance.

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
virtual __fastcall TObject * NewInstance();
```

Description

All constructors call System::TObject::NewInstance automatically. System::TObject::NewInstance calls System::TObject::InstanceSize to determine how much memory to allocate from the heap to contain a particular instance. Do not call System::TObject::NewInstance directly.

Override System::TObject::NewInstance only for special memory allocation requirements. For example, when allocating a large number of identical objects that all need to be in memory at the same time, you could allocate a single block of memory for the entire group, then override System::TObject::NewInstance to use part of that larger block for each instance.

If you override System::TObject::NewInstance to allocate memory, you may need to override System::TObject::FreeInstance to deallocate the memory.

Note: By default System::TObject::NewInstance calls System::TObject::InitInstance.

See Also

System::TObject::FreeInstance (see page 3374)

System::TObject::InstanceSize (see page 3377)

System::TObject::InitInstance (see page 3377)

79.1.1.4.48 TXMLDocument.ReadDOMVendor Method

Pascal

```
procedure ReadDOMVendor(Reader: TReader);
```

C++

```
__fastcall ReadDOMVendor(TReader Reader);
```

Description

This is ReadDOMVendor, a member of class TXMLDocument.

79.1.1.4.49 TXMLDocument.Refresh Method

Updates the parsed XML (see page 7392) document to reflect external changes.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh when the XML (see page 7392) document specified by FileName (see page 7387) has changed due to an external cause. Refresh updates the parsed version of the XML (see page 7392) document (which can be traversed starting with DocumentElement (see page 7383)) to reflect the current contents of the file specified by FileName (see page 7387).

The Active (see page 7381) property must be true when you call Refresh. If the XML (see page 7392) document is not active when you call Refresh, TXMLDocument (see page 7347) raises an EXMLDocError (see page 7639) exception.

Note: Do not call Refresh after making changes directly to the XML (see page 7392) property, because assigning a value to XML (see page 7392) automatically closes the XML (see page 7392) document. To refresh the XML (see page 7392) document after assigning a new value to XML (see page 7392), set the Active (see page 7381) property to true.

See Also

FileName (see page 7387)

Active (see page 7381)

DOMDocument (see page 7384)

DocumentElement (see page 7383)

Resync (see page 7372)

79.1.1.4.50 TXMLDocument.RegisterDocBinding Method

Registers an implementation class for child nodes with a specified tag name.

Pascal

```
procedure RegisterDocBinding(const TagName: DOMString; DocNodeClass: TClass; NamespaceURI:
DOMString = '');
```

C++

```
__fastcall RegisterDocBinding(const DOMString TagName, TClass DocNodeClass, DOMString
NamespaceURI = '');
```

Description

Call RegisterDocBinding to specify the implementation class for one of the child nodes of the document node. RegisterDocBinding replaces the specified node with an instance of the specified class.

TagName is the tag name of the child node to be replaced. Typically, this identifies the document element.

DocNodeClass is the implementation class to use for all child nodes with the specified tag name.

NamespaceURI is the URI of the namespace in which TagName is defined.

See Also

DocumentElement (see page 7383)

GetDocBinding (see page 7362)

ChildNodes (see page 7383)

79.1.1.4.51 TXMLDocument.ReleaseDoc Method

Pascal

```
procedure ReleaseDoc(const CheckSave: Boolean = True); dynamic;
```

C++

```
__fastcall ReleaseDoc(const Boolean CheckSave = True);
```

Description

This is ReleaseDoc, a member of class TXMLDocument.

79.1.1.4.52 TXMLDocument.Resync Method

Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.

Pascal

```
procedure Resync;
```

C++

```
__fastcall Resync();
```

Description

Resync forces the document to reread the values of its child nodes and attribute nodes, discarding any changes that have not been propagated to the underlying DOM implementation.

See Also

ChildNodes (see page 7383)

Refresh (see page 7371)

79.1.1.4.53 TXMLDocument.SaveToFile Method

Saves the XML (see page 7392) document to disk.

Pascal

```
procedure SaveToFile(const AFileName: DOMString = ''); dynamic;
```

C++

```
__fastcall SaveToFile(const DOMString AFileName = '');
```

Description

Call SaveToFile to save any modifications you have made to the parsed XML (see page 7392) document.

AFileName is the name of the file to save. If AFileName is an empty string, TXMLDocument (see page 7347) uses the value of the FileName (see page 7387) property.

See Also

LoadFromFile (see page 7368)

FileName (see page 7387)

SaveToXML (see page 7374)

SaveToStream (see page 7373)

Using Code That the XML Data Binding Wizard Generates

79.1.1.4.54 TXMLDocument.SaveToStream Method

Saves the XML (see page 7392) document to a stream.

Pascal

```
procedure SaveToStream(const Stream: TStream);
```

C++

```
__fastcall SaveToStream(const TStream Stream);
```

Description

Call SaveToStream to save the contents of the XML (see page 7392) document to the stream specified by Stream. Regardless of the encoding system of the original XML (see page 7392) document, SaveToStream always saves the stream in UTF-16.

See Also

LoadFromStream (see page 7369)

SaveToXML (see page 7374)

SaveToFile (see page 7373)

79.1.1.4.55 TXMLDocument.SaveToUTF8String Method

Pascal

```
procedure SaveToUTF8String(var XML: UTF8String);
```

C++

```
__fastcall SaveToUTF8String(UTF8String XML);
```

Description

This is SaveToUTF8String, a member of class TXMLDocument.

79.1.1.4.56 SaveToXML Method

This is the overview for the SaveToXML method overload.

Overload List

	Name	Description
	TXMLDocument.SaveToXML (DOMString) (see page 7374)	Saves the XML (see page 7392) document to a string-type variable.
	TXMLDocument.SaveToXML (UTF8String) (see page 7374)	Saves the XML (see page 7392) document to a string-type variable.
	TXMLDocument.SaveToXML (WideString) (see page 7374)	Saves the XML (see page 7392) document to a string-type variable.

79.1.1.4.56.1 TXMLDocument.SaveToXML Method (DOMString)

Saves the XML (see page 7392) document to a string-type variable.

Pascal

```
procedure SaveToXML(var XML: DOMString); overload;
procedure SaveToXML(var XML: WideString); overload;
procedure SaveToXML(var XML: UTF8String); overload;
```

C++

```
__fastcall SaveToXML(DOMString XML);
__fastcall SaveToXML(BSTR XML);
__fastcall SaveToXML(UTF8String XML);
```

Description

Call SaveToXML to save the contents of the XML (see page 7392) document to the string-type variable specified by XML (see page 7392). SaveToXML writes the contents of XML (see page 7392) document using UTF-8 or UTF-16 as an encoding system, depending on the type of the XML (see page 7392) parameter.

Unlike the XML (see page 7392) property, which lets you write individual lines from the XML (see page 7392) document, SaveToXML writes the entire text of the XML (see page 7392) document.

See Also

LoadFromXML (see page 7370)

SaveToStream (see page 7373)

SaveToFile (see page 7373)

XML (see page 7392)

79.1.1.4.57 TXMLDocument.SaveToXMLStrings Method

Saves the XML (see page 7392) document to an internal string list.

Pascal

```
procedure SaveToXMLStrings;
```

C++

```
__fastcall SaveToXMLStrings();
```

Description

The SaveToXMLStrings procedure saves the content of the XML (see page 7392) document to a TStringList. SaveToXMLStrings writes the content of the XML (see page 7392) document in Unicode.

See Also

SaveToXML (see page 7374)

XML (see page 7392)

79.1.1.4.58 TXMLDocument.SetActive Method

Sets the value of the Active property.

Pascal

```
procedure SetActive(const Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetActive(const Boolean Value);
```

Description

SetActive is the write implementation of the Active property.

Value is the new value to set.

See Also

Active (see page 7661)

79.1.1.4.59 TXMLDocument.SetDocumentElement Method

Sets the value of the DocumentElement property.

Pascal

```
procedure SetDocumentElement(const Value: IXMLNode);
```

C++

```
__fastcall SetDocumentElement(const IXMLNode Value);
```

Description

SetDocumentElement is the write implementation of the DocumentElement property.

Value is the interface for the node tree that replaces the current document element.

See Also

DocumentElement (see page 7663)

79.1.1.4.60 TXMLDocument.SetDOMDocument Method

Sets the value of the DOMDocument property.

Pascal

```
procedure SetDOMDocument(const Value: IDOMDocument);
```

C++

```
__fastcall SetDOMDocument(const IDOMDocument Value);
```

Description

SetDOMDocument is the write implementation of the DOMDocument property.

Value is the DOM interface for the document to assign.

See Also

DOMDocument (see page 7663)

79.1.1.4.61 TXMLDocument.SetEncoding Method

Sets the value of the Encoding property.

Pascal

```
procedure SetEncoding(const Value: DOMString);
```

C++

```
__fastcall SetEncoding(const DOMString Value);
```

Description

SetEncoding is the write implementation of the Encoding property.

Value is the value of the encoding attribute of the document type node.

See Also

Encoding (see page 7664)

79.1.1.4.62 TXMLDocument.SetFileName Method

Sets the value of the FileName property.

Pascal

```
procedure SetFileName(const Value: DOMString);
```

C++

```
__fastcall SetFileName(const DOMString Value);
```

Description

SetFileName is the write implementation of the FileName property.

Value is the name of an XML document or, if the vendor supports it, an URL for the XML document.

See Also

FileName (see page 7664)

79.1.1.4.63 TXMLDocument.SetModified Method

Pascal

```
procedure SetModified(const Value: Boolean);
```

C++

```
__fastcall SetModified(const Boolean Value);
```

Description

This is SetModified, a member of class TXMLDocument.

79.1.1.4.64 TXMLDocument.SetNodeIndentStr Method

Sets the value of the NodeIndentStr property.

Pascal

```
procedure SetNodeIndentStr(const Value: DOMString);
```

C++

```
__fastcall SetNodeIndentStr(const DOMString Value);
```

Description

SetNodeIndentStr is the write implementation of the NodeIndentStr property.

Value is the string that is inserted before nested nodes to indicate a level of nesting.

See Also

NodeIndentStr (see page 7666)

79.1.1.4.65 TXMLDocument.SetOnAsyncLoad Method

Supplies an event handler that responds when the AsyncLoadState property changes.

Pascal

```
procedure SetOnAsyncLoad(const Value: TAsyncEventHandler);
```

C++

```
__fastcall SetOnAsyncLoad(const TAsyncEventHandler Value);
```

Description

Use SetOnAsyncLoad to supply a callback that responds when the asynchronous parsing of an XML document progresses to a certain point.

Value is a method that is called when the AsyncLoadState property changes to reflect a new stage in the parsing process.

See Also

AsyncLoadState (see page 7662)

79.1.1.4.66 TXMLDocument.SetOptions Method

Sets the value of the Options property.

Pascal

```
procedure SetOptions(const Value: TXMLDocOptions);
```

C++

```
__fastcall SetOptions(const TXMLDocOptions Value);
```

Description

GetOptions is the write implementation of the Options property.

Value is the set of options to assign.

See Also

Options (see page 7666)

79.1.1.4.67 TXMLDocument.SetParseOptions Method

Sets the value of the ParseOptions property.

Pascal

```
procedure SetParseOptions(const Value: TParseOptions);
```

C++

```
__fastcall SetParseOptions(const TParseOptions Value);
```

Description

GetParseOptions is the write implementation of the ParseOptions property.

Value is the set of parser options to assign.

See Also

ParseOptions (see page 7667)

79.1.1.4.68 TXMLDocument.SetPrologValue Method

Pascal

```
procedure SetPrologValue(const Value: Variant; PrologItem: TXMLPrologItem);
```

C++

```
__fastcall SetPrologValue(const Variant Value, TXMLPrologItem PrologItem);
```

Description

This is SetPrologValue, a member of class TXMLDocument.

79.1.1.4.69 TXMLDocument.SetStandAlone Method

Sets the value of the StandAlone property.

Pascal

```
procedure SetStandAlone(const Value: DOMString);
```

C++

```
__fastcall SetStandAlone(const DOMString Value);
```

Description

SetStandAlone is the write implementation of the StandAlone property.

Value is the value of the stand-alone attribute of the document type node.

See Also

StandAlone (see page 7668)

79.1.1.4.70 TXMLDocument.SetVersion Method

Sets the value of the Version property.

Pascal

```
procedure SetVersion(const Value: DOMString);
```

C++

```
__fastcall SetVersion(const DOMString Value);
```

Description

SetVersion is the write implementation of the Version property.

Value is the value of the version attribute of the document type node.

See Also

Version (see page 7668)

79.1.1.4.71 TXMLDocument.SetXML Method

Sets the value of the XML property.

Pascal

```
procedure SetXML(const Value: TStrings);
```

C++

```
__fastcall SetXML(const TStrings Value);
```

Description

SetXML is the write implementation of the XML property.

Value contains the raw (unparsed) XML to assign.

See Also

XML (see page 7668)

79.1.1.4.72 TXMLDocument.SetXMLStrings Method

Pascal

```
procedure SetXMLStrings(const Value: string);
```

C++

```
__fastcall SetXMLStrings(const UnicodeString Value);
```

Description

This is SetXMLStrings, a member of class TXMLDocument.

79.1.1.4.73 TXMLDocument.WriteDOMVendor Method

Pascal

```
procedure WriteDOMVendor(Writer: TWriter);
```

C++

```
__fastcall WriteDOMVendor(TWriter Writer);
```

Description

This is WriteDOMVendor, a member of class TXMLDocument.

79.1.1.4.74 TXMLDocument.XMLStringsChanging Method

Pascal

```
procedure XMLStringsChanging(Sender: TObject);
```

C++

```
__fastcall XMLStringsChanging(TObject * Sender);
```

Description

This is XMLStringsChanging, a member of class TXMLDocument.

79.1.1.5 TXMLDocument Properties

The properties of the TXMLDocument class are listed here.

Protected Properties

	Name	Description
R	DocBindingInfo (see page 7383)	This is DocBindingInfo, a member of class TXMLDocument.
	DocSource (see page 7383)	This is DocSource, a member of class TXMLDocument.
R	DOMParseOptions (see page 7385)	This is DOMParseOptions, a member of class TXMLDocument.
R	DOMPersist (see page 7386)	This is DOMPersist, a member of class TXMLDocument.
	PrefixID (see page 7391)	This is PrefixID, a member of class TXMLDocument.

Public Properties

	Name	Description
R	AsyncLoadState (see page 7382)	Indicates the state of the DOM parser when it parses the XML (see page 7392) document asynchronously.
R	ChildNodes (see page 7383)	Lists all of the child nodes of the document.
	DocumentElement (see page 7383)	Provides access to the root node of the XML (see page 7392) document.
	DOMDocument (see page 7384)	Provides access to the DOM interface for the parsed XML (see page 7392) document.
	DOMImplementation (see page 7385)	Provides access to the DOM interface for document-independent functions.
	Encoding (see page 7386)	Indicates the character set that the XML (see page 7392) document uses to encode characters.
R	Modified (see page 7387)	Indicates whether the XML (see page 7392) document has been modified.

R	Node (see page 7388)	Provides access to the document node for the XML (see page 7392) document.
	NSPrefixBase (see page 7389)	Specifies the base string for automatically-generated namespace prefixes.
R	SchemaRef (see page 7391)	Returns the name of the schema associated with this XML (see page 7392) document.
	StandAlone (see page 7391)	Indicates whether the XML (see page 7392) document includes any external markup declarations.
	Version (see page 7391)	Indicates the XML (see page 7392) version that the document uses.

Published Properties

	Name	Description
	Active (see page 7381)	Specifies whether the XML (see page 7392) document has been parsed so that the DOM interfaces are available to examine or change its contents.
	DOMVendor (see page 7386)	Specifies the DOM implementation to use for parsing and manipulating the XML (see page 7392) document.
	FileName (see page 7387)	Specifies the file name for the XML (see page 7392) document associated with this TXMLDocument (see page 7347) object.
	NodeIndentStr (see page 7388)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7392) text.
	Options (see page 7389)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7390)	Specifies implementation-specific options that are followed when parsing the XML (see page 7392) document.
	XML (see page 7392)	Specifies the content of the XML document associated with this TXMLDocument (see page 7347) object.

79.1.1.5.1 TXMLDocument.Active Property

Specifies whether the XML (see page 7392) document has been parsed so that the DOM interfaces are available to examine or change its contents.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before you can use TXMLDocument (see page 7347) to examine or change the contents of an XML (see page 7392) document, it must be active. Setting Active to true causes TXMLDocument (see page 7347) to do the following:

1.Generate a BeforeOpen (see page 7395) event.

2.If necessary, load the DOM parser and assign the DOMImplementation (see page 7385) property.

3.Parse the XML (see page 7392) document specified by FileName (see page 7387) or, if FileName (see page 7387) is an empty string, by the XML (see page 7392) property using the options specified by ParseOptions (see page 7390). If both FileName (see page 7387) and XML (see page 7392) are empty strings, TXMLDocument (see page 7347) creates an empty document. The interface for the parsed document is assigned to the DOMDocument (see page 7384) property.

4. Generate an AfterOpen (see page 7394) event.

Note: Once the DOMDocument (see page 7384) property is assigned, you can also use the DocumentElement (see page 7383) property.

Setting Active to false causes TXMLDocument (see page 7347) to do the following:

1.Generate a BeforeClose (see page 7394) event.

2.Release (see page 3641) all of the DOM interfaces, such as DOMDocument (see page 7384) and DocumentElement (

see page 7383), that represent the parsed XML (see page 7392) document.

3. Generate an AfterClose (see page 7393) event.

See Also

DOMDocument (see page 7384)

DocumentElement (see page 7383)

FileName (see page 7387)

XML (see page 7392)

ParseOptions (see page 7390)

BeforeOpen (see page 7395)

AfterOpen (see page 7394)

DOMImplementation (see page 7385)

BeforeClose (see page 7394)

AfterClose (see page 7393)

Using TXMLDocument

79.1.1.5.2 TXMLDocument.AsyncLoadState Property

Indicates the state of the DOM parser when it parses the XML (see page 7392) document asynchronously.

Pascal

```
property AsyncLoadState: Integer;
```

C++

```
__property int AsyncLoadState;
```

Description

Use AsyncLoadState to determine that status of the DOM parser when it is parsing an XML (see page 7392) document asynchronously. AsyncLoadState is only meaningful when the value of ParseOptions (see page 7390) is poAsyncLoad.

The value of AsyncLoadState is vendor-specific. That is, each DOM parser that loads and parses an XML (see page 7392) document asynchronously supplies its own flags to indicate state information.

When the DOM vendor is MSXML, AsyncLoadState can have any of the following values:

Value	Meaning
0	Uninitialized: The AsyncLoadState is not assigned. (Usually indicates that the parser has not tried to parse a document or it is not parsing the document asynchronously.)
1	Loading: The parser is currently parsing the structure of the XML (see page 7392) document.
2	Loaded (see page 7368): The parser has finished reading and parsing the structure of the XML (see page 7392) document, but the corresponding DOM interfaces are not yet available.
3	Interactive: The parser has parsed the structure of the XML (see page 7392) document, the corresponding DOM interfaces are available, but the parser has not finished reading all the node values.
4	Complete: The parser has fully read and parsed the XML (see page 7392) document.

See Also

OnAsyncLoad (see page 7395)

ParseOptions (see page 7390)

79.1.1.5.3 TXMLDocument.ChildNodes Property

Lists all of the child nodes of the document.

Pascal

```
property ChildNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList ChildNodes;
```

Description

Use ChildNodes to access all of the nodes that are children of the document object. In addition to DocumentElement (see page 7383), which is the root of the data hierarchy, ChildNodes can include nodes for comments, processing instructions, and so on.

Note: ChildNodes is not available unless the XML (see page 7392) document is Active (see page 7381).

See Also

DocumentElement (see page 7383)

Active (see page 7381)

79.1.1.5.4 TXMLDocument.DocBindingInfo Property

Pascal

```
property DocBindingInfo: TNodeClassArray;
```

C++

```
__property TNodeClassArray DocBindingInfo;
```

Description

This is DocBindingInfo, a member of class TXMLDocument.

79.1.1.5.5 TXMLDocument.DocSource Property

Pascal

```
property DocSource: TXMLDocumentSource;
```

C++

```
__property TXMLDocumentSource DocSource;
```

Description

This is DocSource, a member of class TXMLDocument.

79.1.1.5.6 TXMLDocument.DocumentElement Property

Provides access to the root node of the XML (see page 7392) document.

Pascal

```
property DocumentElement: IXMLNode;
```

C++

```
__property IXMLNode DocumentElement;
```

Description

Use DocumentElement to access the root node of the XML (see page 7392) document. Because XML (see page 7392) documents are hierarchical in structure, DocumentElement is the entry point to all data in the XML (see page 7392) document. Setting DocumentElement replaces the entire data hierarchy with a new hierarchy of nodes.

Note: For some DOM implementations, if you set DocumentElement, all of the new nodes must already be associated with this document. That is, the new value should be a node that came from the existing node hierarchy or that was created using the CreateNode (see page 7357) method.

The IXMLNode (see page 7669) interface includes properties and methods for examining and changing the text and attributes of a node, for adding and deleting child nodes, and for traversing the hierarchy of nodes rooted at that node.

Note: DocumentElement is not available unless the XML (see page 7392) document is Active (see page 7381).

See Also

DOMDocument (see page 7384)

Active (see page 7381)

CreateNode (see page 7357)

Using TXMLDocument

Working with XML Nodes

79.1.1.5.7 TXMLDocument.DOMDocument Property

Provides access to the DOM interface for the parsed XML (see page 7392) document.

Pascal

```
property DOMDocument: IDOMDocument;
```

C++

```
__property IDOMDocument DOMDocument;
```

Description

Use DOMDocument to directly access the IDOMDocument (see page 7530) interface for the parsed XML (see page 7392) document. This is the interface supported by the DOM parser for the document that is represented in raw (unparsed) form by the FileName (see page 7387) or XML (see page 7392) property.

DOMDocument provides access to the IDOMImplementation (see page 7552) and IDOMElement (see page 7542) interfaces that are surfaced as the DOMImplementation (see page 7385) and DocumentElement (see page 7383) properties. It also provides access to an IDOMDocumentType (see page 7538) interface that describes the structure of the XML (see page 7392) document, and supports a number of methods for creating elements within the document.

Most applications do not need to use the DOMDocument property directly. Instead, it supplies the underlying support for parsing and manipulating the nodes accessed through DocumentElement (see page 7383). If you do want to make use of DOMDocument's low-level support, you must be familiar with the W3C Document Object Model (DOM) Level 1 Specification.

Note: DOMDocument is not available unless the XML (see page 7392) document is Active (see page 7381).

See Also

Active (see page 7381)

DocumentElement (see page 7383)

DOMImplementation (see page 7385)

XML (see page 7392)

FileName (see page 7387)

79.1.1.5.8 TXMLDocument.DOMImplementation Property

Provides access to the DOM interface for document-independent functions.

Pascal

```
property DOMImplementation: IDOMImplementation;
```

C++

```
__property IDOMImplementation DOMImplementation;
```

Description

Use DOMImplementation to directly access the IDOMImplemenation interface identified by the DOMVendor (see page 7386) property. This is the interface TXMLDocument (see page 7347) uses to generate the IDOMDocument (see page 7530) interface that is the value of DOMDocument (see page 7384).

Typically, the value of DOMImplementation is obtained automatically, based on the value of the DOMVendor (see page 7386) property. You can, however, assign the DOMImplementation property directly to an IDOMImplementation (see page 7552) interface that you have obtained through some other mechanism.

Most applications do not need to use the DOMImplementation property directly. If you do want to make use of DOMImplementation's low-level support, you must be familiar with the W3C Document Object Model (DOM) Level 2 Specification.

You must assign a value to either DOMVendor (see page 7386) or DOMImplementation before you can set the Active (see page 7381) property to true.

See Also

DOMVendor (see page 7386)

DOMDocument (see page 7384)

DOMVendors (see page 7622)

Active (see page 7381)

79.1.1.5.9 TXMLDocument.DOMParseOptions Property

Pascal

```
property DOMParseOptions: IDOMParseOptions;
```

C++

```
__property IDOMParseOptions DOMParseOptions;
```

Description

This is DOMParseOptions, a member of class TXMLDocument.

79.1.1.5.10 TXMLDocument.DOMPersist Property

Pascal

```
property DOMPersist: IDOMPersist;
```

C++

```
__property IDOMPersist DOMPersist;
```

Description

This is DOMPersist, a member of class TXMLDocument.

79.1.1.5.11 TXMLDocument.DOMVendor Property

Specifies the DOM implementation to use for parsing and manipulating the XML (see page 7392) document.

Pascal

```
property DOMVendor: TDOMVendor;
```

C++

```
__property TDOMVendor DOMVendor;
```

Description

DOMVendor is the object that represents a registered DOM implementation. TXMLDocument (see page 7347) uses this object to obtain an IDOMImplementation (see page 7552) interface, which it can use to access all the other DOM interfaces needed for parsing and manipulating the XML (see page 7392) document. Once DOMVendor is assigned, TXMLDocument (see page 7347) obtains the IDOMImplementation (see page 7552) interface (when needed) and assigns it to the DOMImplementation (see page 7385) property.

DOMVendor must be registered before it can be used to obtain an IDOMImplementation (see page 7552) interface. For a list of all the currently registered DOM implementations, use the global DOMVendors (see page 7622) variable. To obtain a specific DOM implementation, given its description, use the global GetDOMVendor (see page 7615) function. Use the RegisterDOMVendor (see page 7617) procedure to register a new DOM implementation.

You must assign a value to either DOMVendor or DOMImplementation (see page 7385) before you can set the Active (see page 7381) property to true.

See Also

DOMImplementation (see page 7385)

DOMVendors (see page 7622)

Active (see page 7381)

RegisterDOMVendor (see page 7617)

GetDOMVendor (see page 7615)

Using TXMLDocument

79.1.1.5.12 TXMLDocument.Encoding Property

Indicates the character set that the XML (see page 7392) document uses to encode characters.

Pascal

```
property Encoding: DOMString;
```

C++

```
__property DOMString Encoding;
```

Description

Encoding is the encoding name that appears in the document type declaration of the XML (see page 7392) document. It is a string such as 'UTF-8', 'UTF-16', or 'ISO-10646-UCS-2' that indicates the character set used in the document.

See Also

FileName (see page 7387)

DOMDocument (see page 7384)

XML (see page 7392)

79.1.1.5.13 TXMLDocument.FileName Property

Specifies the file name for the XML (see page 7392) document associated with this TXMLDocument (see page 7347) object.

Pascal

```
property FileName: DOMString;
```

C++

```
__property DOMString FileName;
```

Description

Set FileName to specify the XML (see page 7392) document you want to examine or manipulate using the TXMLDocument (see page 7347) object. Once you have set FileName to the name of an XML (see page 7392) document, you can activate the XML (see page 7392) document and examine or manipulate it using the DocumentElement (see page 7383) property.

When you set the value of FileName, the XML (see page 7392) property automatically changes (at runtime) to represent the contents of that file.

Note: Setting the value of FileName automatically sets the Active (see page 7381) property to false.

After activating the XML (see page 7392) document, any changes you make to the document are not saved back to disk until you call the SaveToFile (see page 7373) method.

Tip: If the underlying DOM implementation supports it, you can use FileName to specify an URL rather than a file on disk.

See Also

XML (see page 7392)

LoadFromFile (see page 7368)

SaveToFile (see page 7373)

DocumentElement (see page 7383)

Using TXMLDocument

Using Code That the XML Data Binding Wizard Generates

79.1.1.5.14 TXMLDocument.Modified Property

Indicates whether the XML (see page 7392) document has been modified.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Read (see page 3634) Modified to determine whether the application has made any changes to the nodes in the XML (see page 7392) document. When Modified is true, the value of the XML (see page 7392) property may differ from the contents of the file specified by FileName (see page 7387). You can call the SaveToFile (see page 7373) method to update the XML (see page 7392) document file to reflect the changes.

Note: Modfied changes to false when you call the Refresh (see page 7371) or SaveToFile (see page 7373) method.

See Also

BeforeNodeChange (see page 7394)

AfterNodeChange (see page 7393)

Refresh (see page 7371)

SaveToFile (see page 7373)

XML (see page 7392)

FileName (see page 7387)

79.1.1.5.15 TXMLDocument.Node Property

Provides access to the document node for the XML (see page 7392) document.

Pascal

```
property Node: IXMLNode;
```

C++

```
__property IXMLNode Node;
```

Description

Read (see page 3634) Node to access the document node for the XML (see page 7392) document. The document node represents information about the entire document. It may have several child nodes, which represent comments, processing instructions, and which include the DocumentElement (see page 7383) node that acts as the root of the data hierarchy.

See Also

DocumentElement (see page 7383)

ChildNodes (see page 7383)

79.1.1.5.16 TXMLDocument.NodeIndentStr Property

Indicates the string that is inserted before nested nodes in the formatted XML (see page 7392) text.

Pascal

```
property NodeIndentStr: DOMString;
```

C++

```
__property DOMString NodeIndentStr;
```

Description

Use NodeIndentStr to customize how TXMLDocument (see page 7347) formats nodes that are added. When the Options (see page 7389) property includes doNodeAutoIndent, this string is inserted in the generated XML (see page 7392) before any newly added node, once for each nesting level.

If you do not assign a value to NodeIndentStr, TXMLDocument (see page 7347) inserts two spaces to represent each nesting level.

See Also

Options (see page 7389)

NestingLevel (see page 7428)

FormatXMLData (see page 7490)

XML (see page 7392)

79.1.1.5.17 TXMLDocument.NSPrefixBase Property

Specifies the base string for automatically-generated namespace prefixes.

Pascal

```
property NSPrefixBase: DOMString;
```

C++

```
__property DOMString NSPrefixBase;
```

Description

The AddChild (see page 7355) method for each node allows the caller to specify that the new node should use an automatically-generated namespace prefix. When this option is specified, the node uses NSPrefixBase to generate a unique string to act as a namespace prefix. This unique string consists of NSPrefixBase followed by a number that ensures uniqueness. Thus, for example, if NSPrefixBase is 'NS', automatically-generated namespace prefixes have the form 'NS1', 'NS2', and so on.

The generated namespace prefixes are only unique within a single document. If two document components have the same value for NSPrefixBase, they will generate the same namespace prefixes.

See Also

AddChild (see page 7672)

GeneratePrefix (see page 7360)

79.1.1.5.18 TXMLDocument.Options Property

Influences various aspects of the document's behavior.

Pascal

```
property Options: TXMLDocOptions;
```

C++

```
__property TXMLDocOptions Options;
```

Description

Set Options to configure how you want the document to respond when the application tries to read nodes or attributes that do not exist, when it creates a new namespace when adding a node, when it generates XML (see page 7392) text from the nodes in the document, or whether it saves its value automatically when you close the document. Options can include any of the following

values:

Value	Meaning
doNodeAutoCreate	If the application tries to read a node by name, using the Nodes property of an IXMLNodeList (see page 7703) interface, and that node does not exist, then the application creates a new node using the specified name.
doNodeAutoIndent	When formatting the XML (see page 7392) text from the parsed set of nodes, child nodes are automatically indented from their parent nodes.
doAttrNull	When reading the value of an attribute that does not exist, the value is given as a Null (see page 5056) Variant (see page 3421) (as opposed to a value of an empty string).
doAutoPrefix	When generating the name of a new node, the value is automatically given a namespace prefix if a namespace URI is supplied.
doNamespaceDecl	When the AddChild (see page 7355) method must create a new namespace for the node, it also adds a namespace attribute to declare that new namespace. If doNamespaceDecl is not included, AddChild (see page 7355) creates the new namespace but does not add an attribute to declare it.
doAutoSave	When you close the document (set Active (see page 7381) to false), any changes are automatically saved back to the file specified by FileName (see page 7387) or to the XML (see page 7392) property.

See Also

Nodes (see page 7714)

Attributes (see page 7688)

AddChild (see page 7672)

Active (see page 7381)

FileName (see page 7387)

XML (see page 7392)

79.1.1.5.19 TXMLDocument.ParseOptions Property

Specifies implementation-specific options that are followed when parsing the XML (see page 7392) document.

Pascal

```
property ParseOptions: TParseOptions;
```

C++

```
__property TParseOptions ParseOptions;
```

Description

Set ParseOptions to influence the way the DOM implementation parses the XML (see page 7392) document. Different DOM implementations support different options. If you attempt to use an option that is not supported by your DOM implementation, TXMLDocument (see page 7347) raises an EXMLDocError (see page 7639) exception.

See Also

DOMImplementation (see page 7385)

EXMLDocError (see page 7639)

Using TXMLDocument

79.1.1.5.20 TXMLDocument.PrefixID Property

Pascal

```
property PrefixID: Integer;
```

C++

```
__property int PrefixID;
```

Description

This is PrefixID, a member of class TXMLDocument.

79.1.1.5.21 TXMLDocument.SchemaRef Property

Returns the name of the schema associated with this XML (see page 7392) document.

Pascal

```
property SchemaRef: DOMString;
```

C++

```
__property DOMString SchemaRef;
```

Description

Read (see page 3634) SchemaRef to determine the schema associated with this XML (see page 7392) document. If the document does not have an attribute that identifies an associated schema, the value of SchemaRef is an empty string.

See Also

DOMDocument (see page 7384)

79.1.1.5.22 TXMLDocument.StandAlone Property

Indicates whether the XML (see page 7392) document includes any external markup declarations.

Pascal

```
property StandAlone: DOMString;
```

C++

```
__property DOMString StandAlone;
```

Description

StandAlone is the value of the stand-alone attribute on the document type declaration of the XML (see page 7392) document. StandAlone has a value of 'yes' or 'no'.

When StandAlone is 'yes', the document contains no external markup declarations. It may, however, still contain references to external entities, as long as they are not declarations.

When StandAlone is 'no', the document may or may not contain external markup declarations.

See Also

DOMDocument (see page 7384)

79.1.1.5.23 TXMLDocument.Version Property

Indicates the XML (see page 7392) version that the document uses.

Pascal

```
property Version: DOMString;
```

C++

```
__property DOMString Version;
```

Description

Version indicates the XML (see page 7392) version number that the document uses. An XML (see page 7392) version number is a string of the form 'n.m', where n is the major version number and m is the minor version number.

See Also

XML (see page 7392)

79.1.1.5.24 TXMLDocument.XML Property

Specifies the content of the XML document associated with this TXMLDocument (see page 7347) object.

Pascal

```
property XML: TStrings;
```

C++

```
__property TStrings XML;
```

Description

Read (see page 3634) XML to obtain the contents of the associated XML document. Set XML to specify the XML document you want to examine or manipulate. Once XML is set, you can activate the XML document and examine or manipulate it using the DocumentElement (see page 7383) property.

XML is a TStrings object. This means you can supply a value using the Strings editor at design time, or manipulate the XML line by line at runtime. To read or write the XML in the document as a single string, use the LoadFromXML (see page 7370) or SaveToXML (see page 7374) method.

See Also

FileName (see page 7387)

LoadFromXML (see page 7370)

SaveToXML (see page 7374)

DocumentElement (see page 7383)

Using TXMLDocument

Using Code That the XML Data Binding Wizard Generates

79.1.1.6 TXMLDocument Events

The events of the TXMLDocument class are listed here.

Published Events

	Name	Description
	AfterClose (see page 7393)	Occurs after the XML (see page 7392) document is closed.
	AfterNodeChange (see page 7393)	Occurs after a change is made to one of the nodes in the document.
	AfterOpen (see page 7394)	Occurs immediately after the XML (see page 7392) document is opened.
	BeforeClose (see page 7394)	Occurs immediately before the XML (see page 7392) document is closed.

	BeforeNodeChange (see page 7394)	Occurs before a change is made to one of the nodes in the document.
	BeforeOpen (see page 7395)	Occurs immediately before the XML (see page 7392) document is opened.
	OnAsyncLoad (see page 7395)	Occurs at various stages during the asynchronous parsing of an XML (see page 7392) document.

79.1.1.6.1 TXMLDocument.AfterClose Event

Occurs after the XML (see page 7392) document is closed.

Pascal

```
property AfterClose: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterClose;
```

Description

Write (see page 3707) an AfterClose event handler to take specific action after the XML (see page 7392) document interfaces are released. For example, you can use an AfterClose event to update your user interface to indicate that the XML (see page 7392) document is no longer available.

AfterClose is the last event to occur when the Active (see page 7381) property is set to false.

See Also

BeforeClose (see page 7394)

Active (see page 7381)

79.1.1.6.2 TXMLDocument.AfterNodeChange Event

Occurs after a change is made to one of the nodes in the document.

Pascal

```
property AfterNodeChange: TNodeChangeEvent;
```

C++

```
__property TNodeChangeEvent AfterNodeChange;
```

Description

Write (see page 3707) an AfterNodeChange event handler to take specific action after a change is made to a node in the XML (see page 7392) document. When an application makes a change to one of the nodes, the following steps occur:

1. The Modified (see page 7387) property is set to true.
2. A BeforeNodeChange (see page 7394) event occurs.
3. The change is made to the node.
4. An AfterNodeChange event occurs.

See Also

BeforeNodeChange (see page 7394)

Modified (see page 7387)

ChildNodes (see page 7383)

79.1.1.6.3 TXMLDocument.AfterOpen Event

Occurs immediately after the XML (see page 7392) document is opened.

Pascal

```
property AfterOpen: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterOpen;
```

Description

Write (see page 3707) an AfterOpen event handler to take specific action once the XML (see page 7392) document interfaces become available. For example, you can use an AfterOpen event to update your user interface to reflect the structure of the XML (see page 7392) document once it is opened.

AfterOpen is the last event to occur when the Active (see page 7381) property is set to true.

See Also

BeforeOpen (see page 7395)

Active (see page 7381)

79.1.1.6.4 TXMLDocument.BeforeClose Event

Occurs immediately before the XML (see page 7392) document is closed.

Pascal

```
property BeforeClose: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeClose;
```

Description

Write (see page 3707) a BeforeClose event handler to take specific action before the XML (see page 7392) document interfaces are released. For example, you can use an BeforeClose event to cache information about the XML (see page 7392) document before it becomes unavailable.

BeforeClose is the first event to occur when the Active (see page 7381) property is set to false.

See Also

AfterClose (see page 7393)

Active (see page 7381)

79.1.1.6.5 TXMLDocument.BeforeNodeChange Event

Occurs before a change is made to one of the nodes in the document.

Pascal

```
property BeforeNodeChange: TNodeChangeEvent;
```

C++

```
__property TNodeChangeEvent BeforeNodeChange;
```

Description

Write (see page 3707) a BeforeNodeChange event handler to take specific action before a change is made to a node in the XML (see page 7392) document. When an application makes a change to one of the nodes, the following steps occur:

1. The Modified (see page 7387) property is set to true.
2. A BeforeNodeChange event occurs.
3. The change is made to the node.
4. An BeforeNodeChange event occurs.

See Also

AfterNodeChange (see page 7393)

Modified (see page 7387)

ChildNodes (see page 7383)

79.1.1.6.6 TXMLDocument.BeforeOpen Event

Occurs immediately before the XML (see page 7392) document is opened.

Pascal

```
property BeforeOpen: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeOpen;
```

Description

Write (see page 3707) a BeforeOpen event handler to take specific action before the XML (see page 7392) document interfaces become available. For example, you can use a BeforeOpen event to provide feedback to the user that the XML (see page 7392) document is being parsed (which can be cleared in an AfterOpen (see page 7394) event handler).

BeforeOpen is the first event to occur when the Active (see page 7381) property is set to true.

See Also

AfterOpen (see page 7394)

Active (see page 7381)

79.1.1.6.7 TXMLDocument.OnAsyncLoad Event

Occurs at various stages during the asynchronous parsing of an XML (see page 7392) document.

Pascal

```
property OnAsyncLoad: TAsyncEventHandler;
```

C++

```
__property TAsyncEventHandler OnAsyncLoad;
```

Description

Write (see page 3707) a OnAsyncLoad event handler to respond appropriately during the asynchronous parsing of an XML (see page 7392) document. For example, OnAsyncLoad can update a progress indicator, or initiate operations that can't be performed until the document is fully parsed. OnAsyncLoad occurs every time the AsyncLoadState (see page 7382) property

changes to reflect a new stage in the parsing process.

See Also

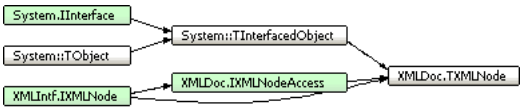
AsyncLoadState (see page 7382)

XML (see page 7392)

79.1.2 TXMLNode Class

TXMLNode represents a node in an XML document.

Class Hierarchy



Pascal

```
TXMLNode = class(TInterfacedObject, IXMLNode, IXMLNodeAccess);
```

C++

```
class TXMLNode : public TInterfacedObject, public IXMLNode, public IXMLNodeAccess;
```

File

XMLDoc

Description

The XML Data Binding Wizard uses TXMLNode as a base class for the classes it generates to represent nodes that have child nodes. For example, if the XML document includes the following:

```
<Address country="US">
  <Name>
    <First> John </First>
    <MI> Q. </MI>
    <Last> Public </Last>
  </Name>
  <Street> 123 Easy Street </Street>
  <City> Anytown </City>
  <State> CA </State>
</Address>
```

then the XML Data Binding Wizard generates TXMLNode descendants for the elements Address and Name. Child nodes and node attributes appear as properties of the TXMLNode descendant.

Note: The XML Data Binding Wizard also generates code that can create TXMLNode objects for attributes as well as element nodes. However, there are no special TXMLNode descendants for attribute nodes. Rather, each attribute is represented directly by TXMLNode.

TXMLNode implements the IXMLNode (see page 7669) interface. Each TXMLNode descendant implements a class-specific interface that descends from IXMLNode (see page 7669). Typically, applications do not work directly with TXMLNode. Instead, they use the IXMLNode (see page 7669) interface or the IXMLNode (see page 7669) descendant that is implemented by a TXMLNode descendant.

See Also

TXMLDocument (see page 7347)

TXMLNodeCollection (see page 7444)

IXMLNode (see page 7669)

TXMLNodeList (see page 7460)

79.1.2.1 TXMLNode Members

The following tables list the members exposed by TXMLNode.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Events

	Name	Description
	OnHostAttrNotify (see page 7443)	Occurs when changes occur to the attribute list of this node's HostNode (see page 7441).
	OnHostChildNotify (see page 7444)	Occurs when changes occur to the list of child nodes on this node's HostNode (see page 7441).

Protected Methods

	Name	Description
	_AddRef (see page 7403)	Increments the reference count for this node.
	_Release (see page 7404)	Decrements the reference count for this node.
	AddChild (see page 7404)	This is the overview for the AddChild method overload.
	AddHostedNode (see page 7405)	Adds a node to the HostedNodes (see page 7441) property list.
	AttributeListNotify (see page 7406)	Responds to notifications of changes in the list of attributes.
	CheckNotHosted (see page 7406)	Raises an EXMLDocError (see page 7639) exception if this is a hosted node.
	CheckReadOnly (see page 7407)	Raises an EXMLDocError (see page 7639) exception if this is a read-only node.
	CheckTextNode (see page 7407)	Generates a DOM text node implementation if it does not yet exist.
V	ChildListNotify (see page 7408)	Responds to notifications of changes in the list of child nodes.
	ClearDocumentRef (see page 7408)	Sets the value of OwnerDocument (see page 7442) to nil (Delphi) or NULL (C++).
	CloneNode (see page 7409)	Creates a copy of this node and returns its interface.
	CreateAttributeList (see page 7409)	Creates the object that implements the AttributeNodes (see page 7438) property.
V	CreateAttributeNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for an attribute of this node.
	CreateChildList (see page 7410)	Creates the object that implements the ChildNodes (see page 7439) property.
V	CreateChildNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for a child node of this node.
	CreateCollection (see page 7411)	Creates an instance of a TXMLNodeCollection (see page 7444) descendant and returns it.
	DeclareNamespace (see page 7412)	Adds an attribute to the node that declares a specified namespace URI.
	DOMElement (see page 7412)	Returns the IDOMElement (see page 7542) interface for this node if it exists.
V	DoNodeChange (see page 7413)	Generates a BeforeNodeChange or AfterNodeChange event on this node's document.
	FindHostedNode (see page 7413)	Returns the IXMLNode (see page 7669) interface for a hosted node given its implementation class.
	FindNamespaceDecl (see page 7414)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7414)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7415)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7415)	Returns the value of the AttributeNodes (see page 7438) property.
	GetAttributeNS (see page 7416)	Returns the value of a specified attribute when you must explicitly specify the namespace for the attribute.
	GetChildNodeClasses (see page 7416)	Returns a list of the classes that can implement child nodes of this node.

	GetChildNodes (see page 7417)	Returns the value of the ChildNodes (see page 7439) property.
	GetChildValue (see page 7417)	Returns the value of a specified child node.
	GetCollection (see page 7418)	Returns the value of the Collection (see page 7439) property.
	GetDOMNode (see page 7418)	Returns the value of the DOMNode (see page 7440) property.
	GetHasChildNodes (see page 7418)	Indicates whether this node has any child nodes.
	GetHostedNodes (see page 7419)	Returns a list an array of the hosted nodes that share this node's attribute and child node lists.
	GetHostNode (see page 7419)	Returns the value of the HostNode (see page 7441) property.
	GetIsTextElement (see page 7419)	Indicates whether the node has a single text value.
	GetLocalName (see page 7420)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7421)	Returns the URI for the namespace used in the qualified node name.
	GetNodeName (see page 7421)	Returns the node name.
	GetNodeObject (see page 7422)	Returns a reference to this TXMLNode (see page 7396) object.
	GetNodeType (see page 7422)	Returns the type of the node.
	GetNodeValue (see page 7423)	Returns the value of this node.
	GetOwnerDocument (see page 7423)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7424)	Returns the interface for the node's parent node.
	GetPrefix (see page 7424)	Returns the namespace prefix of the node's name.
	GetPrefixedName (see page 7425)	Returns a node name includes a namespace prefix for a specified namespace URI.
	GetReadOnly (see page 7425)	Indicates whether the node can be modified.
	GetText (see page 7426)	Returns the text value of the node.
	GetXML (see page 7426)	Returns the XML that corresponds to the subtree rooted at this node.
	HasAttribute (see page 7426)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7427)	This is the overview for the HasChildNode method overload.
	InternalAddChild (see page 7428)	Provides the underlying implementation for the AddChild (see page 7404) method.
	NestingLevel (see page 7428)	Returns the number of parents for this node in the node hierarchy.
	NextSibling (see page 7429)	Returns the next child of this node's parent.
	Normalize (see page 7429)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7430)	Returns the previous child of this node's parent.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	RegisterChildNode (see page 7430)	Registers a descendant of TXMLNode (see page 7396) that can represent the children of this node.
	RegisterChildNodes (see page 7431)	Registers a set of TXMLNode (see page 7396) descendants that can represent the children of this node.
	RemoveHostedNode (see page 7431)	Removes a node from the HostedNodes (see page 7441) property list.
	Resync (see page 7432)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7432)	Sets the value of one of this node's attributes.
V	SetAttributeNodes (see page 7432)	Sets the value of the AttributeNodes (see page 7438) property.
	SetAttributeNS (see page 7433)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
V	SetChildNodes (see page 7433)	Sets the value of the ChildNodes (see page 7439) property.
	SetChildValue (see page 7434)	Sets the value of a specified child node.
	SetCollection (see page 7434)	Sets the value of the Collection (see page 7439) property.
	SetNodeValue (see page 7435)	Sets the value of this node.
V	SetParentNode (see page 7435)	Sets the value of the ParentNode (see page 7443) property.
	SetReadOnly (see page 7436)	Specifies whether the node can be modified.
	SetText (see page 7436)	Sets the text value of the node.
	TransformNode (see page 7437)	This is the overview for the TransformNode method overload.

Protected Properties

	Name	Description
R	AttributeNodes (see page 7438)	Lists the interfaces for nodes that represent attributes of this node.

R	ChildNodeClasses (see page 7438)	Lists the classes that the XML Data Binding wizard defines to represent child nodes of this node.
	ChildNodes (see page 7439)	Lists the child nodes of this node.
	Collection (see page 7439)	Indicates the collection in which this node appears.
R	DOMNode (see page 7440)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HostedNodes (see page 7441)	Lists the nodes that share this node's lists of child and attribute nodes.
	HostNode (see page 7441)	Indicates the main object for the node to which this node corresponds when it represents a specialized view.
R	OwnerDocument (see page 7442)	Provides access to the document that contains this node.
R	ParentNode (see page 7443)	Identifies the object that represents this node's parent node.

Public Methods

	Name	Description
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 7400)	Instantiates a Create object.
	CreateHosted (see page 7401)	Creates a TXMLNode (see page 7396) instance that represents the same DOM node as another "host" node.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 7401)	Frees the memory associated with the TXMLNode (see page 7396) object.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7485)	This is the overview for the HasChildNode method overload.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.

	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	Attributes (see page 7688)	Represents the values of this node's attributes.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.
R	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
R	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
R	NodeName (see page 7693)	Indicates the node name.
R	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
R	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.
	Text (see page 7697)	Represents the Text of the node.
R	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

79.1.2.2 TXMLNode.Create Constructor

Instantiates a Create object.

Pascal

```
constructor Create(const ADOMNode: IDOMNode; const AParentNode: TXMLNode; const OwnerDoc:
TXMLDocument);
```

C++

```
__fastcall TXMLNode(const IDOMNode ADOMNode, const TXMLNode AParentNode, const TXMLDocument
OwnerDoc);
```

Description

Create instantiates a new Create object to wrap an existing DOM node implementation. Using the first syntax,

ADOMNode is the interface for the DOM implementation of the node.

AParentNode is the implementation of the parent node of this node.

OwnerDoc represents the XML document in which the new node occurs.

Using the second syntax,

HostNode (see page 7441) is another Create object that represents the host node of this node. In this case, this node is a "hosted" node, which means it shares the same underlying parent and DOM node as the host node, but represents a different view of the host node. For example, a node that contains some child nodes that are all of the same type creates a hosted node to represent only the set of repeating child nodes.

Typically, applications do not directly call the Create constructor. Instead, new nodes are created automatically for an XML document as necessary when the application reads their interfaces, starting with the DocumentElement property of the TXMLDocument (see page 7347) object. To add new nodes to a document, applications call the parent node's AddChild (see page 7404) method.

See Also

OwnerDocument (see page 7442)

ParentNode (see page 7443)

DocumentElement (see page 7383)

AddChild (see page 7404)

79.1.2.3 TXMLNode.CreateHosted Constructor

Creates a TXMLNode (see page 7396) instance that represents the same DOM node as another "host" node.

Pascal

```
constructor CreateHosted(HostNode: TXMLNode);
```

C++

```
__fastcall TXMLNode(TXMLNode HostNode);
```

Description

CreateHosted instantiates a new TXMLNode (see page 7396) object to represent a specific view on an existing TXMLNode (see page 7396) object.

HostNode (see page 7441) is another TXMLNode (see page 7396) object that represents the host node of this node. The new node becomes a "hosted" node, which means it shares the same underlying parent and DOM node as the host node, but represents a different view of the host node. For example, a node that contains some child nodes that are all of the same type creates a hosted node to represent only the set of repeating child nodes.

Typically, applications do not directly call CreateHosted to create a hosted node. Instead, this method is called in code generated by the XML Data Binding Wizard, or by the CreateCollection (see page 7411) method of the host node.

HostNode (see page 7441) (or, if HostNode (see page 7441) is hosted, the host node of HostNode (see page 7441)) becomes the value of the new node's HostNode (see page 7441) property, and the new node is added to the HostedNodes (see page 7441) property list of the new host node.

See Also

HostedNodes (see page 7441)

HostNode (see page 7441)

OnHostAttrNotify (see page 7443)

OnHostChildNotify (see page 7444)

CreateCollection (see page 7411)

79.1.2.4 TXMLNode.Destroy Destructor

Frees the memory associated with the TXMLNode (see page 7396) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLNode();
```

Description

Do not explicitly destroy TXMLNode (see page 7396) objects. As interfaced objects, XML nodes are destroyed automatically when the reference count of their IXMLNode (see page 7669) interface drops to zero.

See Also

System::TInterfacedObject::RefCount (see page 3347)

79.1.2.5 TXMLNode Methods

The methods of the TXMLNode class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 7403)	Increments the reference count for this node.
	_Release (see page 7404)	Decrements the reference count for this node.
	AddChild (see page 7404)	This is the overview for the AddChild method overload.
	AddHostedNode (see page 7405)	Adds a node to the HostedNodes (see page 7441) property list.
	AttributeListNotify (see page 7406)	Responds to notifications of changes in the list of attributes.
	CheckNotHosted (see page 7406)	Raises an EXMLDocError (see page 7639) exception if this is a hosted node.
	CheckReadOnly (see page 7407)	Raises an EXMLDocError (see page 7639) exception if this is a read-only node.
	CheckTextNode (see page 7407)	Generates a DOM text node implementation if it does not yet exist.
V	ChildListNotify (see page 7408)	Responds to notifications of changes in the list of child nodes.
	ClearDocumentRef (see page 7408)	Sets the value of OwnerDocument (see page 7442) to nil (Delphi) or NULL (C++).
	CloneNode (see page 7409)	Creates a copy of this node and returns its interface.
	CreateAttributeList (see page 7409)	Creates the object that implements the AttributeNodes (see page 7438) property.
V	CreateAttributeNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for an attribute of this node.
	CreateChildList (see page 7410)	Creates the object that implements the ChildNodes (see page 7439) property.
V	CreateChildNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for a child node of this node.
	CreateCollection (see page 7411)	Creates an instance of a TXMLNodeCollection (see page 7444) descendant and returns it.
	DeclareNamespace (see page 7412)	Adds an attribute to the node that declares a specified namespace URI.
	DOMElement (see page 7412)	Returns the IDOMElement (see page 7542) interface for this node if it exists.
V	DoNodeChange (see page 7413)	Generates a BeforeNodeChange or AfterNodeChange event on this node's document.
	FindHostedNode (see page 7413)	Returns the IXMLNode (see page 7669) interface for a hosted node given its implementation class.
	FindNamespaceDecl (see page 7414)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7414)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7415)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7415)	Returns the value of the AttributeNodes (see page 7438) property.
	GetAttributeNS (see page 7416)	Returns the value of a specified attribute when you must explicitly specify the namespace for the attribute.
	GetChildNodeClasses (see page 7416)	Returns a list of the classes that can implement child nodes of this node.
	GetChildNodes (see page 7417)	Returns the value of the ChildNodes (see page 7439) property.
	GetChildValue (see page 7417)	Returns the value of a specified child node.
	GetCollection (see page 7418)	Returns the value of the Collection (see page 7439) property.
	GetDOMNode (see page 7418)	Returns the value of the DOMNode (see page 7440) property.
	GetHasChildNodes (see page 7418)	Indicates whether this node has any child nodes.
	GetHostedNodes (see page 7419)	Returns a list an array of the hosted nodes that share this node's attribute and child node lists.
	GetHostNode (see page 7419)	Returns the value of the HostNode (see page 7441) property.
	GetIsTextElement (see page 7419)	Indicates whether the node has a single text value.
	GetLocalName (see page 7420)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7421)	Returns the URI for the namespace used in the qualified node name.
	GetNodeName (see page 7421)	Returns the node name.

	GetNodeObject (see page 7422)	Returns a reference to this TXMLNode (see page 7396) object.
	GetNodeType (see page 7422)	Returns the type of the node.
	GetNodeValue (see page 7423)	Returns the value of this node.
	GetOwnerDocument (see page 7423)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7424)	Returns the interface for the node's parent node.
	GetPrefix (see page 7424)	Returns the namespace prefix of the node's name.
	GetPrefixedName (see page 7425)	Returns a node name includes a namespace prefix for a specified namespace URI.
	GetReadOnly (see page 7425)	Indicates whether the node can be modified.
	GetText (see page 7426)	Returns the text value of the node.
	GetXML (see page 7426)	Returns the XML that corresponds to the subtree rooted at this node.
	HasAttribute (see page 7426)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7427)	This is the overview for the HasChildNode method overload.
	InternalAddChild (see page 7428)	Provides the underlying implementation for the AddChild (see page 7404) method.
	NestingLevel (see page 7428)	Returns the number of parents for this node in the node hierarchy.
	NextSibling (see page 7429)	Returns the next child of this node's parent.
	Normalize (see page 7429)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7430)	Returns the previous child of this node's parent.
	RegisterChildNode (see page 7430)	Registers a descendant of TXMLNode (see page 7396) that can represent the children of this node.
	RegisterChildNodes (see page 7431)	Registers a set of TXMLNode (see page 7396) descendants that can represent the children of this node.
	RemoveHostedNode (see page 7431)	Removes a node from the HostedNodes (see page 7441) property list.
	Resync (see page 7432)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7432)	Sets the value of one of this node's attributes.
V	SetAttributeNodes (see page 7432)	Sets the value of the AttributeNodes (see page 7438) property.
	SetAttributeNS (see page 7433)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
V	SetChildNodes (see page 7433)	Sets the value of the ChildNodes (see page 7439) property.
	SetChildValue (see page 7434)	Sets the value of a specified child node.
	SetCollection (see page 7434)	Sets the value of the Collection (see page 7439) property.
	SetNodeValue (see page 7435)	Sets the value of this node.
V	SetParentNode (see page 7435)	Sets the value of the ParentNode (see page 7443) property.
	SetReadOnly (see page 7436)	Specifies whether the node can be modified.
	SetText (see page 7436)	Sets the text value of the node.
	TransformNode (see page 7437)	This is the overview for the TransformNode method overload.

79.1.2.5.1 TXMLNode._AddRef Method

Increments the reference count for this node.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef implements the IInterface (see page 3502) or IUnknown (see page 3756) method that is called when an application obtains a reference to this node's interface pointer. __AddRef increments the RefCount property. In addition, to ensure that the document object is alive, it also increments the reference count for the owning document.

When the caller is through with the interface, it calls _Release (see page 7404). This allows the node to free itself when it is no longer used (when the reference count goes to zero).

See Also

_Release (see page 7404)

OwnerDocument (see page 7442)

System::TInterfacedObject::RefCount (see page 3347)

79.1.2.5.2 TXMLNode._Release Method

Decrements the reference count for this node.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release implements the IInterface (see page 3502) or IUnknown (see page 3756) method that is called when an application releases a reference to this node's interface pointer. __Release decrements the RefCount property. In addition, it also decrements the reference count for the owning document, which it incremented when the _AddRef (see page 7403) method was called.

When __Release causes the node's reference count to drop to zero, __Release causes the node to free itself.

See Also

_AddRef (see page 7403)

OwnerDocument (see page 7442)

System::TInterfacedObject::RefCount (see page 3347)

79.1.2.5.3 AddChild Method

This is the overview for the AddChild method overload.

Overload List

	Name	Description
	TXMLNode.AddChild (DOMString, DOMString, Boolean, Integer) (see page 7404)	Adds a new child node to this node.
	TXMLNode.AddChild (DOMString, DOMString, TXMLNodeClass, Integer) (see page 7404)	Adds a new child node to this node.
	TXMLNode.AddChild (DOMString, Integer) (see page 7404)	Adds a new child node to this node.

79.1.2.5.3.1 TXMLNode.AddChild Method (DOMString, DOMString, Boolean, Integer)

Adds a new child node to this node.

Pascal

```
function AddChild(const TagName: DOMString; Index: Integer = -1): IXMLNode; overload;
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString; GenPrefix: Boolean
= False; Index: Integer = -1): IXMLNode; overload;
```

```
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString; NodeClass:
TXMLNodeClass; Index: Integer = -1): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode AddChild(const DOMString TagName, int Index = -1);
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI, Boolean
GenPrefix = False, int Index = -1);
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI,
TXMLNodeClass NodeClass, int Index = -1);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected AddChild method. Only the first two versions of AddChild are available on the IXMLNode (see page 7669) interface. The third syntax is used by TXMLNode (see page 7396) descendants that the XML data binding wizard creates.

AddChild creates a new element node as the child of this node.

TagName provides the tag name of the newly created node.

Index indicates the position of the child node in this node's list of children, where 0 is the first position, 1 is the second position, and so on. If Index is –1, the new node is added to the end.

NamespaceURI identifies the namespace that includes the new node's definition. If NamespaceURI is omitted (the first syntax), the namespace of the new node is deduced from the namespace prefix of TagName. If TagName has no namespace prefix and there is no NamespaceURI parameter, the namespace is the same as this node's NamespaceURI property.

GenPrefix controls whether AddChild generates a namespace prefix for the namespace URI when the NamespaceURI parameter identifies a URI that is not already declared in the document. Note that setting GenPrefix to true does not cause AddChild to add a declaration of the new namespace prefix unless the document's Options property includes doNamespaceDecl.

NodeClass identifies the implementation class to use for the new child node. It must be TXMLNode (see page 7396) or one of its descendants.

AddChild returns the interface for the newly created child node.

Tip: AddChild only adds element nodes. To add other types of child nodes, use the XML document's CreateNode method instead, and then add the resulting node to the ChildNodes (see page 7439) property array.

See Also

ChildNodes (see page 7439)

AddChild (see page 7672)

CreateNode (see page 7357)

Options (see page 7389)

CreateElement (see page 7357)

NSPrefixBase (see page 7389)

DeclareNamespace (see page 7412)

79.1.2.5.4 TXMLNode.AddHostedNode Method

Adds a node to the HostedNodes (see page 7441) property list.

Pascal

```
procedure AddHostedNode(Node: TXMLNode);
```

C++

```
__fastcall AddHostedNode(TXMLNode Node);
```

Description

AddHostedNode is used internally to add nodes to the HostedNodes (see page 7441) array.

Node is the node to add to the array.

See Also

HostedNodes (see page 7441)

RemoveHostedNode (see page 7431)

79.1.2.5.5 TXMLNode.AttributeListNotify Method

Responds to notifications of changes in the list of attributes.

Pascal

```
procedure AttributeListNotify(Operation: TNodeListOperation; var Node: IXMLNode; const
IndexOrName: OleVariant; BeforeOperation: Boolean);
```

C++

```
__fastcall AttributeListNotify(TNodeListOperation Operation, IXMLNode Node, const OleVariant
IndexOrName, Boolean BeforeOperation);
```

Description

Applications can't call this protected method. The class that implements the AttributeNodes (see page 7438) property calls AttributeListNotify when attribute nodes are inserted or removed, or when a new attribute node needs to be created. AttributeListNotify generates a BeforeNodeChange or AfterNodeChange event on the document object, and, if the change has not yet occurred, updates the underlying DOM implementation to reflect the change.

Operation indicates what type of change occurred.

Node is the interface for the attribute node that was added or removed. If a new attribute node needs to be created, Node returns the new node.

IndexOrName is the name of the attribute when Operation is nlCreateNode.

BeforeOperation indicates whether the call occurs before the attribute node is added or removed.

See Also

AttributeNodes (see page 7438)

TNodeListNotification (see page 7499)

BeforeNodeChange (see page 7394)

AfterNodeChange (see page 7393)

79.1.2.5.6 TXMLNode.CheckNotHosted Method

Raises an EXMLDocError (see page 7639) exception if this is a hosted node.

Pascal

```
procedure CheckNotHosted;
```

C++

```
__fastcall CheckNotHosted();
```

Description

Applications can't call this protected method. It is used internally in methods that can only be used by the main node that corresponds to an element. If the node represents a hosted node (that is, if the node is used to represent a subset of the main, or host, node), then CheckNotHosted raises an EXMLDocError (see page 7639) exception.

For example, the CreateCollection (see page 7411) method calls CheckNotHosted, because only the main node for an element can host collection nodes.

See Also

HostNode (see page 7441)

HostedNodes (see page 7441)

EXMLDocError (see page 7639)

CreateCollection (see page 7411)

79.1.2.5.7 TXMLNode.CheckReadOnly Method

Raises an EXMLDocError (see page 7639) exception if this is a read-only node.

Pascal

```
procedure CheckReadOnly;
```

C++

```
__fastcall CheckReadOnly();
```

Description

Applications can't call this protected method. It is used internally in methods that change the value, children, or attributes of the node, to check whether the change is permitted, and if not, raise an exception.

See Also

GetReadOnly (see page 7425)

SetReadOnly (see page 7436)

ReadOnly (see page 7696)

EXMLDocError (see page 7639)

79.1.2.5.8 TXMLNode.CheckTextNode Method

Generates a DOM text node implementation if it does not yet exist.

Pascal

```
procedure CheckTextNode;
```

C++

```
__fastcall CheckTextNode();
```

Description

Applications can't call this protected method. It is used internally to generate a DOM node implementation for text values.

If the XML node is an element that has child nodes (other than a single DOM text node), CheckTextNode raises an exception.

79.1.2.5.9 TXMLNode.ChildListNotify Method

Responds to notifications of changes in the list of child nodes.

Pascal

```
procedure ChildListNotify(Operation: TNodeListOperation; var Node: IXMLNode; const
IndexOrName: OleVariant; BeforeOperation: Boolean); virtual;
```

C++

```
virtual __fastcall ChildListNotify(TNodeListOperation Operation, IXMLNode Node, const
OleVariant IndexOrName, Boolean BeforeOperation);
```

Description

Applications can't call this protected method. The class that implements the ChildNodes (see page 7439) property calls ChildListNotify when child nodes are inserted or removed, or when a node needs to be created. ChildListNotify generates a BeforeNodeChange or AfterNodeChange event on the document object, and, if the change has not yet occurred, updates the underlying DOM implementation to reflect the change.

Operation indicates what type of change is occurring.

Node is the interface for the child node about which this method is called. When nodes are added or removed, this is the node that is added or removed. When a node needs to be created, this parameter returns the newly created node.

IndexOrName is the index of the node that is added or removed when Operation is nlInsert or nlRemove. When Operation is nlCreateNode, IndexOrName is the name of the child node to create.

BeforeOperation indicates whether the call occurs before the child node is added or removed.

See Also

ChildNodes (see page 7439)

AddChild (see page 7404)

TNodeListNotification (see page 7499)

BeforeNodeChange (see page 7394)

AfterNodeChange (see page 7393)

79.1.2.5.10 TXMLNode.ClearDocumentRef Method

Sets the value of OwnerDocument (see page 7442) to nil (Delphi) or NULL (C++).

Pascal

```
procedure ClearDocumentRef;
```

C++

```
__fastcall ClearDocumentRef();
```

Description

Applications can't call this protected method. The document that contains this node calls ClearDocumentRef when it is freed so that the node does not maintain a reference to a non-existent document.

In addition to setting the OwnerDocument (see page 7442) property to nil (Delphi) or NULL (C++), ClearDocumentRef propagates this call to all of this nodes child nodes and attribute nodes.

See Also

OwnerDocument (see page 7442)

ChildNodes (see page 7439)

AttributeNodes (see page 7438)

79.1.2.5.11 TXMLNode.CloneNode Method

Creates a copy of this node and returns its interface.

Pascal

```
function CloneNode(Deep: Boolean): IXMLNode;
```

C++

```
__fastcall IXMLNode CloneNode(Boolean Deep);
```

Description

Applications can't call the protected CloneNode method. To create a copy of this node, use the CloneNode method of this node's IXMLNode (see page 7669) interface.

CloneNode returns a copy of this node that has no parent. Any attributes of this node are copied as well, including attribute nodes that represent default values.

Deep indicates whether the child nodes of this node should be cloned as well. For example, if an element node contains any text, CloneNode only copies then text when deep is true, because in the underlying DOM implementation, the text is contained in a child node.

See Also

ChildNodes (see page 7439)

AddChild (see page 7404)

ParentNode (see page 7443)

CloneNode (see page 7673)

cloneNode (see page 7560)

79.1.2.5.12 TXMLNode.CreateAttributeList Method

Creates the object that implements the AttributeNodes (see page 7438) property.

Pascal

```
function CreateAttributeList: IXMLNodeList; dynamic;
```

C++

```
__fastcall IXMLNodeList CreateAttributeList();
```

Description

Applications can't call the protected CreateAttributeList method. This method is used internally the first time an application reads the AttributeNodes (see page 7438) property.

CreateAttributeList creates an implementation class for the AttributeNodes (see page 7438) property, telling it to call the AttributeListNotify (see page 7406) method when it changes the list of attributes for this node, and filling it with nodes based on the current attributes of this node.

See Also

AttributeNodes (see page 7438)

AttributeListNotify (see page 7406)

79.1.2.5.13 TXMLNode.CreateAttributeNode Method

Creates a new TXMLNode (see page 7396) object for an attribute of this node.

Pascal

```
function CreateAttributeNode(const ADOMNode: IDOMNode): IXMLNode; virtual;
```

C++

```
virtual __fastcall IXMLNode CreateAttributeNode(const IDOMNode ADOMNode);
```

Description

Applications can't call the protected CreateAttributeNode method. TXMLNode (see page 7396) uses this method internally to generate the nodes that populate the AttributeNodes (see page 7438) property.

CreateAttributeNode creates a new TXMLNode (see page 7396) object for the specified IDOMNode (see page 7557) interface and returns its interface.

ADOMNode is the interface for the DOM implementation's version of the attribute node.

See Also

AttributeNodes (see page 7438)

79.1.2.5.14 TXMLNode.CreateChildList Method

Creates the object that implements the ChildNodes (see page 7439) property.

Pascal

```
function CreateChildList: IXMLNodeList; dynamic;
```

C++

```
__fastcall IXMLNodeList CreateChildList();
```

Description

Applications can't call the protected CreateChildList method. This method is used internally the first time an application reads the ChildNodes (see page 7439) property.

CreateChildList creates an implementation class for the ChildNodes (see page 7439) property, telling it to call the ChildListNotify (see page 7408) method when it changes the list of attributes for this node, and filling it with nodes that are based on the current children of this node.

See Also

ChildNodes (see page 7439)

ChildListNotify (see page 7408)

79.1.2.5.15 TXMLNode.CreateChildNode Method

Creates a new TXMLNode (see page 7396) object for a child node of this node.

Pascal

```
function CreateChildNode(const ADOMNode: IDOMNode): IXMLNode; virtual;
```

C++

```
virtual __fastcall IXMLNode CreateChildNode(const IDOMNode ADOMNode);
```

Description

Applications can't call the protected CreateChildNode method. This method is used internally to create the implementation object for a new child node.

CreateChildNode creates a new TXMLNode (see page 7396) descendant for the specified IDOMNode (see page 7557) interface, with this node as the parent. If the node name of the DOM node matches one of the names listed by the ChildNodeClasses (see page 7438) property, the corresponding descendant of TXMLNode (see page 7396) becomes the implementation class of the new node. Otherwise, the new node is an instance of TXMLNode (see page 7396).

ADOMNode is the interface for the DOM implementation's version of the node.

CreateChildNode returns the interface for the newly created child node.

See Also

Create (see page 7400)

ChildNodeClasses (see page 7438)

CreateDOMNode (see page 7488)

79.1.2.5.16 TXMLNode.CreateCollection Method

Creates an instance of a TXMLNodeCollection (see page 7444) descendant and returns it.

Pascal

```
function CreateCollection(const CollectionClass: TXMLNodeCollectionClass; const ItemInterface:
TGuid; const ItemTag: DOMString; ItemNS: DOMString = ''): TXMLNodeCollection;
```

C++

```
__fastcall TXMLNodeCollection CreateCollection(const TXMLNodeCollectionClass CollectionClass,
const TGuid ItemInterface, const DOMString ItemTag, DOMString ItemNS = '');
```

Description

Applications can't call the protected CreateCollection method. It is used internally to generate the collections that are listed in the HostedNodes (see page 7441) property.

CollectionClass specifies the class (a TXMLNodeCollection (see page 7444) descendant) that implements the collection of child nodes.

ItemInterface specifies the interface for each child node in the collection.

ItemTag specifies the tag name for each child node in the collection.

ItemNS specifies the namespace in which ItemTag is defined.

CreateCollection returns the new hosted collection node. This new node has the same parent node, DOM interface, attribute nodes, and child nodes as this node, but it also maintains a list of only those child nodes with the specified tag and interface. The new collection node lists this node as the value of its HostNode (see page 7441) property.

Note: CreateCollection raises an exception if this is a hosted node.

See Also

HostedNodes (see page 7441)

ChildNodes (see page 7439)

ParentNode (see page 7443)

DOMNode (see page 7440)

HostNode (see page 7441)

ItemInterface (see page 7458)

ItemTag (see page 7459)

ItemNS (see page 7458)

79.1.2.5.17 TXMLNode.DeclareNamespace Method

Adds an attribute to the node that declares a specified namespace URI.

Pascal

```
procedure DeclareNamespace(const Prefix: DOMString; const URI: DOMString);
```

C++

```
__fastcall DeclareNamespace(const DOMString Prefix, const DOMString URI);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected DeclareNamespace method. DeclareNamespace adds an attribute to this node that declares the specified namespace URI as the value of the specified prefix.

Prefix is the namespace prefix that appears in tag names that reference the namespace.

URI is the corresponding namespace URI.

Note: This method is called automatically for newly created nodes when the document's Options property includes doNamespaceDecl.

See Also

Options (see page 7389)

AttributeNodes (see page 7438)

FindNamespaceDecl (see page 7414)

DeclareNamespace (see page 7674)

79.1.2.5.18 TXMLNode.DOMElement Method

Returns the IDOMElement (see page 7542) interface for this node if it exists.

Pascal

```
function DOMElement: IDOMElement;
```

C++

```
__fastcall IDOMElement DOMElement();
```

Description

Application's can't call the protected DOMElement method. TXMLNode (see page 7396) uses this method internally to obtain the DOM element interface, which it uses for working with attributes.

If the TXMLNode (see page 7396) instance does not represent an element node, DOMElement raises an EXMLDocError (see page 7639) exception.

See Also

AttributeNodes (see page 7438)

GetAttribute (see page 7415)

SetAttribute (see page 7432)

79.1.2.5.19 TXMLNode.DoNodeChange Method

Generates a BeforeNodeChange or AfterNodeChange event on this node's document.

Pascal

```
procedure DoNodeChange(ChangeType: TNodeChange; BeforeOperation: Boolean); virtual;
```

C++

```
virtual __fastcall DoNodeChange(TNodeChange ChangeType, Boolean BeforeOperation);
```

Description

Applications can't call the protected DoNodeChange method. It is called internally before and after every change that is made to the node. DoNodeChange checks whether the node's OwnerDocument (see page 7442) property is set, and if so, generates a BeforeNodeChange or AfterNodeChange event on that document, as appropriate.

ChangeType indicates the type of change that is occurring to the node.

BeforeOperation is true if the change is about to occur, false if the change has just occurred.

See Also

AfterNodeChange (see page 7393)

BeforeNodeChange (see page 7394)

OwnerDocument (see page 7442)

79.1.2.5.20 TXMLNode.FindHostedNode Method

Returns the IXMLNode (see page 7669) interface for a hosted node given its implementation class.

Pascal

```
function FindHostedNode(const NodeClass: TXMLNodeClass): IXMLNode;
```

C++

```
__fastcall IXMLNode FindHostedNode(const TXMLNodeClass NodeClass);
```

Description

Applications can't call the protected FindHostedNode method. Descendant classes call this method to locate a hosted node of a particular class type.

FindHostedNode searches the nodes in the HostedNodes (see page 7441) list and returns the first one it finds that is an instance of descendant of NodeClass. If this node does not have a hosted node of the specified class, FindHostedNode returns

nil (Delphi) or NULL (C++).

See Also

HostedNodes (see page 7441)

CreateCollection (see page 7411)

79.1.2.5.21 TXMLNode.FindNamespaceDecl Method

Returns the attribute node that declares a specified Namespace URI.

Pascal

```
function FindNamespaceDecl(const NamespaceURI: DOMString): IXMLNode;
```

C++

```
__fastcall IXMLNode FindNamespaceDecl(const DOMString NamespaceURI);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected FindNamespaceDecl method. FindNamespaceDecl searches the node hierarchy that contains this node for an attribute that specifies the mapping between a namespace prefix and the namespace URI specified by NamespaceURI. If it finds such a mapping, FindNamespaceDecl returns the interface for the Attribute node. If it does not find a mapping, FindNamespaceDecl returns nil (Delphi) or NULL (C++).

NamespaceURI is the namespace URI to locate.

See Also

FindNamespaceURI (see page 7414)

DeclareNamespace (see page 7412)

FindNamespaceDecl (see page 7674)

79.1.2.5.22 TXMLNode.FindNamespaceURI Method

Returns the namespace URI for a namespace prefix or qualified tag name.

Pascal

```
function FindNamespaceURI(const TagOrPrefix: DOMString): DOMString;
```

C++

```
__fastcall DOMString FindNamespaceURI(const DOMString TagOrPrefix);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected FindNamespaceURI method. FindNamespaceDecl (see page 7414) searches the node hierarchy that contains this node for an attribute that specifies the mapping between the namespace prefix identified by TagOrPrefix and a namespace URI. If it finds such a mapping, FindNamespaceURI returns the namespace URI. If it does not find a mapping, FindNamespaceURI returns an empty string.

TagOrPrefix is the namespace prefix or a tag name that includes the namespace prefix.

See Also

GetNamespaceURI (see page 7421)

GetPrefix (see page 7424)

FindNamespaceDecl (see page 7414)

FindNamespaceURI (see page 7674)

79.1.2.5.23 TXMLNode.GetAttribute Method

Returns the value of one of this node's attributes.

Pascal

```
function GetAttribute(const AttrName: DOMString): OleVariant;
```

C++

```
__fastcall OleVariant GetAttribute(const DOMString AttrName);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetAttribute method. GetAttribute returns the value of an attribute of this node.

AttrName is the name of the attribute.

GetAttribute returns the value of the specified attribute. Typically, this value is a string. If the node does not have an attribute with the name specified by AttrName, the value that GetAttribute returns is determined by the document's Options property. When Options include doAttrNull, GetAttribute returns a Null (see page 5056) Variant (see page 3421) for missing attributes. When Options does not include doAttrNull, GetAttribute returns an empty string as the value of missing attributes.

If this node is not an element node, GetAttribute raises an EXMLDocError (see page 7639) exception.

See Also

SetAttribute (see page 7432)

AttributeNodes (see page 7438)

GetAttributeNS (see page 7416)

79.1.2.5.24 TXMLNode.GetAttributeNodes Method

Returns the value of the AttributeNodes (see page 7438) property.

Pascal

```
function GetAttributeNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetAttributeNodes();
```

Description

GetAttributeNodes is the read implementation of the AttributeNodes (see page 7438) property on the IXMLNode (see page 7669) interface for this node.

GetAttributeNodes generates the list that implements the AttributeNodes (see page 7438) property the first time an application reads the AttributeNodes (see page 7438) property.

See Also

GetAttribute (see page 7415)

AttributeNodes (see page 7438)

79.1.2.5.25 TXMLNode.GetAttributeNS Method

Returns the value of a specified attribute when you must explicitly specify the namespace for the attribute.

Pascal

```
function GetAttributeNS(const AttrName: DOMString; const NamespaceURI: DOMString): OleVariant;
```

C++

```
__fastcall OleVariant GetAttributeNS(const DOMString AttrName, const DOMString NamespaceURI);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetAttributeNS method. GetAttributeNS returns the value of an attribute of this node.

AttrName is the name of the attribute.

NamespaceURI identifies the namespace in which the attribute resides.

GetAttributeNS returns the value of the specified attribute. If AttrName and NamespaceURI do not identify an attribute of this node, GetAttributeNS returns a Null (see page 5056) Variant (see page 3421).

If this node is not an element node, GetAttributeNS raises an EXMLDocError (see page 7639) exception.

See Also

GetAttribute (see page 7415)

Attributes (see page 7688)

GetNamespaceURI (see page 7421)

SetAttributeNS (see page 7433)

AttributeNodes (see page 7438)

79.1.2.5.26 TXMLNode.GetChildNodeClasses Method

Returns a list of the classes that can implement child nodes of this node.

Pascal

```
function GetChildNodeClasses: TNodeClassArray;
```

C++

```
__fastcall TNodeClassArray GetChildNodeClasses();
```

Description

GetChildNodeClasses is used internally to obtain a list of the classes that can be used to represent child nodes of this node.

If this node is not a hosted node, GetChildNodeClasses returns an array containing every class that has been registered using the RegisterChildNode (see page 7430) method. If this node is a hosted node, GetChildNodeClasses returns the ChildNodeClasses (see page 7438) property of the host node.

See Also

ChildNodeClasses (see page 7438)

RegisterChildNode (see page 7430)

HostNode (see page 7441)

79.1.2.5.27 TXMLNode.GetChildNodes Method

Returns the value of the ChildNodes (see page 7439) property.

Pascal

```
function GetChildNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetChildNodes();
```

Description

GetChildNodes is the protected read implementation of the ChildNodes (see page 7439) property.

GetChildNodes generates the list that implements the ChildNodes (see page 7439) property the first time an application reads the ChildNodes (see page 7439) property.

See Also

GetChildValue (see page 7417)

ChildNodes (see page 7439)

79.1.2.5.28 TXMLNode.GetChildValue Method

Returns the value of a specified child node.

Pascal

```
function GetChildValue(const IndexOrName: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant GetChildValue(const OleVariant IndexOrName);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetChildValue method. GetChildValue returns the value of the node.

IndexOrName identifies the desired child node by either its interface, or by a string that is the local name of the child node.

If IndexOrName does not identify a child of this node, GetChildValue nil (Delphi) or NULL (C++). Otherwise, the return value depends on the type of the child node, as indicated in the following table:

NodeType	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, GetChildValue raises an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntEntityRef	nil (Delphi) or NULL (C++)
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
ntDocFragment	nil (Delphi) or NULL (C++)

Note: Attributes are not considered child nodes of a node. To get the values of this node's attributes, use the GetAttribute (

see page 7415) method instead.

See Also

ChildNodes (see page 7439)

ParentNode (see page 7443)

GetAttribute (see page 7415)

GetNodeValue (see page 7423)

79.1.2.5.29 TXMLNode.GetCollection Method

Returns the value of the Collection (see page 7439) property.

Pascal

```
function GetCollection: IXMLNodeCollection;
```

C++

```
__fastcall IXMLNodeCollection GetCollection();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetCollection method. GetCollection returns the value of the Collection (see page 7439) property. If this node is not a member of a collection (that is, if it does not represent one of a set of child nodes that are all the same type), then GetCollection returns nil (Delphi) or NULL (C++).

See Also

Collection (see page 7439)

79.1.2.5.30 TXMLNode.GetDOMNode Method

Returns the value of the DOMNode (see page 7440) property.

Pascal

```
function GetDOMNode: IDOMNode;
```

C++

```
__fastcall IDOMNode GetDOMNode();
```

Description

GetDOMNode is the protected read implementation of the DOMNode (see page 7440) property.

See Also

DOMNode (see page 7440)

79.1.2.5.31 TXMLNode.GetHasChildNodes Method

Indicates whether this node has any child nodes.

Pascal

```
function GetHasChildNodes: Boolean;
```

C++

```
__fastcall Boolean GetHasChildNodes();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetHasChildNodes method. GetHasChildNodes returns true if the underlying DOM node has any child nodes, false if it doesn't.

Note that even if the underlying DOM node has a child node, there may not be a TXMLNode (see page 7396) object to represent that child. For example, text nodes do not, by default, have corresponding TXMLNode (see page 7396) wrappers. Rather, the text becomes the value of the parent element node.

See Also

ChildNodes (see page 7439)

DOMNode (see page 7440)

GetIsTextElement (see page 7419)

79.1.2.5.32 TXMLNode.GetHostedNodes Method

Returns a list an array of the hosted nodes that share this node's attribute and child node lists.

Pascal

```
function GetHostedNodes: TXMLNodeArray;
```

C++

```
__fastcall TXMLNodeArray GetHostedNodes();
```

Description

GetHostedNodes is the read implementation of the HostedNodes (see page 7441) property. It returns a list an array of all nodes that represent aspects of this node, sharing its attributes and list of child nodes.

See Also

HostedNodes (see page 7441)

79.1.2.5.33 TXMLNode.GetHostNode Method

Returns the value of the HostNode (see page 7441) property.

Pascal

```
function GetHostNode: TXMLNode;
```

C++

```
__fastcall TXMLNode GetHostNode();
```

Description

GetHostNode returns the node that uses this node to represent a particular aspect of it, sharing the same attributes and list of child nodes. If this is not a hosted node, GetHostNode returns nil (Delphi) or NULL (C++).

See Also

HostNode (see page 7441)

79.1.2.5.34 TXMLNode.GetIsTextElement Method

Indicates whether the node has a single text value.

Pascal

```
function GetIsTextElement: Boolean;
```

C++

```
__fastcall Boolean GetIsTextElement();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetIsTextElement method. GetIsTextElement returns true if the node represents an XML fragment such as

```
<Title> Understanding XML </Title>
```

where the node has a tag name (in this case Title) and a single text value (in this case 'Understanding XML').

GetIsTextElement returns false if the node is any other type of node.

Note: In the underlying DOM implementation, nodes for which GetIsTextElement is true are element nodes that have a single child node that is a text node. TXMLNode (see page 7396) flattens this out so that the child text node does not appear as a child node. Instead, the text can be accessed through the GetText (see page 7426) method.

See Also

GetText (see page 7426)

GetHasChildNodes (see page 7418)

79.1.2.5.35 TXMLNode.GetLocalName Method

Returns the name of the node without any namespace prefix.

Pascal

```
function GetLocalName: DOMString;
```

C++

```
__fastcall DOMString GetLocalName();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetLocalName method. GetLocalName returns the local name of the underlying DOM node.

For element nodes, the local name is derived from the name that appears in the XML tag. For example, the local name for <xsi:Name First="John" Last="Doe"> is 'Name'.

For attribute nodes, the local name is derived from the string that appears to the left of the equals sign in the attribute declaration. For example the element <Name First=John Last=Doe> results in two attribute nodes, with the local names 'First' and 'Last'.

For any other node types, the local name is nil (Delphi) or NULL (C++).

Note: If both GetPrefix (see page 7424) and GetLocalName return a value for a node, the node name (returned by GetNodeName (see page 7421)) is the combination of these two values.

See Also

GetNodeName (see page 7421)

GetNodeType (see page 7422)

GetPrefix (see page 7424)

GetNamespaceURI (see page 7421)

localName (see page 7570)

79.1.2.5.36 TXMLNode.GetNamespaceURI Method

Returns the URI for the namespace used in the qualified node name.

Pascal

```
function GetNamespaceURI: DOMString;
```

C++

```
__fastcall DOMString GetNamespaceURI();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetNamespaceURI method. GetNamespaceURI returns the URI for the namespace that should be used to interpret the node's name.

Only element and attribute nodes can have a namespace URI value. For any other node type, GetNamespaceURI returns nil (Delphi) or NULL (C++).

The namespace URI is only available if it is explicitly assigned when the node is created. By default, TXMLNode (see page 7396) does not assign namespaces to the new nodes it creates.

See Also

GetNodeName (see page 7421)

GetNodeType (see page 7422)

GetPrefix (see page 7424)

GetLocalName (see page 7420)

CreateDOMNode (see page 7488)

namespaceURI (see page 7571)

79.1.2.5.37 TXMLNode.GetNodeName Method

Returns the node name.

Pascal

```
function GetNodeName: DOMString;
```

C++

```
__fastcall DOMString GetNodeName();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetNodeName method. GetNodeName returns the name of the underlying DOM node.

The node's name depends on the type of the node, as indicated in the following table:

NodeType	NodeName
ntAttribute	The attribute name
ntElement	The tag name
ntText	'#text'
ntCData	'#cdata-section'

ntEntityRef	The name of the entity reference.
ntEntity	The entity name
ntProcessingInstr	the target of the processing instruction
ntComment	'#comment'
ntDocument	'#document'
ntDocType	The document type name
ntDocFragment	'#document-fragment'
ntNotation	The notation name

Note: If GetPrefix (see page 7424) and GetLocalName (see page 7420) both return values for a node, the node name is the combination of these two values.

See Also

GetNodeType (see page 7422)

GetPrefix (see page 7424)

GetLocalName (see page 7420)

79.1.2.5.38 TXMLNode.GetNodeObject Method

Returns a reference to this TXMLNode (see page 7396) object.

Pascal

```
function GetNodeObject: TXMLNode;
```

C++

```
__fastcall TXMLNode GetNodeObject();
```

Description

GetNodeObject returns Self (Delphi) or this (C++).

79.1.2.5.39 TXMLNode.GetNodeType Method

Returns the type of the node.

Pascal

```
function GetNodeType: TNodeType;
```

C++

```
__fastcall TNodeType GetNodeType();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetNodeType method. GetNodeType returns the type of the underlying DOM node that this TXMLNode (see page 7396) object represents.

See Also

GetIsTextElement (see page 7419)

79.1.2.5.40 TXMLNode.GetNodeValue Method

Returns the value of this node.

Pascal

```
function GetNodeValue: OleVariant;
```

C++

```
__fastcall OleVariant GetNodeValue();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetNodeValue method. GetNodeValue returns the value of the node. This value depends on the type of the node, as indicated in the following table:

NodeType	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, GetNodeValue raises an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntEntityRef	nil (Delphi) or NULL (C++)
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
ntDocFragment	nil (Delphi) or NULL (C++)

See Also

GetChildValue (see page 7417)

GetText (see page 7426)

79.1.2.5.41 TXMLNode.GetOwnerDocument Method

Returns the interface for the document in which this node appears.

Pascal

```
function GetOwnerDocument: IXMLDocument;
```

C++

```
__fastcall IXMLDocument GetOwnerDocument();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetOwnerDocument method. GetOwnerDocument returns the value of the OwnerDocument (see page 7442) property.

See Also

OwnerDocument (see page 7442)

79.1.2.5.42 TXMLNode.GetParentNode Method

Returns the interface for the node's parent node.

Pascal

```
function GetParentNode: IXMLNode;
```

C++

```
__fastcall IXMLNode GetParentNode();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetParentNode method. GetParentNode returns the interface of the node's parent node.

See Also

ParentNode (see page 7443)

79.1.2.5.43 TXMLNode.GetPrefix Method

Returns the namespace prefix of the node's name.

Pascal

```
function GetPrefix: DOMString;
```

C++

```
__fastcall DOMString GetPrefix();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetPrefix method. GetPrefix returns the namespace prefix of an element or attribute node's name. A namespace prefix is a symbolic name for a namespace URI.

For element nodes, the namespace prefix is derived from the name that appears in the XML tag. For example, the namespace prefix for <xsi:Name First="John" Last="Doe"> is 'xsi'.

For attribute nodes, the namespace prefix is derived from the string that appears to the left of the equals sign in the attribute declaration. For example the element <xsi:Name xsn:First="John" Last="Doe"> results in two attribute nodes, with namespace prefixes of 'xsn' and '', respectively. Note that the attribute never inherits a namespace prefix from the node to which it is attached.

For any other node types, the namespace prefix is nil (Delphi) or NULL (C++).

Note: If both GetPrefix and GetLocalName (see page 7420) return a value for a node, the node name (returned by GetNodeName (see page 7421)) is the combination of these two values.

See Also

GetLocalName (see page 7420)

GetNodeType (see page 7422)

GetNamespaceURI (see page 7421)

GetPrefixedName (see page 7425)

79.1.2.5.44 TXMLNode.GetPrefixedName Method

Returns a node name includes a namespace prefix for a specified namespace URI.

Pascal

```
function GetPrefixedName(const Name: DOMString; const NamespaceURI: DOMString): DOMString;
```

C++

```
__fastcall DOMString GetPrefixedName(const DOMString Name, const DOMString NamespaceURI);
```

Description

GetPrefixedName adds a prefix to a local node name based on the specified namespace URI. If there is no corresponding namespace already declared or if the name is already prefixed, GetPrefixedName returns the original node name.

Name is the node name to which the namespace prefix should be added.

NamespaceURI is the URI for the namespace that should be identified by the namespace prefix.

Note: If the document containing this node does not include doAutoPrefix in its Options property, GetPrefixedName always returns the value of Name, without trying to generate or add a namespace prefix.

See Also

GetLocalName (see page 7420)

GetPrefix (see page 7424)

GetNamespaceURI (see page 7421)

Options (see page 7389)

79.1.2.5.45 TXMLNode.GetReadOnly Method

Indicates whether the node can be modified.

Pascal

```
function GetReadOnly: Boolean;
```

C++

```
__fastcall Boolean GetReadOnly();
```

Description

GetReadOnly returns true if the node can't be modified. Read (see page 3634)-only nodes raise an EXMLDocError (see page 7639) exception when an attempt is made to change their value, child nodes, or attributes.

GetReadOnly returns false if the node can be modified.

Note: Use the ReadOnly property on the IXMLNode (see page 7669) interface to specify whether a node is read-only.

See Also

SetReadOnly (see page 7436)

ReadOnly (see page 7696)

EXMLDocError (see page 7639)

79.1.2.5.46 TXMLNode.GetText Method

Returns the text value of the node.

Pascal

```
function GetText: DOMString;
```

C++

```
__fastcall DOMString GetText();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetText method. GetText returns the text of the node. For example, if the node represents an XML fragment such as

```
<Title> Understanding XML </Title>
```

GetText returns the string 'Understanding XML'.

GetText is intended for use when the GetIsTextElement (see page 7419) method returns true. If GetIsTextElement (see page 7419) returns false, GetText returns an empty string if the node has no children, otherwise it raises an exception.

See Also

GetIsTextElement (see page 7419)

GetNodeValue (see page 7423)

SetText (see page 7436)

79.1.2.5.47 TXMLNode.GetXML Method

Returns the XML that corresponds to the subtree rooted at this node.

Pascal

```
function GetXML: DOMString;
```

C++

```
__fastcall DOMString GetXML();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected GetXML method. GetXML returns the XML that corresponds to this node and any child nodes it contains.

Note: GetXML is only available when the DOMVendor used to parse this node's XML document is MSXML.

See Also

GetText (see page 7426)

ChildNodes (see page 7439)

DOMVendor (see page 7386)

79.1.2.5.48 HasAttribute Method

This is the overview for the HasAttribute method overload.

Overload List

	Name	Description
	TXMLNode.HasAttribute (DOMString) (see page 7427)	Indicates whether the node has an attribute with a specified name.
	TXMLNode.HasAttribute (DOMString, DOMString) (see page 7427)	Indicates whether the node has an attribute with a specified name.

79.1.2.5.48.1 TXMLNode.HasAttribute Method (DOMString)

Indicates whether the node has an attribute with a specified name.

Pascal

```
function HasAttribute(const Name: DOMString): Boolean; overload;
function HasAttribute(const Name: DOMString; const NamespaceURI: DOMString): Boolean; overload;
```

C++

```
__fastcall Boolean HasAttribute(const DOMString Name);
__fastcall Boolean HasAttribute(const DOMString Name, const DOMString NamespaceURI);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected HasAttribute method.

Name is the name of the attribute about which you want to know.

NamespaceURI is the namespace of the attribute.

HasAttribute returns true if this node has the specified attribute, false otherwise.

See Also

AttributeNodes (see page 7438)

GetAttribute (see page 7415)

GetAttributeNS (see page 7416)

79.1.2.5.49 HasChildNode Method

This is the overview for the HasChildNode method overload.

Overload List

	Name	Description
	TXMLNode.HasChildNode (DOMString) (see page 7427)	Indicates whether the node has a child node with the specified name.
	TXMLNode.HasChildNode (DOMString, DOMString) (see page 7427)	Indicates whether the node has a child node with the specified name.

79.1.2.5.49.1 TXMLNode.HasChildNode Method (DOMString)

Indicates whether the node has a child node with the specified name.

Pascal

```
function HasChildNode(const ChildTag: DOMString): Boolean; overload;
```

```
function HasChildNode(const ChildTag: DOMString; const NamespaceURI: DOMString): Boolean;
overload;
```

C++

```
__fastcall Boolean HasChildNode(const DOMString ChildTag);
__fastcall Boolean HasChildNode(const DOMString ChildTag, const DOMString NamespaceURI);
```

Description

Applications can't call the protected HasChildNode method. It is used internally to determine when the underlying DOM node has a child with the specified name.

ChildTag is the local tag name of the child to find.

NamespaceURI identifies the namespace in which ChildTag is defined.

HasChildNode returns true if the underlying DOM node includes the specified child node. Otherwise, it returns false.

See Also

ChildNodes (see page 7439)

DOMNode (see page 7440)

79.1.2.5.50 TXMLNode.InternalAddChild Method

Provides the underlying implementation for the AddChild (see page 7404) method.

Pascal

```
function InternalAddChild(NodeClass: TXMLNodeClass; const NodeName: DOMString; const
NamespaceURI: DOMString; Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode InternalAddChild(TXMLNodeClass NodeClass, const DOMString NodeName, const
DOMString NamespaceURI, int Index);
```

Description

Applications can't call the protected InternalAddChild method. It is used internally to perform all the tasks common to the various overloads of the AddChild (see page 7404) method. InternalAddChild creates a new element node as the child of this node and returns its interface.

NodeClass specifies the implementation class to use for the new child node. It must be TXMLNode (see page 7396) or one of its descendants.

NodeName specifies the tag name of the newly created node.

NamespaceURI identifies the namespace that includes the new node's definition.

Index indicates the position of the child node in this node's list of children, where 0 is the first position, 1 is the second position, and so on. If Index is –1, the new node is added to the end.

See Also

AddChild (see page 7404)

79.1.2.5.51 TXMLNode.NestingLevel Method

Returns the number of parents for this node in the node hierarchy.

Pascal

```
function NestingLevel: Integer;
```

C++

```
__fastcall int NestingLevel();
```

Description

Application's can't call the protected NestingLevel property. It is used internally when formatting the XML text that corresponds to this XML document.

NestingLevel returns the number of ancestors for this node in the node hierarchy.

See Also

ParentNode (see page 7443)

ChildNodes (see page 7439)

79.1.2.5.52 TXMLNode.NextSibling Method

Returns the next child of this node's parent.

Pascal

```
function NextSibling: IXMLNode;
```

C++

```
__fastcall IXMLNode NextSibling();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected NextSibling method. NextSibling returns the node that follows this one in the parent node's ChildNodes (see page 7439) property list.

If this node is the last node in its parent's child list, NextSibling raises an exception.

See Also

ParentNode (see page 7443)

PreviousSibling (see page 7430)

ChildNodes (see page 7439)

79.1.2.5.53 TXMLNode.Normalize Method

Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.

Pascal

```
procedure Normalize;
```

C++

```
__fastcall Normalize();
```

Description

Use the IXMLNode (see page 7669) interface to call the protected Normalize method. Normalize consolidates adjacent text nodes and remove any empty text nodes in the subtree beneath this node. This method ensures that for all child nodes of this node and of its attributes, only structure nodes (element nodes, comments, processing instructions, CDATA sections, and entity references) separate text nodes and that there are no empty text nodes.

See Also

ChildNodes (see page 7439)

AttributeNodes (see page 7438)

79.1.2.5.54 TXMLNode.PreviousSibling Method

Returns the previous child of this node's parent.

Pascal

```
function PreviousSibling: IXMLNode;
```

C++

```
__fastcall IXMLNode PreviousSibling();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected PreviousSibling method. PreviousSibling returns the node that precedes this one in the parent node's ChildNodes (see page 7439) property list.

If this node is the first node in its parent's child list, PreviousSibling raises an exception.

See Also

ParentNode (see page 7443)

NextSibling (see page 7429)

ChildNodes (see page 7439)

79.1.2.5.55 TXMLNode.RegisterChildNode Method

Registers a descendant of TXMLNode (see page 7396) that can represent the children of this node.

Pascal

```
procedure RegisterChildNode(const TagName: DOMString; ChildNodeClass: TXMLNodeClass;
NamespaceURI: DOMString = '');
```

C++

```
__fastcall RegisterChildNode(const DOMString TagName, TXMLNodeClass ChildNodeClass, DOMString
NamespaceURI = '');
```

Description

Applications can't call the protected RegisterChildNode method. It is called by the RegisterChildNodes (see page 7431) method to register a TXMLNode (see page 7396) descendant so that it can be used as a child of this node. Each TXMLNode (see page 7396) descendant is specific to the structure of the XML document, with properties that correspond to the child nodes and attributes of a node.

RegisterChildNode adds an entry to the ChildNodeClasses (see page 7438) property for the specified node class and tag name.

TagName is the tag name of the child node that the class represents.

NodeClass is the TXMLNode (see page 7396) descendant that implements child nodes that have the specified tag name.

NamespaceURI identifies the namespace in which TagName is defined.

Note: RegisterChildNode raises an exception if this is a hosted node.

See Also

RegisterChildNodes (see page 7431)

ChildNodeClasses (see page 7438)

79.1.2.5.56 TXMLNode.RegisterChildNodes Method

Registers a set of TXMLNode (see page 7396) descendants that can represent the children of this node.

Pascal

```
procedure RegisterChildNodes(const TagNames: array of DOMString; const NodeClasses: array of
TXMLNodeClass);
```

C++

```
__fastcall RegisterChildNodes(const array of DOMString TagNames, const array of TXMLNodeClass
NodeClasses);
```

Description

Applications can't call the protected RegisterChildNodes method. It is used in code that the XML Data Binding wizard generates to register the special TXMLNode (see page 7396) descendants the are created for nodes in the XML document. Each of these descendant classes is specific to the structure of the XML document, with properties that correspond to the child nodes and attributes of the node.

RegisterChildNodes adds an entry to the ChildNodeClasses (see page 7438) property for each specified node class and tag name.

TagNames is an array containing the names of the child nodes that the classes represent.

TagNames_Size is the index of the last name in TagNames (one less than the number of elements).

NodeClasses is an array containing the TXMLNode (see page 7396) descendants that implement child nodes that have the tag names in the corresponding entries in TagNames.

NodeClasses_Size is the index of the last class in NodeClasses (one less than the number of elements).

See Also

RegisterChildNode (see page 7430)

ChildNodeClasses (see page 7438)

79.1.2.5.57 TXMLNode.RemoveHostedNode Method

Removes a node from the HostedNodes (see page 7441) property list.

Pascal

```
procedure RemoveHostedNode(Node: TXMLNode);
```

C++

```
__fastcall RemoveHostedNode(TXMLNode Node);
```

Description

RemoveHostedNode is used internally to remove nodes from the HostedNodes (see page 7441) array.

Node is the node to remove from the array.

See Also

HostedNodes (see page 7441)

AddHostedNode (see page 7405)

79.1.2.5.58 TXMLNode.Resync Method

Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.

Pascal

```
procedure Resync;
```

C++

```
__fastcall Resync();
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected Resync method. Resync forces the node to reread the values of its child nodes and attribute nodes, discarding any changes that have not been propagated to the underlying DOM implementation.

See Also

ChildNodes (see page 7439)

AttributeNodes (see page 7438)

Refresh (see page 7371)

79.1.2.5.59 TXMLNode.SetAttribute Method

Sets the value of one of this node's attributes.

Pascal

```
procedure SetAttribute(const AttrName: DOMString; const Value: OleVariant);
```

C++

```
__fastcall SetAttribute(const DOMString AttrName, const OleVariant Value);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected SetAttribute method. SetAttribute sets the value of a specified attribute of this node.

AttrName is the name of the attribute. If the attribute already exists for the node, its value is changed. If the attribute does not already exist, a new attribute is created.

Value is the value to assign to the attribute. This value is a string that is not parsed. Any markup (for example, for an entity reference) is treated as literal text, and must include appropriate escape sequences. If Value is NULL, the attribute is removed from this node. If Value is an empty string, the attribute is assigned an empty value.

See Also

GetAttribute (see page 7415)

AttributeNodes (see page 7438)

SetAttributeNS (see page 7433)

79.1.2.5.60 TXMLNode.SetAttributeNodes Method

Sets the value of the AttributeNodes (see page 7438) property.

Pascal

```
procedure SetAttributeNodes(const Value: IXMLNodeList); virtual;
```

C++

```
virtual __fastcall SetAttributeNodes(const IXMLNodeList Value);
```

Description

Applications can't call this protected method. It is called internally the first time an application reads the AttributeNodes (see page 7438) property to supply the interface that implements that property.

See Also

AttributeNodes (see page 7438)

79.1.2.5.61 TXMLNode.SetAttributeNS Method

Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.

Pascal

```
procedure SetAttributeNS(const AttrName: DOMString; const NamespaceURI: DOMString; const
Value: OleVariant);
```

C++

```
__fastcall SetAttributeNS(const DOMString AttrName, const DOMString NamespaceURI, const
OleVariant Value);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected SetAttributeNS method. SetAttributeNS sets the value of a specified attribute of this node.

AttrName is the name of the attribute. If the attribute already exists for the node, its value is changed. If the attribute does not already exist, a new attribute is created.

NamespaceURI is the namespace for the attribute.

Value is the value to assign to the attribute. This value is a string that is not parsed. Any markup (for example, for an entity reference) is treated as literal text, and must include appropriate escape sequences. If Value is NULL, the attribute is removed from this node. If Value is an empty string, the attribute is assigned an empty value.

See Also

SetAttribute (see page 7432)

GetAttributeNS (see page 7416)

AttributeNodes (see page 7438)

79.1.2.5.62 TXMLNode.SetChildNodes Method

Sets the value of the ChildNodes (see page 7439) property.

Pascal

```
procedure SetChildNodes(const Value: IXMLNodeList); virtual;
```

C++

```
virtual __fastcall SetChildNodes(const IXMLNodeList Value);
```

Description

Applications can't call this protected method. It is called internally the first time an application reads the ChildNodes (see page 7439) property to supply the interface that implements that property.

See Also

ChildNodes (see page 7439)

79.1.2.5.63 TXMLNode.SetChildValue Method

Sets the value of a specified child node.

Pascal

```
procedure SetChildValue(const IndexOrName: OleVariant; const Value: OleVariant);
```

C++

```
__fastcall SetChildValue(const OleVariant IndexOrName, const OleVariant Value);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected SetChildValue method. SetChildValue sets the value of a specified child node to a specified value.

IndexOrName identifies the desired child node by either its interface, or by a string that is the local name of the child node. If IndexOrName does not identify a child of this node, SetChildValue raises an exception.

Value is the value to assign. It's interpretation depends on the type of the child node, as indicated in the following table:

NodeType	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, SetChildValue raises an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
If the child node is any other node type, SetChildValue raises an exception.	

Note: Attributes are not considered child nodes of a node. To set the values of this node's attributes, use the SetAttribute (see page 7432) method instead.

See Also

ChildNodes (see page 7439)

ParentNode (see page 7443)

SetAttribute (see page 7432)

SetNodeValue (see page 7435)

79.1.2.5.64 TXMLNode.SetCollection Method

Sets the value of the Collection (see page 7439) property.

Pascal

```
procedure SetCollection(const Value: TXMLNodeCollection);
```

C++

```
__fastcall SetCollection(const TXMLNodeCollection Value);
```

Description

SetCollection assigns Value as the value of the Collection (see page 7439) property. This protected method is called when this node is added to the collection specified by the Value property.

Value is a TXMLNodeCollection (see page 7444) descendant that represents a repeating set of child nodes, of which this node is a member.

See Also

Collection (see page 7439)

79.1.2.5.65 TXMLNode.SetNodeValue Method

Sets the value of this node.

Pascal

```
procedure SetNodeValue(const Value: OleVariant);
```

C++

```
__fastcall SetNodeValue(const OleVariant Value);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected SetNodeValue method. SetNodeValue sets the value of this node.

Value is the value to assign. It's meaning depends on the type of the node, as indicated in the following table:

NodeType	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, SetNodeValue raises an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
If the node is any other node type, SetNodeValue raises an exception.	

See Also

SetChildValue (see page 7434)

SetText (see page 7436)

79.1.2.5.66 TXMLNode.SetParentNode Method

Sets the value of the ParentNode (see page 7443) property.

Pascal

```
procedure SetParentNode(const Value: TXMLNode); virtual;
```

C++

```
virtual __fastcall SetParentNode(const TXMLNode Value);
```

Description

Applications can't use this protected property. It is used internally when nodes are added to the ChildNodes (see page 7439) or AttributeNodes (see page 7438) property.

See Also

ParentNode (see page 7443)

ChildNodes (see page 7439)

AttributeNodes (see page 7438)

79.1.2.5.67 TXMLNode.SetReadOnly Method

Specifies whether the node can be modified.

Pascal

```
procedure SetReadOnly(const Value: Boolean);
```

C++

```
__fastcall SetReadOnly(const Boolean Value);
```

Description

SetReadOnly assigns the read-only status of the node.

Value is the new read-only status of the node. When Value is true, the node raises an EXMLDocError (see page 7639) exception when an attempt is made to change its value, child nodes, or attributes. When Value is false, the node can be modified.

See Also

GetReadOnly (see page 7425)

ReadOnly (see page 7696)

EXMLDocError (see page 7639)

79.1.2.5.68 TXMLNode.SetText Method

Sets the text value of the node.

Pascal

```
procedure SetText(const Value: DOMString);
```

C++

```
__fastcall SetText(const DOMString Value);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected SetText method. SetText replaces the text of the node.

SetText is intended for use when the GetIsTextElement (see page 7419) method returns true. If GetIsTextElement (see page 7419) returns false, SetText adds a new text value to a node that has no children, otherwise, it raises an exception.

See Also

GetIsTextElement (see page 7419)

SetNodeValue (see page 7435)

GetText (see page 7426)

79.1.2.5.69 TransformNode Method

This is the overview for the TransformNode method overload.

Overload List

	Name	Description
	TXMLNode.TransformNode (IXMLNode, IXMLDocument) (see page 7437)	Transforms the subtree rooted at this node, using a specified XSL interface.
	TXMLNode.TransformNode (IXMLNode, WideString) (see page 7437)	Transforms the subtree rooted at this node, using a specified XSL interface.

79.1.2.5.69.1 TXMLNode.TransformNode Method (IXMLNode, IXMLDocument)

Transforms the subtree rooted at this node, using a specified XSL interface.

Pascal

```
procedure TransformNode(const stylesheet: IXMLNode; var output: WideString); overload;
procedure TransformNode(const stylesheet: IXMLNode; const output: IXMLDocument); overload;
```

C++

```
__fastcall TransformNode(const IXMLNode stylesheet, BSTR output);
__fastcall TransformNode(const IXMLNode stylesheet, const IXMLDocument output);
```

Description

Use the TXMLNode (see page 7396) object's IXMLNode (see page 7669) interface to call the protected TransformNode method.

stylesheet is a node in an XML document that represents an XSL transformation. Typically, it is the document element of that document.

output represents the result of the transformation. If output is a WideString (see page 3467), TransformNode returns a string of XML. If output is the interface to an XML document, TransformNode replaces the content of that document with the results of the transformation.

Note: TransformNode is only available when the DOMVendor used to parse this node's XML document is MSXML.

See Also

GetXML (see page 7426)

79.1.2.6 TXMLNode Properties

The properties of the TXMLNode class are listed here.

Protected Properties

	Name	Description
R	AttributeNodes (see page 7438)	Lists the interfaces for nodes that represent attributes of this node.
R	ChildNodeClasses (see page 7438)	Lists the classes that the XML Data Binding wizard defines to represent child nodes of this node.
	ChildNodes (see page 7439)	Lists the child nodes of this node.
	Collection (see page 7439)	Indicates the collection in which this node appears.
R	DOMNode (see page 7440)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HostedNodes (see page 7441)	Lists the nodes that share this node's lists of child and attribute nodes.
	HostNode (see page 7441)	Indicates the main object for the node to which this node corresponds when it represents a specialized view.
R	OwnerDocument (see page 7442)	Provides access to the document that contains this node.
R	ParentNode (see page 7443)	Identifies the object that represents this node's parent node.

79.1.2.6.1 TXMLNode.AttributeNodes Property

Lists the interfaces for nodes that represent attributes of this node.

Pascal

```
property AttributeNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList AttributeNodes;
```

Description

TXMLNode (see page 7396) uses AttributeNodes to keep track of its attributes. AttributeNodes is an IXMLNodeList (see page 7703) interface, which can be used to access individual attribute nodes or to add attributes to or delete them from this node.

Applications can't use this protected property to access the attributes of a node. Instead, they use the AttributeNodes property of the IXMLNode (see page 7669) interface for this node.

Attributes modify a node in an XML document. For example, given the node

```
<Movie genre=scifi title="Star Wars"> ... </Movie>
```

both genre and title are attributes of the node, with values of "scifi" and "Star Wars", respectively.

Only element nodes have attributes, and not every element node has them. If the node does not have any attributes, AttributeNodes is the interface for an empty list.

Note: Attributes are not considered child nodes of a node and can't be accessed using the ChildNodes (see page 7439) property.

See Also

IXMLNode (see page 7669)

ChildNodes (see page 7439)

AttributeNodes (see page 7688)

79.1.2.6.2 TXMLNode.ChildNodeClasses Property

Lists the classes that the XML Data Binding wizard defines to represent child nodes of this node.

Pascal

```
property ChildNodeClasses: TNodeClassArray;
```

C++

```
__property TNodeClassArray ChildNodeClasses;
```

Description

ChildNodeClasses is used internally when creating child nodes for this node. The XML Data Binding wizard defines TXMLNode (see page 7396) descendants for each node in the XML document that represents a node that has (or can have) children. ChildNodeClasses lists only those TXMLNode (see page 7396) descendants that can represent child nodes of this node. These classes become the types of the corresponding properties on the TXMLNode (see page 7396) descendant that represents this node.

Classes are added to ChildNodeClasses by the RegisterChildNode (see page 7430) method.

See Also

RegisterChildNode (see page 7430)

RegisterChildNodes (see page 7431)

ChildNodes (see page 7439)

CreateChildNode (see page 7410)

79.1.2.6.3 TXMLNode.ChildNodes Property

Lists the child nodes of this node.

Pascal

```
property ChildNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList ChildNodes;
```

Description

TXMLNode (see page 7396) uses ChildNodes to keep track of the subnodes of a node. ChildNodes is an IXMLNodeList (see page 7703) interface, which can be used to access individual child nodes or to add child nodes to or delete them from this node. Each child node specifies this node as its parent node.

Applications can't use this protected property to access the child nodes of a node. Instead, they use the ChildNodes property of the IXMLNode (see page 7669) interface for this node.

Note: Attributes are not considered child nodes of a node. To get the values of this node's attributes, use the Attributes property instead.

See Also

IXMLNode (see page 7669)

ChildNodes (see page 7689)

ParentNode (see page 7443)

79.1.2.6.4 TXMLNode.Collection Property

Indicates the collection in which this node appears.

Pascal

```
property Collection: TXMLNodeCollection;
```

C++

```
__property TXMLNodeCollection Collection;
```

Description

Collection indicates the collection that contains this node if it represents one of a repeating set of child nodes. The node specified by Collection represents the same node in the XML document as this node's ParentNode (see page 7443) property, but it is specialized to work with this node and any other child nodes of the same type.

The node identified by Collection is one of the collections listed by the parent node's HostedNodes (see page 7441) property, and it lists ParentNode (see page 7443) as the value of its HostNode (see page 7441) property.

For example, consider the following XML fragment:

```
<students>
  <student name="John Smith">
    <grade>incomplete</grade>
  </student>
  <student name="Jane Doe">
    <grade>B+</grade>
  </student>
  <auditor name="Bill Jones"></auditor>
</students>
```

If this node represents one of the <student> nodes, then ParentNode (see page 7443) represents the <students> node, and Collection represents a copy of the <students> node that is used for only those children that are <student> nodes, and not the <auditor> nodes.

Applications can't use this protected property to access the Collection that contains this node. Instead, they use the Collection property of the IXMLNode (see page 7669) interface for this node.

See Also

ParentNode (see page 7443)

HostedNodes (see page 7441)

HostNode (see page 7441)

Collection (see page 7690)

79.1.2.6.5 TXMLNode.DOMNode Property

Provides access to the IDOMNode (see page 7557) interface for this node.

Pascal

```
property DOMNode: IDOMNode;
```

C++

```
__property IDOMNode DOMNode;
```

Description

IDOMNode (see page 7557) is the interface for this node provided by the DOM implementation that parsed the XML document. It can be accessed through the DOMNode property of the node's IXMLNode (see page 7669) interface.

Typically, applications that contain TXMLNode (see page 7396) descendants use the IXMLNode (see page 7669) interface to work with a node rather than the IDOMNode (see page 7557) interface. IDOMNode (see page 7557) is used more typically in applications that work directly with the DOM interfaces.

The value of DOMNode is set to the IDOMNode (see page 7557) interface that is provided to the TXMLNode (see page 7396) constructor.

See Also

DOMNode (see page 7691)

Create (see page 7400)

79.1.2.6.6 TXMLNode.HostedNodes Property

Lists the nodes that share this node's lists of child and attribute nodes.

Pascal

```
property HostedNodes: TXMLNodeArray;
```

C++

```
__property TXMLNodeArray HostedNodes;
```

Description

TXMLNode (see page 7396) uses HostedNodes to keep track of the nodes it uses to represent this same node, restricted to a specialized purpose. For example, any node that represents a subset of this node's child nodes that are all of the same type is a hosted node.

Each object in the HostedNodes list is a representation of a particular aspect of this node. Each hosted node acts as a sibling to this TXMLNode (see page 7396) object but does not represent a separate element in the XML document. Rather, it represents a different view of this element.

For example, consider the following XML fragment:

```
<students>
  <fulltime student>Joe Smith</fulltime student>
  <fulltime student>Jane Doe</fulltime student>
  <auditor>Bill Jones</auditor>
</students>
```

The TXMLNode (see page 7396) that represents students would define two hosted nodes for collections of repeating child elements, one for the fulltime students, and one for the auditors. The two collections share the same underlying DOM node as students, but each represents only those child elements of a particular type.

See Also

CreateCollection (see page 7411)

ChildNodes (see page 7439)

TXMLNodeCollection (see page 7444)

Collection (see page 7439)

HostNode (see page 7441)

79.1.2.6.7 TXMLNode.HostNode Property

Indicates the main object for the node to which this node corresponds when it represents a specialized view.

Pascal

```
property HostNode: TXMLNode;
```

C++

```
__property TXMLNode HostNode;
```

Description

If this node represents a hosted node, HostNode is the main node for which this node represents a subset or specialized view. For example, if this node represents a set of repeating child elements, HostNode is the node that uses this node to represent its repeating child elements.

For example, consider the following XML fragment:

```
<students>
  <student name="John Smith">
    <grade>incomplete</grade>
  </student>
  <student name="Jane Doe">
    <grade>B+</grade>
  </student>
  <auditor name="Bill Jones"></auditor>
  <auditor name="Susan Brown"></auditor>
</students>
```

The <students> node spawns two hosted nodes to represent the collections of repeating child nodes: one for all of the child nodes of type <student>, and one for all of the child nodes of type <auditor>. If this node represents one of those hosted nodes, then HostNode is the <students> node to which this node belongs. The host node lists this node in its HostedNodes (see page 7441) property.

Applications can't use this protected property to access the host node that created this node. Instead, they use the HostNode property of the IXMLNode (see page 7669) interface for this node.

See Also

Collection (see page 7439)

HostedNodes (see page 7441)

TXMLNodeCollection (see page 7444)

79.1.2.6.8 TXMLNode.OwnerDocument Property

Provides access to the document that contains this node.

Pascal

```
property OwnerDocument: TXMLDocument;
```

C++

```
__property TXMLDocument OwnerDocument;
```

Description

Applications can't use this protected property to access the document that contains this. Instead, they use the OwnerDocument property of the IXMLNode (see page 7669) interface for this node.

The value of OwnerDocument is set to the TXMLDocument (see page 7347) that is provided to the TXMLNode (see page 7396) constructor.

See Also

Create (see page 7400)

OwnerDocument (see page 7695)

79.1.2.6.9 TXMLNode.ParentNode Property

Identifies the object that represents this node's parent node.

Pascal

```
property ParentNode: TXMLNode;
```

C++

```
__property TXMLNode ParentNode;
```

Description

TXMLNode (see page 7396) uses ParentNode to access the implementation of the node's parent, if it exists. Some nodes (for example attribute nodes) do not have parents.

Applications can't use this protected property to access the parent node of a node. Instead, they use the ParentNode property of the IXMLNode (see page 7669) interface for this node.

See Also

ChildNodes (see page 7439)

ParentNode (see page 7695)

79.1.2.7 TXMLNode Events

The events of the TXMLNode class are listed here.

Protected Events

	Name	Description
	OnHostAttrNotify (see page 7443)	Occurs when changes occur to the attribute list of this node's HostNode (see page 7441).
	OnHostChildNotify (see page 7444)	Occurs when changes occur to the list of child nodes on this node's HostNode (see page 7441).

79.1.2.7.1 TXMLNode.OnHostAttrNotify Event

Occurs when changes occur to the attribute list of this node's HostNode (see page 7441).

Pascal

```
property OnHostAttrNotify: TNodeListNotification;
```

C++

```
__property TNodeListNotification OnHostAttrNotify;
```

Description

Use the OnHostAttrNotify event to update a TXMLNode (see page 7396) descendant that represents a hosted node (such as a collection of repeating child elements) when the host node changes its attribute list.

The AttributeListNotify (see page 7406) method of a host node generates an OnHostAttrNotify event on all of its hosted nodes. This allows the hosted nodes (for example, the nodes that represent a subset of the child nodes that are all the same type) to update their own representation of node attributes so that they reflect the attributes of the host node.

See Also

OnHostChildNotify (see page 7444)

AttributeListNotify (see page 7406)

HostNode (see page 7441)

HostedNodes (see page 7441)

AttributeNodes (see page 7438)

79.1.2.7.2 TXMLNode.OnHostChildNotify Event

Occurs when changes occur to the list of child nodes on this node's HostNode (see page 7441).

Pascal

```
property OnHostChildNotify: TNodeListNotification;
```

C++

```
__property TNodeListNotification OnHostChildNotify;
```

Description

Use the OnHostChildNotify event to update a TXMLNode (see page 7396) descendant that represents a hosted node (such as a collection of repeating child elements) when the host node changes its list of child nodes. For example, TXMLNodeCollection (see page 7444) assigns its UpdateCollectionList method as an OnHostChildNotify event handler so that its list of repeating child elements reflects any changes to the host node's list of child nodes.

The ChildListNotify (see page 7408) method of a host node generates an OnHostChildNotify event on all of its hosted nodes.

See Also

OnHostAttrNotify (see page 7443)

ChildListNotify (see page 7408)

HostNode (see page 7441)

HostedNodes (see page 7441)

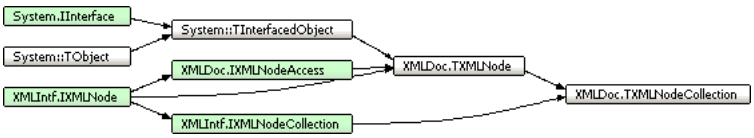
ChildNodes (see page 7439)

UpdateCollectionList (see page 7457)

79.1.3 TXMLNodeCollection Class

TXMLNodeCollection represents a node in an XML document whose children are instances of the same repeating element.

Class Hierarchy



Pascal

```
TXMLNodeCollection = class(TXMLNode, IXMLNodeCollection);
```

C++

```
class TXMLNodeCollection : public TXMLNode, public IXMLNodeCollection;
```

File

XMLDoc

Description

The XML Data Binding Wizard uses TXMLNodeCollection as a base class for the classes it generates to represent nodes that have repeating elements for child nodes. For example, if the XML document includes the following:

```
<students>
  <student name="John Smith">
    <grade>incomplete</grade>
  </student>
  <student name="Jane Doe">
    <grade>B+</grade>
  </student>
  <auditor name="Bill Jones"></auditor>
</students>
```

then the XML Data Binding Wizard generates 3 nodes to represent the <students> node: a TXMLNode (see page 7396) descendant to represent the entire <students> node, and two TXMLNodeCollection descendants to represent the repeating elements: one for the child nodes with the tag <student>, and one for the child nodes with the tag <auditor>.

As with any of the classes the Data Binding Wizard generates to represent nodes in an XML document, child nodes and node attributes appear as properties of the TXMLNodeCollection descendant.

TXMLNodeCollection implements the IXMLNodeCollection (see page 7698) interface. Each TXMLNodeCollection descendant implements a class-specific interface that descends from IXMLNodeCollection (see page 7698). Typically, applications do not work directly with TXMLNodeCollection. Instead, they use the IXMLNodeCollection (see page 7698) interface or the IXMLNodeCollection (see page 7698) descendant that is implemented by a TXMLNodeCollection descendant.

See Also

TXMLDocument (see page 7347)

TXMLNode (see page 7396)

IXMLNodeCollection (see page 7698)

79.1.3.1 TXMLNodeCollection Members

The following tables list the members exposed by TXMLNodeCollection.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Events

	Name	Description
	OnHostAttrNotify (see page 7443)	Occurs when changes occur to the attribute list of this node's HostNode (see page 7441).
	OnHostChildNotify (see page 7444)	Occurs when changes occur to the list of child nodes on this node's HostNode (see page 7441).

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_AddRef (see page 7403)	Increments the reference count for this node.

	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	_Release (see page 7404)	Decrements the reference count for this node.
	AddChild (see page 7404)	This is the overview for the AddChild method overload.
	AddHostedNode (see page 7405)	Adds a node to the HostedNodes (see page 7441) property list.
V	AddItem (see page 7451)	Adds a new repetition of the repeating child element to this node.
	AttributeListNotify (see page 7406)	Responds to notifications of changes in the list of attributes.
	CheckNotHosted (see page 7406)	Raises an EXMLDocError (see page 7639) exception if this is a hosted node.
	CheckReadOnly (see page 7407)	Raises an EXMLDocError (see page 7639) exception if this is a read-only node.
	CheckTextNode (see page 7407)	Generates a DOM text node implementation if it does not yet exist.
V	ChildListNotify (see page 7452)	Responds to notifications of changes in the list of child nodes.
	Clear (see page 7452)	Removes all child nodes in the List (see page 7459) property from the ChildNodes (see page 7439) and List (see page 7459) properties.
	ClearDocumentRef (see page 7408)	Sets the value of OwnerDocument (see page 7442) to nil (Delphi) or NULL (C++).
	CloneNode (see page 7409)	Creates a copy of this node and returns its interface.
	CreateAttributeList (see page 7409)	Creates the object that implements the AttributeNodes (see page 7438) property.
V	CreateAttributeNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for an attribute of this node.
	CreateChildList (see page 7410)	Creates the object that implements the ChildNodes (see page 7439) property.
V	CreateChildNode (see page 7410)	Creates a new TXMLNode (see page 7396) object for a child node of this node.
	CreateCollection (see page 7411)	Creates an instance of a TXMLNodeCollection (see page 7444) descendant and returns it.
	CreateItemList (see page 7453)	Creates the object that implements the List (see page 7459) property.
	DeclareNamespace (see page 7412)	Adds an attribute to the node that declares a specified namespace URI.
	Delete (see page 7453)	Removes one of the repeating child nodes from this node.
	DOMElement (see page 7412)	Returns the IDOMElement (see page 7542) interface for this node if it exists.
V	DoNodeChange (see page 7413)	Generates a BeforeNodeChange or AfterNodeChange event on this node's document.
	FindHostedNode (see page 7413)	Returns the IXMLNode (see page 7669) interface for a hosted node given its implementation class.
	FindNamespaceDecl (see page 7414)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7414)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7415)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7415)	Returns the value of the AttributeNodes (see page 7438) property.
	GetAttributeNS (see page 7416)	Returns the value of a specified attribute when you must explicitly specify the namespace for the attribute.
	GetChildNodeClasses (see page 7416)	Returns a list of the classes that can implement child nodes of this node.
	GetChildNodes (see page 7417)	Returns the value of the ChildNodes (see page 7439) property.
	GetChildValue (see page 7417)	Returns the value of a specified child node.
	GetCollection (see page 7418)	Returns the value of the Collection (see page 7439) property.
	GetCount (see page 7454)	Returns the value of the Count (see page 7457) property.
	GetDOMNode (see page 7418)	Returns the value of the DOMNode (see page 7440) property.
	GetHasChildNodes (see page 7418)	Indicates whether this node has any child nodes.
	GetHostedNodes (see page 7419)	Returns a list an array of the hosted nodes that share this node's attribute and child node lists.
	GetHostNode (see page 7419)	Returns the value of the HostNode (see page 7441) property.
	GetIsTextElement (see page 7419)	Indicates whether the node has a single text value.
V	GetList (see page 7454)	Returns the value of the List (see page 7459) property.
	GetLocalName (see page 7420)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7421)	Returns the URI for the namespace used in the qualified node name.
	GetNode (see page 7454)	Returns the interface for one of the repeating child nodes.
	GetNodeName (see page 7421)	Returns the node name.
	GetNodeObject (see page 7422)	Returns a reference to this TXMLNode (see page 7396) object.
	GetNodeType (see page 7422)	Returns the type of the node.
	GetNodeValue (see page 7423)	Returns the value of this node.

	GetOwnerDocument (see page 7423)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7424)	Returns the interface for the node's parent node.
	GetPrefix (see page 7424)	Returns the namespace prefix of the node's name.
	GetPrefixedName (see page 7425)	Returns a node name includes a namespace prefix for a specified namespace URI.
	GetReadOnly (see page 7425)	Indicates whether the node can be modified.
	GetText (see page 7426)	Returns the text value of the node.
	GetXML (see page 7426)	Returns the XML that corresponds to the subtree rooted at this node.
	HasAttribute (see page 7426)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7427)	This is the overview for the HasChildNode method overload.
	InsertInCollection (see page 7455)	Copies a child node from the ChildNodes (see page 7439) property to the List (see page 7459) property.
	InternalAddChild (see page 7428)	Provides the underlying implementation for the AddChild (see page 7404) method.
	IsCollectionItem (see page 7455)	Indicates whether a specified node represents the type of node that appears as a repeating child of this node.
	NestingLevel (see page 7428)	Returns the number of parents for this node in the node hierarchy.
	NextSibling (see page 7429)	Returns the next child of this node's parent.
	Normalize (see page 7429)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7430)	Returns the previous child of this node's parent.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	RegisterChildNode (see page 7430)	Registers a descendant of TXMLNode (see page 7396) that can represent the children of this node.
	RegisterChildNodes (see page 7431)	Registers a set of TXMLNode (see page 7396) descendants that can represent the children of this node.
	Remove (see page 7456)	Removes one of the repeating child nodes from this node.
	RemoveHostedNode (see page 7431)	Removes a node from the HostedNodes (see page 7441) property list.
	Resync (see page 7432)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7432)	Sets the value of one of this node's attributes.
V	SetAttributeNodes (see page 7432)	Sets the value of the AttributeNodes (see page 7438) property.
	SetAttributeNS (see page 7433)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
V	SetChildNodes (see page 7456)	Sets the value of the ChildNodes (see page 7439) property.
	SetChildValue (see page 7434)	Sets the value of a specified child node.
	SetCollection (see page 7434)	Sets the value of the Collection (see page 7439) property.
	SetNodeValue (see page 7435)	Sets the value of this node.
V	SetParentNode (see page 7435)	Sets the value of the ParentNode (see page 7443) property.
	SetReadOnly (see page 7436)	Specifies whether the node can be modified.
	SetText (see page 7436)	Sets the text value of the node.
	TransformNode (see page 7437)	This is the overview for the TransformNode method overload.
	UpdateCollectionList (see page 7457)	Updates the List (see page 7459) property to reflect changes to the set of child nodes.

Protected Properties

	Name	Description
R	AttributeNodes (see page 7438)	Lists the interfaces for nodes that represent attributes of this node.
R	ChildNodeClasses (see page 7438)	Lists the classes that the XML Data Binding wizard defines to represent child nodes of this node.
	ChildNodes (see page 7439)	Lists the child nodes of this node.
	Collection (see page 7439)	Indicates the collection in which this node appears.
R	Count (see page 7457)	Indicates the number of repeating child nodes.
R	DOMNode (see page 7440)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HostedNodes (see page 7441)	Lists the nodes that share this node's lists of child and attribute nodes.
	HostNode (see page 7441)	Indicates the main object for the node to which this node corresponds when it represents a specialized view.

	ItemInterface (see page 7458)	Indicates the interface type for the repeating child nodes.
	ItemNS (see page 7458)	Indicates the default namespace URI for the tag names of repeating child elements.
	ItemTag (see page 7459)	Indicates the tag name that occurs on the repeating child elements.
R	List (see page 7459)	Lists the interfaces for the children that are repeated elements.
R	OwnerDocument (see page 7442)	Provides access to the document that contains this node.
R	ParentNode (see page 7443)	Identifies the object that represents this node's parent node.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AddChild (see page 7482)	This is AddChild, a member of class IXMLNodeAccess.
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 7451)	Initializes the node collection object once it is fully created.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	CheckTextNode (see page 7483)	This is CheckTextNode, a member of class IXMLNodeAccess.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearDocumentRef (see page 7483)	This is ClearDocumentRef, a member of class IXMLNodeAccess.
	CloneNode (see page 7673)	Creates a copy of this node and returns its interface.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 7400)	Instantiates a Create object.
	CreateAttributeNode (see page 7483)	This is CreateAttributeNode, a member of class IXMLNodeAccess.
	CreateChildNode (see page 7483)	This is CreateChildNode, a member of class IXMLNodeAccess.
	CreateCollection (see page 7483)	This is CreateCollection, a member of class IXMLNodeAccess.
	CreateHosted (see page 7401)	Creates a TXMLNode (see page 7396) instance that represents the same DOM node as another "host" node.
	DeclareNamespace (see page 7674)	Adds an attribute to the node that declares a specified namespace URI.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Destroy (see page 7401)	Frees the memory associated with the TXMLNode (see page 7396) object.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DOMElement (see page 7484)	This is DOMElement, a member of class IXMLNodeAccess.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	FindHostedNode (see page 7484)	This is FindHostedNode, a member of class IXMLNodeAccess.
	FindNamespaceDecl (see page 7674)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7674)	Returns the namespace URI for a namespace prefix or qualified tag name.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetAttribute (see page 7675)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7675)	Returns the value of the AttributeNodes (see page 7688) property.
	GetAttributeNS (see page 7676)	Returns the value of a specified attribute.
	GetChildNodeClasses (see page 7484)	This is GetChildNodeClasses, a member of class IXMLNodeAccess.
	GetChildNodes (see page 7676)	Returns the value of the ChildNodes (see page 7689) property.
	GetChildValue (see page 7676)	Returns the value of a specified child node.

	GetCollection (see page 7677)	Returns the value of the Collection (see page 7690) property.
	GetDOMNode (see page 7677)	Returns the value of the DOMNode (see page 7691) property.
	GetHasChildNodes (see page 7678)	Indicates whether the node has any child nodes.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetHostNode (see page 7484)	This is GetHostNode, a member of class IXMLNodeAccess.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetIsTextElement (see page 7678)	Indicates whether the node has a single text value.
	GetLocalName (see page 7678)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7679)	Returns the namespace URI for the node's qualified name.
	GetNodeName (see page 7679)	Returns the name of the node.
	GetNodeObject (see page 7485)	This is GetNodeObject, a member of class IXMLNodeAccess.
	GetNodeType (see page 7679)	Returns the type of the node.
	GetNodeValue (see page 7680)	Returns the value of the node.
	GetOwnerDocument (see page 7680)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7680)	Returns the interface for the node's parent node.
	GetPrefix (see page 7680)	Returns the namespace prefix from the node's name.
	GetReadOnly (see page 7681)	Returns the value of the ReadOnly (see page 7696) property.
	GetText (see page 7681)	Returns the text value of the node.
	GetXML (see page 7681)	Returns the value of the XML (see page 7697) property.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7485)	This is the overview for the HasChildNode method overload.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	InternalAddChild (see page 7485)	This is InternalAddChild, a member of class IXMLNodeAccess.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NestingLevel (see page 7486)	This is NestingLevel, a member of class IXMLNodeAccess.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NextSibling (see page 7682)	Returns the next child of this node's parent.
	Normalize (see page 7683)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7683)	Returns the previous child of this node's parent.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	RegisterChildNode (see page 7486)	This is RegisterChildNode, a member of class IXMLNodeAccess.
	RegisterChildNodes (see page 7486)	This is RegisterChildNodes, a member of class IXMLNodeAccess.
	Resync (see page 7684)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	SetAttribute (see page 7684)	Sets the value of one of this node's attributes.
	SetAttributeNS (see page 7684)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
	SetChildValue (see page 7685)	Sets the value of a specified child node.
	SetCollection (see page 7486)	This is SetCollection, a member of class IXMLNodeAccess.
	SetNodeValue (see page 7685)	Sets the value of this node.
	SetParentNode (see page 7487)	This is SetParentNode, a member of class IXMLNodeAccess.
	SetReadOnly (see page 7686)	Specifies whether the node can be modified.
	SetText (see page 7686)	Sets the text value of the node.
V	ToString (see page 3380)	Returns a string containing the class name.
	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.

	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	AttributeNodes (see page 7688)	Lists the interfaces for nodes that represent attributes of this node.
	Attributes (see page 7688)	Represents the values of this node's attributes.
R	ChildNodeClasses (see page 7487)	This is ChildNodeClasses, a member of class IXMLNodeAccess.
R	ChildNodes (see page 7689)	Represents the child nodes of the node.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	Collection (see page 7690)	Indicates the collection in which this node appears.
R	DOMNode (see page 7691)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	HostNode (see page 7487)	This is HostNode, a member of class IXMLNodeAccess.
R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.
R	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
R	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
R	NodeName (see page 7693)	Indicates the node name.
R	Nodes (see page 7703)	Lists the interfaces of the repeating child nodes.
R	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
R	OwnerDocument (see page 7695)	Identifies the document in which this node appears.
R	ParentNode (see page 7695)	Identifies the interface of the node's parent node.
R	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.
	Text (see page 7697)	Represents the Text of the node.
R	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

79.1.3.2 TXMLNodeCollection Methods

The methods of the TXMLNodeCollection class are listed here.

Protected Methods

	Name	Description
V	AddItem (see page 7451)	Adds a new repetition of the repeating child element to this node.
V	ChildListNotify (see page 7452)	Responds to notifications of changes in the list of child nodes.
	Clear (see page 7452)	Removes all child nodes in the List (see page 7459) property from the ChildNodes (see page 7439) and List (see page 7459) properties.
	CreateItemList (see page 7453)	Creates the object that implements the List (see page 7459) property.
	Delete (see page 7453)	Removes one of the repeating child nodes from this node.
	GetCount (see page 7454)	Returns the value of the Count (see page 7457) property.
V	GetList (see page 7454)	Returns the value of the List (see page 7459) property.
	GetNode (see page 7454)	Returns the interface for one of the repeating child nodes.
	InsertInCollection (see page 7455)	Copies a child node from the ChildNodes (see page 7439) property to the List (see page 7459) property.
	IsCollectionItem (see page 7455)	Indicates whether a specified node represents the type of node that appears as a repeating child of this node.
	Remove (see page 7456)	Removes one of the repeating child nodes from this node.
V	SetChildNodes (see page 7456)	Sets the value of the ChildNodes (see page 7439) property.
	UpdateCollectionList (see page 7457)	Updates the List (see page 7459) property to reflect changes to the set of child nodes.

Public Methods

	Name	Description
V	AfterConstruction (see page 7451)	Initializes the node collection object once it is fully created.

79.1.3.2.1 TXMLNodeCollection.AddItem Method

Adds a new repetition of the repeating child element to this node.

Pascal

```
function AddItem(Index: Integer): IXMLNode; virtual;
```

C++

```
virtual __fastcall IXMLNode AddItem(int Index);
```

Description

Applications can't call the protected AddItem method. It is used internally to create a new child node for this node that is an instance of the repeating element. The new child node is given the first tag name listed by the ItemTag (see page 7459) property.

Index indicates the position of the new child node in this node's list of children, where 0 is the first position, 1 is the second position, and so on. If Index is –1, the new node is added to the end.

Note: Index refers to the list of repeating elements (the List (see page 7459) property), not the list of all children (the ChildNodes (see page 7439) property).

AddItem returns the interface for the newly created child node.

See Also

AddChild (see page 7404)

InsertInCollection (see page 7455)

ItemTag (see page 7459)

List (see page 7459)

ChildNodes (see page 7439)

79.1.3.2.2 TXMLNodeCollection.AfterConstruction Method

Initializes the node collection object once it is fully created.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

AfterConstruction sets the UpdateCollectionList (see page 7457) method as the event handler for the collection's OnHostChildNotify (see page 7444) event. This allows the collection to update itself when the list of child nodes (for which this collection manages a subset) changes.

See Also

OnHostChildNotify (see page 7444)

UpdateCollectionList (see page 7457)

79.1.3.2.3 TXMLNodeCollection.ChildListNotify Method

Responds to notifications of changes in the list of child nodes.

Pascal

```
procedure ChildListNotify(Operation: TNodeListOperation; var Node: IXMLNode; const
IndexOrName: OleVariant; BeforeOperation: Boolean); override;
```

C++

```
virtual __fastcall ChildListNotify(TNodeListOperation Operation, IXMLNode Node, const
OleVariant IndexOrName, Boolean BeforeOperation);
```

Description

Applications can't call this protected method. The class that implements the ChildNodes (see page 7439) property calls ChildListNotify when child nodes are inserted, removed, or need to be created. ChildListNotify calls the inherited method to generate a BeforeNodeChange or AfterNodeChange event and to ensure that the DOM implementation for this node reflects the change. After calling the inherited method, ChildListNotify updates the List (see page 7459) property so that it stays in sync with the ChildNodes (see page 7439) property.

Operation indicates what type of change is about to occur.

Node is the interface for the child node that is added or removed. If Operation is nlCreateNode, Node returns a newly created child node.

IndexOrName is the index of the node that is added or removed when Operation is nlInsert or nlRemove. When Operation is nlCreateNode, IndexOrName is the name or value of the new node to create.

BeforeOperation indicates whether the call occurs before or after the change.

See Also

ChildNodes (see page 7439)

AddChild (see page 7404)

List (see page 7459)

BeforeNodeChange (see page 7394)

AfterNodeChange (see page 7393)

79.1.3.2.4 TXMLNodeCollection.Clear Method

Removes all child nodes in the List (see page 7459) property from the ChildNodes (see page 7439) and List (see page 7459) properties.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Use the IXMLNodeCollection (see page 7698) interface for this node to call the protected Clear method. Clear deletes every child node from the collection (all the nodes in the List (see page 7459) property), along with the corresponding nodes in the ChildNodes (see page 7439) property.

See Also

List (see page 7459)

Delete (see page 7453)

Remove (see page 7456)

ChildNodes (see page 7439)

Clear (see page 7700)

79.1.3.2.5 TXMLNodeCollection.CreateItemList Method

Creates the object that implements the List (see page 7459) property.

Pascal

```
procedure CreateItemList(CheckFirst: Boolean = False);
```

C++

```
__fastcall CreateItemList(Boolean CheckFirst = False);
```

Description

Applications can't call the protected CreateItemList method. It is used internally when TXMLNodeCollection (see page 7444) needs to create a separate object to implement the List (see page 7459) property. A separate implementation object is only needed if this node contains child nodes that are not in the collection. Otherwise, TXMLNodeCollection (see page 7444) can simply use the ChildNodes (see page 7439) property.

CheckFirst specifies whether CreateItemList should check whether the ChildNodes (see page 7439) property currently includes any nodes that are not in the collection. When CheckFirst is true, CreateItemList first checks the ChildNodes (see page 7439) property, and if all nodes are in the collection, it does not create a separate list to store the nodes of the collection. When CheckFirst is false (or when the ChildNodes (see page 7439) property includes nodes that are not in the collection), CreateItemList instantiates a list to hold the nodes in the collection, and adds to it any nodes listed in ChildNodes (see page 7439) that belong in the collection.

See Also

List (see page 7459)

ChildNodes (see page 7439)

79.1.3.2.6 TXMLNodeCollection.Delete Method

Removes one of the repeating child nodes from this node.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Use the TXMLNodeCollection (see page 7444) object's IXMLNodeCollection (see page 7698) interface to call the protected Delete method. Delete removes a specified child node from this node.

Index identifies the child to remove. It is the index of the child in the list of repeating child nodes (The List (see page 7459) property, not the ChildNodes (see page 7439) property). The index 0 represents the first repetition, 1 represents the second

repetition, and so on.

See Also

Remove (see page 7456)

Delete (see page 7700)

List (see page 7459)

ChildNodes (see page 7439)

79.1.3.2.7 TXMLNodeCollection.GetCount Method

Returns the value of the Count (see page 7457) property.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count (see page 7457) property. It returns the number of nodes in the List (see page 7459) property.

See Also

Count (see page 7457)

List (see page 7459)

79.1.3.2.8 TXMLNodeCollection.GetList Method

Returns the value of the List (see page 7459) property.

Pascal

```
function GetList: IXMLNodeList; virtual;
```

C++

```
virtual __fastcall IXMLNodeList GetList();
```

Description

GetList is the protected read implementation of the List (see page 7459) property.

See Also

List (see page 7459)

79.1.3.2.9 TXMLNodeCollection.GetNode Method

Returns the interface for one of the repeating child nodes.

Pascal

```
function GetNode(Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode GetNode(int Index);
```

Description

Use the TXMLNodeCollection (see page 7444) object's IXMLNodeCollection (see page 7698) interface to call the protected GetNode method. GetNode returns an interface for working with one of the repeating child nodes.

Index identifies which repetition of the child node is desired, where 0 is the first repetition, 1 is the second repetition, and so on. Note that Index is the index of the node in the List (see page 7459) property, not in the index in the ChildNodes (see page 7439) property.

See Also

Nodes (see page 7703)

GetCount (see page 7454)

GetNode (see page 7701)

ChildNodes (see page 7439)

79.1.3.2.10 TXMLNodeCollection.InsertInCollection Method

Copies a child node from the ChildNodes (see page 7439) property to the List (see page 7459) property.

Pascal

```
procedure InsertInCollection(Node: IXMLNode; Index: Integer);
```

C++

```
__fastcall InsertInCollection(IXMLNode Node, int Index);
```

Description

Applications can't call this protected method. It is called automatically when nodes are added to the ChildNodes (see page 7439) property list.

Node is the node that was just added to the ChildNodes (see page 7439) property.

Index is the index of Node in the ChildNodes (see page 7439) property.

InsertInCollection first checks whether Node belongs in the collection. If so, it adds it to the List (see page 7459) property in the position that corresponds to Index (that is, in the index of Node when you ignore all the nodes in ChildNodes (see page 7439) that do not belong in the collection.)

See Also

ChildNodes (see page 7439)

List (see page 7459)

79.1.3.2.11 TXMLNodeCollection.IsCollectionItem Method

Indicates whether a specified node represents the type of node that appears as a repeating child of this node.

Pascal

```
function IsCollectionItem(const Node: IXMLNode): Boolean;
```

C++

```
__fastcall Boolean IsCollectionItem(const IXMLNode Node);
```

Description

Applications can't call the protected IsCollectionItem method. TXMLNodeCollection (see page 7444) uses this method

internally to distinguish nodes that represent instances of the repeating child node type.

IsCollectionItem checks whether Node implements the interface specified by the ItemInterface (see page 7458) property . If so, it returns true. Otherwise, it returns false.

See Also

List (see page 7459)

ItemInterface (see page 7458)

79.1.3.2.12 TXMLNodeCollection.Remove Method

Removes one of the repeating child nodes from this node.

Pascal

```
function Remove(const AItem: IXMLNode): Integer;
```

C++

```
__fastcall int Remove(const IXMLNode AItem);
```

Description

Use the TXMLNodeCollection (see page 7444) object's IXMLNodeCollection (see page 7698) interface to call the protected Remove method. Remove removes a specified child node from this node.

AItem is the interface of the child to remove. It must represent on of the repeating child nodes.

Remove deletes the child node from both the List (see page 7459) property and from the ChildNodes (see page 7439) property. It returns the index that the child node held in the List (see page 7459) property.

To remove a child that is not one of the repeating child nodes, use the ChildNodes (see page 7439) property instead.

See Also

Delete (see page 7453)

List (see page 7459)

ChildNodes (see page 7439)

79.1.3.2.13 TXMLNodeCollection.SetChildNodes Method

Sets the value of the ChildNodes (see page 7439) property.

Pascal

```
procedure SetChildNodes(const Value: IXMLNodeList); override;
```

C++

```
virtual __fastcall SetChildNodes(const IXMLNodeList Value);
```

Description

Applications can't call this protected method. It is called internally the first time an application reads the ChildNodes (see page 7439) property to supply the interface that implements that property.

TXMLNodeCollection (see page 7444) overrides the inherited method to update the List (see page 7459) property as well.

See Also

ChildNodes (see page 7439)

List (see page 7459)

79.1.3.2.14 TXMLNodeCollection.UpdateCollectionList Method

Updates the List (see page 7459) property to reflect changes to the set of child nodes.

Pascal

```
procedure UpdateCollectionList(Operation: TNodeListOperation; var Node: IXMLNode; const
IndexOrName: OleVariant; BeforeOperation: Boolean);
```

C++

```
__fastcall UpdateCollectionList(TNodeListOperation Operation, IXMLNode Node, const OleVariant
IndexOrName, Boolean BeforeOperation);
```

Description

Applications can't call this protected method. This method is called automatically when the ChildNodes (see page 7439) property changes so that the collection can update the List (see page 7459) property to reflect the repeating elements in the current set of child nodes.

Operation indicates whether the change to ChildNodes (see page 7439) is the addition of a new node (nlInsert) or the deletion of a child node (nlRemove).

Node is the interface for a child node that is added or removed.

IndexOrName is the index or tag name of the node that is added or removed.

BeforeOperation indicates whether this method is called before ChildNodes (see page 7439) has changed or after the change has occurred.

See Also

List (see page 7459)

ChildListNotify (see page 7452)

ChildNodes (see page 7439)

OnHostChildNotify (see page 7444)

79.1.3.3 TXMLNodeCollection Properties

The properties of the TXMLNodeCollection class are listed here.

Protected Properties

	Name	Description
R	Count (see page 7457)	Indicates the number of repeating child nodes.
	ItemInterface (see page 7458)	Indicates the interface type for the repeating child nodes.
	ItemNS (see page 7458)	Indicates the default namespace URI for the tag names of repeating child elements.
	ItemTag (see page 7459)	Indicates the tag name that occurs on the repeating child elements.
R	List (see page 7459)	Lists the interfaces for the children that are repeated elements.

79.1.3.3.1 TXMLNodeCollection.Count Property

Indicates the number of repeating child nodes.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use the IXMLNodeCollection (see page 7698) interface to read this protected property. Count is the number of child nodes for this node that are repetitions of the repeating child node type. That is, Count is the number of nodes in the List (see page 7459) property.

Use Count to obtain an upper limit when addressing child nodes by index (for example, when iterating over all nodes in using the GetNode (see page 7454) method).

Count is changed when you add child nodes using the AddChild (see page 7404) method or delete them using the Delete (see page 7453) or Remove (see page 7456) method. You can access the individual repeating child nodes using the GetNode (see page 7454) method.

See Also

GetNode (see page 7454)

AddChild (see page 7672)

Remove (see page 7456)

Delete (see page 7453)

List (see page 7459)

79.1.3.3.2 TXMLNodeCollection.ItemInterface Property

Indicates the interface type for the repeating child nodes.

Pascal

```
property ItemInterface: TGuid;
```

C++

```
__property TGuid ItemInterface;
```

Description

Applications can't use this protected property. It is used internally to identify the interface for all child nodes that represent the repeating child element.

ItemInterface is the GUID for the default interface of the class that implements the nodes in the collection.

See Also

IXMLNode (see page 7669)

IsCollectionItem (see page 7455)

List (see page 7459)

ItemTag (see page 7459)

ItemNS (see page 7458)

79.1.3.3.3 TXMLNodeCollection.ItemNS Property

Indicates the default namespace URI for the tag names of repeating child elements.

Pascal

```
property ItemNS: DOMString;
```

C++

```
__property DOMString ItemNS;
```

Description

Applications can't use this protected property. It is used internally to identify the namespace used to interpret tag names on members of this node collection.

See Also

NamespaceURI (see page 7693)

ItemInterface (see page 7458)

List (see page 7459)

ItemTag (see page 7459)

79.1.3.3.4 TXMLNodeCollection.ItemTag Property

Indicates the tag name that occurs on the repeating child elements.

Pascal

```
property ItemTag: DOMString;
```

C++

```
__property DOMString ItemTag;
```

Description

Applications can't use this protected property. It is used internally to identify the tag name that appears on members of this node collection.

ItemTag is interpreted in the context of the namespace specified by the ItemNS (see page 7458) property.

See Also

NodeName (see page 7693)

ItemInterface (see page 7458)

List (see page 7459)

ItemNS (see page 7458)

79.1.3.3.5 TXMLNodeCollection.List Property

Lists the interfaces for the children that are repeated elements.

Pascal

```
property List: IXMLNodeList;
```

C++

```
__property IXMLNodeList List;
```

Description

Applications can't use the protected List property. TXMLNodeCollection (see page 7444) uses this property internally to identify those child nodes that are repeated elements. Because TXMLNodeCollection (see page 7444) can correspond to a

node in the XML document that has additional children that are not instances of the repeating node type, List is kept separate from the ChildNodes (see page 7439) property, which lists all child nodes.

Applications that need to access the child nodes in this list should use the Nodes property of the IXMLNodeCollection (see page 7698) interface for this node or the Items property of an IXMLNodeCollection (see page 7698) descendant that is generated by the XML Data Binding wizard.

See Also

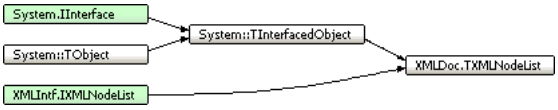
Nodes (see page 7703)

ChildNodes (see page 7439)

79.1.4 TXMLNodeList Class

TXMLNodeList represents a set of nodes in an XML document.

Class Hierarchy



Pascal

```
TXMLNodeList = class(TInterfacedObject, IXMLNodeList);
```

C++

```
class TXMLNodeList : public TInterfacedObject, public IXMLNodeList;
```

File

XMLDoc

Description

TXMLNodeList is used to represent a set of related nodes (IXMLNode (see page 7669) interfaces) in an XML document. For example, TXMLNodeList is used to represent all of the children of a node, or all of the attributes of a node, or all of the nodes in a collection of repeating nodes.

TXMLNodeList can be used to add or delete nodes from the collection, or to access specific nodes.

Typically, applications do not use TXMLNodeList directly. Instead, they access it through the IXMLNodeList (see page 7703) interface.

See Also

ChildNodes (see page 7439)

AttributeNodes (see page 7438)

TXMLNodeCollection (see page 7444)

IXMLNodeList (see page 7703)

IXMLNode (see page 7669)

TObjectList

TInterfaceList

79.1.4.1 TXMLNodeList Members

The following tables list the members exposed by TXMLNodeList.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Events

	Name	Description
R	NotificationProc (see page 7476)	Specifies a callback that TXMLNodeList (see page 7460) calls when nodes are added to or removed from the list, or when new nodes need to be created

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	Add (see page 7464)	Adds a new node to the end of the list.
	BeginUpdate (see page 7465)	Increments the value of UpdateCount (see page 7476).
	Clear (see page 7465)	Removes all nodes from the list.
	Delete (see page 7465)	This is the overview for the Delete method overload.
	DoNotify (see page 7466)	Executes the callback specified by NotificationProc (see page 7476).
	EndUpdate (see page 7467)	Decrements the value of UpdateCount (see page 7476).
	FindNode (see page 7467)	This is the overview for the FindNode method overload.
	FindSibling (see page 7468)	Returns a node that appears a specified amount before or after another node.
	First (see page 7469)	Returns the first node in the list.
	Get (see page 7469)	Returns a specified node in the list.
	GetCount (see page 7470)	Returns the number of nodes in the list.
	GetNode (see page 7470)	Returns a specified node from the list.
	GetUpdateCount (see page 7471)	Returns the value of the UpdateCount (see page 7476) property.
	IndexOf (see page 7471)	This is the overview for the IndexOf method overload.
	Insert (see page 7472)	Inserts a new node into a specified position in the list.
	InternalInsert (see page 7472)	Provides the underlying implementation of the Insert (see page 7472) method
	Last (see page 7473)	Returns the last node in the list.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	Remove (see page 7473)	Removes a specified node from the list.
	ReplaceNode (see page 7473)	Replaces a node in the list with another node.

Protected Properties

	Name	Description
R	Count (see page 7474)	Indicates the number of nodes in the collection.
R	DefaultNamespaceURI (see page 7475)	Identifies the default Namespace for the nodes in this collection.
R	List (see page 7475)	Stores the interfaces for every node in the list.
R	Owner (see page 7475)	Specifies the node that uses this TXMLNodeList (see page 7460) object to manage a set of its child or attribute nodes.
R	UpdateCount (see page 7476)	Indicates the number of times an application has called BeginUpdate (see page 7465) without a matching call to EndUpdate (see page 7467).

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.

	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 7462)	Instantiates a TXMLNodeList (see page 7460) object.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Delete (see page 7706)	This is the overview for the Delete method overload.
	Destroy (see page 7463)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	FindNode (see page 7708)	This is the overview for the FindNode method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 7711)	This is the overview for the IndexOf method overload.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	Nodes (see page 7714)	Provides access to the nodes in the list.
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

79.1.4.2 TXMLNodeList.Create Constructor

Instantiates a TXMLNodeList (see page 7460) object.

Pascal

```
constructor Create(Owner: TXMLNode; const DefaultNamespaceURI: DOMString; NotificationProc:
```

```
TNodeListNotification);
```

C++

```
__fastcall TXMLNodeList(TXMLNode Owner, const DOMString DefaultNamespaceURI,
TNodeListNotification NotificationProc);
```

Description

Createinstantiates a new TXMLNodeList (see page 7460) object. Typically, TXMLNodeList (see page 7460) is created by another object that represents a node. The TXMLNodeList (see page 7460) represents a set of nodes that are of interest to the other object that creates it.

AOwner is the node that creates TXMLNodeList (see page 7460) to represent a set of its child nodes or attributes.

DefaultNamespaceURI (see page 7475) identifies the namespace that is used by default for nodes added to this list when no namespace is explicitly specified.

NotificationProc (see page 7476) is a callback that TXMLNodeList (see page 7460) calls when nodes are added to or removed from the list, or when new nodes need to be created.

See Also

DefaultNamespaceURI (see page 7475)

Owner (see page 7475)

NotificationProc (see page 7476)

79.1.4.3 TXMLNodeList.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLNodeList();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 3372)

79.1.4.4 TXMLNodeList Methods

The methods of the TXMLNodeList class are listed here.

Protected Methods

	Name	Description
	Add (see page 7464)	Adds a new node to the end of the list.
	BeginUpdate (see page 7465)	Increments the value of UpdateCount (see page 7476).
	Clear (see page 7465)	Removes all nodes from the list.
	Delete (see page 7465)	This is the overview for the Delete method overload.
	DoNotify (see page 7466)	Executes the callback specified by NotificationProc (see page 7476).
	EndUpdate (see page 7467)	Decrements the value of UpdateCount (see page 7476).
	FindNode (see page 7467)	This is the overview for the FindNode method overload.
	FindSibling (see page 7468)	Returns a node that appears a specified amount before or after another node.
	First (see page 7469)	Returns the first node in the list.
	Get (see page 7469)	Returns a specified node in the list.
	GetCount (see page 7470)	Returns the number of nodes in the list.
	GetNode (see page 7470)	Returns a specified node from the list.
	GetUpdateCount (see page 7471)	Returns the value of the UpdateCount (see page 7476) property.
	IndexOf (see page 7471)	This is the overview for the IndexOf method overload.
	Insert (see page 7472)	Inserts a new node into a specified position in the list.
	InternalInsert (see page 7472)	Provides the underlying implementation of the Insert (see page 7472) method
	Last (see page 7473)	Returns the last node in the list.
	Remove (see page 7473)	Removes a specified node from the list.
	ReplaceNode (see page 7473)	Replaces a node in the list with another node.

79.1.4.4.1 TXMLNodeList.Add Method

Adds a new node to the end of the list.

Pascal

```
function Add(const Node: IXMLNode): Integer;
```

C++

```
__fastcall int Add(const IXMLNode Node);
```

Description

Call Add to add a node to the end of the list. Add returns the index of the node once it is added, where 0 is the index of the first node in the list, 1 is the index of the second node, and so on.

Node is the node to add to the list.

See Also

Delete (see page 7466)

Remove (see page 7473)

IndexOf (see page 7471)

Insert (see page 7472)

List (see page 7475)

79.1.4.4.2 TXMLNodeList.BeginUpdate Method

Increments the value of UpdateCount (see page 7476).

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

Call BeginUpdate before making several changes to the nodes in the list (such as adding or removing several nodes). BeginUpdate increments the UpdateCount (see page 7476) property, to keep track of the fact that the list is in the middle of an update. When the update is complete, call EndUpdate (see page 7467) to decrement the UpdateCount (see page 7476) property.

Every call to BeginUpdate should be matched by a call to EndUpdate (see page 7467), so that the UpdateCount (see page 7476) property accurately reflects whether an update operation is underway.

See Also

UpdateCount (see page 7476)

EndUpdate (see page 7467)

79.1.4.4.3 TXMLNodeList.Clear Method

Removes all nodes from the list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the list.

Note: Clear does not call the BeginUpdate (see page 7465) and EndUpdate (see page 7467) methods. NotificationProc (see page 7476) is called for every node in the list as it is removed.

See Also

Delete (see page 7466)

Remove (see page 7473)

List (see page 7475)

NotificationProc (see page 7476)

79.1.4.4.4 Delete Method

This is the overview for the Delete method overload.

Overload List

	Name	Description
	TXMLNodeList.Delete (DOMString) (see page 7466)	Removes a specified node from the list.
	TXMLNodeList.Delete (DOMString, DOMString) (see page 7466)	Removes a specified node from the list.
	TXMLNodeList.Delete (Integer) (see page 7466)	Removes a specified node from the list.

79.1.4.4.4.1 TXMLNodeList.Delete Method (DOMString)

Removes a specified node from the list.

Pascal

```
function Delete(const Index: Integer): Integer; overload;
function Delete(const Name: DOMString): Integer; overload;
function Delete(const Name: DOMString; const NamespaceURI: DOMString): Integer; overload;
```

C++

```
__fastcall int Delete(const int Index);
__fastcall int Delete(const DOMString Name);
__fastcall int Delete(const DOMString Name, const DOMString NamespaceURI);
```

Description

Delete removes the node specified by the Index or Name parameter.

Name identifies the node to remove from the list. This is the local name of the node to remove.

NamespaceURI identifies the namespace to use when interpreting Name. If the node is identified by Name, but no NamespaceURI parameter is provided, Delete uses DefaultNamespaceURI (see page 7475).

Index identifies the node to remove by index rather than name. Index ranges from 0 to one less than the value of the Count (see page 7474) property.

Delete returns the index of the node that was removed. If there was no node that matched the value of Index or Name, Delete returns –1.

See Also

Remove (see page 7473)

Clear (see page 7465)

IndexOf (see page 7471)

LocalName (see page 7692)

DefaultNamespaceURI (see page 7475)

NamespaceURI (see page 7693)

79.1.4.4.5 TXMLNodeList.DoNotify Method

Executes the callback specified by NotificationProc (see page 7476).

Pascal

```
function DoNotify(Operation: TNodeListOperation; const Node: IXMLNode; const IndexOrName:
```

```
OleVariant; BeforeOperation: Boolean): IXMLNode;
```

C++

```
__fastcall IXMLNode DoNotify(TNodeListOperation Operation, const IXMLNode Node, const
OleVariant IndexOrName, Boolean BeforeOperation);
```

Description

DoNotify executes the callback that is assigned to NotificationProc (see page 7476) when the list adds, deletes, or needs to create nodes in the list. The parameters are supplied as parameters to the callback, and DoNotify returns the node that was added, deleted, or created.

Operation indicates what change is about to occur or has just occurred.

Node is the node that is being added or removed from the list, or that acts as a parent if the callback must create a node (when Operation is nlCreateNode).

IndexOrName is the name of the node to be created when Operation is nlCreateNode. Otherwise, it is the name or index of the node being deleted or added.

BeforeOperation indicates whether the call occurs before the indicated operation or after. When nodes are inserted and removed, a call is made first with BeforeOperation set to true, then the operation occurs, and then a second callback is made with BeforeOperation set to false. When nodes must be created, only one call is made, with BeforeOperation set to true.

See Also

NotificationProc (see page 7476)

79.1.4.4.6 TXMLNodeList.EndUpdate Method

Decrements the value of UpdateCount (see page 7476).

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Call EndUpdate after making several changes to the nodes in the list (such as adding or removing several nodes). EndUpdate decrements the UpdateCount (see page 7476) property, which was incremented by a previous call to BeginUpdate (see page 7465).

Every call to BeginUpdate (see page 7465) should be matched by a call to EndUpdate, so that the UpdateCount (see page 7476) property accurately reflects whether an update operation is underway.

See Also

UpdateCount (see page 7476)

BeginUpdate (see page 7465)

79.1.4.4.7 FindNode Method

This is the overview for the FindNode method overload.

Overload List

	Name	Description
	TXMLNodeList.FindNode (DOMString) (see page 7468)	Returns a specified node from the list.
	TXMLNodeList.FindNode (DOMString, DOMString) (see page 7468)	Returns a specified node from the list.
	TXMLNodeList.FindNode (TGuid) (see page 7468)	Returns a specified node from the list.

79.1.4.4.7.1 TXMLNodeList.FindNode Method (DOMString)

Returns a specified node from the list.

Pascal

```
function FindNode(NodeName: DOMString): IXMLNode; overload;
function FindNode(NodeName: DOMString; NamespaceURI: DOMString): IXMLNode; overload;
function FindNode(ChildNodeType: TGuid): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode FindNode(DOMString NodeName);
__fastcall IXMLNode FindNode(DOMString NodeName, DOMString NamespaceURI);
__fastcall IXMLNode FindNode(TGuid ChildNodeType);
```

Description

Call FindNode to access a particular node in the list.

NodeName is the node to access. It specifies the LocalName property of the desired node.

NamespaceURI identifies the namespace that qualifies NodeName. It is the same as the NamespaceURI property of the desired node. If the first syntax is used (omitting NamespaceURI), FindNode uses the value of the DefaultNamespaceURI (see page 7475) property.

ChildNodeType identifies the node to access by its interface type (GUID), rather than by name. When using ChildNodeType, FindNode returns the first child node it finds that implements the specified interface.

FindNode returns the interface for the node if it is in the list. If NodeName or ChildNodeType does not specify a node in the list, FindNode returns nil (Delphi) or NULL (C++).

See Also

FindSibling (see page 7468)

First (see page 7469)

Last (see page 7473)

IndexOf (see page 7471)

LocalName (see page 7692)

NamespaceURI (see page 7693)

DefaultNamespaceURI (see page 7475)

79.1.4.4.8 TXMLNodeList.FindSibling Method

Returns a node that appears a specified amount before or after another node.

Pascal

```
function FindSibling(const Node: IXMLNode; Delta: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode FindSibling(const IXMLNode Node, int Delta);
```

Description

Call FindSibling to access the node whose position has a specified relationship to another node.

Node is a node in the list to use as a reference point.

Delta indicates where the desired node appears, relative to Node. If Delta is positive, FindSibling returns the node that appears Delta positions after Node. If Delta is negative, FindSibling returns a node that appears before Node.

FindSibling returns the node that appears at the position offset by Delta, relative to the position of Node. If Delta specifies a position before the first node or after the last node in the list, FindSibling returns nil (Delphi) or NULL (C++).

See Also

FindNode (see page 7468)

First (see page 7469)

Last (see page 7473)

IndexOf (see page 7471)

79.1.4.4.9 TXMLNodeList.First Method

Returns the first node in the list.

Pascal

```
function First: IXMLNode;
```

C++

```
__fastcall IXMLNode First();
```

Description

Call First to access the first node in the list. If the list is empty, First raises an exception.

See Also

FindNode (see page 7468)

FindSibling (see page 7468)

Last (see page 7473)

79.1.4.4.10 TXMLNodeList.Get Method

Returns a specified node in the list.

Pascal

```
function Get(Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode Get(int Index);
```

Description

Call Get to retrieve a node from the list, given its index.

Index specifies the node to fetch, where 0 identifies the first node, 1 identifies the second node, and so on. Index should be less than the value of the Count (see page 7474) property.

See Also

List (see page 7475)

GetNode (see page 7470)

Count (see page 7474)

79.1.4.4.11 TXMLNodeList.GetCount Method

Returns the number of nodes in the list.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the read implementation of the Count (see page 7474) property.

See Also

Count (see page 7474)

79.1.4.4.12 TXMLNodeList.GetNode Method

Returns a specified node from the list.

Pascal

```
function GetNode(const IndexOrName: OleVariant): IXMLNode;
```

C++

```
__fastcall IXMLNode GetNode(const OleVariant IndexOrName);
```

Description

GetNode returns the interface to a node that is identified by name or by position.

IndexOrName identifies the desired node. It can be

The index of the node, where 0 is the index of the first node, 1 is the index of the second node, and so on.

The LocalName property of a node in the list.

If IndexOrName does not identify a node in the list, GetNode tries to create a new node with the name specified by IndexOrName. If it can't create the new node, GetNode raises an exception.

See Also

FindNode (see page 7468)

List (see page 7475)

LocalName (see page 7692)

Get (see page 7469)

79.1.4.4.13 TXMLNodeList.GetUpdateCount Method

Returns the value of the UpdateCount (see page 7476) property.

Pascal

```
function GetUpdateCount: Integer;
```

C++

```
__fastcall int GetUpdateCount();
```

Description

GetUpdateCount is the read implementation of the UpdateCount (see page 7476) property.

See Also

UpdateCount (see page 7476)

79.1.4.4.14 IndexOf Method

This is the overview for the IndexOf method overload.

Overload List

	Name	Description
	TXMLNodeList.IndexOf (DOMString) (see page 7471)	Returns the index of a specified node.
	TXMLNodeList.IndexOf (DOMString, DOMString) (see page 7471)	Returns the index of a specified node.
	TXMLNodeList.IndexOf (IXMLNode) (see page 7471)	Returns the index of a specified node.

79.1.4.4.14.1 TXMLNodeList.IndexOf Method (DOMString)

Returns the index of a specified node.

Pascal

```
function IndexOf(const Node: IXMLNode): Integer; overload;
function IndexOf(const Name: DOMString): Integer; overload;
function IndexOf(const Name: DOMString; const NamespaceURI: DOMString): Integer; overload;
```

C++

```
__fastcall int IndexOf(const IXMLNode Node);
__fastcall int IndexOf(const DOMString Name);
__fastcall int IndexOf(const DOMString Name, const DOMString NamespaceURI);
```

Description

Call IndexOf to locate a node in the list. You can specify which node to locate using its name or its interface.

Name is the LocalName property of the node to locate.

NamespaceURI identifies the namespace to use when interpreting LocalName. If Name is used without a NamespaceURI parameter (the first syntax), IndexOf uses the value of the DefaultNamespaceURI (see page 7475) property.

Node is the interface of the node to locate.

IndexOf returns the index of the specified node, where 0 is the index of the first node, 1 is the index of the second node, and so on. If the specified node is not in the list, IndexOf returns -1.

See Also

FindNode (see page 7468)

LocalName (see page 7692)

NamespaceURI (see page 7693)

DefaultNamespaceURI (see page 7475)

79.1.4.4.15 TXMLNodeList.Insert Method

Inserts a new node into a specified position in the list.

Pascal

```
procedure Insert(Index: Integer; const Node: IXMLNode);
```

C++

```
__fastcall Insert(int Index, const IXMLNode Node);
```

Description

Call Insert to add a node at the position specified by Index.

Index specifies where to insert the node, where 0 is the first position, 1 is second position, and so on. If Index does not specify a valid index, Insert raises an exception.

Node is the node to add to the list.

See Also

Delete (see page 7466)

Remove (see page 7473)

IndexOf (see page 7471)

Add (see page 7464)

79.1.4.4.16 TXMLNodeList.InternalInsert Method

Provides the underlying implementation of the Insert (see page 7472) method

Pascal

```
function InternalInsert(Index: Integer; const Node: IXMLNode): Integer;
```

C++

```
__fastcall int InternalInsert(int Index, const IXMLNode Node);
```

Description

The Insert (see page 7472) method calls InternalInsert to add a node at the position specified by Index.

Index specifies where to insert the node, where 0 is the first position, 1 is second position, and so on. If Index is –1, the node is added to the end of the list.

Node is the node to add to the list.

InternalInsert returns the index of the node after it is inserted. This is the same as the Index parameter when Index is not –1.

See Also

Insert (see page 7472)

79.1.4.4.17 TXMLNodeList.Last Method

Returns the last node in the list.

Pascal

```
function Last: IXMLNode;
```

C++

```
__fastcall IXMLNode Last();
```

Description

Call Last to access the last node in the list. If the list is empty, Last raises an exception.

See Also

FindNode (see page 7468)

FindSibling (see page 7468)

First (see page 7469)

79.1.4.4.18 TXMLNodeList.Remove Method

Removes a specified node from the list.

Pascal

```
function Remove(const Node: IXMLNode): Integer;
```

C++

```
__fastcall int Remove(const IXMLNode Node);
```

Description

Remove removes the specified node from the list.

Node is the node to remove from the list.

Remove returns the index of Node before it was removed. If node is not a node in the list, Remove returns -1.

See Also

Delete (see page 7466)

Clear (see page 7465)

79.1.4.4.19 TXMLNodeList.ReplaceNode Method

Replaces a node in the list with another node.

Pascal

```
function ReplaceNode(const OldNode: IXMLNode; const NewNode: IXMLNode): IXMLNode;
```

C++

```
__fastcall IXMLNode ReplaceNode(const IXMLNode OldNode, const IXMLNode NewNode);
```

Description

Call ReplaceNode to replace the node specified by OldNode with the node specified by NewNode.

OldNode is the node to replace. If OldNode does not appear in the list, then ReplaceNode adds the new node to the end of the list.

NewNode is the node to add to the list in place of OldNode.

ReplaceNode returns OldNode (even if OldNode did not appear in the list).

See Also

List (see page 7475)

79.1.4.5 TXMLNodeList Properties

The properties of the TXMLNodeList class are listed here.

Protected Properties

	Name	Description
	Count (see page 7474)	Indicates the number of nodes in the collection.
	DefaultNamespaceURI (see page 7475)	Identifies the default Namespace for the nodes in this collection.
	List (see page 7475)	Stores the interfaces for every node in the list.
	Owner (see page 7475)	Specifies the node that uses this TXMLNodeList (see page 7460) object to manage a set of its child or attribute nodes.
	UpdateCount (see page 7476)	Indicates the number of times an application has called BeginUpdate (see page 7465) without a matching call to EndUpdate (see page 7467).

79.1.4.5.1 TXMLNodeList.Count Property

Indicates the number of nodes in the collection.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read (see page 3634) Count to determine the number of nodes in the list. To change the value of Count, use the IXMLNodeList (see page 7703) interface. Add (see page 7464) nodes using the Add (see page 7464) or Insert (see page 7472) method, or remove them using the Delete (see page 7466) or Remove (see page 7473) method.

See Also

Nodes (see page 7714)

Add (see page 7705)

Delete (see page 7707)

Remove (see page 7713)

Insert (see page 7712)

79.1.4.5.2 TXMLNodeList.DefaultNamespaceURI Property

Identifies the default Namespace for the nodes in this collection.

Pascal

```
property DefaultNamespaceURI: DOMString;
```

C++

```
__property DOMString DefaultNamespaceURI;
```

Description

Read (see page 3634) DefaultNamespaceURI to determine the namespace that is used by default when locating nodes in the list. The IndexOf (see page 7471), FindNode (see page 7468), and Delete (see page 7466) methods all use this namespace when trying to match the name of a node if a namespace is not explicitly supplied.

The value of DefaultNamespaceURI is set by the TXMLNodeList (see page 7460) constructor.

See Also

NamespaceURI (see page 7693)

Create (see page 7462)

IndexOf (see page 7471)

FindNode (see page 7468)

Delete (see page 7466)

79.1.4.5.3 TXMLNodeList.List Property

Stores the interfaces for every node in the list.

Pascal

```
property List: IInterfaceList;
```

C++

```
__property IInterfaceList List;
```

Description

TXMLNodeList (see page 7460) uses List internally to store and manage the interfaces to the nodes it represents.

See Also

Count (see page 7474)

Nodes (see page 7714)

79.1.4.5.4 TXMLNodeList.Owner Property

Specifies the node that uses this TXMLNodeList (see page 7460) object to manage a set of its child or attribute nodes.

Pascal

```
property Owner: TXMLNode;
```

C++

```
__property TXMLNode Owner;
```

Description

Owner designates the node that instantiates TXMLNodeList (see page 7460) to manage a set of its child or attribute nodes. This value is supplied to the TXMLNodeList (see page 7460) constructor.

See Also

ChildNodes (see page 7439)

Create (see page 7462)

AttributeNodes (see page 7438)

79.1.4.5.5 TXMLNodeList.UpdateCount Property

Indicates the number of times an application has called BeginUpdate (see page 7465) without a matching call to EndUpdate (see page 7467).

Pascal

```
property UpdateCount: Integer;
```

C++

```
__property int UpdateCount;
```

Description

UpdateCount keeps track of whether all update operations have been completed. When an application starts making changes to the list, it calls BeginUpdate (see page 7465), which increments UpdateCount. When those changes are complete, it calls EndUpdate (see page 7467), which decrements UpdateCount. Thus, UpdateCount allows calls to BeginUpdate (see page 7465) and EndUpdate (see page 7467) to be nested.

Applications can avoid responding to updates in a piecemeal fashion by checking UpdateCount and only responding when it is 0. For example, the callback that is supplied to the TXMLNodeList (see page 7460) constructor typically checks UpdateCount before responding to change notifications.

See Also

BeginUpdate (see page 7465)

EndUpdate (see page 7467)

Create (see page 7462)

79.1.4.6 TXMLNodeList Events

The events of the TXMLNodeList class are listed here.

Protected Events

	Name	Description
	NotificationProc (see page 7476)	Specifies a callback that TXMLNodeList (see page 7460) calls when nodes are added to or removed from the list, or when new nodes need to be created

79.1.4.6.1 TXMLNodeList.NotificationProc Event

Specifies a callback that TXMLNodeList (see page 7460) calls when nodes are added to or removed from the list, or when new nodes need to be created

Pascal

```
property NotificationProc: TNodeListNotification;
```

C++

```
__property TNodeListNotification NotificationProc;
```

Description

The node that instantiates TXMLNodeList (see page 7460) to manage a set of its child or attribute nodes supplies the value of this callback to the TXMLNodeList (see page 7460) constructor. TXMLNodeList (see page 7460) then calls this callback when its methods are used to add, create, or remove nodes.

See Also

ChildListNotify (see page 7408)

Create (see page 7462)

AttributeListNotify (see page 7406)

79.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IXMLDocumentAccess (see page 7478)	This is class XMLDoc.IXMLDocumentAccess.
	IXMLNodeAccess (see page 7480)	This is class XMLDoc.IXMLNodeAccess.

79.2.1 IXMLDocumentAccess Interface

Class Hierarchy

XMLDoc.IXMLDocumentAccess

Pascal

```
IXMLDocumentAccess = interface;
```

C++

```
__interface IXMLDocumentAccess;
```

File

XMLDoc

Description

This is class XMLDoc.IXMLDocumentAccess.

79.2.1.1 IXMLDocumentAccess Members

The following tables list the members exposed by IXMLDocumentAccess.

Public Methods

	Name	Description
	GetDocumentObject (see page 7479)	This is GetDocumentObject, a member of class IXMLDocumentAccess.
	GetDOMPersist (see page 7479)	This is GetDOMPersist, a member of class IXMLDocumentAccess.

Public Properties

	Name	Description
R	DocumentObject (see page 7479)	This is DocumentObject, a member of class IXMLDocumentAccess.
R	DOMPersist (see page 7480)	This is DOMPersist, a member of class IXMLDocumentAccess.

79.2.1.2 IXMLDocumentAccess Methods

The methods of the IXMLDocumentAccess class are listed here.

Public Methods

	Name	Description
	GetDocumentObject (see page 7479)	This is GetDocumentObject, a member of class IXMLDocumentAccess.
	GetDOMPersist (see page 7479)	This is GetDOMPersist, a member of class IXMLDocumentAccess.

79.2.1.2.1 IXMLDocumentAccess.GetDocumentObject Method

Pascal

```
function GetDocumentObject: TXMLDocument;
```

C++

```
__fastcall TXMLDocument GetDocumentObject();
```

Description

This is GetDocumentObject, a member of class IXMLDocumentAccess.

79.2.1.2.2 IXMLDocumentAccess.GetDOMPersist Method

Pascal

```
function GetDOMPersist: IDOMPersist;
```

C++

```
__fastcall IDOMPersist GetDOMPersist();
```

Description

This is GetDOMPersist, a member of class IXMLDocumentAccess.

79.2.1.3 IXMLDocumentAccess Properties

The properties of the IXMLDocumentAccess class are listed here.

Public Properties

	Name	Description
R	DocumentObject (see page 7479)	This is DocumentObject, a member of class IXMLDocumentAccess.
R	DOMPersist (see page 7480)	This is DOMPersist, a member of class IXMLDocumentAccess.

79.2.1.3.1 IXMLDocumentAccess.DocumentObject Property

Pascal

```
property DocumentObject: TXMLDocument;
```

C++

```
__property TXMLDocument DocumentObject;
```

Description

This is DocumentObject, a member of class IXMLDocumentAccess.

79.2.1.3.2 IXMLDocumentAccess.DOMPersist Property

Pascal

```
property DOMPersist: IDOMPersist;
```

C++

```
__property IDOMPersist DOMPersist;
```

Description

This is DOMPersist, a member of class IXMLDocumentAccess.

79.2.2 IXMLNodeAccess Interface

Class Hierarchy

Pascal

```
IXMLNodeAccess = interface(IXMLNode);
```

C++

```
__interface IXMLNodeAccess : public IXMLNode;
```

File

XMLDoc

Description

This is class XMLDoc.IXMLNodeAccess.

79.2.2.1 IXMLNodeAccess Members

The following tables list the members exposed by IXMLNodeAccess.

Public Methods

	Name	Description
	AddChild (see page 7482)	This is AddChild, a member of class IXMLNodeAccess.
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
	CheckTextNode (see page 7483)	This is CheckTextNode, a member of class IXMLNodeAccess.
	ClearDocumentRef (see page 7483)	This is ClearDocumentRef, a member of class IXMLNodeAccess.
	CloneNode (see page 7673)	Creates a copy of this node and returns its interface.
	CreateAttributeNode (see page 7483)	This is CreateAttributeNode, a member of class IXMLNodeAccess.
	CreateChildNode (see page 7483)	This is CreateChildNode, a member of class IXMLNodeAccess.
	CreateCollection (see page 7483)	This is CreateCollection, a member of class IXMLNodeAccess.
	DeclareNamespace (see page 7674)	Adds an attribute to the node that declares a specified namespace URI.
	DOMElement (see page 7484)	This is DOMElement, a member of class IXMLNodeAccess.
	FindHostedNode (see page 7484)	This is FindHostedNode, a member of class IXMLNodeAccess.
	FindNamespaceDecl (see page 7674)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7674)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7675)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7675)	Returns the value of the AttributeNodes (see page 7688) property.

	GetAttributeNS (see page 7676)	Returns the value of a specified attribute.
	GetChildNodeClasses (see page 7484)	This is GetChildNodeClasses, a member of class IXMLNodeAccess.
	GetChildNodes (see page 7676)	Returns the value of the ChildNodes (see page 7689) property.
	GetChildValue (see page 7676)	Returns the value of a specified child node.
	GetCollection (see page 7677)	Returns the value of the Collection (see page 7690) property.
	GetDOMNode (see page 7677)	Returns the value of the DOMNode (see page 7691) property.
	GetHasChildNodes (see page 7678)	Indicates whether the node has any child nodes.
	GetHostNode (see page 7484)	This is GetHostNode, a member of class IXMLNodeAccess.
	GetIsTextElement (see page 7678)	Indicates whether the node has a single text value.
	GetLocalName (see page 7678)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7679)	Returns the namespace URI for the node's qualified name.
	GetNodeName (see page 7679)	Returns the name of the node.
	GetNodeObject (see page 7485)	This is GetNodeObject, a member of class IXMLNodeAccess.
	GetNodeType (see page 7679)	Returns the type of the node.
	GetNodeValue (see page 7680)	Returns the value of the node.
	GetOwnerDocument (see page 7680)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7680)	Returns the interface for the node's parent node.
	GetPrefix (see page 7680)	Returns the namespace prefix from the node's name.
	GetReadOnly (see page 7681)	Returns the value of the ReadOnly (see page 7696) property.
	GetText (see page 7681)	Returns the text value of the node.
	GetXML (see page 7681)	Returns the value of the XML (see page 7697) property.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	HasChildNode (see page 7485)	This is the overview for the HasChildNode method overload.
	InternalAddChild (see page 7485)	This is InternalAddChild, a member of class IXMLNodeAccess.
	NestingLevel (see page 7486)	This is NestingLevel, a member of class IXMLNodeAccess.
	NextSibling (see page 7682)	Returns the next child of this node's parent.
	Normalize (see page 7683)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7683)	Returns the previous child of this node's parent.
	RegisterChildNode (see page 7486)	This is RegisterChildNode, a member of class IXMLNodeAccess.
	RegisterChildNodes (see page 7486)	This is RegisterChildNodes, a member of class IXMLNodeAccess.
	Resync (see page 7684)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7684)	Sets the value of one of this node's attributes.
	SetAttributeNS (see page 7684)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
	SetChildValue (see page 7685)	Sets the value of a specified child node.
	SetCollection (see page 7486)	This is SetCollection, a member of class IXMLNodeAccess.
	SetNodeValue (see page 7685)	Sets the value of this node.
	SetParentNode (see page 7487)	This is SetParentNode, a member of class IXMLNodeAccess.
	SetReadOnly (see page 7686)	Specifies whether the node can be modified.
	SetText (see page 7686)	Sets the text value of the node.
	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.

Public Properties

	Name	Description
R	AttributeNodes (see page 7688)	Lists the interfaces for nodes that represent attributes of this node.
	Attributes (see page 7688)	Represents the values of this node's attributes.
R	ChildNodeClasses (see page 7487)	This is ChildNodeClasses, a member of class IXMLNodeAccess.
R	ChildNodes (see page 7689)	Represents the child nodes of the node.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	Collection (see page 7690)	Indicates the collection in which this node appears.
R	DOMNode (see page 7691)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	HostNode (see page 7487)	This is HostNode, a member of class IXMLNodeAccess.

R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.
R	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
R	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
R	NodeName (see page 7693)	Indicates the node name.
R	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
R	OwnerDocument (see page 7695)	Identifies the document in which this node appears.
R	ParentNode (see page 7695)	Identifies the interface of the node's parent node.
R	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
	Text (see page 7697)	Represents the Text of the node.
R	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

79.2.2.2 IXMLNodeAccess Methods

The methods of the IXMLNodeAccess class are listed here.

Public Methods

	Name	Description
	AddChild (see page 7482)	This is AddChild, a member of class IXMLNodeAccess.
	CheckTextNode (see page 7483)	This is CheckTextNode, a member of class IXMLNodeAccess.
	ClearDocumentRef (see page 7483)	This is ClearDocumentRef, a member of class IXMLNodeAccess.
	CreateAttributeNode (see page 7483)	This is CreateAttributeNode, a member of class IXMLNodeAccess.
	CreateChildNode (see page 7483)	This is CreateChildNode, a member of class IXMLNodeAccess.
	CreateCollection (see page 7483)	This is CreateCollection, a member of class IXMLNodeAccess.
	DOMElement (see page 7484)	This is DOMElement, a member of class IXMLNodeAccess.
	FindHostedNode (see page 7484)	This is FindHostedNode, a member of class IXMLNodeAccess.
	GetChildNodeClasses (see page 7484)	This is GetChildNodeClasses, a member of class IXMLNodeAccess.
	GetHostNode (see page 7484)	This is GetHostNode, a member of class IXMLNodeAccess.
	GetNodeObject (see page 7485)	This is GetNodeObject, a member of class IXMLNodeAccess.
	HasChildNode (see page 7485)	This is the overview for the HasChildNode method overload.
	InternalAddChild (see page 7485)	This is InternalAddChild, a member of class IXMLNodeAccess.
	NestingLevel (see page 7486)	This is NestingLevel, a member of class IXMLNodeAccess.
	RegisterChildNode (see page 7486)	This is RegisterChildNode, a member of class IXMLNodeAccess.
	RegisterChildNodes (see page 7486)	This is RegisterChildNodes, a member of class IXMLNodeAccess.
	SetCollection (see page 7486)	This is SetCollection, a member of class IXMLNodeAccess.
	SetParentNode (see page 7487)	This is SetParentNode, a member of class IXMLNodeAccess.

79.2.2.2.1 IXMLNodeAccess.AddChild Method

Pascal

```
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString; NodeClass:
TXMLNodeClass; Index: Integer = -1): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI,
TXMLNodeClass NodeClass, int Index = -1);
```

Description

This is AddChild, a member of class IXMLNodeAccess.

79.2.2.2.2 IXMLNodeAccess.CheckTextNode Method

Pascal

```
procedure CheckTextNode;
```

C++

```
__fastcall CheckTextNode();
```

Description

This is CheckTextNode, a member of class IXMLNodeAccess.

79.2.2.2.3 IXMLNodeAccess.ClearDocumentRef Method

Pascal

```
procedure ClearDocumentRef;
```

C++

```
__fastcall ClearDocumentRef();
```

Description

This is ClearDocumentRef, a member of class IXMLNodeAccess.

79.2.2.2.4 IXMLNodeAccess.CreateAttributeNode Method

Pascal

```
function CreateAttributeNode(const ADOMNode: IDOMNode): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateAttributeNode(const IDOMNode ADOMNode);
```

Description

This is CreateAttributeNode, a member of class IXMLNodeAccess.

79.2.2.2.5 IXMLNodeAccess.CreateChildNode Method

Pascal

```
function CreateChildNode(const ADOMNode: IDOMNode): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateChildNode(const IDOMNode ADOMNode);
```

Description

This is CreateChildNode, a member of class IXMLNodeAccess.

79.2.2.2.6 IXMLNodeAccess.CreateCollection Method

Pascal

```
function CreateCollection(const CollectionClass: TXMLNodeCollectionClass; const ItemIterface:
TGuid; const ItemTag: DOMString; ItemNS: DOMString = ''): TXMLNodeCollection;
```

C++

```
__fastcall TXMLNodeCollection CreateCollection(const TXMLNodeCollectionClass CollectionClass,
const TGuid ItemIterface, const DOMString ItemTag, DOMString ItemNS = '');
```

Description

This is CreateCollection, a member of class IXMLNodeAccess.

79.2.2.2.7 IXMLNodeAccess.DOMElement Method

Pascal

```
function DOMElement: IDOMElement;
```

C++

```
__fastcall IDOMElement DOMElement();
```

Description

This is DOMElement, a member of class IXMLNodeAccess.

79.2.2.2.8 IXMLNodeAccess.FindHostedNode Method

Pascal

```
function FindHostedNode(const NodeClass: TXMLNodeClass): IXMLNode;
```

C++

```
__fastcall IXMLNode FindHostedNode(const TXMLNodeClass NodeClass);
```

Description

This is FindHostedNode, a member of class IXMLNodeAccess.

79.2.2.2.9 IXMLNodeAccess.GetChildNodeClasses Method

Pascal

```
function GetChildNodeClasses: TNodeClassArray;
```

C++

```
__fastcall TNodeClassArray GetChildNodeClasses();
```

Description

This is GetChildNodeClasses, a member of class IXMLNodeAccess.

79.2.2.2.10 IXMLNodeAccess.GetHostNode Method

Pascal

```
function GetHostNode: TXMLNode;
```

C++

```
__fastcall TXMLNode GetHostNode();
```

Description

This is GetHostNode, a member of class IXMLNodeAccess.

79.2.2.2.11 IXMLNodeAccess.GetNodeObject Method

Pascal

```
function GetNodeObject: TXMLNode;
```

C++

```
__fastcall TXMLNode GetNodeObject();
```

Description

This is GetNodeObject, a member of class IXMLNodeAccess.

79.2.2.2.12 HasChildNode Method

This is the overview for the HasChildNode method overload.

Overload List

	Name	Description
	IXMLNodeAccess.HasChildNode (DOMString) (see page 7485)	This is HasChildNode, a member of class IXMLNodeAccess.
	IXMLNodeAccess.HasChildNode (DOMString, DOMString) (see page 7485)	This is HasChildNode, a member of class IXMLNodeAccess.

79.2.2.2.12.1 IXMLNodeAccess.HasChildNode Method (DOMString)

Pascal

```
function HasChildNode(const ChildTag: DOMString): Boolean; overload;
```

C++

```
__fastcall Boolean HasChildNode(const DOMString ChildTag);
```

Description

This is HasChildNode, a member of class IXMLNodeAccess.

79.2.2.2.12.2 IXMLNodeAccess.HasChildNode Method (DOMString, DOMString)

Pascal

```
function HasChildNode(const ChildTag: DOMString; const NamespaceURI: DOMString): Boolean;
overload;
```

C++

```
__fastcall Boolean HasChildNode(const DOMString ChildTag, const DOMString NamespaceURI);
```

Description

This is HasChildNode, a member of class IXMLNodeAccess.

79.2.2.2.13 IXMLNodeAccess.InternalAddChild Method

Pascal

```
function InternalAddChild(NodeClass: TXMLNodeClass; const NodeName: DOMString; const
NamespaceURI: DOMString; Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode InternalAddChild(TXMLNodeClass NodeClass, const DOMString NodeName, const
DOMString NamespaceURI, int Index);
```

Description

This is InternalAddChild, a member of class IXMLNodeAccess.

79.2.2.2.14 IXMLNodeAccess.NestingLevel Method

Pascal

```
function NestingLevel: Integer;
```

C++

```
__fastcall int NestingLevel();
```

Description

This is NestingLevel, a member of class IXMLNodeAccess.

79.2.2.2.15 IXMLNodeAccess.RegisterChildNode Method

Pascal

```
procedure RegisterChildNode(const TagName: DOMString; ChildNodeClass: TXMLNodeClass;
NamespaceURI: DOMString = '');
```

C++

```
__fastcall RegisterChildNode(const DOMString TagName, TXMLNodeClass ChildNodeClass, DOMString
NamespaceURI = '');
```

Description

This is RegisterChildNode, a member of class IXMLNodeAccess.

79.2.2.2.16 IXMLNodeAccess.RegisterChildNodes Method

Pascal

```
procedure RegisterChildNodes(const TagNames: array of DOMString; const NodeClasses: array of
TXMLNodeClass);
```

C++

```
__fastcall RegisterChildNodes(const array of DOMString TagNames, const array of TXMLNodeClass
NodeClasses);
```

Description

This is RegisterChildNodes, a member of class IXMLNodeAccess.

79.2.2.2.17 IXMLNodeAccess.SetCollection Method

Pascal

```
procedure SetCollection(const Value: TXMLNodeCollection);
```

C++

```
__fastcall SetCollection(const TXMLNodeCollection Value);
```

Description

This is SetCollection, a member of class IXMLNodeAccess.

79.2.2.2.18 IXMLNodeAccess.SetParentNode Method

Pascal

```
procedure SetParentNode(const Value: TXMLNode);
```

C++

```
__fastcall SetParentNode(const TXMLNode Value);
```

Description

This is SetParentNode, a member of class IXMLNodeAccess.

79.2.2.3 IXMLNodeAccess Properties

The properties of the IXMLNodeAccess class are listed here.

Public Properties

	Name	Description
	ChildNodeClasses (see page 7487)	This is ChildNodeClasses, a member of class IXMLNodeAccess.
	HostNode (see page 7487)	This is HostNode, a member of class IXMLNodeAccess.

79.2.2.3.1 IXMLNodeAccess.ChildNodeClasses Property

Pascal

```
property ChildNodeClasses: TNodeClassArray;
```

C++

```
__property TNodeClassArray ChildNodeClasses;
```

Description

This is ChildNodeClasses, a member of class IXMLNodeAccess.

79.2.2.3.2 IXMLNodeAccess.HostNode Property

Pascal

```
property HostNode: TXMLNode;
```

C++

```
__property TXMLNode HostNode;
```

Description

This is HostNode, a member of class IXMLNodeAccess.

79.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CheckEncoding (see page 7488)	This is function XMLDoc.CheckEncoding.
	CreateDOMNode (see page 7488)	Creates a new DOM node and returns its interface.
	DetectCharEncoding (see page 7489)	This is function XMLDoc.DetectCharEncoding.
	FormatXMLData (see page 7490)	Formats a string of XML so that it is more readable.
	LoadXMLData (see page 7490)	Creates and returns the interface of an XML document object, given a string of XML.
	LoadXMLData (see page 7490)	Creates and returns the interface of an XML document object, given a string of XML.
	LoadXMLDocument (see page 7491)	Returns the interface for an XML document given the name of an XML file.
	NewXMLDocument (see page 7491)	Returns the interface for a new, empty XML document.
	XMLDocError (see page 7492)	Raises an EXMLDocError (see page 7639) exception.
	XMLDocError (see page 7492)	Raises an EXMLDocError (see page 7639) exception.
	XMLStringToUnicodeString (see page 7492)	This is function XMLDoc.XMLStringToUnicodeString.
	XMLStringToWideString (see page 7492)	This is function XMLDoc.XMLStringToWideString.

79.3.1 XMLDoc.CheckEncoding Function

Pascal

```
procedure CheckEncoding(var XMLData: DOMString; const ValidEncodings: array of string);
```

C++

```
CheckEncoding(DOMString XMLData, const array of string ValidEncodings);
```

File

XMLDoc

Description

This is function XMLDoc.CheckEncoding.

79.3.2 XMLDoc.CreateDOMNode Function

Creates a new DOM node and returns its interface.

Pascal

```
function CreateDOMNode(Doc: IDOMDocument; const NameOrData: DOMString; NodeType: TNodeType =
ntElement; const AddlData: DOMString = ''): IDOMNode;
```

C++

```
IDOMNode CreateDOMNode(IDOMDocument Doc, const DOMString NameOrData, TNodeType NodeType =
ntElement, const DOMString AddlData = '');
```

File

XMLDoc

Description

CreateDOMNode generates a new DOM node.

Doc is the DOM interface for the document to which the new node will belong.

NameOrData provides the tag name or value of the newly created node. Its interpretation depends on the type of node created, as indicated in the following table:

NodeType	NameOrData
ntElement	The tag name.
ntAttribute	The attribute name.
ntText	The value of the node.
ntCData	The value of the CDATA section.
ntEntityRef	The name of the referenced entity.
ntProcessingInstr	The target of the processing instruction.
ntComment	The value (text) of the comment.
ntDocFragment	Not used.

NodeType indicates the type of node to create. It can only be one of the types listed in the previous table.

The meaning of AddlData depends on the node type, as indicated in the following table:

NodeType	AddlData
ntElement	The namespace URI that qualifies the tag name.
ntAttribute	The namespace URI that qualifies the attribute name.
ntProcessingInstr	The content of the processing instruction, except for the target.

CreateDOMNode returns the interface for the newly created DOM node.

79.3.3 XMLDoc.DetectCharEncoding Function

Pascal

```
function DetectCharEncoding(S: TStream): TXmlEncodingType;
```

C++

```
TXmlEncodingType DetectCharEncoding(TStream S);
```

File

XMLDoc

Description

This is function XMLDoc.DetectCharEncoding.

79.3.4 XMLDoc.FormatXMLData Function

Formats a string of XML so that it is more readable.

Pascal

```
function FormatXMLData(const XMLData: DOMString): DOMString;
```

C++

```
DOMString FormatXMLData(const DOMString XMLData);
```

File

XMLDoc

Description

Use FormatXMLData to convert a string of XML into a format that represents its structure. FormatXMLData changes the input string (XMLData) so that each element node appears on its own line, indented appropriately to reflect its nesting in the node hierarchy.

79.3.5 XMLDoc.LoadXMLData Function

Creates and returns the interface of an XML document object, given a string of XML.

Pascal

```
function LoadXMLData(const XMLData: DOMString): IXMLDocument; overload;
function LoadXMLData(const XMLData: AnsiString): IXMLDocument; overload;
```

C++

```
IXMLDocument LoadXMLData(const DOMString XMLData);
IXMLDocument LoadXMLData(const AnsiString XMLData);
```

File

XMLDoc

Description

Call LoadXMLData to create an XML document that represents a specified XML string and obtain its interface.

XMLData is the XML for which you want an IXMLDocument (see page 7640) interface.

LoadXMLData returns an interface for the parsed value of XMLData.

LoadXMLData creates a new TXMLDocument (see page 7347) object to parse the XML and returns its IXMLDocument (see page 7640). The TXMLDocument (see page 7347) component is not given an owner, which means that it behaves like an interfaced object. When the application releases the interface that LoadXMLData returns, the TXMLDocument (see page 7347) instance is automatically freed.

See Also

TXMLDocument (see page 7347)

NewXMLDocument (see page 7491)

LoadXMLDocument (see page 7491)

79.3.6 XMLDoc.LoadXMLDocument Function

Returns the interface for an XML document given the name of an XML file.

Pascal

```
function LoadXMLDocument(const FileName: DOMString): IXMLDocument;
```

C++

```
IXMLDocument LoadXMLDocument(const DOMString FileName);
```

File

XMLDoc

Description

Call LoadXMLDocument to load an XML document from a file on disk and obtain its interface. LoadXMLDocument creates a new TXMLDocument (see page 7347) object and uses it to parse the file specified by the FileName parameter. The TXMLDocument (see page 7347) component is not given an owner, which means that it behaves like an interfaced object. When the application releases the interface that LoadXMLDocument returns, the TXMLDocument (see page 7347) instance is automatically freed.

See Also

TXMLDocument (see page 7347)

NewXMLDocument (see page 7491)

LoadXMLData (see page 7490)

79.3.7 XMLDoc.NewXMLDocument Function

Returns the interface for a new, empty XML document.

Pascal

```
function NewXMLDocument(Version: DOMString = '1.0'): IXMLDocument;
```

C++

```
IXMLDocument NewXMLDocument(DOMString Version = '1.0');
```

File

XMLDoc

Description

Call NewXMLDocument to create a TXMLDocument (see page 7347) object for a new, empty XML document.

Version specifies the XML version that the document should use. It becomes the value of the new document's Version property.

See Also

TXMLDocument (see page 7347)

LoadXMLDocument (see page 7491)

IXMLDocument (see page 7640)

79.3.8 XMLDoc.XMLDocError Function

Raises an EXMLDocError (see page 7639) exception.

Pascal

```
procedure XMLDocError(const Msg: string); overload;
procedure XMLDocError(const Msg: string; const Args: array of const); overload;
```

C++

```
XMLDocError(const UnicodeString Msg);
XMLDocError(const UnicodeString Msg, const array of const Args);
```

File

XMLDoc

Description

Call XMLDocError to raise an EXMLDocError (see page 7639) exception. Using XMLDocError rather than explicitly creating the EXMLDocError (see page 7639) instance can result in more space-efficient code.

Msg is the error message associated with the EXMLDocError (see page 7639) instance.

Args supplies arguments for any format specifiers embedded in Msg.

Note: Args_Size is the index of the last entry in the Args array. That is one less than the total number of arguments.

See Also

EXMLDocError (see page 7639)

79.3.9 XMLDoc.XMLStringToUnicodeString Function

Pascal

```
function XMLStringToUnicodeString(const XMLString: AnsiString): UnicodeString;
```

C++

```
UnicodeString XMLStringToUnicodeString(const AnsiString XMLString);
```

File

XMLDoc

Description

This is function XMLDoc.XMLStringToUnicodeString.

79.3.10 XMLDoc.XMLStringToWideString Function

Pascal

```
function XMLStringToWideString(const XMLString: AnsiString): WideString; deprecated;
```

C++

```
BSTR XMLStringToWideString(const AnsiString XMLString);
```

File

XMLDoc

Description

This is function XMLDoc.XMLStringToWideString.

79.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TNodeChange (see page 7494)	TNodeChange indicates the type of change made to a node in an XML document.
	TNodeListOperation (see page 7495)	TNodeListOperation indicates what type of change is about to occur using an IXMLNodeList (see page 7703) interface.
	TXMLDocumentSource (see page 7496)	This is record XMLDoc.TXMLDocumentSource.
	TXMLPrologItem (see page 7497)	This is record XMLDoc.TXMLPrologItem.

Records

	Name	Description
	TNodeClassInfo (see page 7495)	TNodeClassInfo and TNodeClassArray (see page 7499) represent information about the classes that implement XML node interfaces.

79.4.1 XMLDoc.TNodeChange Enumeration

TNodeChange indicates the type of change made to a node in an XML document.

Pascal

```
TNodeChange = (
  ncUpdateValue,
  ncInsertChild,
  ncRemoveChild,
  ncAddAttribute,
  ncRemoveAttribute
);
```

C++

```
enum TNodeChange {
  ncUpdateValue,
  ncInsertChild,
  ncRemoveChild,
  ncAddAttribute,
  ncRemoveAttribute
};
```

File

XMLDoc

Description

The following table lists the possible values:

Value	Meaning
ncUpdateValue	The value of the node is changed.
ncInsertChild	A new child node is added to the node.
ncRemoveChild	A child node is removed from the node.

ncAddAttribute	A new attribute is added to the node.
ncRemoveAttribute	An attribute is removed from the node.

See Also

TNodeChangeEvent (see page 7498)

79.4.2 XMLDoc.TNodeClassInfo Record

TNodeClassInfo and TNodeClassArray (see page 7499) represent information about the classes that implement XML node interfaces.

Pascal

```
TNodeClassInfo = record
  NodeName: DOMString;
  NamespaceURI: DOMString;
  NodeClass: TXMLNodeClass;
end;
```

C++

```
struct TNodeClassInfo {
  DOMString NodeName;
  DOMString NamespaceURI;
  TXMLNodeClass NodeClass;
};
```

File

XMLDoc

Description

TNodeClassArray (see page 7499) is a dynamic array of TNodeClassInfo values. Each element of the array describes the implementation of a node.

TNodeClassInfo describes the name and implementation class for a node in an XML document. It contains the following fields:

Field	Meaning
NodeName	The name of the node. This string describes the identifier or use of the node. For example, on element nodes, this is the tag name. On attribute nodes, this is the name of the attribute. On comment nodes, this is the string "#comment". This is the value returned by a node's NodeName property, and is used as a property name in classes generated by the XML Data Binding Wizard.
NamespaceURI	The namespace of the node's name. This string is a Uniform Resource Identifier that identifies the namespace that contains NodeName. It is used to interpret the value of NodeName.
NodeClass	The class of a TXMLNode (see page 7396) descendant that represents the node.

79.4.3 XMLDoc.TNodeListOperation Enumeration

TNodeListOperation indicates what type of change is about to occur using an IXMLNodeList (see page 7703) interface.

Pascal

```
TNodeListOperation = (
  nlInsert,
  nlRemove,
  nlCreateNode
);
```

C++

```
enum TNodeListOperation {
  nlInsert,
  nlRemove,
  nlCreateNode
};
```

File

XMLDoc

Description

When an application makes a change using the IXMLNodeList (see page 7703) interface, the implementing object sends its owner a notification of that change. TNodeListOperation identifies the type of change that is about to occur. The following table lists the possible values:

Value	Meaning
nlInsert	An existing node is about to be added to the list.
nlRemove	A node is about to be removed from the list.
nlCreateNode	A new node needs to be created so that it can be added to the list.

79.4.4 XMLDoc.TXMLDocumentSource Enumeration

Pascal

```
TXMLDocumentSource = (
  xdsNone,
  xdsXMLProperty,
  xdsXMLData,
  xdsFile,
  xdsStream
);
```

C++

```
enum TXMLDocumentSource {
  xdsNone,
  xdsXMLProperty,
  xdsXMLData,
  xdsFile,
  xdsStream
};
```

File

XMLDoc

Description

This is record XMLDoc.TXMLDocumentSource.

79.4.5 XMLDoc.TXMLPrologItem Enumeration

Pascal

```
TXMLPrologItem = (
  xpVersion,
  xpEncoding,
  xpStandalone
);
```

C++

```
enum TXMLPrologItem {
  xpVersion,
  xpEncoding,
  xpStandalone
};
```

File

XMLDoc

Description

This is record XMLDoc.TXMLPrologItem.

79.5 Types

The following table lists types in this documentation.

Types

Name	Description
TNodeChangeEvent (see page 7498)	TNodeChangeEvent is the type for event handlers that respond when XML nodes are changed.
TNodeClassArray (see page 7499)	This is type XMLDoc.TNodeClassArray.
TNodeListNotification (see page 7499)	TNodeListNotification is the type of the callback the TXMLNodeList (see page 7460) calls when it adds, deletes, or creates XML nodes.
TXMLNodeArray (see page 7500)	TXMLNodeArray is a dynamic array of TXMLNode (see page 7396) objects.
TXMLNodeClass (see page 7501)	TXMLNodeClass is a class reference to a TXMLNode (see page 7396) descendant.
TXMLNodeCollectionClass (see page 7501)	TXMLNodeCollectionClass is a class reference to a TXMLNodeCollection (see page 7444) descendant.

79.5.1 XMLDoc.TNodeChangeEvent Type

TNodeChangeEvent is the type for event handlers that respond when XML nodes are changed.

Pascal

```
TNodeChangeEvent = procedure (const Node: IXMLNode; ChangeType: TNodeChange) of object;
```

C++

```
(const Node: IXMLNode; ChangeType: TNodeChange) ( TNodeChangeEvent)();
```

File

XMLDoc

Description

TNodeChangeEvent is the type for the BeforeNodeChange and AfterNodeChange event handlers. These events occur before and after changes are made to the nodes in an XML document.

Node identifies the node to which the change occurs.

ChangeType indicates the type of change made to Node.

See Also

BeforeNodeChange (see page 7394)

AfterNodeChange (see page 7393)

Procedural types

Creating events

79.5.2 XMLDoc.TNodeClassArray Type

Pascal

```
TNodeClassArray = array of TNodeClassInfo;
```

C++

```
array of TNodeClassInfo TNodeClassArray;
```

File

XMLDoc

Description

This is type XMLDoc.TNodeClassArray.

79.5.3 XMLDoc.TNodeListNotification Type

TNodeListNotification is the type of the callback the TXMLNodeList (see page 7460) calls when it adds, deletes, or creates XML nodes.

Pascal

```
TNodeListNotification = procedure (Operation: TNodeListOperation; var Node: IXMLNode; const
IndexOrName: OleVariant; BeforeOperation: Boolean) of object;
```

C++

```
(Operation: TNodeListOperation; var Node: IXMLNode; const IndexOrName: OleVariant;
BeforeOperation: Boolean) ( TNodeListNotification)();
```

File

XMLDoc

Description

TNodeListNotification is the type for the callback supplied to TXMLNodeList (see page 7460) in its constructor. TXMLNodeList (see page 7460) calls this procedure before and after it adds or deletes nodes in the list and when it needs to create a new node.

Operation indicates what change is about to occur or has just occurred.

Node specifies the node that is the focus of that change. It's use depends on the operation, as indicated in the following table:

Operation	Node
nlInsert	The node that is about to be added to the list or that has just been added.
nlRemove	The node that is about to be removed from the list or that has just been removed.
nlCreateNode	The newly-created node. This should be created by the callback and returned as the Node parameter.
ntElement	The tag name.
ntAttribute	The name of the attribute.
ntText	The value of the node.

ntCData	The value of the CDATA section.
ntEntityRef	The name of the referenced entity.
ntProcessingInstr	The target of the processing instruction.
ntComment	The value (text) of the comment.
ntDocFragment	Not used.

IndexOrName is used only when Operation is nlCreateNode. It is the value assigned to the Nodes property using the index of a node that does not yet exist. The interpretation of IndexOrName depends on the type of node that the callback creates, as indicated in the following table:

NodeType	IndexOrName
ntElement	The tag name.
ntAttribute	The name of the attribute.
ntText	The value of the node.
ntCData	The value of the CDATA section.
ntEntityRef	The name of the referenced entity.
ntProcessingInstr	The target of the processing instruction.
ntComment	The value (text) of the comment.
ntDocFragment	Not used.

BeforeOperation indicates whether the callback occurs before the indicated operation or after. When nodes are inserted and removed, the callback is called first with BeforeOperation set to true, then the operation occurs, and then a second callback is made with BeforeOperation set to false. When nodes must be created, only one call is made, with BeforeOperation set to true.

See Also

TXMLNodeList (see page 7460)

TXMLNode (see page 7396)

IXMLNodeList (see page 7703)

79.5.4 XMLDoc.TXMLNodeArray Type

TXMLNodeArray is a dynamic array of TXMLNode (see page 7396) objects.

Pascal

```
TXMLNodeArray = array of TXMLNode;
```

C++

```
array of TXMLNode TXMLNodeArray;
```

File

XMLDoc

Description

TXMLNodeArray is a dynamic array of TXMLNode (see page 7396) objects, each of which represents a node in an XML document.

79.5.5 XMLDoc.TXMLNodeClass Type

TXMLNodeClass is a class reference to a TXMLNode (see page 7396) descendant.

Pascal

```
TXMLNodeClass = class of TXMLNode;
```

C++

```
TXMLNode TXMLNodeClass;
```

File

XMLDoc

Description

TXMLNodeClass describes a class that descends from TXMLNode (see page 7396).

See Also

Class References

79.5.6 XMLDoc.TXMLNodeCollectionClass Type

TXMLNodeCollectionClass is a class reference to a TXMLNodeCollection (see page 7444) descendant.

Pascal

```
TXMLNodeCollectionClass = class of TXMLNodeCollection;
```

C++

```
TXMLNodeCollection TXMLNodeCollectionClass;
```

File

XMLDoc

Description

TXMLNodeCollectionClass describes a class that descends from TXMLNodeCollection (see page 7444).

79.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
UseXSDBooleanStrings (see page 7502)	This is variable XMLDoc.UseXSDBooleanStrings.

79.6.1 XMLDoc.UseXSDBooleanStrings Variable

Pascal

```
UseXSDBooleanStrings: Boolean = True;
```

C++

```
Boolean UseXSDBooleanStrings = True;
```

File

XMLDoc

Description

This is variable XMLDoc.UseXSDBooleanStrings.

80 xmldom Namespace

This is namespace xmldom.

Topics

Name	Description
Classes (see page 7506)	The following table lists classes in this documentation.
Interfaces (see page 7521)	The following table lists interfaces in this documentation.
Functions (see page 7612)	The following table lists functions in this documentation.
Types (see page 7619)	The following table lists types in this documentation.
Variables (see page 7622)	The following table lists variables in this documentation.
Constants (see page 7624)	The following table lists constants in this documentation.

Classes

	Name	Description
	DOMException (see page 7506)	This is class xmldom.DOMException.
	EDOMParseError (see page 7508)	EDOMParseError is the exception class for errors that occur when a DOM implementation parses an XML document.
	TDOMVendor (see page 7514)	TDOMVendor is the base class for components that provide access to a DOM implementation.
	TDOMVendorList (see page 7516)	TDOMVendorList represents a collection of available DOM implementations.

Constants

Name	Description
ATTRIBUTE_NODE (see page 7624)	This is constant xmldom.ATTRIBUTE_NODE.
CDATA_SECTION_NODE (see page 7625)	This is constant xmldom.CDATA_SECTION_NODE.
COMMENT_NODE (see page 7625)	This is constant xmldom.COMMENT_NODE.
DOCUMENT_FRAGMENT_NODE (see page 7625)	This is constant xmldom.DOCUMENT_FRAGMENT_NODE.
DOCUMENT_NODE (see page 7626)	This is constant xmldom.DOCUMENT_NODE.
DOCUMENT_TYPE_NODE (see page 7626)	This is constant xmldom.DOCUMENT_TYPE_NODE.
DOMSTRING_SIZE_ERR (see page 7626)	This is constant xmldom.DOMSTRING_SIZE_ERR.
DOMWrapperVersion (see page 7627)	Indicates the version number for the vendor-neutral DOM interfaces.
ELEMENT_NODE (see page 7627)	This is constant xmldom.ELEMENT_NODE.
ENTITY_NODE (see page 7627)	This is constant xmldom.ENTITY_NODE.
ENTITY_REFERENCE_NODE (see page 7628)	This is constant xmldom.ENTITY_REFERENCE_NODE.
HIERARCHY_REQUEST_ERR (see page 7628)	This is constant xmldom.HIERARCHY_REQUEST_ERR.
INDEX_SIZE_ERR (see page 7628)	This is constant xmldom.INDEX_SIZE_ERR.

INUSE_ATTRIBUTE_ERR (see page 7629)	This is constant xmldom.INUSE_ATTRIBUTE_ERR.
INVALID_ACCESS_ERR (see page 7629)	This is constant xmldom.INVALID_ACCESS_ERR.
INVALID_CHARACTER_ERR (see page 7629)	This is constant xmldom.INVALID_CHARACTER_ERR.
INVALID_MODIFICATION_ERR (see page 7630)	This is constant xmldom.INVALID_MODIFICATION_ERR.
INVALID_STATE_ERR (see page 7630)	This is constant xmldom.INVALID_STATE_ERR.
NAMESPACE_ERR (see page 7630)	This is constant xmldom.NAMESPACE_ERR.
NO_DATA_ALLOWED_ERR (see page 7631)	This is constant xmldom.NO_DATA_ALLOWED_ERR.
NO_MODIFICATION_ALLOWED_ERR (see page 7631)	This is constant xmldom.NO_MODIFICATION_ALLOWED_ERR.
NOT_FOUND_ERR (see page 7631)	This is constant xmldom.NOT_FOUND_ERR.
NOT_SUPPORTED_ERR (see page 7632)	This is constant xmldom.NOT_SUPPORTED_ERR.
NOTATION_NODE (see page 7632)	This is constant xmldom.NOTATION_NODE.
NSDelim (see page 7632)	This is constant xmldom.NSDelim.
PROCESSING_INSTRUCTION_NODE (see page 7633)	This is constant xmldom.PROCESSING_INSTRUCTION_NODE.
SEncoding (see page 7633)	This is constant xmldom.SEncoding.
SHttp (see page 7633)	This is constant xmldom.SHttp.
SStandalone (see page 7634)	This is constant xmldom.SStandalone.
SVersion (see page 7634)	This is constant xmldom.SVersion.
SXML (see page 7634)	This is constant xmldom.SXML.
SXMLNamespaceURI (see page 7635)	This is constant xmldom.SXMLNamespaceURI.
SXMLNS (see page 7635)	This is constant xmldom.SXMLNS.
SXMLPrefixNamespaceURI (see page 7635)	This is constant xmldom.SXMLPrefixNamespaceURI.
SYNTAX_ERR (see page 7636)	This is constant xmldom.SYNTAX_ERR.
TEXT_NODE (see page 7636)	This is constant xmldom.TEXT_NODE.
WRONG_DOCUMENT_ERR (see page 7636)	This is constant xmldom.WRONG_DOCUMENT_ERR.

Functions

	Name	Description
	DOMVendorNotSupported (see page 7612)	This is function xmldom.DOMVendorNotSupported.
	ExtractLocalName (see page 7612)	Strips the namespace prefix, if present, from the tag name of an XML node.
	ExtractPrefix (see page 7613)	Returns the namespace prefix of an XML node's tag name.
	GetDOM (see page 7614)	Returns the top-level DOM interface for a registered DOM implementation.
	GetDOMNodeEx (see page 7614)	This is function xmldom.GetDOMNodeEx.
	GetDOMVendor (see page 7615)	Returns the TDOMVendor (see page 7514) object for a specified DOM vendor.
	IsPrefixed (see page 7615)	Indicates whether an XML tag name includes a namespace prefix.
	MakeNodeName (see page 7616)	Assembles a full tag name from a local name and namespace prefix.
	NodeMatches (see page 7616)	Indicates whether a specified node matches a given namespace and tag name.
	RegisterDOMVendor (see page 7617)	Registers an implementation of the DOM interfaces so that it is available to the TXMLDocument class.
	SameNamespace (see page 7617)	Indicates whether a specified node is defined within a specified namespace.
	SameNamespace (see page 7617)	Indicates whether a specified node is defined within a specified namespace.
	UnRegisterDOMVendor (see page 7618)	Unregisters a DOM implementation that was registered using RegisterDOMVendor (see page 7617) .

Interfaces

	Name	Description
	IDOMAttr (see page 7521)	This is class xmldom.IDOMAttr.
	IDOMCDATASection (see page 7525)	This is class xmldom.IDOMCDATASection.
	IDOMCharacterData (see page 7526)	This is class xmldom.IDOMCharacterData.
	IDOMComment (see page 7530)	This is class xmldom.IDOMComment.
	IDOMDocument (see page 7530)	This is class xmldom.IDOMDocument.
	IDOMDocumentFragment (see page 7537)	This is class xmldom.IDOMDocumentFragment.
	IDOMDocumentType (see page 7538)	This is class xmldom.IDOMDocumentType.
	IDOMElement (see page 7542)	This is class xmldom.IDOMElement.
	IDOMEntity (see page 7549)	This is class xmldom.IDOMEntity.
	IDOMEntityReference (see page 7552)	This is class xmldom.IDOMEntityReference.

	IDOMImplementation (see page 7552)	This is class xmldom.IDOMImplementation.
	IDOMNamedNodeMap (see page 7554)	This is class xmldom.IDOMNamedNodeMap.
	IDOMNode (see page 7557)	IDOMNode is the DOM interface for a node in an XML document.
	IDOMNodeEx (see page 7577)	This is class xmldom.IDOMNodeEx.
	IDOMNodeList (see page 7581)	This is class xmldom.IDOMNodeList.
	IDOMNodeSelect (see page 7583)	This is class xmldom.IDOMNodeSelect.
	IDOMNotation (see page 7584)	This is class xmldom.IDOMNotation.
	IDOMParseError (see page 7586)	This is class xmldom.IDOMParseError.
	IDOMParseOptions (see page 7591)	This is class xmldom.IDOMParseOptions.
	IDOMPersist (see page 7595)	This is class xmldom.IDOMPersist.
	IDOMProcessingInstruction (see page 7599)	This is class xmldom.IDOMProcessingInstruction.
	IDOMText (see page 7602)	This is class xmldom.IDOMText.
	IDOMXMLProlog (see page 7604)	This is class xmldom.IDOMXMLProlog.
	IDOMXSLProcessor (see page 7607)	This is class xmldom.IDOMXSLProcessor.

Types

Name	Description
DOMNodeType (see page 7619)	DOMNodeType indicates the type of a node in an XML document, as parsed by a DOM parser.
DOMString (see page 7619)	DOMString is the type for strings that are used by a DOM parser.
DOMTimeStamp (see page 7620)	This is type xmldom.DOMTimeStamp.
TAsyncEventHandler (see page 7620)	TAsyncEventHandler is the type of event handlers that respond when the AsyncLoadState of an XML document changes.
TDOMVendorArray (see page 7621)	This is type xmldom.TDOMVendorArray.

Variables

Name	Description
DefaultDOMVendor (see page 7622)	Identifies the DOM implementation that is used by default.
DOMVendors (see page 7622)	Lists all registered DOM Vendors.

80.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	DOMException (see page 7506)	This is class xmldom.DOMException.
	EDOMParseError (see page 7508)	EDOMParseError is the exception class for errors that occur when a DOM implementation parses an XML document.
	TDOMVendor (see page 7514)	TDOMVendor is the base class for components that provide access to a DOM implementation.
	TDOMVendorList (see page 7516)	TDOMVendorList represents a collection of available DOM implementations.

80.1.1 DOMException Class

Class Hierarchy

Pascal

```
DOMException = class(Exception);
```

C++

```
class DOMException : public Exception;
```

File

xmldom

Description

This is class xmldom.DOMException.

80.1.1.1 DOMException Members

The following tables list the members exposed by DOMException.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	code (see page 7508)	This is code, a member of class DOMException.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3380)	Returns a string containing the class name.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

80.1.1.2 DOMException Fields

The fields of the DOMException class are listed here.

Public Fields

	Name	Description
	code (see page 7508)	This is code, a member of class DOMException.

80.1.1.2.1 DOMException.code Field

Pascal

```
code: Word;
```

C++

```
Word code;
```

Description

This is code, a member of class DOMException.

80.1.2 EDOMParseError Class

EDOMParseError is the exception class for errors that occur when a DOM implementation parses an XML document.

Class Hierarchy

Pascal

```
EDOMParseError = class(Exception);
```

C++

```
class EDOMParseError : public Exception;
```

File

xmldom

Description

EDOMParseError is raised when TXMLDocument encounters an error while parsing an XML document. It wraps the information that is available from the DOM implementation's IDOMParseError (see page 7586) interface.

See Also

TXMLDocument (see page 7347)

80.1.2.1 EDOMParseError Members

The following tables list the members exposed by EDOMParseError.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
V	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Protected Properties

	Name	Description
R	ParseError (see page 7512)	This is ParseError, a member of class EDOMParseError.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 7510)	This is Create, a member of class EDOMParseError.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Destroy (see page 3960)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
	ToString (see page 3380)	Returns a string containing the class name.
	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	ErrorCode (see page 7511)	Indicates the error code that the DOM parser returned.
	FilePos (see page 7511)	Indicates the offset in the XML document where the parser encountered an error.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Line (see page 7512)	Indicates the line of the XML document where the parser encountered an error.
	LinePos (see page 7512)	Indicates the position within the problem line where the parser encountered an error.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
	Reason (see page 7513)	Indicates the error code that the DOM parser returned.
	SrcText (see page 7513)	Indicates the text of the line where the parser encountered an error.
	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.
	URL (see page 7513)	Identifies the source that could not be parsed by its URL.

80.1.2.2 EDOMParseError.Create Constructor

Pascal

```
constructor Create(const ParseError: IDOMParseError; const Msg: string);
```

C++

```
__fastcall EDOMParseError(const IDOMParseError ParseError, const UnicodeString Msg);
```

Description

This is Create, a member of class EDOMParseError.

80.1.2.3 EDOMParseError Properties

The properties of the EDOMParseError class are listed here.

Protected Properties

	Name	Description
	ParseError (see page 7512)	This is ParseError, a member of class EDOMParseError.

Public Properties

	Name	Description
	ErrorCode (see page 7511)	Indicates the error code that the DOM parser returned.
	FilePos (see page 7511)	Indicates the offset in the XML document where the parser encountered an error.
	Line (see page 7512)	Indicates the line of the XML document where the parser encountered an error.
	LinePos (see page 7512)	Indicates the position within the problem line where the parser encountered an error.
	Reason (see page 7513)	Indicates the error code that the DOM parser returned.
	SrcText (see page 7513)	Indicates the text of the line where the parser encountered an error.
	URL (see page 7513)	Identifies the source that could not be parsed by its URL.

80.1.2.3.1 EDOMParseError.ErrorCode Property

Indicates the error code that the DOM parser returned.

Pascal

```
property ErrorCode: Integer;
```

C++

```
__property int ErrorCode;
```

Description

ErrorCode is the error code supplied by the DOM parser when it encountered a problem parsing the XML document.

See Also

Reason (see page 7513)

80.1.2.3.2 EDOMParseError.FilePos Property

Indicates the offset in the XML document where the parser encountered an error.

Pascal

```
property FilePos: Integer;
```

C++

```
__property int FilePos;
```

Description

FilePos is the offset in the XML document where the parser detected the error.

See Also

Line (see page 7512)

LinePos (see page 7512)

SrcText (see page 7513)

URL (see page 7513)

80.1.2.3.3 EDOMParseError.Line Property

Indicates the line of the XML document where the parser encountered an error.

Pascal

```
property Line: Integer;
```

C++

```
__property int Line;
```

Description

Line is the line of the XML document where the parser detected the error.

See Also

FilePos (see page 7511)

LinePos (see page 7512)

SrcText (see page 7513)

URL (see page 7513)

80.1.2.3.4 EDOMParseError.LinePos Property

Indicates the position within the problem line where the parser encountered an error.

Pascal

```
property LinePos: Integer;
```

C++

```
__property int LinePos;
```

Description

LinePos is the offset in the line specified by the Line (see page 7512) property where the DOM parser detected an error.

See Also

Line (see page 7512)

FilePos (see page 7511)

SrcText (see page 7513)

URL (see page 7513)

80.1.2.3.5 EDOMParseError.ParseError Property

Pascal

```
property ParseError: IDOMParseError;
```

C++

```
__property IDOMParseError ParseError;
```

Description

This is ParseError, a member of class EDOMParseError.

80.1.2.3.6 EDOMParseError.Reason Property

Indicates the error code that the DOM parser returned.

Pascal

```
property Reason: DOMString;
```

C++

```
__property DOMString Reason;
```

Description

Reason is a short text string that describes the error that was encountered. It corresponds to the error code specified by ErrorCode (see page 7511).

See Also

ErrorCode (see page 7511)

Message (see page 3965)

80.1.2.3.7 EDOMParseError.SrcText Property

Indicates the text of the line where the parser encountered an error.

Pascal

```
property SrcText: DOMString;
```

C++

```
__property DOMString SrcText;
```

Description

SrcText is the text from the XML document that the DOM parser could not interpret.

See Also

Line (see page 7512)

80.1.2.3.8 EDOMParseError.URL Property

Identifies the source that could not be parsed by its URL.

Pascal

```
property URL: DOMString;
```

C++

```
__property DOMString URL;
```

Description

URL identifies the problem the DOM parser encountered by its URL.

See Also

SrcText (see page 7513)

80.1.3 TDOMVendor Class

TDOMVendor is the base class for components that provide access to a DOM implementation.

Class Hierarchy

Pascal

```
TDOMVendor = class;
```

C++

```
class TDOMVendor;
```

File

xmldom

Description

Note: Use TDOMVendor as a base class for a class that can be used to represent a DOM implementation. TDOMVendor introduces two abstract (pure virtual) methods, which provide information about a specific DOM implementation. One returns the IDOMImplementation (see page 7552) interface that acts as the top-level interface for a DOM vendor's implementation. The other returns a unique string that identifies the DOM implementation.

Once a TDOMVendor object has been registered, TXMLDocument objects can assign the DOM implementation as the value of their DOMVendor property by choosing the identifying string in the Object Inspector.

See Also

RegisterDOMVendor (see page 7617)

UnRegisterDOMVendor (see page 7618)

TXMLDocument (see page 7347)

GetDOMVendor (see page 7615)

Using the Document Object Model

80.1.3.1 TDOMVendor Members

The following tables list the members exposed by TDOMVendor.

Public Methods

	Name	Description
	Description (see page 7515)	Returns a string that uniquely identifies the associated DOM implementation.
	DOMImplementation (see page 7515)	Returns the IDOMImplementation (see page 7552) interface for the associated DOM implementation.

80.1.3.2 TDOMVendor Methods

The methods of the TDOMVendor class are listed here.

Public Methods

	Name	Description
	Description (see page 7515)	Returns a string that uniquely identifies the associated DOM implementation.
	DOMImplementation (see page 7515)	Returns the IDOMImplementation (see page 7552) interface for the associated DOM implementation.

80.1.3.2.1 TDOMVendor.Description Method

Returns a string that uniquely identifies the associated DOM implementation.

Pascal

```
function Description: string; virtual; abstract;
```

C++

```
virtual __fastcall UnicodeString Description() = 0;
```

Description

Description returns the name, or description, of the associated DOM implementation. This is the string that appears in the Object Inspector for a TXMLDocument object's DOMVendor property.

Description is an abstract (pure virtual) method in TDOMVendor (see page 7514). Descendant classes override this method to provide a unique identifier for the DOM implementation.

See Also

DOMVendor (see page 7386)

GetDOMVendor (see page 7615)

80.1.3.2.2 TDOMVendor.DOMImplementation Method

Returns the IDOMImplementation (see page 7552) interface for the associated DOM implementation.

Pascal

```
function DOMImplementation: IDOMImplementation; virtual; abstract;
```

C++

```
virtual __fastcall IDOMImplementation DOMImplementation() = 0;
```

Description

DOMImplementation returns the top-level interface for a DOM implementation. This interface is the starting point for any application that uses the DOM implementation to parse and edit an XML document.

DOMImplementation is an abstract (pure virtual) method in TDOMVendor (see page 7514). Descendant classes override this method to return the IDOMImplementation (see page 7552) interface for the associated DOM implementation.

Note: For more information about the IDOMImplementation (see page 7552), see the W3C Document Object Model (DOM) Level 2 Specification or the documentation provided by your DOM vendor.

See Also

DOMImplementation (see page 7385)

Description (see page 7515)

80.1.4 TDOMVendorList Class

TDOMVendorList represents a collection of available DOM implementations.

Class Hierarchy

Pascal

```
TDOMVendorList = class;
```

C++

```
class TDOMVendorList;
```

File

xmldom

Description

TDOMVendorList is the type of the global DOMVendors (see page 7622) variable. It represents a collection of DOM implementations (TDOMVendor (see page 7514) objects).

TDOMVendorList introduces a single property, Vendors (see page 7519), that can be used to iterate through all the DOM vendors in the collection. It also introduces methods that can be used to add, delete, or locate vendors.

Note: Do not explicitly use TDOMVendorList methods to add or delete vendors from the global DOMVendors (see page 7622) variable. Instead, add or remove vendors from this global list by calling the global RegisterDOMVendor (see page 7617) and UnRegisterDOMVendor (see page 7618) procedures.

See Also

DOMVendors (see page 7622)

TXMLDocument (see page 7347)

RegisterDOMVendor (see page 7617)

TDOMVendor (see page 7514)

UnRegisterDOMVendor (see page 7618)

80.1.4.1 TDOMVendorList Members

The following tables list the members exposed by TDOMVendorList.

Protected Methods

	Name	Description
	GetVendors (see page 7518)	This is GetVendors, a member of class TDOMVendorList.

Public Methods

	Name	Description
	Add (see page 7517)	Adds a new DOM implementation to the end of the list.
	Count (see page 7517)	Returns the number of DOM vendors in the collection.
	Find (see page 7518)	Returns a vendor from the list, given its description.
	Remove (see page 7519)	Removes a specified vendor from the list.

Public Properties

	Name	Description
	Vendors (see page 7519)	Lists the DOM vendors maintained by this TDOMVendorList (see page 7516) object.

80.1.4.2 TDOMVendorList Methods

The methods of the TDOMVendorList class are listed here.

Protected Methods

	Name	Description
	GetVendors (see page 7518)	This is GetVendors, a member of class TDOMVendorList.

Public Methods

	Name	Description
	Add (see page 7517)	Adds a new DOM implementation to the end of the list.
	Count (see page 7517)	Returns the number of DOM vendors in the collection.
	Find (see page 7518)	Returns a vendor from the list, given its description.
	Remove (see page 7519)	Removes a specified vendor from the list.

80.1.4.2.1 TDOMVendorList.Add Method

Adds a new DOM implementation to the end of the list.

Pascal

```
procedure Add(const Vendor: TDOMVendor);
```

C++

```
__fastcall Add(const TDOMVendor Vendor);
```

Description

Call Add to add a DOM vendor to the end of the list.

Vendor is an object that provides access to the IDOMImplementation (see page 7552) interface for the new DOM vendor.

If the list already includes a DOM vendor with the same description as that supplied by Vendor, Add raises an exception.

See Also

Count (see page 7517)

Vendors (see page 7519)

Find (see page 7518)

Remove (see page 7519)

Description (see page 7515)

80.1.4.2.2 TDOMVendorList.Count Method

Returns the number of DOM vendors in the collection.

Pascal

```
function Count: Integer;
```

C++

```
__fastcall int Count();
```

Description

Call Count to determine the number of DOM implementations stored in the list. Count returns a value that can be used as an upper bound when iterating over the vendors using the Vendors (see page 7519) property.

Count increases when the Add (see page 7517) method adds a vendor to the list and decreases when the Remove (see page 7519) method removes a vendor from the list.

See Also

Vendors (see page 7519)

Add (see page 7517)

Remove (see page 7519)

80.1.4.2.3 TDOMVendorList.Find Method

Returns a vendor from the list, given its description.

Pascal

```
function Find(const VendorDesc: string): TDOMVendor;
```

C++

```
__fastcall TDOMVendor Find(const UnicodeString VendorDesc);
```

Description

Call Find to access a vendor in the list, given its description. If there is no vendor in the list with the specified description, Find returns nil (Delphi) or NULL (C++).

VendorDesc is the string that is returned by the TDOMVendor (see page 7514) object's Description method.

Find returns a TDOMVendor (see page 7514) object, which can be used as a value for the DOMVendor property of a TXMLDocument component.

See Also

Vendors (see page 7519)

Description (see page 7515)

DOMVendor (see page 7386)

80.1.4.2.4 TDOMVendorList.GetVendors Method

Pascal

```
function GetVendors(Index: Integer): TDOMVendor;
```

C++

```
__fastcall TDOMVendor GetVendors(int Index);
```

Description

This is GetVendors, a member of class TDOMVendorList.

80.1.4.2.5 TDOMVendorList.Remove Method

Removes a specified vendor from the list.

Pascal

```
procedure Remove(const Vendor: TDOMVendor);
```

C++

```
__fastcall Remove(const TDOMVendor Vendor);
```

Description

Remove removes the specified vendor from the list.

Vendor is the DOM vendor to remove from the list. If the list does not include a vendor with the same description as this parameter, Remove does nothing.

See Also

Count (see page 7517)

Vendors (see page 7519)

Find (see page 7518)

Add (see page 7517)

Description (see page 7515)

80.1.4.3 TDOMVendorList Properties

The properties of the TDOMVendorList class are listed here.

Public Properties

	Name	Description
	Vendors (see page 7519)	Lists the DOM vendors maintained by this TDOMVendorList (see page 7516) object.

80.1.4.3.1 TDOMVendorList.Vendors Property

Lists the DOM vendors maintained by this TDOMVendorList (see page 7516) object.

Pascal

```
property Vendors [Index: Integer]: TDOMVendor;
```

C++

```
__property TDOMVendor Vendors[int Index];
```

Description

Use Vendors to access the DOM vendors in this collection. Index is the index of the vendor. Its value ranges from 0 to one less than the value returned by the Count (see page 7517) method.

Note: In Delphi, Vendors is the default property for TDOMVendorList (see page 7516). This means that the property name can be omitted in code. That is, the statement

for i := 0 to DOMVendors. Count (see page 7517) do

StringList1.Add (see page 7517)(DOMVendors.Vendors[i].Description);

Can be written

for i := 0 to DOMVendors.Count (see page 7517) do

StringList1.Add (see page 7517)(DOMVendors (see page 7622)[i].Description);

Note: In C++, Vendors can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

Count (see page 7517)

Add (see page 7517)

Find (see page 7518)

Remove (see page 7519)

80.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDOMAttr (see page 7521)	This is class xmldom.IDOMAttr.
	IDOMCDATASection (see page 7525)	This is class xmldom.IDOMCDATASection.
	IDOMCharacterData (see page 7526)	This is class xmldom.IDOMCharacterData.
	IDOMComment (see page 7530)	This is class xmldom.IDOMComment.
	IDOMDocument (see page 7530)	This is class xmldom.IDOMDocument.
	IDOMDocumentFragment (see page 7537)	This is class xmldom.IDOMDocumentFragment.
	IDOMDocumentType (see page 7538)	This is class xmldom.IDOMDocumentType.
	IDOMElement (see page 7542)	This is class xmldom.IDOMElement.
	IDOMEntity (see page 7549)	This is class xmldom.IDOMEntity.
	IDOMEntityReference (see page 7552)	This is class xmldom.IDOMEntityReference.
	IDOMImplementation (see page 7552)	This is class xmldom.IDOMImplementation.
	IDOMNamedNodeMap (see page 7554)	This is class xmldom.IDOMNamedNodeMap.
	IDOMNode (see page 7557)	IDOMNode is the DOM interface for a node in an XML document.
	IDOMNodeEx (see page 7577)	This is class xmldom.IDOMNodeEx.
	IDOMNodeList (see page 7581)	This is class xmldom.IDOMNodeList.
	IDOMNodeSelect (see page 7583)	This is class xmldom.IDOMNodeSelect.
	IDOMNotation (see page 7584)	This is class xmldom.IDOMNotation.
	IDOMParseError (see page 7586)	This is class xmldom.IDOMParseError.
	IDOMParseOptions (see page 7591)	This is class xmldom.IDOMParseOptions.
	IDOMPersist (see page 7595)	This is class xmldom.IDOMPersist.
	IDOMProcessingInstruction (see page 7599)	This is class xmldom.IDOMProcessingInstruction.
	IDOMText (see page 7602)	This is class xmldom.IDOMText.
	IDOMXMLProlog (see page 7604)	This is class xmldom.IDOMXMLProlog.
	IDOMXSLProcessor (see page 7607)	This is class xmldom.IDOMXSLProcessor.

80.2.1 IDOMAttr Interface

Class Hierarchy

Pascal

```
IDOMAttr = interface(IDOMNode);
```

C++

```
__interface IDOMAttr : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMAttr.

80.2.1.1 IDOMAttr Members

The following tables list the members exposed by IDOMAttr.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_name (see page 7523)	This is get_name, a member of class IDOMAttr.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_ownerElement (see page 7523)	This is get_ownerElement, a member of class IDOMAttr.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_specified (see page 7523)	This is get_specified, a member of class IDOMAttr.
	get_value (see page 7524)	This is get_value, a member of class IDOMAttr.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	set_value (see page 7524)	This is set_value, a member of class IDOMAttr.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	name (see page 7524)	This is name, a member of class IDOMAttr.
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.

R	ownerElement (see page 7524)	This is ownerElement, a member of class IDOMAttr.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	specified (see page 7525)	This is specified, a member of class IDOMAttr.
	value (see page 7525)	This is value, a member of class IDOMAttr.

80.2.1.2 IDOMAttr Methods

The methods of the IDOMAttr class are listed here.

Public Methods

	Name	Description
	get_name (see page 7523)	This is get_name, a member of class IDOMAttr.
	get_ownerElement (see page 7523)	This is get_ownerElement, a member of class IDOMAttr.
	get_specified (see page 7523)	This is get_specified, a member of class IDOMAttr.
	get_value (see page 7524)	This is get_value, a member of class IDOMAttr.
	set_value (see page 7524)	This is set_value, a member of class IDOMAttr.

80.2.1.2.1 IDOMAttr.get_name Method

Pascal

```
function get_name: DOMString; safecall;
```

C++

```
__fastcall DOMString get_name();
```

Description

This is get_name, a member of class IDOMAttr.

80.2.1.2.2 IDOMAttr.get_ownerElement Method

Pascal

```
function get_ownerElement: IDOMElement; safecall;
```

C++

```
__fastcall IDOMElement get_ownerElement();
```

Description

This is get_ownerElement, a member of class IDOMAttr.

80.2.1.2.3 IDOMAttr.get_specified Method

Pascal

```
function get_specified: WordBool; safecall;
```

C++

```
__fastcall WordBool get_specified();
```

Description

This is get_specified, a member of class IDOMAttr.

80.2.1.2.4 IDOMAttr.get_value Method

Pascal

```
function get_value: DOMString; safecall;
```

C++

```
__fastcall DOMString get_value();
```

Description

This is get_value, a member of class IDOMAttr.

80.2.1.2.5 IDOMAttr.set_value Method

Pascal

```
procedure set_value(const attributeValue: DOMString); safecall;
```

C++

```
__fastcall set_value(const DOMString attributeValue);
```

Description

This is set_value, a member of class IDOMAttr.

80.2.1.3 IDOMAttr Properties

The properties of the IDOMAttr class are listed here.

Public Properties

	Name	Description
R	name (see page 7524)	This is name, a member of class IDOMAttr.
R	ownerElement (see page 7524)	This is ownerElement, a member of class IDOMAttr.
R	specified (see page 7525)	This is specified, a member of class IDOMAttr.
	value (see page 7525)	This is value, a member of class IDOMAttr.

80.2.1.3.1 IDOMAttr.name Property

Pascal

```
property name: DOMString;
```

C++

```
__property DOMString name;
```

Description

This is name, a member of class IDOMAttr.

80.2.1.3.2 IDOMAttr.ownerElement Property

Pascal

```
property ownerElement: IDOMElement;
```

C++

```
__property IDOMElement ownerElement;
```

Description

This is ownerElement, a member of class IDOMAttr.

80.2.1.3.3 IDOMAttr.specified Property

Pascal

```
property specified: WordBool;
```

C++

```
__property WordBool specified;
```

Description

This is specified, a member of class IDOMAttr.

80.2.1.3.4 IDOMAttr.value Property

Pascal

```
property value: DOMString;
```

C++

```
__property DOMString value;
```

Description

This is value, a member of class IDOMAttr.

80.2.2 IDOMCDATASection Interface

Class Hierarchy

Pascal

```
IDOMCDATASection = interface(IDOMText);
```

C++

```
__interface IDOMCDATASection : public IDOMText;
```

File

xmldom

Description

This is class xmldom.IDOMCDATASection.

80.2.3 IDOMCharacterData Interface

Class Hierarchy

Pascal

```
IDOMCharacterData = interface(IDOMNode);
```

C++

```
__interface IDOMCharacterData : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMCharacterData.

80.2.3.1 IDOMCharacterData Members

The following tables list the members exposed by IDOMCharacterData.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	appendData (see page 7527)	This is appendData, a member of class IDOMCharacterData.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	deleteData (see page 7528)	This is deleteData, a member of class IDOMCharacterData.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_data (see page 7528)	This is get_data, a member of class IDOMCharacterData.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_length (see page 7528)	This is get_length, a member of class IDOMCharacterData.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	insertData (see page 7528)	This is insertData, a member of class IDOMCharacterData.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.

	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	replaceData (see page 7528)	This is replaceData, a member of class IDOMCharacterData.
	set_data (see page 7529)	This is set_data, a member of class IDOMCharacterData.
	set_nodeValue (see page 7567)	Sets the value of the node.
	substringData (see page 7529)	This is substringData, a member of class IDOMCharacterData.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
	data (see page 7529)	This is data, a member of class IDOMCharacterData.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	length (see page 7529)	This is length, a member of class IDOMCharacterData.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.

80.2.3.2 IDOMCharacterData Methods

The methods of the IDOMCharacterData class are listed here.

Public Methods

	Name	Description
	appendData (see page 7527)	This is appendData, a member of class IDOMCharacterData.
	deleteData (see page 7528)	This is deleteData, a member of class IDOMCharacterData.
	get_data (see page 7528)	This is get_data, a member of class IDOMCharacterData.
	get_length (see page 7528)	This is get_length, a member of class IDOMCharacterData.
	insertData (see page 7528)	This is insertData, a member of class IDOMCharacterData.
	replaceData (see page 7528)	This is replaceData, a member of class IDOMCharacterData.
	set_data (see page 7529)	This is set_data, a member of class IDOMCharacterData.
	substringData (see page 7529)	This is substringData, a member of class IDOMCharacterData.

80.2.3.2.1 IDOMCharacterData.appendData Method

Pascal

```
procedure appendData(const data: DOMString); safecall;
```

C++

```
__fastcall appendData(const DOMString data);
```

Description

This is appendData, a member of class IDOMCharacterData.

80.2.3.2.2 IDOMCharacterData.deleteData Method

Pascal

```
procedure deleteData(offset: Integer; count: Integer); safecall;
```

C++

```
__fastcall deleteData(int offset, int count);
```

Description

This is deleteData, a member of class IDOMCharacterData.

80.2.3.2.3 IDOMCharacterData.get_data Method

Pascal

```
function get_data: DOMString; safecall;
```

C++

```
__fastcall DOMString get_data();
```

Description

This is get_data, a member of class IDOMCharacterData.

80.2.3.2.4 IDOMCharacterData.get_length Method

Pascal

```
function get_length: Integer; safecall;
```

C++

```
__fastcall int get_length();
```

Description

This is get_length, a member of class IDOMCharacterData.

80.2.3.2.5 IDOMCharacterData.insertData Method

Pascal

```
procedure insertData(offset: Integer; const data: DOMString); safecall;
```

C++

```
__fastcall insertData(int offset, const DOMString data);
```

Description

This is insertData, a member of class IDOMCharacterData.

80.2.3.2.6 IDOMCharacterData.replaceData Method

Pascal

```
procedure replaceData(offset: Integer; count: Integer; const data: DOMString); safecall;
```

C++

```
__fastcall replaceData(int offset, int count, const DOMString data);
```

Description

This is replaceData, a member of class IDOMCharacterData.

80.2.3.2.7 IDOMCharacterData.set_data Method

Pascal

```
procedure set_data(const data: DOMString); safecall;
```

C++

```
__fastcall set_data(const DOMString data);
```

Description

This is set_data, a member of class IDOMCharacterData.

80.2.3.2.8 IDOMCharacterData.substringData Method

Pascal

```
function substringData(offset: Integer; count: Integer): DOMString; safecall;
```

C++

```
__fastcall DOMString substringData(int offset, int count);
```

Description

This is substringData, a member of class IDOMCharacterData.

80.2.3.3 IDOMCharacterData Properties

The properties of the IDOMCharacterData class are listed here.

Public Properties

	Name	Description
	data (see page 7529)	This is data, a member of class IDOMCharacterData.
R	length (see page 7529)	This is length, a member of class IDOMCharacterData.

80.2.3.3.1 IDOMCharacterData.data Property

Pascal

```
property data: DOMString;
```

C++

```
__property DOMString data;
```

Description

This is data, a member of class IDOMCharacterData.

80.2.3.3.2 IDOMCharacterData.length Property

Pascal

```
property length: Integer;
```

C++

```
__property int length;
```

Description

This is length, a member of class IDOMCharacterData.

80.2.4 IDOMComment Interface

Class Hierarchy

Pascal

```
IDOMComment = interface(IDOMCharacterData);
```

C++

```
__interface IDOMComment : public IDOMCharacterData;
```

File

xmldom

Description

This is class xmldom.IDOMComment.

80.2.5 IDOMDocument Interface

Class Hierarchy

Pascal

```
IDOMDocument = interface(IDOMNode);
```

C++

```
__interface IDOMDocument : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMDocument.

80.2.5.1 IDOMDocument Members

The following tables list the members exposed by IDOMDocument.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	createAttribute (see page 7532)	This is createAttribute, a member of class IDOMDocument.
	createAttributeNS (see page 7533)	This is createAttributeNS, a member of class IDOMDocument.
	createCDATASection (see page 7533)	This is createCDATASection, a member of class IDOMDocument.
	createComment (see page 7533)	This is createComment, a member of class IDOMDocument.
	createDocumentFragment (see page 7533)	This is createDocumentFragment, a member of class IDOMDocument.
	createElement (see page 7533)	This is createElement, a member of class IDOMDocument.
	createElementNS (see page 7534)	This is createElementNS, a member of class IDOMDocument.
	createEntityReference (see page 7534)	This is createEntityReference, a member of class IDOMDocument.
	createProcessingInstruction (see page 7534)	This is createProcessingInstruction, a member of class IDOMDocument.
	createTextNode (see page 7534)	This is createTextNode, a member of class IDOMDocument.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_doctype (see page 7535)	This is get_doctype, a member of class IDOMDocument.
	get_documentElement (see page 7535)	This is get_documentElement, a member of class IDOMDocument.
	get_domImplementation (see page 7535)	This is get_domImplementation, a member of class IDOMDocument.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	getElementById (see page 7535)	This is getElementById, a member of class IDOMDocument.
	getElementsByTagName (see page 7536)	This is getElementsByTagName, a member of class IDOMDocument.
	getElementsByTagNameNS (see page 7536)	This is getElementsByTagNameNS, a member of class IDOMDocument.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	importNode (see page 7536)	This is importNode, a member of class IDOMDocument.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_documentElement (see page 7536)	This is set_documentElement, a member of class IDOMDocument.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	doctype (see page 7537)	This is doctype, a member of class IDOMDocument.
	documentElement (see page 7537)	This is documentElement, a member of class IDOMDocument.

R	domImplementation (see page 7537)	This is domImplementation, a member of class IDOMDocument.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.

80.2.5.2 IDOMDocument Methods

The methods of the IDOMDocument class are listed here.

Public Methods

	Name	Description
	createAttribute (see page 7532)	This is createAttribute, a member of class IDOMDocument.
	createAttributeNS (see page 7533)	This is createAttributeNS, a member of class IDOMDocument.
	createCDATASection (see page 7533)	This is createCDATASection, a member of class IDOMDocument.
	createComment (see page 7533)	This is createComment, a member of class IDOMDocument.
	createDocumentFragment (see page 7533)	This is createDocumentFragment, a member of class IDOMDocument.
	createElement (see page 7533)	This is createElement, a member of class IDOMDocument.
	createElementNS (see page 7534)	This is createElementNS, a member of class IDOMDocument.
	createEntityReference (see page 7534)	This is createEntityReference, a member of class IDOMDocument.
	createProcessingInstruction (see page 7534)	This is createProcessingInstruction, a member of class IDOMDocument.
	createTextNode (see page 7534)	This is createTextNode, a member of class IDOMDocument.
	get_doctype (see page 7535)	This is get_doctype, a member of class IDOMDocument.
	get_documentElement (see page 7535)	This is get_documentElement, a member of class IDOMDocument.
	get_domImplementation (see page 7535)	This is get_domImplementation, a member of class IDOMDocument.
	getElementById (see page 7535)	This is getElementById, a member of class IDOMDocument.
	getElementsByTagName (see page 7536)	This is getElementsByTagName, a member of class IDOMDocument.
	getElementsByTagNameNS (see page 7536)	This is getElementsByTagNameNS, a member of class IDOMDocument.
	importNode (see page 7536)	This is importNode, a member of class IDOMDocument.
	set_documentElement (see page 7536)	This is set_documentElement, a member of class IDOMDocument.

80.2.5.2.1 IDOMDocument.createAttribute Method

Pascal

```
function createAttribute(const name: DOMString): IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr createAttribute(const DOMString name);
```

Description

This is createAttribute, a member of class IDOMDocument.

80.2.5.2.2 IDOMDocument.createAttributeNS Method

Pascal

```
function createAttributeNS(const namespaceURI: DOMString; const qualifiedName: DOMString):
IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr createAttributeNS(const DOMString namespaceURI, const DOMString
qualifiedName);
```

Description

This is createAttributeNS, a member of class IDOMDocument.

80.2.5.2.3 IDOMDocument.createCDATASection Method

Pascal

```
function createCDATASection(const data: DOMString): IDOMCDATASection; safecall;
```

C++

```
__fastcall IDOMCDATASection createCDATASection(const DOMString data);
```

Description

This is createCDATASection, a member of class IDOMDocument.

80.2.5.2.4 IDOMDocument.createComment Method

Pascal

```
function createComment(const data: DOMString): IDOMComment; safecall;
```

C++

```
__fastcall IDOMComment createComment(const DOMString data);
```

Description

This is createComment, a member of class IDOMDocument.

80.2.5.2.5 IDOMDocument.createDocumentFragment Method

Pascal

```
function createDocumentFragment: IDOMDocumentFragment; safecall;
```

C++

```
__fastcall IDOMDocumentFragment createDocumentFragment();
```

Description

This is createDocumentFragment, a member of class IDOMDocument.

80.2.5.2.6 IDOMDocument.createElement Method

Pascal

```
function createElement(const tagName: DOMString): IDOMElement; safecall;
```

C++

```
__fastcall IDOMElement createElement(const DOMString tagName);
```

Description

This is createElement, a member of class IDOMDocument.

80.2.5.2.7 IDOMDocument.createElementNS Method

Pascal

```
function createElementNS(const namespaceURI: DOMString; const qualifiedName: DOMString):
IDOMElement; safecall;
```

C++

```
__fastcall IDOMElement createElementNS(const DOMString namespaceURI, const DOMString
qualifiedName);
```

Description

This is createElementNS, a member of class IDOMDocument.

80.2.5.2.8 IDOMDocument.createEntityReference Method

Pascal

```
function createEntityReference(const name: DOMString): IDOMEntityReference; safecall;
```

C++

```
__fastcall IDOMEntityReference createEntityReference(const DOMString name);
```

Description

This is createEntityReference, a member of class IDOMDocument.

80.2.5.2.9 IDOMDocument.createProcessingInstruction Method

Pascal

```
function createProcessingInstruction(const target: DOMString; const data: DOMString):
IDOMProcessingInstruction; safecall;
```

C++

```
__fastcall IDOMProcessingInstruction createProcessingInstruction(const DOMString target, const
DOMString data);
```

Description

This is createProcessingInstruction, a member of class IDOMDocument.

80.2.5.2.10 IDOMDocument.createTextNode Method

Pascal

```
function createTextNode(const data: DOMString): IDOMText; safecall;
```

C++

```
__fastcall IDOMText createTextNode(const DOMString data);
```

Description

This is createTextNode, a member of class IDOMDocument.

80.2.5.2.11 IDOMDocument.get_doctype Method

Pascal

```
function get_doctype: IDOMDocumentType; safecall;
```

C++

```
__fastcall IDOMDocumentType get_doctype();
```

Description

This is get_doctype, a member of class IDOMDocument.

80.2.5.2.12 IDOMDocument.get_documentElement Method

Pascal

```
function get_documentElement: IDOMElement; safecall;
```

C++

```
__fastcall IDOMElement get_documentElement();
```

Description

This is get_documentElement, a member of class IDOMDocument.

80.2.5.2.13 IDOMDocument.get_domImplementation Method

Pascal

```
function get_domImplementation: IDOMImplementation; safecall;
```

C++

```
__fastcall IDOMImplementation get_domImplementation();
```

Description

This is get_domImplementation, a member of class IDOMDocument.

80.2.5.2.14 IDOMDocument.getElementById Method

Pascal

```
function getElementById(const elementId: DOMString): IDOMElement; safecall;
```

C++

```
__fastcall IDOMElement getElementById(const DOMString elementId);
```

Description

This is getElementById, a member of class IDOMDocument.

80.2.5.2.15 IDOMDocument.getElementsByTagName Method

Pascal

```
function getElementsByTagName(const tagName: DOMString): IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList getElementsByTagName(const DOMString tagName);
```

Description

This is getElementsByTagName, a member of class IDOMDocument.

80.2.5.2.16 IDOMDocument.getElementsByTagNameNS Method

Pascal

```
function getElementsByTagNameNS(const namespaceURI: DOMString; const localName: DOMString):
IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList getElementsByTagNameNS(const DOMString namespaceURI, const DOMString
localName);
```

Description

This is getElementsByTagNameNS, a member of class IDOMDocument.

80.2.5.2.17 IDOMDocument.importNode Method

Pascal

```
function importNode(importedNode: IDOMNode; deep: WordBool): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode importNode(IDOMNode importedNode, WordBool deep);
```

Description

This is importNode, a member of class IDOMDocument.

80.2.5.2.18 IDOMDocument.set_documentElement Method

Pascal

```
procedure set_documentElement(const Element: IDOMElement); safecall;
```

C++

```
__fastcall set_documentElement(const IDOMElement Element);
```

Description

This is set_documentElement, a member of class IDOMDocument.

80.2.5.3 IDOMDocument Properties

The properties of the IDOMDocument class are listed here.

Public Properties

	Name	Description
	doctype (see page 7537)	This is doctype, a member of class IDOMDocument.
	documentElement (see page 7537)	This is documentElement, a member of class IDOMDocument.
	domImplementation (see page 7537)	This is domImplementation, a member of class IDOMDocument.

80.2.5.3.1 IDOMDocument.doctype Property

Pascal

```
property doctype: IDOMDocumentType;
```

C++

```
__property IDOMDocumentType doctype;
```

Description

This is doctype, a member of class IDOMDocument.

80.2.5.3.2 IDOMDocument.documentElement Property

Pascal

```
property documentElement: IDOMElement;
```

C++

```
__property IDOMElement documentElement;
```

Description

This is documentElement, a member of class IDOMDocument.

80.2.5.3.3 IDOMDocument.domImplementation Property

Pascal

```
property domImplementation: IDOMImplementation;
```

C++

```
__property IDOMImplementation domImplementation;
```

Description

This is domImplementation, a member of class IDOMDocument.

80.2.6 IDOMDocumentFragment Interface

Class Hierarchy

Pascal

```
IDOMDocumentFragment = interface(IDOMNode);
```

C++

```
__interface IDOMDocumentFragment : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMDocumentFragment.

80.2.7 IDOMDocumentType Interface

Class Hierarchy

Pascal

```
IDOMDocumentType = interface(IDOMNode);
```

C++

```
__interface IDOMDocumentType : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMDocumentType.

80.2.7.1 IDOMDocumentType Members

The following tables list the members exposed by IDOMDocumentType.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_entities (see page 7540)	This is get_entities, a member of class IDOMDocumentType.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_internalSubset (see page 7540)	This is get_internalSubset, a member of class IDOMDocumentType.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_name (see page 7540)	This is get_name, a member of class IDOMDocumentType.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_notations (see page 7540)	This is get_notations, a member of class IDOMDocumentType.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.

	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_publicId (see page 7540)	This is get_publicId, a member of class IDOMDocumentType.
	get_systemId (see page 7541)	This is get_systemId, a member of class IDOMDocumentType.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	entities (see page 7541)	This is entities, a member of class IDOMDocumentType.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	internalSubset (see page 7541)	This is internalSubset, a member of class IDOMDocumentType.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	name (see page 7542)	This is name, a member of class IDOMDocumentType.
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	notations (see page 7542)	This is notations, a member of class IDOMDocumentType.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	publicId (see page 7542)	This is publicId, a member of class IDOMDocumentType.
R	systemId (see page 7542)	This is systemId, a member of class IDOMDocumentType.

80.2.7.2 IDOMDocumentType Methods

The methods of the IDOMDocumentType class are listed here.

Public Methods

	Name	Description
	get_entities (see page 7540)	This is get_entities, a member of class IDOMDocumentType.
	get_internalSubset (see page 7540)	This is get_internalSubset, a member of class IDOMDocumentType.
	get_name (see page 7540)	This is get_name, a member of class IDOMDocumentType.
	get_notations (see page 7540)	This is get_notations, a member of class IDOMDocumentType.
	get_publicId (see page 7540)	This is get_publicId, a member of class IDOMDocumentType.
	get_systemId (see page 7541)	This is get_systemId, a member of class IDOMDocumentType.

80.2.7.2.1 IDOMDocumentType.get_entities Method

Pascal

```
function get_entities: IDOMNamedNodeMap; safecall;
```

C++

```
__fastcall IDOMNamedNodeMap get_entities();
```

Description

This is get_entities, a member of class IDOMDocumentType.

80.2.7.2.2 IDOMDocumentType.get_internalSubset Method

Pascal

```
function get_internalSubset: DOMString; safecall;
```

C++

```
__fastcall DOMString get_internalSubset();
```

Description

This is get_internalSubset, a member of class IDOMDocumentType.

80.2.7.2.3 IDOMDocumentType.get_name Method

Pascal

```
function get_name: DOMString; safecall;
```

C++

```
__fastcall DOMString get_name();
```

Description

This is get_name, a member of class IDOMDocumentType.

80.2.7.2.4 IDOMDocumentType.get_notations Method

Pascal

```
function get_notations: IDOMNamedNodeMap; safecall;
```

C++

```
__fastcall IDOMNamedNodeMap get_notations();
```

Description

This is get_notations, a member of class IDOMDocumentType.

80.2.7.2.5 IDOMDocumentType.get_publicId Method

Pascal

```
function get_publicId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_publicId();
```

Description

This is get_publicId, a member of class IDOMDocumentType.

80.2.7.2.6 IDOMDocumentType.get_systemId Method

Pascal

```
function get_systemId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_systemId();
```

Description

This is get_systemId, a member of class IDOMDocumentType.

80.2.7.3 IDOMDocumentType Properties

The properties of the IDOMDocumentType class are listed here.

Public Properties

	Name	Description
	entities (see page 7541)	This is entities, a member of class IDOMDocumentType.
	internalSubset (see page 7541)	This is internalSubset, a member of class IDOMDocumentType.
	name (see page 7542)	This is name, a member of class IDOMDocumentType.
	notations (see page 7542)	This is notations, a member of class IDOMDocumentType.
	publicId (see page 7542)	This is publicId, a member of class IDOMDocumentType.
	systemId (see page 7542)	This is systemId, a member of class IDOMDocumentType.

80.2.7.3.1 IDOMDocumentType.entities Property

Pascal

```
property entities: IDOMNamedNodeMap;
```

C++

```
__property IDOMNamedNodeMap entities;
```

Description

This is entities, a member of class IDOMDocumentType.

80.2.7.3.2 IDOMDocumentType.internalSubset Property

Pascal

```
property internalSubset: DOMString;
```

C++

```
__property DOMString internalSubset;
```

Description

This is internalSubset, a member of class IDOMDocumentType.

80.2.7.3.3 IDOMDocumentType.name Property

Pascal

```
property name: DOMString;
```

C++

```
__property DOMString name;
```

Description

This is name, a member of class IDOMDocumentType.

80.2.7.3.4 IDOMDocumentType.notations Property

Pascal

```
property notations: IDOMNamedNodeMap;
```

C++

```
__property IDOMNamedNodeMap notations;
```

Description

This is notations, a member of class IDOMDocumentType.

80.2.7.3.5 IDOMDocumentType.publicId Property

Pascal

```
property publicId: DOMString;
```

C++

```
__property DOMString publicId;
```

Description

This is publicId, a member of class IDOMDocumentType.

80.2.7.3.6 IDOMDocumentType.systemId Property

Pascal

```
property systemId: DOMString;
```

C++

```
__property DOMString systemId;
```

Description

This is systemId, a member of class IDOMDocumentType.

80.2.8 IDOMElement Interface

Class Hierarchy

Pascal

```
IDOMElement = interface(IDOMNode);
```

C++

```
__interface IDOMElement : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMElement.

80.2.8.1 IDOMElement Members

The following tables list the members exposed by IDOMElement.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_tagName (see page 7545)	This is get_tagName, a member of class IDOMElement.
	getAttribute (see page 7545)	This is getAttribute, a member of class IDOMElement.
	getAttributeNode (see page 7545)	This is getAttributeNode, a member of class IDOMElement.
	getAttributeNodeNS (see page 7545)	This is getAttributeNodeNS, a member of class IDOMElement.
	getAttributeNS (see page 7545)	This is getAttributeNS, a member of class IDOMElement.
	getElementsByTagName (see page 7546)	This is getElementsByTagName, a member of class IDOMElement.
	getElementsByTagNameNS (see page 7546)	This is getElementsByTagNameNS, a member of class IDOMElement.
	hasAttribute (see page 7546)	This is hasAttribute, a member of class IDOMElement.
	hasAttributeNS (see page 7546)	This is hasAttributeNS, a member of class IDOMElement.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeAttribute (see page 7547)	This is removeAttribute, a member of class IDOMElement.
	removeAttributeNode (see page 7547)	This is removeAttributeNode, a member of class IDOMElement.
	removeAttributeNS (see page 7547)	This is removeAttributeNS, a member of class IDOMElement.

	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	setAttribute (see page 7547)	This is setAttribute, a member of class IDOMElement.
	setAttributeNode (see page 7547)	This is setAttributeNode, a member of class IDOMElement.
	setAttributeNodeNS (see page 7548)	This is setAttributeNodeNS, a member of class IDOMElement.
	setAttributeNS (see page 7548)	This is setAttributeNS, a member of class IDOMElement.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	tagName (see page 7548)	This is tagName, a member of class IDOMElement.

80.2.8.2 IDOMElement Methods

The methods of the IDOMElement class are listed here.

Public Methods

	Name	Description
	get_tagName (see page 7545)	This is get_tagName, a member of class IDOMElement.
	getAttribute (see page 7545)	This is getAttribute, a member of class IDOMElement.
	getAttributeNode (see page 7545)	This is getAttributeNode, a member of class IDOMElement.
	getAttributeNodeNS (see page 7545)	This is getAttributeNodeNS, a member of class IDOMElement.
	getAttributeNS (see page 7545)	This is getAttributeNS, a member of class IDOMElement.
	getElementsByTagName (see page 7546)	This is getElementsByTagName, a member of class IDOMElement.
	getElementsByTagNameNS (see page 7546)	This is getElementsByTagNameNS, a member of class IDOMElement.
	hasAttribute (see page 7546)	This is hasAttribute, a member of class IDOMElement.
	hasAttributeNS (see page 7546)	This is hasAttributeNS, a member of class IDOMElement.
	removeAttribute (see page 7547)	This is removeAttribute, a member of class IDOMElement.
	removeAttributeNode (see page 7547)	This is removeAttributeNode, a member of class IDOMElement.
	removeAttributeNS (see page 7547)	This is removeAttributeNS, a member of class IDOMElement.
	setAttribute (see page 7547)	This is setAttribute, a member of class IDOMElement.
	setAttributeNode (see page 7547)	This is setAttributeNode, a member of class IDOMElement.
	setAttributeNodeNS (see page 7548)	This is setAttributeNodeNS, a member of class IDOMElement.
	setAttributeNS (see page 7548)	This is setAttributeNS, a member of class IDOMElement.

80.2.8.2.1 IDOMElement.get_tagName Method

Pascal

```
function get_tagName: DOMString; safecall;
```

C++

```
__fastcall DOMString get_tagName();
```

Description

This is get_tagName, a member of class IDOMElement.

80.2.8.2.2 IDOMElement.getAttribute Method

Pascal

```
function getAttribute(const name: DOMString): DOMString; safecall;
```

C++

```
__fastcall DOMString getAttribute(const DOMString name);
```

Description

This is getAttribute, a member of class IDOMElement.

80.2.8.2.3 IDOMElement.getAttributeNode Method

Pascal

```
function getAttributeNode(const name: DOMString): IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr getAttributeNode(const DOMString name);
```

Description

This is getAttributeNode, a member of class IDOMElement.

80.2.8.2.4 IDOMElement.getAttributeNodeNS Method

Pascal

```
function getAttributeNodeNS(const namespaceURI: DOMString; const localName: DOMString):
IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr getAttributeNodeNS(const DOMString namespaceURI, const DOMString
localName);
```

Description

This is getAttributeNodeNS, a member of class IDOMElement.

80.2.8.2.5 IDOMElement.getAttributeNS Method

Pascal

```
function getAttributeNS(const namespaceURI: DOMString; const localName: DOMString): DOMString;
safecall;
```

C++

```
__fastcall DOMString getAttributeNS(const DOMString namespaceURI, const DOMString localName);
```

Description

This is getAttributeNS, a member of class IDOMElement.

80.2.8.2.6 IDOMElement.getElementsByTagName Method

Pascal

```
function getElementsByTagName(const name: DOMString): IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList getElementsByTagName(const DOMString name);
```

Description

This is getElementsByTagName, a member of class IDOMElement.

80.2.8.2.7 IDOMElement.getElementsByTagNameNS Method

Pascal

```
function getElementsByTagNameNS(const namespaceURI: DOMString; const localName: DOMString):
IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList getElementsByTagNameNS(const DOMString namespaceURI, const DOMString
localName);
```

Description

This is getElementsByTagNameNS, a member of class IDOMElement.

80.2.8.2.8 IDOMElement.hasAttribute Method

Pascal

```
function hasAttribute(const name: DOMString): WordBool; safecall;
```

C++

```
__fastcall WordBool hasAttribute(const DOMString name);
```

Description

This is hasAttribute, a member of class IDOMElement.

80.2.8.2.9 IDOMElement.hasAttributeNS Method

Pascal

```
function hasAttributeNS(const namespaceURI: DOMString; const localName: DOMString): WordBool;
safecall;
```

C++

```
__fastcall WordBool hasAttributeNS(const DOMString namespaceURI, const DOMString localName);
```

Description

This is hasAttributeNS, a member of class IDOMElement.

80.2.8.2.10 IDOMElement.removeAttribute Method

Pascal

```
procedure removeAttribute(const name: DOMString); safecall;
```

C++

```
__fastcall removeAttribute(const DOMString name);
```

Description

This is removeAttribute, a member of class IDOMElement.

80.2.8.2.11 IDOMElement.removeAttributeNode Method

Pascal

```
function removeAttributeNode(const oldAttr: IDOMAttr): IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr removeAttributeNode(const IDOMAttr oldAttr);
```

Description

This is removeAttributeNode, a member of class IDOMElement.

80.2.8.2.12 IDOMElement.removeAttributeNS Method

Pascal

```
procedure removeAttributeNS(const namespaceURI: DOMString; const localName: DOMString);
safecall;
```

C++

```
__fastcall removeAttributeNS(const DOMString namespaceURI, const DOMString localName);
```

Description

This is removeAttributeNS, a member of class IDOMElement.

80.2.8.2.13 IDOMElement.setAttribute Method

Pascal

```
procedure setAttribute(const name: DOMString; const value: DOMString); safecall;
```

C++

```
__fastcall setAttribute(const DOMString name, const DOMString value);
```

Description

This is setAttribute, a member of class IDOMElement.

80.2.8.2.14 IDOMElement.setAttributeNode Method

Pascal

```
function setAttributeNode(const newAttr: IDOMAttr): IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr setAttributeNode(const IDOMAttr newAttr);
```

Description

This is setAttributeNode, a member of class IDOMElement.

80.2.8.2.15 IDOMElement.setAttributeNodeNS Method

Pascal

```
function setAttributeNodeNS(const newAttr: IDOMAttr): IDOMAttr; safecall;
```

C++

```
__fastcall IDOMAttr setAttributeNodeNS(const IDOMAttr newAttr);
```

Description

This is setAttributeNodeNS, a member of class IDOMElement.

80.2.8.2.16 IDOMElement.setAttributeNS Method

Pascal

```
procedure setAttributeNS(const namespaceURI: DOMString; const qulifiedName: DOMString; const
value: DOMString); safecall;
```

C++

```
__fastcall setAttributeNS(const DOMString namespaceURI, const DOMString qulifiedName, const
DOMString value);
```

Description

This is setAttributeNS, a member of class IDOMElement.

80.2.8.3 IDOMElement Properties

The properties of the IDOMElement class are listed here.

Public Properties

	Name	Description
	tagName (see page 7548)	This is tagName, a member of class IDOMElement.

80.2.8.3.1 IDOMElement.tagName Property

Pascal

```
property tagName: DOMString;
```

C++

```
__property DOMString tagName;
```

Description

This is tagName, a member of class IDOMElement.

80.2.9 IDOMEntity Interface

Class Hierarchy

Pascal

```
IDOMEntity = interface(IDOMNode);
```

C++

```
__interface IDOMEntity : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMEntity.

80.2.9.1 IDOMEntity Members

The following tables list the members exposed by IDOMEntity.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_notationName (see page 7550)	This is get_notationName, a member of class IDOMEntity.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_publicId (see page 7550)	This is get_publicId, a member of class IDOMEntity.
	get_systemId (see page 7551)	This is get_systemId, a member of class IDOMEntity.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.

	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	notationName (see page 7551)	This is notationName, a member of class IDOMEntity.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	publicId (see page 7551)	This is publicId, a member of class IDOMEntity.
R	systemId (see page 7551)	This is systemId, a member of class IDOMEntity.

80.2.9.2 IDOMEntity Methods

The methods of the IDOMEntity class are listed here.

Public Methods

	Name	Description
	get_notationName (see page 7550)	This is get_notationName, a member of class IDOMEntity.
	get_publicId (see page 7550)	This is get_publicId, a member of class IDOMEntity.
	get_systemId (see page 7551)	This is get_systemId, a member of class IDOMEntity.

80.2.9.2.1 IDOMEntity.get_notationName Method

Pascal

```
function get_notationName: DOMString; safecall;
```

C++

```
__fastcall DOMString get_notationName();
```

Description

This is get_notationName, a member of class IDOMEntity.

80.2.9.2.2 IDOMEntity.get_publicId Method

Pascal

```
function get_publicId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_publicId();
```

Description

This is get_publicId, a member of class IDOMEntity.

80.2.9.2.3 IDOMEntity.get_systemId Method

Pascal

```
function get_systemId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_systemId();
```

Description

This is get_systemId, a member of class IDOMEntity.

80.2.9.3 IDOMEntity Properties

The properties of the IDOMEntity class are listed here.

Public Properties

	Name	Description
	notationName (see page 7551)	This is notationName, a member of class IDOMEntity.
	publicId (see page 7551)	This is publicId, a member of class IDOMEntity.
	systemId (see page 7551)	This is systemId, a member of class IDOMEntity.

80.2.9.3.1 IDOMEntity.notationName Property

Pascal

```
property notationName: DOMString;
```

C++

```
__property DOMString notationName;
```

Description

This is notationName, a member of class IDOMEntity.

80.2.9.3.2 IDOMEntity.publicId Property

Pascal

```
property publicId: DOMString;
```

C++

```
__property DOMString publicId;
```

Description

This is publicId, a member of class IDOMEntity.

80.2.9.3.3 IDOMEntity.systemId Property

Pascal

```
property systemId: DOMString;
```

C++

```
__property DOMString systemId;
```

Description

This is systemId, a member of class IDOMEntity.

80.2.10 IDOMEntityReference Interface

Class Hierarchy

Pascal

```
IDOMEntityReference = interface(IDOMNode);
```

C++

```
__interface IDOMEntityReference : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMEntityReference.

80.2.11 IDOMImplementation Interface

Class Hierarchy

Pascal

```
IDOMImplementation = interface;
```

C++

```
__interface IDOMImplementation;
```

File

xmldom

Description

This is class xmldom.IDOMImplementation.

80.2.11.1 IDOMImplementation Members

The following tables list the members exposed by IDOMImplementation.

Public Methods

	Name	Description
	createDocument (see page 7553)	This is createDocument, a member of class IDOMImplementation.
	createDocumentType (see page 7553)	This is createDocumentType, a member of class IDOMImplementation.
	hasFeature (see page 7553)	This is hasFeature, a member of class IDOMImplementation.

80.2.11.2 IDOMImplementation Methods

The methods of the IDOMImplementation class are listed here.

Public Methods

	Name	Description
	createDocument (see page 7553)	This is createDocument, a member of class IDOMImplementation.
	createDocumentType (see page 7553)	This is createDocumentType, a member of class IDOMImplementation.
	hasFeature (see page 7553)	This is hasFeature, a member of class IDOMImplementation.

80.2.11.2.1 IDOMImplementation.createDocument Method

Pascal

```
function createDocument(const namespaceURI: DOMString; const qualifiedName: DOMString;
doctype: IDOMDocumentType): IDOMDocument; safecall;
```

C++

```
__fastcall IDOMDocument createDocument(const DOMString namespaceURI, const DOMString
qualifiedName, IDOMDocumentType doctype);
```

Description

This is createDocument, a member of class IDOMImplementation.

80.2.11.2.2 IDOMImplementation.createDocumentType Method

Pascal

```
function createDocumentType(const qualifiedName: DOMString; const publicId: DOMString; const
systemId: DOMString): IDOMDocumentType; safecall;
```

C++

```
__fastcall IDOMDocumentType createDocumentType(const DOMString qualifiedName, const DOMString
publicId, const DOMString systemId);
```

Description

This is createDocumentType, a member of class IDOMImplementation.

80.2.11.2.3 IDOMImplementation.hasFeature Method

Pascal

```
function hasFeature(const feature: DOMString; const version: DOMString): WordBool;
```

C++

```
__fastcall WordBool hasFeature(const DOMString feature, const DOMString version);
```

Description

This is hasFeature, a member of class IDOMImplementation.

80.2.12 IDOMNamedNodeMap Interface

Class Hierarchy

Pascal

```
IDOMNamedNodeMap = interface;
```

C++

```
__interface IDOMNamedNodeMap;
```

File

xmldom

Description

This is class xmldom.IDOMNamedNodeMap.

80.2.12.1 IDOMNamedNodeMap Members

The following tables list the members exposed by IDOMNamedNodeMap.

Public Methods

	Name	Description
	get_item (see page 7555)	This is get_item, a member of class IDOMNamedNodeMap.
	get_length (see page 7555)	This is get_length, a member of class IDOMNamedNodeMap.
	getNamedItem (see page 7555)	This is getNamedItem, a member of class IDOMNamedNodeMap.
	getNamedItemNS (see page 7555)	This is getNamedItemNS, a member of class IDOMNamedNodeMap.
	removeNamedItem (see page 7556)	This is removeNamedItem, a member of class IDOMNamedNodeMap.
	removeNamedItemNS (see page 7556)	This is removeNamedItemNS, a member of class IDOMNamedNodeMap.
	setNamedItem (see page 7556)	This is setNamedItem, a member of class IDOMNamedNodeMap.
	setNamedItemNS (see page 7556)	This is setNamedItemNS, a member of class IDOMNamedNodeMap.

Public Properties

	Name	Description
R	item (see page 7557)	This is item, a member of class IDOMNamedNodeMap.
R	length (see page 7557)	This is length, a member of class IDOMNamedNodeMap.

80.2.12.2 IDOMNamedNodeMap Methods

The methods of the IDOMNamedNodeMap class are listed here.

Public Methods

	Name	Description
	get_item (see page 7555)	This is get_item, a member of class IDOMNamedNodeMap.
	get_length (see page 7555)	This is get_length, a member of class IDOMNamedNodeMap.
	getNamedItem (see page 7555)	This is getNamedItem, a member of class IDOMNamedNodeMap.
	getNamedItemNS (see page 7555)	This is getNamedItemNS, a member of class IDOMNamedNodeMap.
	removeNamedItem (see page 7556)	This is removeNamedItem, a member of class IDOMNamedNodeMap.
	removeNamedItemNS (see page 7556)	This is removeNamedItemNS, a member of class IDOMNamedNodeMap.

	setNamedItem (see page 7556)	This is setNamedItem, a member of class IDOMNamedNodeMap.
	setNamedItemNS (see page 7556)	This is setNamedItemNS, a member of class IDOMNamedNodeMap.

80.2.12.2.1 IDOMNamedNodeMap.get_item Method

Pascal

```
function get_item(index: Integer): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_item(int index);
```

Description

This is get_item, a member of class IDOMNamedNodeMap.

80.2.12.2.2 IDOMNamedNodeMap.get_length Method

Pascal

```
function get_length: Integer; safecall;
```

C++

```
__fastcall int get_length();
```

Description

This is get_length, a member of class IDOMNamedNodeMap.

80.2.12.2.3 IDOMNamedNodeMap.getNamedItem Method

Pascal

```
function getNamedItem(const name: DOMString): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode getNamedItem(const DOMString name);
```

Description

This is getNamedItem, a member of class IDOMNamedNodeMap.

80.2.12.2.4 IDOMNamedNodeMap.getNamedItemNS Method

Pascal

```
function getNamedItemNS(const namespaceURI: DOMString; const localName: DOMString): IDOMNode;
safecall;
```

C++

```
__fastcall IDOMNode getNamedItemNS(const DOMString namespaceURI, const DOMString localName);
```

Description

This is getNamedItemNS, a member of class IDOMNamedNodeMap.

80.2.12.2.5 IDOMNamedNodeMap.removeNamedItem Method

Pascal

```
function removeNamedItem(const name: DOMString): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode removeNamedItem(const DOMString name);
```

Description

This is removeNamedItem, a member of class IDOMNamedNodeMap.

80.2.12.2.6 IDOMNamedNodeMap.removeNamedItemNS Method

Pascal

```
function removeNamedItemNS(const namespaceURI: DOMString; const localName: DOMString):
IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode removeNamedItemNS(const DOMString namespaceURI, const DOMString localName);
```

Description

This is removeNamedItemNS, a member of class IDOMNamedNodeMap.

80.2.12.2.7 IDOMNamedNodeMap.setNamedItem Method

Pascal

```
function setNamedItem(const arg: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode setNamedItem(const IDOMNode arg);
```

Description

This is setNamedItem, a member of class IDOMNamedNodeMap.

80.2.12.2.8 IDOMNamedNodeMap.setNamedItemNS Method

Pascal

```
function setNamedItemNS(const arg: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode setNamedItemNS(const IDOMNode arg);
```

Description

This is setNamedItemNS, a member of class IDOMNamedNodeMap.

80.2.12.3 IDOMNamedNodeMap Properties

The properties of the IDOMNamedNodeMap class are listed here.

Public Properties

	Name	Description
	item (see page 7557)	This is item, a member of class IDOMNamedNodeMap.
	length (see page 7557)	This is length, a member of class IDOMNamedNodeMap.

80.2.12.3.1 IDOMNamedNodeMap.item Property

Pascal

```
property item [index: Integer]: IDOMNode;
```

C++

```
__property IDOMNode item[int index];
```

Description

This is item, a member of class IDOMNamedNodeMap.

80.2.12.3.2 IDOMNamedNodeMap.length Property

Pascal

```
property length: Integer;
```

C++

```
__property int length;
```

Description

This is length, a member of class IDOMNamedNodeMap.

80.2.13 IDOMNode Interface

IDOMNode is the DOM interface for a node in an XML document.

Class Hierarchy

Pascal

```
IDOMNode = interface(IInterface);
```

C++

```
__interface IDOMNode : public IInterface;
```

File

xmldom

Description

IDOMNode is a vendor-neutral version of the DOM interface for a node in an XML document. It conforms to the W3CXML DOM level 2 specification. Use IDOMNode to work with a node in an XML document when you are using standard DOM interfaces rather than the IXMLNode interface. (IXMLNode is the node interface used by TXMLDocument document.)

IDOMNode represents an element in an XML document that has been parsed by a DOM parser. It includes properties and methods for navigating the node hierarchy of an XML document, for accessing the attributes (see page 7568) of a node, and

for drilling down to obtain the node's value.

For more information about IDOMNode and the other standard DOM interfaces, see the DOM specification on the W3 website or the documentation provided by your DOM vendor.

Note: C++ method declarations that use IDOMNode use the _di_IDOMNode type instead. This type is a DelphiInterface (see page 3256) wrapper around the IDOMNode interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IDOMNode >  _di_IDOMNode;
```

See Also

IXMLNode (see page 7669)

TXMLDocument (see page 7347)

CreateDOMNode (see page 7488)

80.2.13.1 IDOMNode Members

The following tables list the members exposed by IDOMNode.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.

	childNodes (see page 7568)	Represents the child nodes of the node.
	firstChild (see page 7569)	Represents the first child node of this node.
	lastChild (see page 7569)	Represents the last child node of this node.
	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
	nextSibling (see page 7571)	Represents the next child of this node's parent.
	nodeName (see page 7572)	Indicates the name of the node.
	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
	prefix (see page 7576)	Indicates the namespace prefix for the node.
	previousSibling (see page 7576)	Represents the preceding child of this node's parent.

80.2.13.2 IDOMNode Methods

The methods of the IDOMNode class are listed here.

Public Methods

	Name	Description
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

80.2.13.2.1 IDOMNode.appendChild Method

Adds a new child node to this node.

Pascal

```
function appendChild(const newChild: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode appendChild(const IDOMNode newChild);
```

Description

Use appendChild to add a child node to the end of this node's list of children. If the new node is already in the document's node hierarchy, it is first removed from its parent node. If this node is read-only, newChild was created using a different document, or if newChild is of a nodeType (see page 7572) that is not permitted as a child of this node, appendChild raises an exception.

newChild is the child node to add. It can be a node that currently has another parent node, or a new node created using the methods of the document interface. If it is of nodeType (see page 7572) DOCUMENT_FRAGMENT_NODE (see page 7625), the entire contents of the document fragment are moved into this node's childNodes (see page 7568) property list.

appendChild returns the interface for the newly added child node.

See Also

insertBefore (see page 7565)

childNodes (see page 7568)

replaceChild (see page 7566)

removeChild (see page 7566)

nodeType (see page 7572)

ownerDocument (see page 7575)

80.2.13.2.2 IDOMNode.cloneNode Method

Returns a duplicate of this node.

Pascal

```
function cloneNode(deep: WordBool): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode cloneNode(WordBool deep);
```

Description

Use cloneNode to obtain a copy of this node. The cloneNode method returns a copy of this node that has no parent. Any attributes (see page 7568) are copied as well, including any attribute nodes that represent default values.

deep indicates whether the child nodes of this node should be cloned as well. For example, if an element node contains any text, cloneNode only copies then text when deep is true, because the text is contained in a child node of type TEXT_NODE (see page 7636).

Note: When cloning an attribute node directly (as opposed to copying the attributes (see page 7568) when cloning an element node), the returned node's specified property is always true, even if this node does not represent a specified attribute.

Note: Cloning an immutable subtree produces a mutable copy, but the children of an entity-reference node are read-only.

Note: DOM implementations may differ in the way they clone nodes of type DOCUMENT_NODE (see page 7626), DOCUMENT_TYPE_NODE (see page 7626), ENTITY_NODE (see page 7627), and NOTATION_NODE (see page 7632).

See Also

insertBefore (see page 7565)

childNodes (see page 7568)

replaceChild (see page 7566)

removeChild (see page 7566)

nodeType (see page 7572)

ownerDocument (see page 7575)

80.2.13.2.3 IDOMNode.get_attributes Method

Returns the value of the get_attributes property.

Pascal

```
function get_attributes: IDOMNamedNodeMap; safecall;
```

C++

```
__fastcall IDOMNamedNodeMap get_attributes();
```

Description

get_get_attributes is the read implementation of the get_attributes property.

80.2.13.2.4 IDOMNode.get_childNodes Method

Returns the value of the get_childNodes property.

Pascal

```
function get_childNodes: IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList get_childNodes();
```

Description

get_get_childNodes is the read implementation of the get_childNodes property.

80.2.13.2.5 IDOMNode.get_firstChild Method

Returns the value of the get_firstChild property.

Pascal

```
function get_firstChild: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_firstChild();
```

Description

get_get_firstChild is the read implementation of the get_firstChild property.

80.2.13.2.6 IDOMNode.get_lastChild Method

Returns the value of the get_lastChild property.

Pascal

```
function get_lastChild: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_lastChild();
```

Description

get_get_lastChild is the read implementation of the get_lastChild property.

80.2.13.2.7 IDOMNode.get_localName Method

Returns the value of the get_localName property.

Pascal

```
function get_localName: DOMString; safecall;
```

C++

```
__fastcall DOMString get_localName();
```

Description

get_get_localName is the read implementation of the get_localName property.

80.2.13.2.8 IDOMNode.get_namespaceURI Method

Returns the value of the get_namespaceURI property.

Pascal

```
function get_namespaceURI: DOMString; safecall;
```

C++

```
__fastcall DOMString get_namespaceURI();
```

Description

get_get_namespaceURI is the read implementation of the get_namespaceURI property.

80.2.13.2.9 IDOMNode.get_nextSibling Method

Returns the value of the get_nextSibling property.

Pascal

```
function get_nextSibling: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_nextSibling();
```

Description

get_get_nextSibling is the read implementation of the get_nextSibling property.

80.2.13.2.10 IDOMNode.get_nodeName Method

Returns the value of the get_nodeName property.

Pascal

```
function get_nodeName: DOMString; safecall;
```

C++

```
__fastcall DOMString get_nodeName();
```

Description

get_get_nodeName is the read implementation of the get_nodeName property.

80.2.13.2.11 IDOMNode.get_nodeType Method

Returns the value of the get_nodeType property.

Pascal

```
function get_nodeType: DOMNodeType; safecall;
```

C++

```
__fastcall DOMNodeType get_nodeType();
```

Description

get_get_nodeType is the read implementation of the get_nodeType property.

80.2.13.2.12 IDOMNode.get_nodeValue Method

Returns the value of the get_nodeValue property.

Pascal

```
function get_nodeValue: DOMString; safecall;
```

C++

```
__fastcall DOMString get_nodeValue();
```

Description

get_get_nodeValue is the read implementation of the get_nodeValue property.

80.2.13.2.13 IDOMNode.get_ownerDocument Method

Returns the value of the get_ownerDocument property.

Pascal

```
function get_ownerDocument: IDOMDocument; safecall;
```

C++

```
__fastcall IDOMDocument get_ownerDocument();
```

Description

get_get_ownerDocument is the read implementation of the get_ownerDocument property.

80.2.13.2.14 IDOMNode.get_parentNode Method

Returns the value of the get_parentNode property.

Pascal

```
function get_parentNode: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_parentNode();
```

Description

get_get_parentNode is the read implementation of the get_parentNode property.

80.2.13.2.15 IDOMNode.get_prefix Method

Returns the value of the get_prefix property.

Pascal

```
function get_prefix: DOMString; safecall;
```

C++

```
__fastcall DOMString get_prefix();
```

Description

get_get_prefix is the read implementation of the get_prefix property.

80.2.13.2.16 IDOMNode.get_previousSibling Method

Returns the value of the get_previousSibling property.

Pascal

```
function get_previousSibling: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_previousSibling();
```

Description

get_get_previousSibling is the read implementation of the get_previousSibling property.

80.2.13.2.17 IDOMNode.hasChildNodes Method

Indicates whether the node has any child nodes.

Pascal

```
function hasChildNodes: WordBool; safecall;
```

C++

```
__fastcall WordBool hasChildNodes();
```

Description

hasChildNodes returns true if this node has any child nodes, false if it has no children.

See Also

childNodes (see page 7568)

firstChild (see page 7569)

lastChild (see page 7569)

80.2.13.2.18 IDOMNode.insertBefore Method

Inserts a new child node before a specified child of the node.

Pascal

```
function insertBefore(const newChild: IDOMNode; const refChild: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode insertBefore(const IDOMNode newChild, const IDOMNode refChild);
```

Description

Use insertBefore to add a child node at a specified position in this node's list of children. If the new node is already in the document's node hierarchy, it is first removed from its parent node. If this node is read-only, refChild is a node that is not in this node's child list, newChild was created using a different document, or if newChild is of a nodeType (see page 7572) that is not permitted as a child of this node, insertBefore raises an exception.

newChild is the child node to add. It can be a node that currently has another parent node, or a new node created using the methods of the document interface. If it is of nodeType (see page 7572) DOCUMENT_FRAGMENT_NODE (see page 7625), the entire contents of the document fragment are moved into this node's childNodes (see page 7568) property list.

refChild is a child of this node before which to insert the new node. If refChild is nil (Delphi) or NULL (C++), the new node is added to the end of this node's child list.

insertBefore returns the interface for the newly added child node.

See Also

appendChild (see page 7559)

childNodes (see page 7568)

replaceChild (see page 7566)

removeChild (see page 7566)

nodeType (see page 7572)

ownerDocument (see page 7575)

80.2.13.2.19 IDOMNode.normalize Method

Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.

Pascal

```
procedure normalize; safecall;
```

C++

```
__fastcall normalize();
```

Description

Call normalize to consolidate adjacent text nodes and remove any empty text nodes in the subtree beneath this node. This method ensures that for all child nodes of this node and of its attributes (see page 7568), only structure nodes (element nodes, comments, processing instructions, CDATA sections, and entity references) separate text nodes and that there are no empty text nodes. This is useful for operations (such as XPointer lookups) that depend on a particular structure in the node hierarchy.

See Also

childNodes (see page 7568)

nodeType (see page 7572)

attributes (see page 7568)

80.2.13.2.20 IDOMNode.removeChild Method

Removes a child node from this node.

Pascal

```
function removeChild(const childNode: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode removeChild(const IDOMNode childNode);
```

Description

removeChild removes a specified child node from this node, and returns its interface. If this node is read-only, or if the specified child node is not a child of this node, removeChild raises an exception.

childNode the node to remove.

See Also

appendChild (see page 7559)

childNodes (see page 7568)

replaceChild (see page 7566)

80.2.13.2.21 IDOMNode.replaceChild Method

Replaces one of this node's children with a specified node.

Pascal

```
function replaceChild(const newChild: IDOMNode; const oldChild: IDOMNode): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode replaceChild(const IDOMNode newChild, const IDOMNode oldChild);
```

Description

Use replaceChild to remove a child of this node and replace it with the node specified by newChild. If the new node is already in the document's node hierarchy, it is first removed from its parent node.

If this node is read-only, refChild is a node that is not in this node's child list, newChild was created using a different document, or if newChild is of a nodeType (see page 7572) that is not permitted as a child of this node, replaceChild raises an exception.

newChild is the child node that replaces oldChild. It can be a node that currently has another parent node, or a new node created using the methods of the document interface. If it is of nodeType (see page 7572) DOCUMENT_FRAGMENT_NODE (see page 7625), the entire contents of the document fragment are moved into this node's childNodes (see page 7568) property list.

refChild is a child that newChild replaces. If refChild is nil (Delphi) or NULL (C++), the new node is added to the end of this node's child list.

replaceChild returns the interface for refChild (the replaced node).

See Also

appendChild (see page 7559)

childNodes (see page 7568)

insertBefore (see page 7565)

80.2.13.2.22 IDOMNode.set_nodeValue Method

Sets the value of the node.

Pascal

```
procedure set_nodeValue(value: DOMString); safecall;
```

C++

```
__fastcall set_nodeValue(DOMString value);
```

Description

set_set_nodeValue is the write implementation of the set_nodeValue property.

value is the new value for the node.

80.2.13.2.23 IDOMNode.supports Method

Indicates whether the node supports a specified feature.

Pascal

```
function supports(const feature: DOMString; const version: DOMString): WordBool;
```

C++

```
__fastcall WordBool supports(const DOMString feature, const DOMString version);
```

Description

supports returns true if the DOM implementation implements the specified feature and this node supports that feature. Otherwise, supports returns false.

feature is the name of the feature in question.

version is the version of the feature. If no version is specified, supports returns true if any version of the feature is supported.

80.2.13.3 IDOMNode Properties

The properties of the IDOMNode class are listed here.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.

R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.

80.2.13.3.1 IDOMNode.attributes Property

Represents the attributes of an element node.

Pascal

```
property attributes: IDOMNamedNodeMap;
```

C++

```
__property IDOMNamedNodeMap attributes;
```

Description

Use attributes to access the attribute nodes for this node. The IDOMNamedNodeMap (see page 7554) interface provides access to a collection of DOM nodes that can be identified by name.

Attributes modify a node in an XML document. For example, given the node for

```
<Movie genre=scifi title="Star Wars">
```

both genre and title are attributes of the node, with values of "scifi" and "Star Wars", respectively.

DOM parsers represent each attribute as a separate node, which is listed by IDOMNamedNodeMap (see page 7554).

Only element nodes have attributes, and not every element node has them. If the node does not have any attributes, the value of attributes is nil (Delphi) or NULL (C++).

Note: Attributes are not considered child nodes of a node and can't be accessed using the childNodes (see page 7568) property.

See Also

childNodes (see page 7568)

80.2.13.3.2 IDOMNode.childNodes Property

Represents the child nodes of the node.

Pascal

```
property childNodes: IDOMNodeList;
```

C++

```
__property IDOMNodeList childNodes;
```

Description

The childNodes property lists the nodes that are children of this DOM node. If this node has no child nodes, childNodes is the interface of an empty list.

You can use childNodes to iterate through a node's children, or you can the firstChild (see page 7569) and lastChild (see page 7569) properties along with the nextSibling (see page 7571) method on each child node.

Note: Attributes are not considered child nodes of a node. To get the values of this node's attributes (see page 7568), use the attributes (see page 7568) property instead.

Note: IDOMNode (see page 7557) identifies child nodes slightly differently than does the IXMLNode interface. When using the DOM, the values of many nodes are treated as separate child nodes, where the two are merged when using IXMLNode. For example, given the following fragment from an XML document:

```
<Time>8:00 pm est</Time>
```

Note: The DOM parses this string into two nodes: the <Time (see page 4297)> node (an element node), and a single child node of the <Time (see page 4297)> node (an text node with the value '8:00 pm est'). IXMLNode treats this as a single node with the name 'Time (see page 4297)' and the value '8:00 pm est'.

See Also

attributes (see page 7568)

parentNode (see page 7575)

firstChild (see page 7569)

lastChild (see page 7569)

nextSibling (see page 7571)

previousSibling (see page 7576)

hasChildNodes (see page 7564)

replaceChild (see page 7566)

removeChild (see page 7566)

appendChild (see page 7559)

IXMLNode (see page 7669)

80.2.13.3.3 IDOMNode.firstChild Property

Represents the first child node of this node.

Pascal

```
property firstChild: IDOMNode;
```

C++

```
__property IDOMNode firstChild;
```

Description

Use firstChild to obtain the IDOMNode (see page 7557) interface of this node's first child node. If the node does not have any children, the value of firstChild is nil (Delphi) or NULL (C++).

The firstChild property is useful for iterating through all the children of a node.

See Also

childNodes (see page 7568)

lastChild (see page 7569)

nextSibling (see page 7571)

previousSibling (see page 7576)

hasChildNodes (see page 7564)

80.2.13.3.4 IDOMNode.lastChild Property

Represents the last child node of this node.

Pascal

```
property lastChild: IDOMNode;
```

C++

```
__property IDOMNode lastChild;
```

Description

Use lastChild to obtain the IDOMNode (see page 7557) interface of this node's last child node. If there are no child nodes, the value of lastChild is nil (Delphi) or NULL (C++).

The lastChild property is useful when iterating through all the children of a node.

See Also

childNodes (see page 7568)

firstChild (see page 7569)

nextSibling (see page 7571)

previousSibling (see page 7576)

80.2.13.3.5 IDOMNode.localName Property

Indicates the name of the node without any namespace prefix (see page 7576).

Pascal

```
property localName: DOMString;
```

C++

```
__property DOMString localName;
```

Description

Read (see page 3634) localName to determine the name of the DOM node with any namespace prefix (see page 7576) stripped away.

The localName property is only defined for element nodes and attribute nodes (nodes with nodeType (see page 7572) ELEMENT_NODE (see page 7627) and ATTRIBUTE_NODE (see page 7624)).

For element nodes, the local name is derived from the name that appears in the XML tag. For example, the local name for <xsi:Name First=John Last=Doe> is 'Name'.

For attribute nodes, the local name is derived from the string that appears to the left of the equals sign in the attribute declaration. For example, the element <Name First=John Last=Doe> results in two attribute nodes, with the local names 'First' and 'Last'.

For any other node types, localName is nil (Delphi) or NULL (C++).

Note: If the prefix (see page 7576) and localName properties are defined for a node, nodeName (see page 7572) is the combination of those two values.

Note: localName is nil (Delphi) or NULL (C++) for nodes created with a DOM level 1 interface such as the document's createElement method, even if they are element or attribute nodes.

See Also

prefix (see page 7576)

nodeType (see page 7572)

nodeName (see page 7572)

80.2.13.3.6 IDOMNode.namespaceURI Property

Indicates the URI for the namespace used in the qualified node name.

Pascal

```
property namespaceURI: DOMString;
```

C++

```
__property DOMString namespaceURI;
```

Description

Read (see page 3634) namespaceURI to determine the URI for the namespace assigned to the node when it is created. If a namespace URI was not given when the node was created, namespaceURI is nil (Delphi) or NULL (C++). That is, namespaceURI does not supply a value if the namespace URI must be computed from namespace declarations in scope.

Only element and attribute nodes can have a namespaceURI value. For any other node types, namespaceURI is always nil (Delphi) or NULL (C++). Attribute nodes do not inherit a namespace from the element node to which they are attached. If an attribute is not explicitly given a namespace, its namespaceURI is nil (Delphi) or NULL (C++).

Note: namespaceURI is nil (Delphi) or NULL (C++) for nodes created with a DOM level 1 interface such as the document's createElement method, even if they are element or attribute nodes.

See Also

localName (see page 7570)

prefix (see page 7576)

nodeType (see page 7572)

nodeName (see page 7572)

80.2.13.3.7 IDOMNode.nextSibling Property

Represents the next child of this node's parent.

Pascal

```
property nextSibling: IDOMNode;
```

C++

```
__property IDOMNode nextSibling;
```

Description

Use nextSibling to obtain the IDOMNode (see page 7557) interface of the node that immediately follows this node. If the node's parent does not have any more child nodes after this one, the value of nextSibling is nil (Delphi) or NULL (C++).

The nextSibling property is useful for iterating through all the children of a node.

See Also

childNodes (see page 7568)

parentNode (see page 7575)

previousSibling (see page 7576)

hasChildNodes (see page 7564)

80.2.13.3.8 IDOMNode.nodeName Property

Indicates the name of the node.

Pascal

```
property nodeName: DOMString;
```

C++

```
__property DOMString nodeName;
```

Description

Read (see page 3634) nodeName to determine the name of the DOM node. The value of nodeName depends on the type of the node, as indicated in the following table:

nodeType (see page 7572)	nodeName
ATTRIBUTE_NODE (see page 7624)	The name of the attribute.
ELEMENT_NODE (see page 7627)	The tag name for the node.
TEXT_NODE (see page 7636)	#text
CDATA_SECTION_NODE (see page 7625)	#cdata-section
ENTITY_REFERENCE_NODE (see page 7628)	The name of the entity reference.
ENTITY_NODE (see page 7627)	The entity name.
PROCESSING_INSTRUCTION_NODE (see page 7633)	The target of the processing instruction.
COMMENT_NODE (see page 7625)	#comment
DOCUMENT_NODE (see page 7626)	#document
DOCUMENT_TYPE_NODE (see page 7626)	The document type name.
DOCUMENT_FRAGMENT_NODE (see page 7625)	#document-fragment
NOTATION_NODE (see page 7632)	The notation name.

Note: If the prefix (see page 7576) and localName (see page 7570) properties are defined for a node, nodeName is the combination of those two values.

See Also

localName (see page 7570)

nodeType (see page 7572)

nodeValue (see page 7574)

prefix (see page 7576)

80.2.13.3.9 IDOMNode.nodeType Property

Indicates the type of the node.

Pascal

```
property nodeType: DOMNodeType;
```

C++

```
__property DOMNodeType nodeType;
```

Description

Read (see page 3634) nodeType to determine the type of the node. The type reflects the way the node is used in the XML document. The following table lists the possible values:

nodeType	Meaning
ATTRIBUTE_NODE (see page 7624)	The node represents an attribute of an element. It is not the child of another node, but its value can be accessed using the attributes (see page 7568) property of the element node's interface. An attribute node can have child nodes of type TEXT_NODE (see page 7636) and ENTITY_REFERENCE_NODE (see page 7628).
ELEMENT_NODE (see page 7627)	The node represents a tagged element. The child nodes of an element node can be of types: ELEMENT_NODE (see page 7627), TEXT_NODE (see page 7636), COMMENT_NODE (see page 7625), CDATA_SECTION_NODE (see page 7625), ENTITY_REFERENCE_NODE (see page 7628), and PROCESSING_INSTRUCTION_NODE (see page 7633). Element nodes can also have attributes (see page 7568) (ATTRIBUTE_NODE (see page 7624)). Element nodes can be the child of a node of type DOCUMENT_FRAGMENT_NODE (see page 7625), ELEMENT_NODE (see page 7627), DOCUMENT_NODE (see page 7626), and ENTITY_REFERENCE_NODE (see page 7628).
TEXT_NODE (see page 7636)	The node represents the text value associated with another node. A text node cannot have any child nodes, but can appear as the child node of a node of type ATTRIBUTE_NODE (see page 7624), ELEMENT_NODE (see page 7627), DOCUMENT_FRAGMENT_NODE (see page 7625), or ENTITY_REFERENCE_NODE (see page 7628).
CDATA_SECTION_NODE (see page 7625)	The node represents a CDATA section in the XML source. CDATA sections identify blocks of text that would otherwise be interpreted as markup. A CDATA_SECTION_NODE (see page 7625) node can't have any child nodes. They can appear as the child of an ELEMENT_NODE (see page 7627), DOCUMENT_FRAGMENT_NODE (see page 7625), or ENTITY_REFERENCE_NODE (see page 7628) node.
ENTITY_REFERENCE_NODE (see page 7628)	The node represents a reference to an entity in the XML document. This can be any type of entity, including character entity references. The children of an entity reference node can be of the following types: ELEMENT_NODE (see page 7627), COMMENT_NODE (see page 7625), CDATA_SECTION_NODE (see page 7625), PROCESSING_INSTRUCTION_NODE (see page 7633), TEXT_NODE (see page 7636), and ENTITY_REFERENCE_NODE (see page 7628). The entity reference node can appear as the child of a DOCUMENT_FRAGMENT_NODE (see page 7625), ATTRIBUTE_NODE (see page 7624), ELEMENT_NODE (see page 7627), or ENTITY_REFERENCE_NODE (see page 7628) node.
ENTITY_NODE (see page 7627)	The node represents an expanded entity. Entity nodes can have child nodes that represent the expanded entity (for example, TEXT_NODE (see page 7636) and ENTITY_REFERENCE_NODE (see page 7628) nodes). Entity nodes only appear as the child of a DOCUMENT_TYPE_NODE (see page 7626) node.
PROCESSING_INSTRUCTION_NODE (see page 7633)	The node represents a processing instruction (PI) from the XML document. A PI node cannot have any child nodes, but can appear as the child node of a node of type DOCUMENT_NODE (see page 7626), DOCUMENT_FRAGMENT_NODE (see page 7625), ELEMENT_NODE (see page 7627), or ENTITY_REFERENCE_NODE (see page 7628).

COMMENT_NODE (see page 7625)	The node represents a comment in the XML document. Comment nodes do not have child nodes. They appear as the child of an ELEMENT_NODE (see page 7627), DOCUMENT_NODE (see page 7626), DOCUMENT_FRAGMENT_NODE (see page 7625), or ENTITY_REFERENCE_NODE (see page 7628) node.
DOCUMENT_NODE (see page 7626)	The node represents a document object, which is the root of the entire XML document. Document nodes have a single ELEMENT_NODE (see page 7627) node as a child (the documentElement). In addition, they can have child nodes of type COMMENT_NODE (see page 7625), DOCUMENT_TYPE_NODE (see page 7626), and PROCESSING_INSTRUCTION_NODE (see page 7633). Because the document is the root of the XML document, it never appears as a child node.
DOCUMENT_TYPE_NODE (see page 7626)	The node represents the document type declaration, indicated by the <!DOCTYPE > tag. The document type node can child nodes of type NOTATION_NODE (see page 7632) and ENTITY_NODE (see page 7627). It is appears the child of the document node.
DOCUMENT_FRAGMENT_NODE (see page 7625)	The node represents a document fragment. A document fragment node associates a node or subtree with a document without actually being contained in the document. Document fragment nodes can have child nodes of type ELEMENT_NODE (see page 7627), COMMENT_NODE (see page 7625), PROCESSING_INSTRUCTION_NODE (see page 7633), CDATA_SECTION_NODE (see page 7625), TEXT_NODE (see page 7636), and ENTITY_REFERENCE_NODE (see page 7628). It never appears as the child of another node.
NOTATION_NODE (see page 7632)	The node represents a notation in the document type declaration. It always appears as the child of a DOCUMENT_TYPE_NODE (see page 7626) node and never has any child nodes.

See Also

nodeName (see page 7572)

nodeValue (see page 7574)

80.2.13.3.10 IDOMNode.nodeValue Property

Indicates the value of the node.

Pascal

```
property nodeValue: DOMString;
```

C++

```
__property DOMString nodeValue;
```

Description

Read (see page 3634) nodeValue to determine the value of the DOM node. Set nodeValue to change the value of a node.

Note: You can't set the value of a node whose value is listed as nil (Delphi) or NULL (C++) in the following table.

The value of nodeValue depends on the type of the node, as indicated in the following table:

nodeType (see page 7572)	nodeValue
ATTRIBUTE_NODE (see page 7624)	The value of the attribute.
ELEMENT_NODE (see page 7627)	nil (Delphi) or NULL (C++).
TEXT_NODE (see page 7636)	The content of the text node.

CDATA_SECTION_NODE (see page 7625)	The content of the CDATA section.
ENTITY_REFERENCE_NODE (see page 7628)	nil (Delphi) or NULL (C++).
ENTITY_NODE (see page 7627)	nil (Delphi) or NULL (C++).
PROCESSING_INSTRUCTION_NODE (see page 7633)	The content of the processing instruction except for the target.
COMMENT_NODE (see page 7625)	The content of the comment.
DOCUMENT_NODE (see page 7626)	nil (Delphi) or NULL (C++).
DOCUMENT_TYPE_NODE (see page 7626)	nil (Delphi) or NULL (C++).
DOCUMENT_FRAGMENT_NODE (see page 7625)	nil (Delphi) or NULL (C++).
NOTATION_NODE (see page 7632)	nil (Delphi) or NULL (C++).

See Also

localName (see page 7570)

nodeType (see page 7572)

80.2.13.3.11 IDOMNode.ownerDocument Property

Represents the interface for the document that contains this node.

Pascal

```
property ownerDocument: IDOMDocument;
```

C++

```
__property IDOMDocument ownerDocument;
```

Description

Use ownerDocument to obtain the interface of the document that contains this node. The IDOMDocument (see page 7530) interface can be used to create new nodes.

If this node has nodeType (see page 7572) of DOCUMENT_NODE (see page 7626) or DOCUMENT_TYPE_NODE (see page 7626), the value of ownerDocument is nil (Delphi) or NULL (C++).

See Also

parentNode (see page 7575)

nodeType (see page 7572)

80.2.13.3.12 IDOMNode.parentNode Property

Provides access to the interface of the node's parent node.

Pascal

```
property parentNode: IDOMNode;
```

C++

```
__property IDOMNode parentNode;
```

Description

Read (see page 3634) parentNode to access the node's parent node, if it exists. If the node does not have a parent node, the value of parentNode is nil (Delphi) or NULL (C++).

Nodes of type ATTRIBUTE_NODE (see page 7624), DOCUMENT_NODE (see page 7626), and DOCUMENT_FRAGMENT_NODE (see page 7625) never have parents. Nodes of type ENTITY_NODE (see page 7627) and NOTATION_NODE (see page 7632) may not have a parent. Nodes of other types have a parent unless they have just been created but not yet added to the hierarchy, or if they have just been removed from the hierarchy.

See Also

nodeType (see page 7572)

80.2.13.3.13 IDOMNode.prefix Property

Indicates the namespace prefix for the node.

Pascal

```
property prefix: DOMString;
```

C++

```
__property DOMString prefix;
```

Description

Read (see page 3634) prefix to determine the namespace prefix for an element or attribute node.

For element nodes, prefix is derived from the name that appears in the XML tag. For example, the prefix for <xsi:Name First=John Last=Doe> is 'xsi'.

For attribute nodes, prefix is derived from the string that appears to the left of the equals sign in the attribute declaration. For example, with the element <xsi:Name xsi:First=John xsi:Last=Doe>, both attribute nodes have the prefix of 'xsi'. Attribute nodes do not inherit a prefix value from the element node to which they are attached. For example, with the element <xsi:Name First=John Last=Doe>, both attributes (see page 7568) have a prefix of nil (Delphi) or NULL (C++).

For any other node types, prefix is nil (Delphi) or NULL (C++).

Note: If the prefix and localName (see page 7570) properties are defined for a node, nodeName (see page 7572) is the combination of those two values.

Note: prefix is nil (Delphi) or NULL (C++) for nodes created with a DOM level 1 interface such as the document's createElement method, even if they are element or attribute nodes.

See Also

localName (see page 7570)

namespaceURI (see page 7571)

nodeType (see page 7572)

nodeName (see page 7572)

80.2.13.3.14 IDOMNode.previousSibling Property

Represents the preceding child of this node's parent.

Pascal

```
property previousSibling: IDOMNode;
```

C++

```
__property IDOMNode previousSibling;
```

Description

Use previousSibling to obtain the IDOMNode (see page 7557) interface of the node that immediately precedes this node. If the node's parent does not have any more child nodes before this one, the value of previousSibling is nil (Delphi) or NULL (C++).

See Also

childNodes (see page 7568)

parentNode (see page 7575)

hasChildNodes (see page 7564)

80.2.14 IDOMNodeEx Interface

Class Hierarchy

Pascal

```
IDOMNodeEx = interface(IDOMNode);
```

C++

```
__interface IDOMNodeEx : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMNodeEx.

80.2.14.1 IDOMNodeEx Members

The following tables list the members exposed by IDOMNodeEx.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.

	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_text (see page 7579)	This is get_text, a member of class IDOMNodeEx.
	get_xml (see page 7579)	This is get_xml, a member of class IDOMNodeEx.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	set_text (see page 7579)	This is set_text, a member of class IDOMNodeEx.
	supports (see page 7567)	Indicates whether the node supports a specified feature.
	transformNode (see page 7579)	This is the overview for the transformNode method overload.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
	text (see page 7580)	This is text, a member of class IDOMNodeEx.
R	xml (see page 7580)	This is xml, a member of class IDOMNodeEx.

80.2.14.2 IDOMNodeEx Methods

The methods of the IDOMNodeEx class are listed here.

Public Methods

	Name	Description
	get_text (see page 7579)	This is get_text, a member of class IDOMNodeEx.
	get_xml (see page 7579)	This is get_xml, a member of class IDOMNodeEx.
	set_text (see page 7579)	This is set_text, a member of class IDOMNodeEx.
	transformNode (see page 7579)	This is the overview for the transformNode method overload.

80.2.14.2.1 IDOMNodeEx.get_text Method

Pascal

```
function get_text: DOMString; safecall;
```

C++

```
__fastcall DOMString get_text();
```

Description

This is get_text, a member of class IDOMNodeEx.

80.2.14.2.2 IDOMNodeEx.get_xml Method

Pascal

```
function get_xml: DOMString; safecall;
```

C++

```
__fastcall DOMString get_xml();
```

Description

This is get_xml, a member of class IDOMNodeEx.

80.2.14.2.3 IDOMNodeEx.set_text Method

Pascal

```
procedure set_text(const Value: DOMString); safecall;
```

C++

```
__fastcall set_text(const DOMString Value);
```

Description

This is set_text, a member of class IDOMNodeEx.

80.2.14.2.4 transformNode Method

This is the overview for the transformNode method overload.

Overload List

	Name	Description
	IDOMNodeEx.transformNode (IDOMNode, IDOMDocument) (see page 7579)	This is transformNode, a member of class IDOMNodeEx.
	IDOMNodeEx.transformNode (IDOMNode, WideString) (see page 7580)	This is transformNode, a member of class IDOMNodeEx.

80.2.14.2.4.1 IDOMNodeEx.transformNode Method (IDOMNode, IDOMDocument)

Pascal

```
procedure transformNode(const stylesheet: IDOMNode; const output: IDOMDocument); safecall;
overload;
```

C++

```
__fastcall transformNode(const IDOMNode stylesheet, const IDOMDocument output);
```

Description

This is transformNode, a member of class IDOMNodeEx.

80.2.14.2.4.2 IDOMNodeEx.transformNode Method (IDOMNode, WideString)

Pascal

```
procedure transformNode(const stylesheet: IDOMNode; var output: WideString); safecall;
overload;
```

C++

```
__fastcall transformNode(const IDOMNode stylesheet, BSTR output);
```

Description

This is transformNode, a member of class IDOMNodeEx.

80.2.14.3 IDOMNodeEx Properties

The properties of the IDOMNodeEx class are listed here.

Public Properties

	Name	Description
	text (see page 7580)	This is text, a member of class IDOMNodeEx.
R	xml (see page 7580)	This is xml, a member of class IDOMNodeEx.

80.2.14.3.1 IDOMNodeEx.text Property

Pascal

```
property text: DOMString;
```

C++

```
__property DOMString text;
```

Description

This is text, a member of class IDOMNodeEx.

80.2.14.3.2 IDOMNodeEx.xml Property

Pascal

```
property xml: DOMString;
```

C++

```
__property DOMString xml;
```

Description

This is xml, a member of class IDOMNodeEx.

80.2.15 IDOMNodeList Interface

Class Hierarchy

Pascal

```
IDOMNodeList = interface;
```

C++

```
__interface IDOMNodeList;
```

File

xmldom

Description

This is class xmldom.IDOMNodeList.

80.2.15.1 IDOMNodeList Members

The following tables list the members exposed by IDOMNodeList.

Public Methods

	Name	Description
	get_item (see page 7581)	This is get_item, a member of class IDOMNodeList.
	get_length (see page 7582)	This is get_length, a member of class IDOMNodeList.

Public Properties

	Name	Description
R	item (see page 7582)	This is item, a member of class IDOMNodeList.
R	length (see page 7582)	This is length, a member of class IDOMNodeList.

80.2.15.2 IDOMNodeList Methods

The methods of the IDOMNodeList class are listed here.

Public Methods

	Name	Description
	get_item (see page 7581)	This is get_item, a member of class IDOMNodeList.
	get_length (see page 7582)	This is get_length, a member of class IDOMNodeList.

80.2.15.2.1 IDOMNodeList.get_item Method

Pascal

```
function get_item(index: Integer): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode get_item(int index);
```

Description

This is get_item, a member of class IDOMNodeList.

80.2.15.2.2 IDOMNodeList.get_length Method

Pascal

```
function get_length: Integer; safecall;
```

C++

```
__fastcall int get_length();
```

Description

This is get_length, a member of class IDOMNodeList.

80.2.15.3 IDOMNodeList Properties

The properties of the IDOMNodeList class are listed here.

Public Properties

	Name	Description
	item (see page 7582)	This is item, a member of class IDOMNodeList.
	length (see page 7582)	This is length, a member of class IDOMNodeList.

80.2.15.3.1 IDOMNodeList.item Property

Pascal

```
property item [index: Integer]: IDOMNode;
```

C++

```
__property IDOMNode item[int index];
```

Description

This is item, a member of class IDOMNodeList.

80.2.15.3.2 IDOMNodeList.length Property

Pascal

```
property length: Integer;
```

C++

```
__property int length;
```

Description

This is length, a member of class IDOMNodeList.

80.2.16 IDOMNodeSelect Interface

Class Hierarchy

Pascal

```
IDOMNodeSelect = interface(IInterface);
```

C++

```
__interface IDOMNodeSelect : public IInterface;
```

File

xmldom

Description

This is class xmldom.IDOMNodeSelect.

80.2.16.1 IDOMNodeSelect Members

The following tables list the members exposed by IDOMNodeSelect.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	selectNode (see page 7583)	This is selectNode, a member of class IDOMNodeSelect.
	selectNodes (see page 7584)	This is selectNodes, a member of class IDOMNodeSelect.

80.2.16.2 IDOMNodeSelect Methods

The methods of the IDOMNodeSelect class are listed here.

Public Methods

	Name	Description
	selectNode (see page 7583)	This is selectNode, a member of class IDOMNodeSelect.
	selectNodes (see page 7584)	This is selectNodes, a member of class IDOMNodeSelect.

80.2.16.2.1 IDOMNodeSelect.selectNode Method

Pascal

```
function selectNode(const nodePath: WideString): IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode selectNode(const BSTR nodePath);
```

Description

This is selectNode, a member of class IDOMNodeSelect.

80.2.16.2.2 IDOMNodeSelect.selectNodes Method

Pascal

```
function selectNodes(const nodePath: WideString): IDOMNodeList; safecall;
```

C++

```
__fastcall IDOMNodeList selectNodes(const BSTR nodePath);
```

Description

This is selectNodes, a member of class IDOMNodeSelect.

80.2.17 IDOMNotation Interface

Class Hierarchy

Pascal

```
IDOMNotation = interface(IDOMNode);
```

C++

```
__interface IDOMNotation : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMNotation.

80.2.17.1 IDOMNotation Members

The following tables list the members exposed by IDOMNotation.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.

	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_publicId (see page 7585)	This is get_publicId, a member of class IDOMNotation.
	get_systemId (see page 7586)	This is get_systemId, a member of class IDOMNotation.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	publicId (see page 7586)	This is publicId, a member of class IDOMNotation.
R	systemId (see page 7586)	This is systemId, a member of class IDOMNotation.

80.2.17.2 IDOMNotation Methods

The methods of the IDOMNotation class are listed here.

Public Methods

	Name	Description
	get_publicId (see page 7585)	This is get_publicId, a member of class IDOMNotation.
	get_systemId (see page 7586)	This is get_systemId, a member of class IDOMNotation.

80.2.17.2.1 IDOMNotation.get_publicId Method

Pascal

```
function get_publicId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_publicId();
```

Description

This is get_publicId, a member of class IDOMNotation.

80.2.17.2.2 IDOMNotation.get_systemId Method

Pascal

```
function get_systemId: DOMString; safecall;
```

C++

```
__fastcall DOMString get_systemId();
```

Description

This is get_systemId, a member of class IDOMNotation.

80.2.17.3 IDOMNotation Properties

The properties of the IDOMNotation class are listed here.

Public Properties

	Name	Description
R	publicId (see page 7586)	This is publicId, a member of class IDOMNotation.
R	systemId (see page 7586)	This is systemId, a member of class IDOMNotation.

80.2.17.3.1 IDOMNotation.publicId Property

Pascal

```
property publicId: DOMString;
```

C++

```
__property DOMString publicId;
```

Description

This is publicId, a member of class IDOMNotation.

80.2.17.3.2 IDOMNotation.systemId Property

Pascal

```
property systemId: DOMString;
```

C++

```
__property DOMString systemId;
```

Description

This is systemId, a member of class IDOMNotation.

80.2.18 IDOMParseError Interface

Class Hierarchy

Pascal

```
IDOMParseError = interface;
```

C++

```
__interface IDOMParseError;
```

File

xmldom

Description

This is class xmldom.IDOMParseError.

80.2.18.1 IDOMParseError Members

The following tables list the members exposed by IDOMParseError.

Public Methods

	Name	Description
	get_errorCode (see page 7588)	This is get_errorCode, a member of class IDOMParseError.
	get_filepos (see page 7588)	This is get_filepos, a member of class IDOMParseError.
	get_line (see page 7588)	This is get_line, a member of class IDOMParseError.
	get_linepos (see page 7588)	This is get_linepos, a member of class IDOMParseError.
	get_reason (see page 7588)	This is get_reason, a member of class IDOMParseError.
	get_srcText (see page 7589)	This is get_srcText, a member of class IDOMParseError.
	get_url (see page 7589)	This is get_url, a member of class IDOMParseError.

Public Properties

	Name	Description
R	errorCode (see page 7589)	This is errorCode, a member of class IDOMParseError.
R	filePos (see page 7590)	This is filePos, a member of class IDOMParseError.
R	line (see page 7590)	This is line, a member of class IDOMParseError.
R	linePos (see page 7590)	This is linePos, a member of class IDOMParseError.
R	reason (see page 7590)	This is reason, a member of class IDOMParseError.
R	srcText (see page 7590)	This is srcText, a member of class IDOMParseError.
R	url (see page 7591)	This is url, a member of class IDOMParseError.

80.2.18.2 IDOMParseError Methods

The methods of the IDOMParseError class are listed here.

Public Methods

	Name	Description
	get_errorCode (see page 7588)	This is get_errorCode, a member of class IDOMParseError.
	get_filepos (see page 7588)	This is get_filepos, a member of class IDOMParseError.
	get_line (see page 7588)	This is get_line, a member of class IDOMParseError.
	get_linepos (see page 7588)	This is get_linepos, a member of class IDOMParseError.
	get_reason (see page 7588)	This is get_reason, a member of class IDOMParseError.
	get_srcText (see page 7589)	This is get_srcText, a member of class IDOMParseError.
	get_url (see page 7589)	This is get_url, a member of class IDOMParseError.

80.2.18.2.1 IDOMParseError.get_errorCode Method

Pascal

```
function get_errorCode: Integer; safecall;
```

C++

```
__fastcall int get_errorCode();
```

Description

This is get_errorCode, a member of class IDOMParseError.

80.2.18.2.2 IDOMParseError.get_filepos Method

Pascal

```
function get_filepos: Integer; safecall;
```

C++

```
__fastcall int get_filepos();
```

Description

This is get_filepos, a member of class IDOMParseError.

80.2.18.2.3 IDOMParseError.get_line Method

Pascal

```
function get_line: Integer; safecall;
```

C++

```
__fastcall int get_line();
```

Description

This is get_line, a member of class IDOMParseError.

80.2.18.2.4 IDOMParseError.get_linepos Method

Pascal

```
function get_linepos: Integer; safecall;
```

C++

```
__fastcall int get_linepos();
```

Description

This is get_linepos, a member of class IDOMParseError.

80.2.18.2.5 IDOMParseError.get_reason Method

Pascal

```
function get_reason: DOMString; safecall;
```

C++

```
__fastcall DOMString get_reason();
```

Description

This is get_reason, a member of class IDOMParseError.

80.2.18.2.6 IDOMParseError.get_srcText Method

Pascal

```
function get_srcText: DOMString; safecall;
```

C++

```
__fastcall DOMString get_srcText();
```

Description

This is get_srcText, a member of class IDOMParseError.

80.2.18.2.7 IDOMParseError.get_url Method

Pascal

```
function get_url: DOMString; safecall;
```

C++

```
__fastcall DOMString get_url();
```

Description

This is get_url, a member of class IDOMParseError.

80.2.18.3 IDOMParseError Properties

The properties of the IDOMParseError class are listed here.

Public Properties

	Name	Description
	errorCode (see page 7589)	This is errorCode, a member of class IDOMParseError.
	filePos (see page 7590)	This is filePos, a member of class IDOMParseError.
	line (see page 7590)	This is line, a member of class IDOMParseError.
	linePos (see page 7590)	This is linePos, a member of class IDOMParseError.
	reason (see page 7590)	This is reason, a member of class IDOMParseError.
	srcText (see page 7590)	This is srcText, a member of class IDOMParseError.
	url (see page 7591)	This is url, a member of class IDOMParseError.

80.2.18.3.1 IDOMParseError.errorCode Property

Pascal

```
property errorCode: Integer;
```

C++

```
__property int errorCode;
```

Description

This is errorCode, a member of class IDOMParseError.

80.2.18.3.2 IDOMParseError.filePos Property

Pascal

```
property filePos: Integer;
```

C++

```
__property int filePos;
```

Description

This is filePos, a member of class IDOMParseError.

80.2.18.3.3 IDOMParseError.line Property

Pascal

```
property line: Integer;
```

C++

```
__property int line;
```

Description

This is line, a member of class IDOMParseError.

80.2.18.3.4 IDOMParseError.linePos Property

Pascal

```
property linePos: Integer;
```

C++

```
__property int linePos;
```

Description

This is linePos, a member of class IDOMParseError.

80.2.18.3.5 IDOMParseError.reason Property

Pascal

```
property reason: DOMString;
```

C++

```
__property DOMString reason;
```

Description

This is reason, a member of class IDOMParseError.

80.2.18.3.6 IDOMParseError.srcText Property

Pascal

```
property srcText: DOMString;
```

C++

```
__property DOMString srcText;
```

Description

This is srcText, a member of class IDOMParseError.

80.2.18.3.7 IDOMParseError.url Property

Pascal

```
property url: DOMString;
```

C++

```
__property DOMString url;
```

Description

This is url, a member of class IDOMParseError.

80.2.19 IDOMParseOptions Interface

Class Hierarchy

Pascal

```
IDOMParseOptions = interface;
```

C++

```
__interface IDOMParseOptions;
```

File

xmldom

Description

This is class xmldom.IDOMParseOptions.

80.2.19.1 IDOMParseOptions Members

The following tables list the members exposed by IDOMParseOptions.

Public Methods

	Name	Description
	get_async (see page 7592)	This is get_async, a member of class IDOMParseOptions.
	get_preserveWhiteSpace (see page 7592)	This is get_preserveWhiteSpace, a member of class IDOMParseOptions.
	get_resolveExternals (see page 7592)	This is get_resolveExternals, a member of class IDOMParseOptions.
	get_validate (see page 7593)	This is get_validate, a member of class IDOMParseOptions.
	set_async (see page 7593)	This is set_async, a member of class IDOMParseOptions.
	set_preserveWhiteSpace (see page 7593)	This is set_preserveWhiteSpace, a member of class IDOMParseOptions.
	set_resolveExternals (see page 7593)	This is set_resolveExternals, a member of class IDOMParseOptions.
	set_validate (see page 7593)	This is set_validate, a member of class IDOMParseOptions.

Public Properties

	Name	Description
	async (see page 7594)	This is async, a member of class IDOMParseOptions.

	preserveWhiteSpace (see page 7594)	This is preserveWhiteSpace, a member of class IDOMParseOptions.
	resolveExternals (see page 7594)	This is resolveExternals, a member of class IDOMParseOptions.
	validate (see page 7595)	This is validate, a member of class IDOMParseOptions.

80.2.19.2 IDOMParseOptions Methods

The methods of the IDOMParseOptions class are listed here.

Public Methods

	Name	Description
	get_async (see page 7592)	This is get_async, a member of class IDOMParseOptions.
	get_preserveWhiteSpace (see page 7592)	This is get_preserveWhiteSpace, a member of class IDOMParseOptions.
	get_resolveExternals (see page 7592)	This is get_resolveExternals, a member of class IDOMParseOptions.
	get_validate (see page 7593)	This is get_validate, a member of class IDOMParseOptions.
	set_async (see page 7593)	This is set_async, a member of class IDOMParseOptions.
	set_preserveWhiteSpace (see page 7593)	This is set_preserveWhiteSpace, a member of class IDOMParseOptions.
	set_resolveExternals (see page 7593)	This is set_resolveExternals, a member of class IDOMParseOptions.
	set_validate (see page 7593)	This is set_validate, a member of class IDOMParseOptions.

80.2.19.2.1 IDOMParseOptions.get_async Method

Pascal

```
function get_async: Boolean; safecall;
```

C++

```
__fastcall Boolean get_async();
```

Description

This is get_async, a member of class IDOMParseOptions.

80.2.19.2.2 IDOMParseOptions.get_preserveWhiteSpace Method

Pascal

```
function get_preserveWhiteSpace: Boolean; safecall;
```

C++

```
__fastcall Boolean get_preserveWhiteSpace();
```

Description

This is get_preserveWhiteSpace, a member of class IDOMParseOptions.

80.2.19.2.3 IDOMParseOptions.get_resolveExternals Method

Pascal

```
function get_resolveExternals: Boolean; safecall;
```

C++

```
__fastcall Boolean get_resolveExternals();
```

Description

This is get_resolveExternals, a member of class IDOMParseOptions.

80.2.19.2.4 IDOMParseOptions.get_validate Method

Pascal

```
function get_validate: Boolean; safecall;
```

C++

```
__fastcall Boolean get_validate();
```

Description

This is get_validate, a member of class IDOMParseOptions.

80.2.19.2.5 IDOMParseOptions.set_async Method

Pascal

```
procedure set_async(Value: Boolean); safecall;
```

C++

```
__fastcall set_async(Boolean Value);
```

Description

This is set_async, a member of class IDOMParseOptions.

80.2.19.2.6 IDOMParseOptions.set_preserveWhiteSpace Method

Pascal

```
procedure set_preserveWhiteSpace(Value: Boolean); safecall;
```

C++

```
__fastcall set_preserveWhiteSpace(Boolean Value);
```

Description

This is set_preserveWhiteSpace, a member of class IDOMParseOptions.

80.2.19.2.7 IDOMParseOptions.set_resolveExternals Method

Pascal

```
procedure set_resolveExternals(Value: Boolean); safecall;
```

C++

```
__fastcall set_resolveExternals(Boolean Value);
```

Description

This is set_resolveExternals, a member of class IDOMParseOptions.

80.2.19.2.8 IDOMParseOptions.set_validate Method

Pascal

```
procedure set_validate(Value: Boolean); safecall;
```

C++

```
__fastcall set_validate(Boolean Value);
```

Description

This is set_validate, a member of class IDOMParseOptions.

80.2.19.3 IDOMParseOptions Properties

The properties of the IDOMParseOptions class are listed here.

Public Properties

	Name	Description
	async (see page 7594)	This is async, a member of class IDOMParseOptions.
	preserveWhiteSpace (see page 7594)	This is preserveWhiteSpace, a member of class IDOMParseOptions.
	resolveExternals (see page 7594)	This is resolveExternals, a member of class IDOMParseOptions.
	validate (see page 7595)	This is validate, a member of class IDOMParseOptions.

80.2.19.3.1 IDOMParseOptions.async Property

Pascal

```
property async: Boolean;
```

C++

```
__property Boolean async;
```

Description

This is async, a member of class IDOMParseOptions.

80.2.19.3.2 IDOMParseOptions.preserveWhiteSpace Property

Pascal

```
property preserveWhiteSpace: Boolean;
```

C++

```
__property Boolean preserveWhiteSpace;
```

Description

This is preserveWhiteSpace, a member of class IDOMParseOptions.

80.2.19.3.3 IDOMParseOptions.resolveExternals Property

Pascal

```
property resolveExternals: Boolean;
```

C++

```
__property Boolean resolveExternals;
```

Description

This is resolveExternals, a member of class IDOMParseOptions.

80.2.19.3.4 IDOMParseOptions.validate Property

Pascal

```
property validate: Boolean;
```

C++

```
__property Boolean validate;
```

Description

This is validate, a member of class IDOMParseOptions.

80.2.20 IDOMPersist Interface

Class Hierarchy

Pascal

```
IDOMPersist = interface;
```

C++

```
__interface IDOMPersist;
```

File

xmldom

Description

This is class xmldom.IDOMPersist.

80.2.20.1 IDOMPersist Members

The following tables list the members exposed by IDOMPersist.

Public Methods

	Name	Description
	asyncLoadState (see page 7596)	This is asyncLoadState, a member of class IDOMPersist.
	get_xml (see page 7596)	This is get_xml, a member of class IDOMPersist.
	load (see page 7596)	This is load, a member of class IDOMPersist.
	loadFromStream (see page 7597)	This is the overview for the loadFromStream method overload.
	loadxml (see page 7597)	This is loadxml, a member of class IDOMPersist.
	save (see page 7597)	This is save, a member of class IDOMPersist.
	saveToStream (see page 7598)	This is the overview for the saveToStream method overload.
	set_OnAsyncLoad (see page 7598)	This is set_OnAsyncLoad, a member of class IDOMPersist.

Public Properties

	Name	Description
R	xml (see page 7599)	This is xml, a member of class IDOMPersist.

80.2.20.2 IDOMPersist Methods

The methods of the IDOMPersist class are listed here.

Public Methods

	Name	Description
	asyncLoadState (see page 7596)	This is asyncLoadState, a member of class IDOMPersist.
	get_xml (see page 7596)	This is get_xml, a member of class IDOMPersist.
	load (see page 7596)	This is load, a member of class IDOMPersist.
	loadFromStream (see page 7597)	This is the overview for the loadFromStream method overload.
	loadxml (see page 7597)	This is loadxml, a member of class IDOMPersist.
	save (see page 7597)	This is save, a member of class IDOMPersist.
	saveToStream (see page 7598)	This is the overview for the saveToStream method overload.
	set_OnAsyncLoad (see page 7598)	This is set_OnAsyncLoad, a member of class IDOMPersist.

80.2.20.2.1 IDOMPersist.asyncLoadState Method

Pascal

```
function asyncLoadState: Integer; safecall;
```

C++

```
__fastcall int asyncLoadState();
```

Description

This is asyncLoadState, a member of class IDOMPersist.

80.2.20.2.2 IDOMPersist.get_xml Method

Pascal

```
function get_xml: DOMString; safecall;
```

C++

```
__fastcall DOMString get_xml();
```

Description

This is get_xml, a member of class IDOMPersist.

80.2.20.2.3 IDOMPersist.load Method

Pascal

```
function load(source: OleVariant): WordBool; safecall;
```

C++

```
__fastcall WordBool load(OleVariant source);
```

Description

This is load, a member of class IDOMPersist.

80.2.20.2.4 loadFromStream Method

This is the overview for the loadFromStream method overload.

Overload List

	Name	Description
	IDOMPersist.loadFromStream (IStream) (see page 7597)	This is loadFromStream, a member of class IDOMPersist.
	IDOMPersist.loadFromStream (TStream) (see page 7597)	This is loadFromStream, a member of class IDOMPersist.

80.2.20.2.4.1 IDOMPersist.loadFromStream Method (IStream)

Pascal

```
function loadFromStream(const stream: IStream): WordBool; safecall; overload;
```

C++

```
__fastcall WordBool loadFromStream(const IStream stream);
```

Description

This is loadFromStream, a member of class IDOMPersist.

80.2.20.2.4.2 IDOMPersist.loadFromStream Method (TStream)

Pascal

```
function loadFromStream(const stream: TStream): WordBool; safecall; overload;
```

C++

```
__fastcall WordBool loadFromStream(const TStream stream);
```

Description

This is loadFromStream, a member of class IDOMPersist.

80.2.20.2.5 IDOMPersist.loadxml Method

Pascal

```
function loadxml(const Value: DOMString): WordBool; safecall;
```

C++

```
__fastcall WordBool loadxml(const DOMString Value);
```

Description

This is loadxml, a member of class IDOMPersist.

80.2.20.2.6 IDOMPersist.save Method

Pascal

```
procedure save(destination: OleVariant); safecall;
```

C++

```
__fastcall save(OleVariant destination);
```

Description

This is save, a member of class IDOMPersist.

80.2.20.2.7 saveToStream Method

This is the overview for the saveToStream method overload.

Overload List

	Name	Description
	IDOMPersist.saveToStream (IStream) (see page 7598)	This is saveToStream, a member of class IDOMPersist.
	IDOMPersist.saveToStream (TStream) (see page 7598)	This is saveToStream, a member of class IDOMPersist.

80.2.20.2.7.1 IDOMPersist.saveToStream Method (IStream)

Pascal

```
procedure saveToStream(const stream: IStream); safecall; overload;
```

C++

```
__fastcall saveToStream(const IStream stream);
```

Description

This is saveToStream, a member of class IDOMPersist.

80.2.20.2.7.2 IDOMPersist.saveToStream Method (TStream)

Pascal

```
procedure saveToStream(const stream: TStream); safecall; overload;
```

C++

```
__fastcall saveToStream(const TStream stream);
```

Description

This is saveToStream, a member of class IDOMPersist.

80.2.20.2.8 IDOMPersist.set_OnAsyncLoad Method

Pascal

```
procedure set_OnAsyncLoad(const Sender: TObject; EventHandler: TAsyncEventHandler); safecall;
```

C++

```
__fastcall set_OnAsyncLoad(const TObject * Sender, TAsyncEventHandler EventHandler);
```

Description

This is set_OnAsyncLoad, a member of class IDOMPersist.

80.2.20.3 IDOMPersist Properties

The properties of the IDOMPersist class are listed here.

Public Properties

	Name	Description
	xml (see page 7599)	This is xml, a member of class IDOMPersist.

80.2.20.3.1 IDOMPersist.xml Property

Pascal

```
property xml: DOMString;
```

C++

```
__property DOMString xml;
```

Description

This is xml, a member of class IDOMPersist.

80.2.21 IDOMProcessingInstruction Interface

Class Hierarchy

Pascal

```
IDOMProcessingInstruction = interface(IDOMNode);
```

C++

```
__interface IDOMProcessingInstruction : public IDOMNode;
```

File

xmldom

Description

This is class xmldom.IDOMProcessingInstruction.

80.2.21.1 IDOMProcessingInstruction Members

The following tables list the members exposed by IDOMProcessingInstruction.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.

	get_data (see page 7601)	This is get_data, a member of class IDOMProcessingInstruction.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	get_target (see page 7601)	This is get_target, a member of class IDOMProcessingInstruction.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	set_data (see page 7601)	This is set_data, a member of class IDOMProcessingInstruction.
	set_nodeValue (see page 7567)	Sets the value of the node.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
	data (see page 7601)	This is data, a member of class IDOMProcessingInstruction.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.
R	target (see page 7602)	This is target, a member of class IDOMProcessingInstruction.

80.2.21.2 IDOMProcessingInstruction Methods

The methods of the IDOMProcessingInstruction class are listed here.

Public Methods

	Name	Description
	get_data (see page 7601)	This is get_data, a member of class IDOMProcessingInstruction.
	get_target (see page 7601)	This is get_target, a member of class IDOMProcessingInstruction.
	set_data (see page 7601)	This is set_data, a member of class IDOMProcessingInstruction.

80.2.21.2.1 IDOMProcessingInstruction.get_data Method

Pascal

```
function get_data: DOMString; safecall;
```

C++

```
__fastcall DOMString get_data();
```

Description

This is get_data, a member of class IDOMProcessingInstruction.

80.2.21.2.2 IDOMProcessingInstruction.get_target Method

Pascal

```
function get_target: DOMString; safecall;
```

C++

```
__fastcall DOMString get_target();
```

Description

This is get_target, a member of class IDOMProcessingInstruction.

80.2.21.2.3 IDOMProcessingInstruction.set_data Method

Pascal

```
procedure set_data(const value: DOMString); safecall;
```

C++

```
__fastcall set_data(const DOMString value);
```

Description

This is set_data, a member of class IDOMProcessingInstruction.

80.2.21.3 IDOMProcessingInstruction Properties

The properties of the IDOMProcessingInstruction class are listed here.

Public Properties

	Name	Description
	data (see page 7601)	This is data, a member of class IDOMProcessingInstruction.
R	target (see page 7602)	This is target, a member of class IDOMProcessingInstruction.

80.2.21.3.1 IDOMProcessingInstruction.data Property

Pascal

```
property data: DOMString;
```

C++

```
__property DOMString data;
```

Description

This is data, a member of class IDOMProcessingInstruction.

80.2.21.3.2 IDOMProcessingInstruction.target Property

Pascal

```
property target: DOMString;
```

C++

```
__property DOMString target;
```

Description

This is target, a member of class IDOMProcessingInstruction.

80.2.22 IDOMText Interface

Class Hierarchy

Pascal

```
IDOMText = interface(IDOMCharacterData);
```

C++

```
__interface IDOMText : public IDOMCharacterData;
```

File

xmldom

Description

This is class xmldom.IDOMText.

80.2.22.1 IDOMText Members

The following tables list the members exposed by IDOMText.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	appendChild (see page 7559)	Adds a new child node to this node.
	appendData (see page 7527)	This is appendData, a member of class IDOMCharacterData.
	cloneNode (see page 7560)	Returns a duplicate of this node.
	deleteData (see page 7528)	This is deleteData, a member of class IDOMCharacterData.
	get_attributes (see page 7561)	Returns the value of the get_attributes property.
	get_childNodes (see page 7561)	Returns the value of the get_childNodes property.
	get_data (see page 7528)	This is get_data, a member of class IDOMCharacterData.
	get_firstChild (see page 7561)	Returns the value of the get_firstChild property.
	get_lastChild (see page 7561)	Returns the value of the get_lastChild property.

	get_length (see page 7528)	This is get_length, a member of class IDOMCharacterData.
	get_localName (see page 7562)	Returns the value of the get_localName property.
	get_namespaceURI (see page 7562)	Returns the value of the get_namespaceURI property.
	get_nextSibling (see page 7562)	Returns the value of the get_nextSibling property.
	get_nodeName (see page 7562)	Returns the value of the get_nodeName property.
	get_nodeType (see page 7563)	Returns the value of the get_nodeType property.
	get_nodeValue (see page 7563)	Returns the value of the get_nodeValue property.
	get_ownerDocument (see page 7563)	Returns the value of the get_ownerDocument property.
	get_parentNode (see page 7563)	Returns the value of the get_parentNode property.
	get_prefix (see page 7564)	Returns the value of the get_prefix property.
	get_previousSibling (see page 7564)	Returns the value of the get_previousSibling property.
	hasChildNodes (see page 7564)	Indicates whether the node has any child nodes.
	insertBefore (see page 7565)	Inserts a new child node before a specified child of the node.
	insertData (see page 7528)	This is insertData, a member of class IDOMCharacterData.
	normalize (see page 7565)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	removeChild (see page 7566)	Removes a child node from this node.
	replaceChild (see page 7566)	Replaces one of this node's children with a specified node.
	replaceData (see page 7528)	This is replaceData, a member of class IDOMCharacterData.
	set_data (see page 7529)	This is set_data, a member of class IDOMCharacterData.
	set_nodeValue (see page 7567)	Sets the value of the node.
	splitText (see page 7604)	This is splitText, a member of class IDOMText.
	substringData (see page 7529)	This is substringData, a member of class IDOMCharacterData.
	supports (see page 7567)	Indicates whether the node supports a specified feature.

Public Properties

	Name	Description
R	attributes (see page 7568)	Represents the attributes of an element node.
R	childNodes (see page 7568)	Represents the child nodes of the node.
	data (see page 7529)	This is data, a member of class IDOMCharacterData.
R	firstChild (see page 7569)	Represents the first child node of this node.
R	lastChild (see page 7569)	Represents the last child node of this node.
R	length (see page 7529)	This is length, a member of class IDOMCharacterData.
R	localName (see page 7570)	Indicates the name of the node without any namespace prefix (see page 7576).
R	namespaceURI (see page 7571)	Indicates the URI for the namespace used in the qualified node name.
R	nextSibling (see page 7571)	Represents the next child of this node's parent.
R	nodeName (see page 7572)	Indicates the name of the node.
R	nodeType (see page 7572)	Indicates the type of the node.
	nodeValue (see page 7574)	Indicates the value of the node.
R	ownerDocument (see page 7575)	Represents the interface for the document that contains this node.
R	parentNode (see page 7575)	Provides access to the interface of the node's parent node.
R	prefix (see page 7576)	Indicates the namespace prefix for the node.
R	previousSibling (see page 7576)	Represents the preceding child of this node's parent.

80.2.22.2 IDOMText Methods

The methods of the IDOMText class are listed here.

Public Methods

	Name	Description
	splitText (see page 7604)	This is splitText, a member of class IDOMText.

80.2.22.2.1 IDOMText.splitText Method

Pascal

```
function splitText(offset: Integer): IDOMText; safecall;
```

C++

```
__fastcall IDOMText splitText(int offset);
```

Description

This is splitText, a member of class IDOMText.

80.2.23 IDOMXMLProlog Interface

Class Hierarchy

Pascal

```
IDOMXMLProlog = interface;
```

C++

```
__interface IDOMXMLProlog;
```

File

xmldom

Description

This is class xmldom.IDOMXMLProlog.

80.2.23.1 IDOMXMLProlog Members

The following tables list the members exposed by IDOMXMLProlog.

Public Methods

	Name	Description
	get_Encoding (see page 7605)	This is get_Encoding, a member of class IDOMXMLProlog.
	get_Standalone (see page 7605)	This is get_Standalone, a member of class IDOMXMLProlog.
	get_Version (see page 7605)	This is get_Version, a member of class IDOMXMLProlog.
	set_Encoding (see page 7605)	This is set_Encoding, a member of class IDOMXMLProlog.
	set_Standalone (see page 7606)	This is set_Standalone, a member of class IDOMXMLProlog.
	set_Version (see page 7606)	This is set_Version, a member of class IDOMXMLProlog.

Public Properties

	Name	Description
	Encoding (see page 7606)	This is Encoding, a member of class IDOMXMLProlog.
	Standalone (see page 7607)	This is Standalone, a member of class IDOMXMLProlog.
	Version (see page 7607)	This is Version, a member of class IDOMXMLProlog.

80.2.23.2 IDOMXMLProlog Methods

The methods of the IDOMXMLProlog class are listed here.

Public Methods

	Name	Description
	get_Encoding (see page 7605)	This is get_Encoding, a member of class IDOMXMLProlog.
	get_Standalone (see page 7605)	This is get_Standalone, a member of class IDOMXMLProlog.
	get_Version (see page 7605)	This is get_Version, a member of class IDOMXMLProlog.
	set_Encoding (see page 7605)	This is set_Encoding, a member of class IDOMXMLProlog.
	set_Standalone (see page 7606)	This is set_Standalone, a member of class IDOMXMLProlog.
	set_Version (see page 7606)	This is set_Version, a member of class IDOMXMLProlog.

80.2.23.2.1 IDOMXMLProlog.get_Encoding Method

Pascal

```
function get_Encoding: DOMString; safecall;
```

C++

```
__fastcall DOMString get_Encoding();
```

Description

This is get_Encoding, a member of class IDOMXMLProlog.

80.2.23.2.2 IDOMXMLProlog.get_Standalone Method

Pascal

```
function get_Standalone: DOMString; safecall;
```

C++

```
__fastcall DOMString get_Standalone();
```

Description

This is get_Standalone, a member of class IDOMXMLProlog.

80.2.23.2.3 IDOMXMLProlog.get_Version Method

Pascal

```
function get_Version: DOMString; safecall;
```

C++

```
__fastcall DOMString get_Version();
```

Description

This is get_Version, a member of class IDOMXMLProlog.

80.2.23.2.4 IDOMXMLProlog.set_Encoding Method

Pascal

```
procedure set_Encoding(const Value: DOMString); safecall;
```

C++

```
__fastcall set_Encoding(const DOMString Value);
```

Description

This is set_Encoding, a member of class IDOMXMLProlog.

80.2.23.2.5 IDOMXMLProlog.set_Standalone Method

Pascal

```
procedure set_Standalone(const Value: DOMString); safecall;
```

C++

```
__fastcall set_Standalone(const DOMString Value);
```

Description

This is set_Standalone, a member of class IDOMXMLProlog.

80.2.23.2.6 IDOMXMLProlog.set_Version Method

Pascal

```
procedure set_Version(const Value: DOMString); safecall;
```

C++

```
__fastcall set_Version(const DOMString Value);
```

Description

This is set_Version, a member of class IDOMXMLProlog.

80.2.23.3 IDOMXMLProlog Properties

The properties of the IDOMXMLProlog class are listed here.

Public Properties

	Name	Description
	Encoding (see page 7606)	This is Encoding, a member of class IDOMXMLProlog.
	Standalone (see page 7607)	This is Standalone, a member of class IDOMXMLProlog.
	Version (see page 7607)	This is Version, a member of class IDOMXMLProlog.

80.2.23.3.1 IDOMXMLProlog.Encoding Property

Pascal

```
property Encoding: DOMString;
```

C++

```
__property DOMString Encoding;
```

Description

This is Encoding, a member of class IDOMXMLProlog.

80.2.23.3.2 IDOMXMLProlog.Standalone Property

Pascal

```
property Standalone: DOMString;
```

C++

```
__property DOMString Standalone;
```

Description

This is Standalone, a member of class IDOMXMLProlog.

80.2.23.3.3 IDOMXMLProlog.Version Property

Pascal

```
property Version: DOMString;
```

C++

```
__property DOMString Version;
```

Description

This is Version, a member of class IDOMXMLProlog.

80.2.24 IDOMXSLProcessor Interface

Class Hierarchy

Pascal

```
IDOMXSLProcessor = interface(IInterface);
```

C++

```
__interface IDOMXSLProcessor : public IInterface;
```

File

xmldom

Description

This is class xmldom.IDOMXSLProcessor.

80.2.24.1 IDOMXSLProcessor Members

The following tables list the members exposed by IDOMXSLProcessor.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	Get_input (see page 7608)	This is Get_input, a member of class IDOMXSLProcessor.

	Get_output (see page 7608)	This is Get_output, a member of class IDOMXSLProcessor.
	Get_stylesheet (see page 7609)	This is Get_stylesheet, a member of class IDOMXSLProcessor.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	reset (see page 7609)	This is reset, a member of class IDOMXSLProcessor.
	Set_input (see page 7609)	This is Set_input, a member of class IDOMXSLProcessor.
	Set_output (see page 7609)	This is Set_output, a member of class IDOMXSLProcessor.
	setParameter (see page 7609)	This is setParameter, a member of class IDOMXSLProcessor.
	transform (see page 7610)	This is transform, a member of class IDOMXSLProcessor.

Public Properties

	Name	Description
	input (see page 7610)	This is input, a member of class IDOMXSLProcessor.
	output (see page 7610)	This is output, a member of class IDOMXSLProcessor.
R	stylesheet (see page 7611)	This is stylesheet, a member of class IDOMXSLProcessor.

80.2.24.2 IDOMXSLProcessor Methods

The methods of the IDOMXSLProcessor class are listed here.

Public Methods

	Name	Description
	Get_input (see page 7608)	This is Get_input, a member of class IDOMXSLProcessor.
	Get_output (see page 7608)	This is Get_output, a member of class IDOMXSLProcessor.
	Get_stylesheet (see page 7609)	This is Get_stylesheet, a member of class IDOMXSLProcessor.
	reset (see page 7609)	This is reset, a member of class IDOMXSLProcessor.
	Set_input (see page 7609)	This is Set_input, a member of class IDOMXSLProcessor.
	Set_output (see page 7609)	This is Set_output, a member of class IDOMXSLProcessor.
	setParameter (see page 7609)	This is setParameter, a member of class IDOMXSLProcessor.
	transform (see page 7610)	This is transform, a member of class IDOMXSLProcessor.

80.2.24.2.1 IDOMXSLProcessor.Get_input Method

Pascal

```
function Get_input: OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_input();
```

Description

This is Get_input, a member of class IDOMXSLProcessor.

80.2.24.2.2 IDOMXSLProcessor.Get_output Method

Pascal

```
function Get_output: OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_output();
```

Description

This is Get_output, a member of class IDOMXSLProcessor.

80.2.24.2.3 IDOMXSLProcessor.Get_stylesheet Method

Pascal

```
function Get_stylesheet: IDOMNode; safecall;
```

C++

```
__fastcall IDOMNode Get_stylesheet();
```

Description

This is Get_stylesheet, a member of class IDOMXSLProcessor.

80.2.24.2.4 IDOMXSLProcessor.reset Method

Pascal

```
procedure reset; safecall;
```

C++

```
__fastcall reset();
```

Description

This is reset, a member of class IDOMXSLProcessor.

80.2.24.2.5 IDOMXSLProcessor.Set_input Method

Pascal

```
procedure Set_input(const value: OleVariant); safecall;
```

C++

```
__fastcall Set_input(const OleVariant value);
```

Description

This is Set_input, a member of class IDOMXSLProcessor.

80.2.24.2.6 IDOMXSLProcessor.Set_output Method

Pascal

```
procedure Set_output(const value: OleVariant); safecall;
```

C++

```
__fastcall Set_output(const OleVariant value);
```

Description

This is Set_output, a member of class IDOMXSLProcessor.

80.2.24.2.7 IDOMXSLProcessor.setParameter Method

Pascal

```
procedure setParameter(const Name: DOMString; Value: OleVariant; const namespaceURI:
DOMString); safecall;
```

C++

```
__fastcall setParameter(const DOMString Name, OleVariant Value, const DOMString namespaceURI);
```

Description

This is setParameter, a member of class IDOMXSLProcessor.

80.2.24.2.8 IDOMXSLProcessor.transform Method

Pascal

```
function transform: WordBool; safecall;
```

C++

```
__fastcall WordBool transform();
```

Description

This is transform, a member of class IDOMXSLProcessor.

80.2.24.3 IDOMXSLProcessor Properties

The properties of the IDOMXSLProcessor class are listed here.

Public Properties

	Name	Description
	input (see page 7610)	This is input, a member of class IDOMXSLProcessor.
	output (see page 7610)	This is output, a member of class IDOMXSLProcessor.
R	stylesheet (see page 7611)	This is stylesheet, a member of class IDOMXSLProcessor.

80.2.24.3.1 IDOMXSLProcessor.input Property

Pascal

```
property input: OleVariant;
```

C++

```
__property OleVariant input;
```

Description

This is input, a member of class IDOMXSLProcessor.

80.2.24.3.2 IDOMXSLProcessor.output Property

Pascal

```
property output: OleVariant;
```

C++

```
__property OleVariant output;
```

Description

This is output, a member of class IDOMXSLProcessor.

80.2.24.3.3 IDOMXSLProcessor.stylesheet Property

Pascal

```
property stylesheet: IDOMNode;
```

C++

```
__property IDOMNode stylesheet;
```

Description

This is stylesheet, a member of class IDOMXSLProcessor.

80.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DOMVendorNotSupported (see page 7612)	This is function xmldom.DOMVendorNotSupported.
	ExtractLocalName (see page 7612)	Strips the namespace prefix, if present, from the tag name of an XML node.
	ExtractPrefix (see page 7613)	Returns the namespace prefix of an XML node's tag name.
	GetDOM (see page 7614)	Returns the top-level DOM interface for a registered DOM implementation.
	GetDOMNodeEx (see page 7614)	This is function xmldom.GetDOMNodeEx.
	GetDOMVendor (see page 7615)	Returns the TDOMVendor (see page 7514) object for a specified DOM vendor.
	IsPrefixed (see page 7615)	Indicates whether an XML tag name includes a namespace prefix.
	MakeNodeName (see page 7616)	Assembles a full tag name from a local name and namespace prefix.
	NodeMatches (see page 7616)	Indicates whether a specified node matches a given namespace and tag name.
	RegisterDOMVendor (see page 7617)	Registers an implementation of the DOM interfaces so that it is available to the TXMLDocument class.
	SameNamespace (see page 7617)	Indicates whether a specified node is defined within a specified namespace.
	SameNamespace (see page 7617)	Indicates whether a specified node is defined within a specified namespace.
	UnRegisterDOMVendor (see page 7618)	Unregisters a DOM implementation that was registered using RegisterDOMVendor (see page 7617) .

80.3.1 xmldom.DOMVendorNotSupported Function

Pascal

```
procedure DOMVendorNotSupported(const PropOrMethod: string; const VendorName: string);
```

C++

```
DOMVendorNotSupported(const UnicodeString PropOrMethod, const UnicodeString VendorName);
```

File

xmldom

Description

This is function xmldom.DOMVendorNotSupported.

80.3.2 xmldom.ExtractLocalName Function

Strips the namespace prefix, if present, from the tag name of an XML node.

Pascal

```
function ExtractLocalName(const AName: DOMString): DOMString;
```

C++

```
DOMString ExtractLocalName(const DOMString AName);
```

File

xmldom

Description

Call ExtractLocalName to convert a full tag name for an XML node into the corresponding local name.

AName is the tag name to be converted.

ExtractLocalName returns the value of AName with any namespace prefix stripped away.

See Also

ExtractPrefix (see page 7613)

IsPrefixed (see page 7615)

NodeMatches (see page 7616)

IXMLNode (see page 7669)

SameNamespace (see page 7617)

80.3.3 xmldom.ExtractPrefix Function

Returns the namespace prefix of an XML node's tag name.

Pascal

```
function ExtractPrefix(const AName: DOMString): DOMString;
```

C++

```
DOMString ExtractPrefix(const DOMString AName);
```

File

xmldom

Description

Call ExtractPrefix to determine the namespace prefix, if any, of a full tag name for an XML node.

AName is the tag name of the XML node.

ExtractPrefix returns the namespace prefix, not including the colon (:) that separates the namespace from the local name of the XML node. If the tag name does not include a namespace prefix, ExtractPrefix returns an empty string.

See Also

ExtractLocalName (see page 7612)

IsPrefixed (see page 7615)

SameNamespace (see page 7617)

NodeMatches (see page 7616)

80.3.4 xmldom.GetDOM Function

Returns the top-level DOM interface for a registered DOM implementation.

Pascal

```
function GetDOM(const VendorDesc: string = ''): IDOMImplementation;
```

C++

```
IDOMImplementation GetDOM(const UnicodeString VendorDesc = '');
```

File

xmldom

Description

Call GetDOM to obtain an IDOMImplementation (see page 7552) interface that you can use for parsing and editing XML documents. The IDOMImplementation (see page 7552) interface is the top-level DOM interface, which you can use to check for the presence of a specific feature or to obtain an interface for working with a DOM document.

VendorDesc is a short descriptive name that identifies the DOM implementation. This name is returned by the Description method of the DOM implementation factory that is used to register the implementation.

Note: The DOM implementation must be registered before you can access it using GetDOM. To register a DOM implementation, use the RegisterDOMVendor (see page 7617) procedure.

See Also

RegisterDOMVendor (see page 7617)

DOMVendors (see page 7622)

GetDOMVendor (see page 7615)

TXMLDocument (see page 7347)

Using the Document Object Model

80.3.5 xmldom.GetDOMNodeEx Function

Pascal

```
function GetDOMNodeEx(const Node: IDOMNode): IDOMNodeEx;
```

C++

```
IDOMNodeEx GetDOMNodeEx(const IDOMNode Node);
```

File

xmldom

Description

This is function xmldom.GetDOMNodeEx.

80.3.6 xmldom.GetDOMVendor Function

Returns the TDOMVendor (see page 7514) object for a specified DOM vendor.

Pascal

```
function GetDOMVendor(VendorDesc: string): TDOMVendor;
```

C++

```
TDOMVendor GetDOMVendor(UnicodeString VendorDesc);
```

File

xmldom

Description

Call GetDOMVendor to obtain the TDOMVendor (see page 7514) object that represents a registered DOM implementation. You can then assign this return value as the DOMVendor property of TXMLDocument, or call this object's DOMImplementation method to access the IDOMImplementation (see page 7552) interface for the DOM implementation.

VendorDesc is the descriptive string that identifies the particular DOM implementation that is desired. This is the value returned by the TDOMVendor (see page 7514) object's Description method.

See Also

RegisterDOMVendor (see page 7617)

DOMVendors (see page 7622)

TXMLDocument (see page 7347)

80.3.7 xmldom.IsPrefixed Function

Indicates whether an XML tag name includes a namespace prefix.

Pascal

```
function IsPrefixed(const AName: DOMString): Boolean;
```

C++

```
Boolean IsPrefixed(const DOMString AName);
```

File

xmldom

Description

Call IsPrefixed to determine whether a tag name includes a namespace prefix.

AName is the tag name of the XML node.

IsPrefixed returns true if AName includes a namespace prefix followed by the colon (:) separator character, false otherwise.

See Also

ExtractLocalName (see page 7612)

ExtractPrefix (see page 7613)

IXMLNode (see page 7669)

80.3.8 xmldom.MakeNodeName Function

Assembles a full tag name from a local name and namespace prefix.

Pascal

```
function MakeNodeName(const Prefix: DOMString; const LocalName: DOMString): DOMString;
```

C++

```
DOMString MakeNodeName(const DOMString Prefix, const DOMString LocalName);
```

File

xmldom

Description

Call MakeNodeName to create a tag name from a namespace prefix and a local tag name.

Prefix is the namespace prefix.

LocalName is the local name for the node.

MakeNodeName returns the full tag name that consists of the namespace prefix, followed by a colon and then the local name.

See Also

ExtractPrefix (see page 7613)

ExtractLocalName (see page 7612)

80.3.9 xmldom.NodeMatches Function

Indicates whether a specified node matches a given namespace and tag name.

Pascal

```
function NodeMatches(const Node: IDOMNode; const TagName: DOMString; const NamespaceURI:
DOMString): Boolean; overload;
```

C++

```
Boolean NodeMatches(const IDOMNode Node, const DOMString TagName, const DOMString
NamespaceURI);
```

File

xmldom

Description

Call NodeMatches to determine whether the node with the interface specified by Node refers to the same node as is described by the TagName and namespaceURI parameters.

NodeMatches returns true if

The value of Node's namespaceURI property is the same as the namespaceURI parameter.

The local name or tag name of Node is the same as the TagName parameter.

Tip: Given an IXMLNode interface, you can obtain the IDOMNode (see page 7557) interface required for the Node parameter by reading its DOMNode property.

See Also

ExtractLocalName (see page 7612)

ExtractPrefix (see page 7613)

IXMLNode (see page 7669)

SameNamespace (see page 7617)

80.3.10 xmldom.RegisterDOMVendor Function

Registers an implementation of the DOM interfaces so that it is available to the TXMLDocument class.

Pascal

```
procedure RegisterDOMVendor(const Vendor: TDOMVendor);
```

C++

```
RegisterDOMVendor(const TDOMVendor Vendor);
```

File

xmldom

Description

Call RegisterDOMVendor to register a DOM implementation that you want to use for parsing XML documents. A DOM (Document Object Model) implementation is a set of objects that implement the standard DOM interfaces.

If you are using another DOM implementation, you must create a TDOMVendor (see page 7514) descendant that can supply the IDOMImplementation (see page 7552) interface and description string for the DOM implementation. Pass an instance of this object as the Vendor parameter to RegisterDOMVendor.

See Also

UnRegisterDOMVendor (see page 7618)

TXMLDocument (see page 7347)

DOMVendors (see page 7622)

Using the Document Object Model

80.3.11 xmldom.SameNamespace Function

Indicates whether a specified node is defined within a specified namespace.

Pascal

```
function SameNamespace(const Node: IDOMNode; const namespaceURI: WideString): Boolean;
overload;
function SameNamespace(const URI1: WideString; const URI2: WideString): Boolean; overload;
```

C++

```
Boolean SameNamespace(const IDOMNode Node, const BSTR namespaceURI);
```

```
Boolean SameNamespace(const BSTR URI1, const BSTR URI2);
```

File

xmldom

Description

Call SameNamespace to determine whether the two parameters identify the same namespace.

Using the first syntax, the Node parameter identifies a node and the namespaceURI parameter a namespace. SameNamespace checks whether the node is defined in the specified namespace.

Using the second syntax, both parameters are namespace URI values. SameNamespace checks whether they both identify the same namespace.

Tip: Given an IXMLNode interface, you can obtain the IDOMNode (see page 7557) interface required for the Node parameter by reading its DOMNode property.

See Also

ExtractLocalName (see page 7612)

ExtractPrefix (see page 7613)

IXMLNode (see page 7669)

80.3.12 xmldom.UnRegisterDOMVendor Function

Unregisters a DOM implementation that was registered using RegisterDOMVendor (see page 7617) .

Pascal

```
procedure UnRegisterDOMVendor(const Vendor: TDOMVendor);
```

C++

```
UnRegisterDOMVendor(const TDOMVendor Vendor);
```

File

xmldom

Description

Call UnRegisterDOMVendor to unregister a DOM implementation when it is no longer available. After unregistering a DOM implementation, it can't be used by TXMLDocument for parsing XML documents.

Vendor is the TDOMVendor (see page 7514) descendant the represents the DOM implementation that is to be unregistered. It must be the same object used when registering the DOM implementation when you called RegisterDOMVendor (see page 7617).

See Also

RegisterDOMVendor (see page 7617)

TXMLDocument (see page 7347)

DOMVendors (see page 7622)

Using the Document Object Model

80.4 Types

The following table lists types in this documentation.

Types

Name	Description
DOMNodeType (see page 7619)	DOMNodeType indicates the type of a node in an XML document, as parsed by a DOM parser.
DOMString (see page 7619)	DOMString is the type for strings that are used by a DOM parser.
DOMTimeStamp (see page 7620)	This is type xmldom.DOMTimeStamp.
TAsyncEventHandler (see page 7620)	TAsyncEventHandler is the type of event handlers that respond when the AsyncLoadState of an XML document changes.
TDOMVendorArray (see page 7621)	This is type xmldom.TDOMVendorArray.

80.4.1 xmldom.DOMNodeType Type

DOMNodeType indicates the type of a node in an XML document, as parsed by a DOM parser.

Pascal

```
DOMNodeType = Word;
```

C++

```
Word DOMNodeType;
```

File

xmldom

Description

DOMNodeType is the type of the nodeType property on the IDOMNode (see page 7557) interface. It is a flag, defined by W3C, that indicates the role played by a node in the parsed version of an XML document.

See Also

IDOMNode (see page 7557)

80.4.2 xmldom.DOMString Type

DOMString is the type for strings that are used by a DOM parser.

Pascal

```
DOMString = UnicodeString;
```

C++

```
UnicodeString DOMString;
```

File

xmldom

Description

DOM implementations work with wide characters. The strings that are used, therefore, when working with DOM interfaces, are of type DOMString, which simply maps to the WideString (see page 3467) type.

80.4.3 xmldom.DOMTimeStamp Type

Pascal

```
DOMTimeStamp = Int64;
```

C++

```
Int64 DOMTimeStamp;
```

File

xmldom

Description

This is type xmldom.DOMTimeStamp.

80.4.4 xmldom.TAsyncEventHandler Type

TAsyncEventHandler is the type of event handlers that respond when the AsyncLoadState of an XML document changes.

Pascal

```
TAsyncEventHandler = procedure (Sender: TObject; AsyncLoadState: Integer) of object;
```

C++

```
(Sender: TObject; AsyncLoadState: Integer) ( TAsyncEventHandler)();
```

File

xmldom

Description

TAsyncEventHandler is the type for event handlers that respond at various stages during the asynchronous parsing of an XML document.

Sender is the TXMLDocument object that receives the event.

AsyncLoadState is an integer that indicates the current stage of the parsing process. Its value is vendor-specific, and corresponds to the document's AsyncLoadState property.

See Also

TXMLDocument (see page 7347)

IXMLDocument (see page 7640)

AsyncLoadState (see page 7382)

80.4.5 xmldom.TDOMVendorArray Type

Pascal

```
TDOMVendorArray = array of TDOMVendor;
```

C++

```
array of TDOMVendor TDOMVendorArray;
```

File

xmldom

Description

This is type xmldom.TDOMVendorArray.

80.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
DefaultDOMVendor (see page 7622)	Identifies the DOM implementation that is used by default.
DOMVendors (see page 7622)	Lists all registered DOM Vendors.

80.5.1 xmldom.DefaultDOMVendor Variable

Identifies the DOM implementation that is used by default.

Pascal

```
DefaultDOMVendor: string;
```

C++

```
UnicodeString DefaultDOMVendor;
```

File

xmldom

Description

DefaultDOMVendor is the descriptive string that was used to register the default DOM implementation. The default DOM implementation is used to parse an XML document when a vendor is not explicitly specified.

Tip: To obtain the IDOMImplementation (see page 7552) interface from DefaultDOMVendor, use the global GetDOMVendor (see page 7615) function.

Note: The value of DefaultDOMVendor should be the same as the value of the DefaultVendorName variable.

See Also

RegisterDOMVendor (see page 7617)

UnRegisterDOMVendor (see page 7618)

TXMLDocument (see page 7347)

GetDOMVendor (see page 7615)

DOMVendors (see page 7622)

80.5.2 xmldom.DOMVendors Variable

Lists all registered DOM Vendors.

Pascal

```
DOMVendors: TDOMVendorList;
```

C++

```
TDOMVendorList DOMVendors;
```

File

xmldom

Description

Use DOMVendors to determine all the DOM implementations currently registered with an application. For example, you can iterate through the Vendors property to obtain each registered TDOMVendor (see page 7514) object, which can then be used to extract its IDOMImplementation (see page 7552) interface or a descriptive string. Any of the TDOMVendor (see page 7514) objects in the list can be assigned as the DOMVendor property of an XML document component.

Do not add or delete vendors using this global variable: Instead, add and remove vendors by calling the RegisterDOMVendor (see page 7617) or UnRegisterDOMVendor (see page 7618) procedure.

See Also

RegisterDOMVendor (see page 7617)

UnRegisterDOMVendor (see page 7618)

TDOMVendor (see page 7514)

TXMLDocument (see page 7347)

GetDOMVendor (see page 7615)

DefaultDOMVendor (see page 7622)

80.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
ATTRIBUTE_NODE (see page 7624)	This is constant xmldom.ATTRIBUTE_NODE.
CDATA_SECTION_NODE (see page 7625)	This is constant xmldom.CDATA_SECTION_NODE.
COMMENT_NODE (see page 7625)	This is constant xmldom.COMMENT_NODE.
DOCUMENT_FRAGMENT_NODE (see page 7625)	This is constant xmldom.DOCUMENT_FRAGMENT_NODE.
DOCUMENT_NODE (see page 7626)	This is constant xmldom.DOCUMENT_NODE.
DOCUMENT_TYPE_NODE (see page 7626)	This is constant xmldom.DOCUMENT_TYPE_NODE.
DOMSTRING_SIZE_ERR (see page 7626)	This is constant xmldom.DOMSTRING_SIZE_ERR.
DOMWrapperVersion (see page 7627)	Indicates the version number for the vendor-neutral DOM interfaces.
ELEMENT_NODE (see page 7627)	This is constant xmldom.ELEMENT_NODE.
ENTITY_NODE (see page 7627)	This is constant xmldom.ENTITY_NODE.
ENTITY_REFERENCE_NODE (see page 7628)	This is constant xmldom.ENTITY_REFERENCE_NODE.
HIERARCHY_REQUEST_ERR (see page 7628)	This is constant xmldom.HIERARCHY_REQUEST_ERR.
INDEX_SIZE_ERR (see page 7628)	This is constant xmldom.INDEX_SIZE_ERR.
INUSE_ATTRIBUTE_ERR (see page 7629)	This is constant xmldom.INUSE_ATTRIBUTE_ERR.
INVALID_ACCESS_ERR (see page 7629)	This is constant xmldom.INVALID_ACCESS_ERR.
INVALID_CHARACTER_ERR (see page 7629)	This is constant xmldom.INVALID_CHARACTER_ERR.
INVALID_MODIFICATION_ERR (see page 7630)	This is constant xmldom.INVALID_MODIFICATION_ERR.
INVALID_STATE_ERR (see page 7630)	This is constant xmldom.INVALID_STATE_ERR.
NAMESPACE_ERR (see page 7630)	This is constant xmldom.NAMESPACE_ERR.
NO_DATA_ALLOWED_ERR (see page 7631)	This is constant xmldom.NO_DATA_ALLOWED_ERR.
NO_MODIFICATION_ALLOWED_ERR (see page 7631)	This is constant xmldom.NO_MODIFICATION_ALLOWED_ERR.
NOT_FOUND_ERR (see page 7631)	This is constant xmldom.NOT_FOUND_ERR.
NOT_SUPPORTED_ERR (see page 7632)	This is constant xmldom.NOT_SUPPORTED_ERR.
NOTATION_NODE (see page 7632)	This is constant xmldom.NOTATION_NODE.
NSDelim (see page 7632)	This is constant xmldom.NSDelim.
PROCESSING_INSTRUCTION_NODE (see page 7633)	This is constant xmldom.PROCESSING_INSTRUCTION_NODE.
SEncoding (see page 7633)	This is constant xmldom.SEncoding.
SHttp (see page 7633)	This is constant xmldom.SHttp.
SStandalone (see page 7634)	This is constant xmldom.SStandalone.
SVersion (see page 7634)	This is constant xmldom.SVersion.
SXML (see page 7634)	This is constant xmldom.SXML.
SXMLNamespaceURI (see page 7635)	This is constant xmldom.SXMLNamespaceURI.
SXMLNS (see page 7635)	This is constant xmldom.SXMLNS.
SXMLPrefixNamespaceURI (see page 7635)	This is constant xmldom.SXMLPrefixNamespaceURI.
SYNTAX_ERR (see page 7636)	This is constant xmldom.SYNTAX_ERR.
TEXT_NODE (see page 7636)	This is constant xmldom.TEXT_NODE.
WRONG_DOCUMENT_ERR (see page 7636)	This is constant xmldom.WRONG_DOCUMENT_ERR.

80.6.1 xmldom.ATTRIBUTE_NODE Constant

Pascal

```
ATTRIBUTE_NODE = 2;
```

C++

```
ATTRIBUTE_NODE = 2;
```

File

xmldom

Description

This is constant xmldom.ATTRIBUTE_NODE.

80.6.2 xmldom.CDATA_SECTION_NODE Constant

Pascal

```
CDATA_SECTION_NODE = 4;
```

C++

```
CDATA_SECTION_NODE = 4;
```

File

xmldom

Description

This is constant xmldom.CDATA_SECTION_NODE.

80.6.3 xmldom.COMMENT_NODE Constant

Pascal

```
COMMENT_NODE = 8;
```

C++

```
COMMENT_NODE = 8;
```

File

xmldom

Description

This is constant xmldom.COMMENT_NODE.

80.6.4 xmldom.DOCUMENT_FRAGMENT_NODE Constant

Pascal

```
DOCUMENT_FRAGMENT_NODE = 11;
```

C++

```
DOCUMENT_FRAGMENT_NODE = 11;
```

File

xmldom

Description

This is constant xmldom.DOCUMENT_FRAGMENT_NODE.

80.6.5 xmldom.DOCUMENT_NODE Constant

Pascal

```
DOCUMENT_NODE = 9;
```

C++

```
DOCUMENT_NODE = 9;
```

File

xmldom

Description

This is constant xmldom.DOCUMENT_NODE.

80.6.6 xmldom.DOCUMENT_TYPE_NODE Constant

Pascal

```
DOCUMENT_TYPE_NODE = 10;
```

C++

```
DOCUMENT_TYPE_NODE = 10;
```

File

xmldom

Description

This is constant xmldom.DOCUMENT_TYPE_NODE.

80.6.7 xmldom.DOMSTRING_SIZE_ERR Constant

Pascal

```
DOMSTRING_SIZE_ERR = 2;
```

C++

```
DOMSTRING_SIZE_ERR = 2;
```

File

xmldom

Description

This is constant xmldom.DOMSTRING_SIZE_ERR.

80.6.8 xmldom.DOMWrapperVersion Constant

Indicates the version number for the vendor-neutral DOM interfaces.

Pascal

```
DOMWrapperVersion = 1.3;
```

C++

```
DOMWrapperVersion = 1.3;
```

File

xmldom

Description

DOMWrapperVersion specifies the version number of the DOM interfaces (IDOMImplementation (see page 7552), IDOMNode (see page 7557), IDOMElement (see page 7542), and so on).

80.6.9 xmldom.ELEMENT_NODE Constant

Pascal

```
ELEMENT_NODE = 1;
```

C++

```
ELEMENT_NODE = 1;
```

File

xmldom

Description

This is constant xmldom.ELEMENT_NODE.

80.6.10 xmldom.ENTITY_NODE Constant

Pascal

```
ENTITY_NODE = 6;
```

C++

```
ENTITY_NODE = 6;
```

File

xmldom

Description

This is constant xmldom.ENTITY_NODE.

80.6.11 xmldom.ENTITY_REFERENCE_NODE Constant

Pascal

```
ENTITY_REFERENCE_NODE = 5;
```

C++

```
ENTITY_REFERENCE_NODE = 5;
```

File

xmldom

Description

This is constant xmldom.ENTITY_REFERENCE_NODE.

80.6.12 xmldom.HIERARCHY_REQUEST_ERR Constant

Pascal

```
HIERARCHY_REQUEST_ERR = 3;
```

C++

```
HIERARCHY_REQUEST_ERR = 3;
```

File

xmldom

Description

This is constant xmldom.HIERARCHY_REQUEST_ERR.

80.6.13 xmldom.INDEX_SIZE_ERR Constant

Pascal

```
INDEX_SIZE_ERR = 1;
```

C++

```
INDEX_SIZE_ERR = 1;
```

File

xmldom

Description

This is constant xmldom.INDEX_SIZE_ERR.

80.6.14 xmldom.INUSE_ATTRIBUTE_ERR Constant

Pascal

```
INUSE_ATTRIBUTE_ERR = 10;
```

C++

```
INUSE_ATTRIBUTE_ERR = 10;
```

File

xmldom

Description

This is constant xmldom.INUSE_ATTRIBUTE_ERR.

80.6.15 xmldom.INVALID_ACCESS_ERR Constant

Pascal

```
INVALID_ACCESS_ERR = 15;
```

C++

```
INVALID_ACCESS_ERR = 15;
```

File

xmldom

Description

This is constant xmldom.INVALID_ACCESS_ERR.

80.6.16 xmldom.INVALID_CHARACTER_ERR Constant

Pascal

```
INVALID_CHARACTER_ERR = 5;
```

C++

```
INVALID_CHARACTER_ERR = 5;
```

File

xmldom

Description

This is constant xmldom.INVALID_CHARACTER_ERR.

80.6.17 xmldom.INVALID_MODIFICATION_ERR Constant

Pascal

```
INVALID_MODIFICATION_ERR = 13;
```

C++

```
INVALID_MODIFICATION_ERR = 13;
```

File

xmldom

Description

This is constant xmldom.INVALID_MODIFICATION_ERR.

80.6.18 xmldom.INVALID_STATE_ERR Constant

Pascal

```
INVALID_STATE_ERR = 11;
```

C++

```
INVALID_STATE_ERR = 11;
```

File

xmldom

Description

This is constant xmldom.INVALID_STATE_ERR.

80.6.19 xmldom.NAMESPACE_ERR Constant

Pascal

```
NAMESPACE_ERR = 14;
```

C++

```
NAMESPACE_ERR = 14;
```

File

xmldom

Description

This is constant xmldom.NAMESPACE_ERR.

80.6.20 xmldom.NO_DATA_ALLOWED_ERR Constant

Pascal

```
NO_DATA_ALLOWED_ERR = 6;
```

C++

```
NO_DATA_ALLOWED_ERR = 6;
```

File

xmldom

Description

This is constant xmldom.NO_DATA_ALLOWED_ERR.

80.6.21 xmldom.NO_MODIFICATION_ALLOWED_ERR Constant

Pascal

```
NO_MODIFICATION_ALLOWED_ERR = 7;
```

C++

```
NO_MODIFICATION_ALLOWED_ERR = 7;
```

File

xmldom

Description

This is constant xmldom.NO_MODIFICATION_ALLOWED_ERR.

80.6.22 xmldom.NOT_FOUND_ERR Constant

Pascal

```
NOT_FOUND_ERR = 8;
```

C++

```
NOT_FOUND_ERR = 8;
```

File

xmldom

Description

This is constant xmldom.NOT_FOUND_ERR.

80.6.23 xmldom.NOT_SUPPORTED_ERR Constant

Pascal

```
NOT_SUPPORTED_ERR = 9;
```

C++

```
NOT_SUPPORTED_ERR = 9;
```

File

xmldom

Description

This is constant xmldom.NOT_SUPPORTED_ERR.

80.6.24 xmldom.NOTATION_NODE Constant

Pascal

```
NOTATION_NODE = 12;
```

C++

```
NOTATION_NODE = 12;
```

File

xmldom

Description

This is constant xmldom.NOTATION_NODE.

80.6.25 xmldom.NSDelim Constant

Pascal

```
NSDelim = ':';
```

C++

```
NSDelim = ':';
```

File

xmldom

Description

This is constant xmldom.NSDelim.

80.6.26 xmldom.PROCESSING_INSTRUCTION_NODE Constant

Pascal

```
PROCESSING_INSTRUCTION_NODE = 7;
```

C++

```
PROCESSING_INSTRUCTION_NODE = 7;
```

File

xmldom

Description

This is constant xmldom.PROCESSING_INSTRUCTION_NODE.

80.6.27 xmldom.SEncoding Constant

Pascal

```
SEncoding = 'encoding';
```

C++

```
SEncoding = 'encoding';
```

File

xmldom

Description

This is constant xmldom.SEncoding.

80.6.28 xmldom.SHttp Constant

Pascal

```
SHttp = 'http:/';
```

C++

```
SHttp = 'http:/';
```

File

xmldom

Description

This is constant xmldom.SHttp.

80.6.29 xmldom.SStandalone Constant

Pascal

```
SStandalone = 'standalone';
```

C++

```
SStandalone = 'standalone';
```

File

xmldom

Description

This is constant xmldom.SStandalone.

80.6.30 xmldom.SVersion Constant

Pascal

```
SVersion = 'version';
```

C++

```
SVersion = 'version';
```

File

xmldom

Description

This is constant xmldom.SVersion.

80.6.31 xmldom.SXML Constant

Pascal

```
SXML = 'xml';
```

C++

```
SXML = 'xml';
```

File

xmldom

Description

This is constant xmldom.SXML.

80.6.32 xmldom.SXMLNamespaceURI Constant

Pascal

```
SXMLNamespaceURI = SHttp+'/www.w3.org/2000/xmlns/';
```

C++

```
SXMLNamespaceURI = SHttp+'/www.w3.org/2000/xmlns/';
```

File

xmldom

Description

This is constant xmldom.SXMLNamespaceURI.

80.6.33 xmldom.SXMLNS Constant

Pascal

```
SXMLNS = 'xmlns';
```

C++

```
SXMLNS = 'xmlns';
```

File

xmldom

Description

This is constant xmldom.SXMLNS.

80.6.34 xmldom.SXMLPrefixNamespaceURI Constant

Pascal

```
SXMLPrefixNamespaceURI = SHttp+'/www.w3.org/XML/1998/namespace';
```

C++

```
SXMLPrefixNamespaceURI = SHttp+'/www.w3.org/XML/1998/namespace';
```

File

xmldom

Description

This is constant xmldom.SXMLPrefixNamespaceURI.

80.6.35 xmldom.SYNTAX_ERR Constant

Pascal

```
SYNTAX_ERR = 12;
```

C++

```
SYNTAX_ERR = 12;
```

File

xmldom

Description

This is constant xmldom.SYNTAX_ERR.

80.6.36 xmldom.TEXT_NODE Constant

Pascal

```
TEXT_NODE = 3;
```

C++

```
TEXT_NODE = 3;
```

File

xmldom

Description

This is constant xmldom.TEXT_NODE.

80.6.37 xmldom.WRONG_DOCUMENT_ERR Constant

Pascal

```
WRONG_DOCUMENT_ERR = 4;
```

C++

```
WRONG_DOCUMENT_ERR = 4;
```

File

xmldom

Description

This is constant xmldom.WRONG_DOCUMENT_ERR.

81 XMLIntf Namespace

This is namespace XMLIntf.

Topics

Name	Description
Classes (see page 7639)	The following table lists classes in this documentation.
Interfaces (see page 7640)	The following table lists interfaces in this documentation.
Structs, Records, Enums (see page 7716)	The following table lists structs, records, enums in this documentation.
Types (see page 7721)	The following table lists types in this documentation.
Constants (see page 7723)	The following table lists constants in this documentation.

Classes

	Name	Description
	EXMLDocError (see page 7639)	EXMLDocError is the exception class for errors editing or parsing an XML document.

Constants

Name	Description
NodeTypeNames (see page 7723)	This is constant XMLIntf.NodeTypeNames.

Interfaces

	Name	Description
	IXMLDocument (see page 7640)	IXMLDocument represents an XML (see page 7668) document.
	IXMLNode (see page 7669)	IXMLNode is the interface for a node in an XML (see page 7697) document.
	IXMLNodeCollection (see page 7698)	IXMLNodeCollection is the interface for a set of child nodes that are all the same type.
	IXMLNodeList (see page 7703)	IXMLNodeList represents a set of nodes in an XML document.

Structs, Records, Enums

	Name	Description
	TNodeType (see page 7716)	TNodeType identifies the type of a node in an XML document.
	TParseOption (see page 7718)	TParseOption and TParseOptions (see page 7721) represent implementation-specific options that are followed when parsing the XML document.
	TXMLDocOption (see page 7718)	TXMLDocOption and TXMLDocOptions (see page 7722) indicate types of information that an XML document automatically supplies.
	TXMLEncodingType (see page 7719)	TXMLEncodingType indicates the character set used to encode characters in an XML document.

Types

Name	Description
TParseOptions (see page 7721)	TParseOptions and TParseOption (see page 7718) represent implementation-specific options that are followed when parsing the XML document.
TXMLDocOptions (see page 7722)	This is type XMLIntf.TXMLDocOptions.

81.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EXMLDocError (see page 7639)	EXMLDocError is the exception class for errors editing or parsing an XML document.

81.1.1 EXMLDocError Class

EXMLDocError is the exception class for errors editing or parsing an XML document.

Class Hierarchy

Pascal

```
EXMLDocError = class(Exception);
```

C++

```
class EXMLDocError : public Exception;
```

File

XMLIntf

Description

EXMLDocError is raised by TXMLDocument or TXMLNode when

An error occurs when loading an XML document.

An error occurs when creating a node in an XML document.

A required DOM interface is not found.

An option is requested that is not supported by the DOM implementation.

An attempt is made to perform an action that is not consistent with the specified node type.

See Also

XMLDocError (see page 7492)

TXMLDocument (see page 7347)

TXMLNode (see page 7396)

81.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IXMLDocument (see page 7640)	IXMLDocument represents an XML (see page 7668) document.
	IXMLNode (see page 7669)	IXMLNode is the interface for a node in an XML (see page 7697) document.
	IXMLNodeCollection (see page 7698)	IXMLNodeCollection is the interface for a set of child nodes that are all the same type.
	IXMLNodeList (see page 7703)	IXMLNodeList represents a set of nodes in an XML document.

81.2.1 IXMLDocument Interface

IXMLDocument represents an XML (see page 7668) document.

Class Hierarchy

Pascal

```
IXMLDocument = interface(IInterface);
```

C++

```
__interface IXMLDocument : public IInterface;
```

File

XMLIntf

Description

Use IXMLDocument to work with an XML (see page 7668) document. Applications can obtain an IXMLDocument interface through a TXMLDocument component, using the global LoadXMLDocument function, or through the OwnerDocument property of any node in the document.

Like the related DOM interface IDOMDocument (see page 7530), you can use IXMLDocument to access the contents of an XML (see page 7668) document and to create new nodes. In addition, IXMLDocument lets you load an XML (see page 7668) document that is stored on disk or assign a string of raw (unparsed) XML (see page 7668) as the contents of the document.

TXMLDocument implements the IXMLDocument interface. Typically, the TXMLDocument component is the starting point for working with an XML (see page 7668) document.

Note: C++ method declarations that use IXMLDocument use the _di_IXMLDocument type instead. This type is a DelphiInterface (see page 3256) wrapper around the IXMLDocument interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IXMLDocument >  _di_IXMLDocument;
```

See Also

IXMLNode (see page 7669)

EXMLDocError (see page 7639)

TXMLDocument (see page 7347)

LoadXMLDocument (see page 7491)

81.2.1.1 IXMLDocument Members

The following tables list the members exposed by IXMLDocument.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AddChild (see page 7643)	This is the overview for the AddChild method overload.
	CreateElement (see page 7644)	Creates a new element node that is associated with this document.
	CreateNode (see page 7645)	Creates a new node that is associated with this document.
	GeneratePrefix (see page 7646)	Generates a unique namespace prefix that can be used for a node in the document.
	GetActive (see page 7646)	Returns the value of the Active (see page 7661) property.
	GetAsyncLoadState (see page 7647)	Returns the value of the AsyncLoadState (see page 7662) property.
	GetChildNodes (see page 7647)	Returns the value of the ChildNodes (see page 7663) property.
	GetDocBinding (see page 7647)	Replaces a specified child node with an instance of a specified implementation class.
	GetDocumentElement (see page 7648)	Returns the value of the DocumentElement (see page 7663) property.
	GetDocumentNode (see page 7648)	Returns the value of the Node (see page 7665) property.
	GetDOMDocument (see page 7648)	Returns the value of the DOMDocument (see page 7663) property.
	GetEncoding (see page 7649)	Returns the value of the Encoding (see page 7664) property.
	GetFileName (see page 7649)	Returns the value of the FileName (see page 7664) property.
	GetModified (see page 7649)	Returns the value of the Modified (see page 7665) property.
	GetNodeIndentStr (see page 7650)	Returns the value of the NodeIndentStr (see page 7666) property.
	GetOptions (see page 7650)	Returns the value of the Options (see page 7666) property.
	GetParseOptions (see page 7650)	Returns the value of the ParseOptions (see page 7667) property.
	GetSchemaRef (see page 7650)	Returns the value of the SchemaRef (see page 7667) property.
	GetStandAlone (see page 7651)	Returns the value of the StandAlone (see page 7668) property.
	GetVersion (see page 7651)	Returns the value of the Version (see page 7668) property.
	GetXML (see page 7651)	Returns the value of the XML (see page 7668) property.
	IsEmptyDoc (see page 7652)	Indicates whether the IXMLDocument (see page 7640) instance represents an empty document.
	LoadFromFile (see page 7652)	Loads an XML (see page 7668) document from disk.
	LoadFromStream (see page 7653)	Loads an XML (see page 7668) document from a stream and activates it.
	LoadFromXML (see page 7653)	This is the overview for the LoadFromXML method overload.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	Refresh (see page 7654)	Updates the parsed XML (see page 7668) document to reflect external changes.
	RegisterDocBinding (see page 7654)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7655)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7655)	Saves the XML (see page 7668) document to disk.
	SaveToStream (see page 7656)	Saves the XML (see page 7668) document to a stream.
	SaveToXML (see page 7656)	This is the overview for the SaveToXML method overload.
	SetActive (see page 7657)	Sets the value of the Active (see page 7661) property.
	SetDocumentElement (see page 7657)	Sets the value of the DocumentElement (see page 7663) property.
	SetDOMDocument (see page 7658)	Sets the value of the DOMDocument (see page 7663) property.
	SetEncoding (see page 7658)	Sets the value of the Encoding (see page 7664) property.

	SetFileName (see page 7658)	Sets the value of the FileName (see page 7664) property.
	SetNodeIndentStr (see page 7659)	Sets the value of the NodeIndentStr (see page 7666) property.
	SetOnAsyncLoad (see page 7659)	Supplies an event handler that responds when the AsyncLoadState (see page 7662) property changes.
	SetOptions (see page 7659)	Sets the value of the Options (see page 7666) property.
	SetParseOptions (see page 7660)	Sets the value of the ParseOptions (see page 7667) property.
	SetStandAlone (see page 7660)	Sets the value of the StandAlone (see page 7668) property.
	SetVersion (see page 7660)	Sets the value of the Version (see page 7668) property.
	SetXML (see page 7661)	Sets the value of the XML (see page 7668) property.

Public Properties

	Name	Description
	Active (see page 7661)	Specifies whether the XML (see page 7668) document has been parsed so that the DOM interfaces are available to examine or change its contents.
R	AsyncLoadState (see page 7662)	Indicates the state of the DOM parser when it parses the XML (see page 7668) document asynchronously.
R	ChildNodes (see page 7663)	Lists all of the child nodes of the document.
	DocumentElement (see page 7663)	Provides access to the root node of the XML (see page 7668) document.
	DOMDocument (see page 7663)	Provides access to the DOM interface for the parsed XML (see page 7668) document.
	Encoding (see page 7664)	Indicates the character set that the XML (see page 7668) document uses to encode characters.
	FileName (see page 7664)	Indicates the XML (see page 7668) document file, if any, that this interface represents.
R	Modified (see page 7665)	Indicates whether the XML (see page 7668) document has been modified.
R	Node (see page 7665)	Provides access to the document node for the XML (see page 7668) document.
	NodeIndentStr (see page 7666)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7668) text.
	Options (see page 7666)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7667)	Specifies implementation-specific options that are followed when parsing the XML (see page 7668) document.
R	SchemaRef (see page 7667)	Returns the name of the schema associated with this XML (see page 7668) document.
	StandAlone (see page 7668)	Indicates whether the XML (see page 7668) document includes any external markup declarations.
	Version (see page 7668)	Indicates the XML (see page 7668) version that the document uses.
	XML (see page 7668)	Specifies the content of the XML document associated with this IXMLDocument (see page 7640) interface.

81.2.1.2 IXMLDocument Methods

The methods of the IXMLDocument class are listed here.

Public Methods

	Name	Description
	AddChild (see page 7643)	This is the overview for the AddChild method overload.
	CreateElement (see page 7644)	Creates a new element node that is associated with this document.
	CreateNode (see page 7645)	Creates a new node that is associated with this document.
	GeneratePrefix (see page 7646)	Generates a unique namespace prefix that can be used for a node in the document.
	GetActive (see page 7646)	Returns the value of the Active (see page 7661) property.
	GetAsyncLoadState (see page 7647)	Returns the value of the AsyncLoadState (see page 7662) property.
	GetChildNodes (see page 7647)	Returns the value of the ChildNodes (see page 7663) property.
	GetDocBinding (see page 7647)	Replaces a specified child node with an instance of a specified implementation class.
	GetDocumentElement (see page 7648)	Returns the value of the DocumentElement (see page 7663) property.

	GetDocumentNode (see page 7648)	Returns the value of the Node (see page 7665) property.
	GetDOMDocument (see page 7648)	Returns the value of the DOMDocument (see page 7663) property.
	GetEncoding (see page 7649)	Returns the value of the Encoding (see page 7664) property.
	GetFileName (see page 7649)	Returns the value of the FileName (see page 7664) property.
	GetModified (see page 7649)	Returns the value of the Modified (see page 7665) property.
	GetNodeIndentStr (see page 7650)	Returns the value of the NodeIndentStr (see page 7666) property.
	GetOptions (see page 7650)	Returns the value of the Options (see page 7666) property.
	GetParseOptions (see page 7650)	Returns the value of the ParseOptions (see page 7667) property.
	GetSchemaRef (see page 7650)	Returns the value of the SchemaRef (see page 7667) property.
	GetStandAlone (see page 7651)	Returns the value of the StandAlone (see page 7668) property.
	GetVersion (see page 7651)	Returns the value of the Version (see page 7668) property.
	GetXML (see page 7651)	Returns the value of the XML (see page 7668) property.
	IsEmptyDoc (see page 7652)	Indicates whether the IXMLDocument (see page 7640) instance represents an empty document.
	LoadFromFile (see page 7652)	Loads an XML (see page 7668) document from disk.
	LoadFromStream (see page 7653)	Loads an XML (see page 7668) document from a stream and activates it.
	LoadFromXML (see page 7653)	This is the overview for the LoadFromXML method overload.
	Refresh (see page 7654)	Updates the parsed XML (see page 7668) document to reflect external changes.
	RegisterDocBinding (see page 7654)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7655)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7655)	Saves the XML (see page 7668) document to disk.
	SaveToStream (see page 7656)	Saves the XML (see page 7668) document to a stream.
	SaveToXML (see page 7656)	This is the overview for the SaveToXML method overload.
	SetActive (see page 7657)	Sets the value of the Active (see page 7661) property.
	SetDocumentElement (see page 7657)	Sets the value of the DocumentElement (see page 7663) property.
	SetDOMDocument (see page 7658)	Sets the value of the DOMDocument (see page 7663) property.
	SetEncoding (see page 7658)	Sets the value of the Encoding (see page 7664) property.
	SetFileName (see page 7658)	Sets the value of the FileName (see page 7664) property.
	SetNodeIndentStr (see page 7659)	Sets the value of the NodeIndentStr (see page 7666) property.
	SetOnAsyncLoad (see page 7659)	Supplies an event handler that responds when the AsyncLoadState (see page 7662) property changes.
	SetOptions (see page 7659)	Sets the value of the Options (see page 7666) property.
	SetParseOptions (see page 7660)	Sets the value of the ParseOptions (see page 7667) property.
	SetStandAlone (see page 7660)	Sets the value of the StandAlone (see page 7668) property.
	SetVersion (see page 7660)	Sets the value of the Version (see page 7668) property.
	SetXML (see page 7661)	Sets the value of the XML (see page 7668) property.

81.2.1.2.1 AddChild Method

This is the overview for the AddChild method overload.

Overload List

	Name	Description
	IXMLDocument.AddChild (DOMString) (see page 7643)	Creates and adds a node to the child nodes of this document.
	IXMLDocument.AddChild (DOMString, DOMString) (see page 7643)	Creates and adds a node to the child nodes of this document.

81.2.1.2.1.1 IXMLDocument.AddChild Method (DOMString)

Creates and adds a node to the child nodes of this document.

Pascal

```
function AddChild(const TagName: DOMString): IXMLNode; overload;
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode AddChild(const DOMString TagName);
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI);
```

Description

Call AddChild to add a new child element node to the document itself. The new node is added to the end of the list maintained by the ChildNodes (see page 7663) property.

TagName is the tag name for the new element node.

NamespaceURI identifies the namespace, if any, that includes the new node's definition.

AddChild returns the interface for the newly created node.

Note: Do not call AddChild to add a child to the document element of this document. When adding data to the XML (see page 7668) document, use the AddChild method of the document element or of the node in the hierarchy that should be the parent of the new node.

See Also

AddChild (see page 7672)

CreateNode (see page 7645)

CreateElement (see page 7644)

ChildNodes (see page 7663)

DocumentElement (see page 7663)

81.2.1.2.2 IXMLDocument.CreateElement Method

Creates a new element node that is associated with this document.

Pascal

```
function CreateElement(const TagOrData: DOMString; const NamespaceURI: DOMString): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateElement(const DOMString TagOrData, const DOMString NamespaceURI);
```

Description

Call CreateElement to create a new generic element node. The resulting node does not have a parent, but can be added to the ChildNodes (see page 7663) list of any node in the document (including this document's ChildNodes (see page 7663) property). It can also be assigned to the DocumentElement (see page 7663) property to replace the entire data hierarchy of this document.

TagOrData provides the tag name of the newly created node.

NamespaceURI identifies the namespace that includes the new node's definition.

CreateElement returns the interface for the new node.

Note: To add a node as the child of another node in this document, it is simpler to call that node's AddChild (see page 7643) method.

See Also

AddChild (see page 7672)

ChildNodes (see page 7663)

DocumentElement (see page 7663)

AddChild (see page 7643)

CreateNode (see page 7645)

81.2.1.2.3 IXMLDocument.CreateNode Method

Creates a new node that is associated with this document.

Pascal

```
function CreateNode(const NameOrData: DOMString; NodeType: TNodeType = ntElement; const
AddlData: DOMString = ''): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateNode(const DOMString NameOrData, TNodeType NodeType = ntElement,
const DOMString AddlData = '');
```

Description

Call CreateNode to create a new generic XML (see page 7668) node. The resulting node does not have a parent, but can be added to the ChildNodes (see page 7663) or AttributeNodes list of any node in the document (including this document's ChildNodes (see page 7663) property).

NameOrData provides the tag name or value of the newly created node. Its interpretation depends on the type of node created, as indicated in the following table:

NodeType	NameOrData
ntElement	The tag name.
ntAttribute	The attribute name.
ntText	The value of the node.
ntCData	The value of the CDATA section.
ntEntityRef	The name of the referenced entity.
ntProcessingInstr	The target of the processing instruction.
ntComment	The value (text) of the comment.
ntDocFragment	Not used.
ntElement	The namespace URI that qualifies the tag name.
ntAttribute	The namespace URI that qualifies the attribute name.
ntProcessingInstr	The content of the processing instruction, except for the target.

NodeType indicates the type of node to create. It can only be one of the types listed in the previous table.

The meaning of AddlData depends on the node type, as indicated in the following table:

NodeType	AddlData
ntElement	The namespace URI that qualifies the tag name.
ntAttribute	The namespace URI that qualifies the attribute name.

ntProcessingInstr	The content of the processing instruction, except for the target.

CreateNode returns the interface for the new node.

Note: To add a node as the child of another node in this document, it is simpler to call that node's AddChild (see page 7643) method.

See Also

AddChild (see page 7672)

ChildNodes (see page 7663)

AttributeNodes (see page 7688)

DocumentElement (see page 7663)

CreateElement (see page 7644)

AddChild (see page 7643)

81.2.1.2.4 IXMLDocument.GeneratePrefix Method

Generates a unique namespace prefix that can be used for a node in the document.

Pascal

```
function GeneratePrefix(const Node: IXMLNode): DOMString;
```

C++

```
__fastcall DOMString GeneratePrefix(const IXMLNode Node);
```

Description

The AddChild (see page 7643) method for each node allows the caller to specify that the new node should use an automatically-generated namespace prefix. When this option is specified, the node calls GeneratePrefix to generate a unique string to act as a namespace prefix.

Node (see page 7665) is the interface for the node which will use the newly-generated namespace prefix.

GeneratePrefix returns a unique string that is not already used in the document to represent a namespace URI. The generated namespace prefixes are only unique within a single document.

See Also

AddChild (see page 7672)

81.2.1.2.5 IXMLDocument.GetActive Method

Returns the value of the Active (see page 7661) property.

Pascal

```
function GetActive: Boolean;
```

C++

```
__fastcall Boolean GetActive();
```

Description

GetActive is the read implementation of the Active (see page 7661) property.

See Also

Active (see page 7661)

81.2.1.2.6 IXMLDocument.GetAsyncLoadState Method

Returns the value of the AsyncLoadState (see page 7662) property.

Pascal

```
function GetAsyncLoadState: Integer;
```

C++

```
__fastcall int GetAsyncLoadState();
```

Description

GetAsyncLoadState is the read implementation of the AsyncLoadState (see page 7662) property.

See Also

AsyncLoadState (see page 7662)

81.2.1.2.7 IXMLDocument.GetChildNodes Method

Returns the value of the ChildNodes (see page 7663) property.

Pascal

```
function GetChildNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetChildNodes();
```

Description

GetChildNodes is the read implementation of the ChildNodes (see page 7663) property.

See Also

ChildNodes (see page 7663)

81.2.1.2.8 IXMLDocument.GetDocBinding Method

Replaces a specified child node with an instance of a specified implementation class.

Pascal

```
function GetDocBinding(const TagName: DOMString; DocNodeClass: TClass; NamespaceURI: DOMString
= ''): IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocBinding(const DOMString TagName, TClass DocNodeClass, DOMString
NamespaceURI = '');
```

Description

Call GetDocBinding to specify the implementation class for one of the child nodes of the document node. After replacing the specified node with an instance of the specified class, GetDocBinding returns the interface of the document element.

TagName is the tag name of the child node to be replaced. Typically, this identifies the document element.

DocNodeClass is the implementation class to use for all child nodes with the specified tag name.

NamespaceURI is the URI of the namespace in which TagName is defined.

See Also

DocumentElement (see page 7663)

RegisterDocBinding (see page 7654)

ChildNodes (see page 7663)

81.2.1.2.9 IXMLDocument.GetDocumentElement Method

Returns the value of the DocumentElement (see page 7663) property.

Pascal

```
function GetDocumentElement: IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocumentElement();
```

Description

GetDocumentElement is the read implementation of the DocumentElement (see page 7663) property.

See Also

DocumentElement (see page 7663)

81.2.1.2.10 IXMLDocument.GetDocumentNode Method

Returns the value of the Node (see page 7665) property.

Pascal

```
function GetDocumentNode: IXMLNode;
```

C++

```
__fastcall IXMLNode GetDocumentNode();
```

Description

GetDocumentNode is the read implementation of the Node (see page 7665) property.

See Also

Node (see page 7665)

81.2.1.2.11 IXMLDocument.GetDOMDocument Method

Returns the value of the DOMDocument (see page 7663) property.

Pascal

```
function GetDOMDocument: IDOMDocument;
```

C++

```
__fastcall IDOMDocument GetDOMDocument();
```

Description

GetDOMDocument is the read implementation of the DOMDocument (see page 7663) property.

See Also

DOMDocument (see page 7663)

81.2.1.2.12 IXMLDocument.GetEncoding Method

Returns the value of the Encoding (see page 7664) property.

Pascal

```
function GetEncoding: DOMString;
```

C++

```
__fastcall DOMString GetEncoding();
```

Description

GetEncoding is the read implementation of the Encoding (see page 7664) property.

See Also

Encoding (see page 7664)

81.2.1.2.13 IXMLDocument.GetFileName Method

Returns the value of the FileName (see page 7664) property.

Pascal

```
function GetFileName: DOMString;
```

C++

```
__fastcall DOMString GetFileName();
```

Description

GetFileName is the read implementation of the FileName (see page 7664) property.

See Also

FileName (see page 7664)

81.2.1.2.14 IXMLDocument.GetModified Method

Returns the value of the Modified (see page 7665) property.

Pascal

```
function GetModified: Boolean;
```

C++

```
__fastcall Boolean GetModified();
```

Description

GetModified is the read implementation of the Modified (see page 7665) property.

See Also

Modified (see page 7665)

81.2.1.2.15 IXMLDocument.GetNodeIndentStr Method

Returns the value of the NodeIndentStr (see page 7666) property.

Pascal

```
function GetNodeIndentStr: DOMString;
```

C++

```
__fastcall DOMString GetNodeIndentStr();
```

Description

GetNodeIndentStr is the read implementation of the NodeIndentStr (see page 7666) property.

See Also

NodeIndentStr (see page 7666)

81.2.1.2.16 IXMLDocument.GetOptions Method

Returns the value of the Options (see page 7666) property.

Pascal

```
function GetOptions: TXMLDocOptions;
```

C++

```
__fastcall TXMLDocOptions GetOptions();
```

Description

GetOptions is the read implementation of the Options (see page 7666) property.

See Also

Options (see page 7666)

81.2.1.2.17 IXMLDocument.GetParseOptions Method

Returns the value of the ParseOptions (see page 7667) property.

Pascal

```
function GetParseOptions: TParseOptions;
```

C++

```
__fastcall TParseOptions GetParseOptions();
```

Description

GetParseOptions is the read implementation of the ParseOptions (see page 7667) property.

See Also

ParseOptions (see page 7667)

81.2.1.2.18 IXMLDocument.GetSchemaRef Method

Returns the value of the SchemaRef (see page 7667) property.

Pascal

```
function GetSchemaRef: DOMString;
```

C++

```
__fastcall DOMString GetSchemaRef();
```

Description

GetSchemaRef is the read implementation of the SchemaRef (see page 7667) property.

See Also

SchemaRef (see page 7667)

81.2.1.2.19 IXMLDocument.GetStandAlone Method

Returns the value of the StandAlone (see page 7668) property.

Pascal

```
function GetStandAlone: DOMString;
```

C++

```
__fastcall DOMString GetStandAlone();
```

Description

GetStandAlone is the read implementation of the StandAlone (see page 7668) property.

See Also

StandAlone (see page 7668)

81.2.1.2.20 IXMLDocument.GetVersion Method

Returns the value of the Version (see page 7668) property.

Pascal

```
function GetVersion: DOMString;
```

C++

```
__fastcall DOMString GetVersion();
```

Description

GetVersion is the read implementation of the Version (see page 7668) property.

See Also

Version (see page 7668)

81.2.1.2.21 IXMLDocument.GetXML Method

Returns the value of the XML (see page 7668) property.

Pascal

```
function GetXML: TStrings;
```

C++

```
__fastcall TStrings GetXML();
```

Description

GetXML is the read implementation of the XML (see page 7668) property.

See Also

XML (see page 7668)

81.2.1.2.22 IXMLDocument.IsEmptyDoc Method

Indicates whether the IXMLDocument (see page 7640) instance represents an empty document.

Pascal

```
function IsEmptyDoc: Boolean;
```

C++

```
__fastcall Boolean IsEmptyDoc();
```

Description

Call IsEmptyDoc to determine whether the IXMLDocument (see page 7640) instance represents an empty document. IsEmptyDoc returns true if the DOMDocument (see page 7663) property is not set (for example, if there is no DOM implementation) or if this interface represents a document with no child nodes.

See Also

XML (see page 7668)

ChildNodes (see page 7663)

DOMDocument (see page 7663)

81.2.1.2.23 IXMLDocument.LoadFromFile Method

Loads an XML (see page 7668) document from disk.

Pascal

```
procedure LoadFromFile(const AFileName: DOMString);
```

C++

```
__fastcall LoadFromFile(const DOMString AFileName);
```

Description

Call LoadFromFile to load the XML (see page 7668) document specified by AFileName so that you can examine or modify it.

AFileName is the name of the file to load.

Once you have loaded an XML (see page 7668) document, any changes you make to the document are not saved back to disk until you call the SaveToFile (see page 7655) method.

See Also

SaveToFile (see page 7655)

XML (see page 7668)

FileName (see page 7664)

81.2.1.2.24 IXMLDocument.LoadFromStream Method

Loads an XML (see page 7668) document from a stream and activates it.

Pascal

```
procedure LoadFromStream(const Stream: TStream; EncodingType: TXMLEncodingType = xetUnknown);
```

C++

```
__fastcall LoadFromStream(const TStream Stream, TXMLEncodingType EncodingType = xetUnknown);
```

Description

Call LoadFromStream to load the XML (see page 7668) document from a stream.

Stream is a stream object that can be used to read the string of XML (see page 7668) that makes up the document.

EncodingType indicates the character set that is used for Stream. If EncodingType is xetUnknown (the default), LoadFromStream attempts to infer the encoding type from the XML (see page 7668) encoding declaration at the beginning of the document.

After loading the document from Stream, LoadFromStream sets the Active (see page 7661) property to true.

See Also

SaveToStream (see page 7656)

LoadFromFile (see page 7652)

LoadFromXML (see page 7653)

Active (see page 7661)

81.2.1.2.25 LoadFromXML Method

This is the overview for the LoadFromXML method overload.

Overload List

	Name	Description
	IXMLDocument.LoadFromXML (AnsiString) (see page 7653)	Loads a string representation of an XML (see page 7668) document and activates it.
	IXMLDocument.LoadFromXML (DOMString) (see page 7653)	Loads a string representation of an XML (see page 7668) document and activates it.

81.2.1.2.25.1 IXMLDocument.LoadFromXML Method (AnsiString)

Loads a string representation of an XML (see page 7668) document and activates it.

Pascal

```
procedure LoadFromXML(const XML: AnsiString); overload;
procedure LoadFromXML(const XML: DOMString); overload;
```

C++

```
__fastcall LoadFromXML(const AnsiString XML);
__fastcall LoadFromXML(const DOMString XML);
```

Description

Call LoadFromXML to assign a string as the value of the XML (see page 7668) document. Unlike the XML (see page 7668)

property, which lets you assign XML (see page 7668) on a line-by-line basis, LoadFromXML treats the text of the XML (see page 7668) document as a whole.

After assigning the XML (see page 7668) property as the contents of the document, LoadFromXML sets the Active (see page 7661) property to true.

See Also

SaveToXML (see page 7656)

LoadFromFile (see page 7652)

Active (see page 7661)

LoadFromStream (see page 7653)

XML (see page 7668)

81.2.1.2.26 IXMLDocument.Refresh Method

Updates the parsed XML (see page 7668) document to reflect external changes.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh when the XML (see page 7668) document specified by FileName (see page 7664) has changed due to an external cause. Refresh updates the parsed version of the XML (see page 7668) document (which can be traversed starting with DocumentElement (see page 7663)) to reflect the current contents of the file specified by FileName (see page 7664).

The Active (see page 7661) property must be true when you call Refresh.

Note: Do not call Refresh after making changes directly to the XML (see page 7668) property, because assigning a value to XML (see page 7668) automatically closes the XML (see page 7668) document. To refresh the XML (see page 7668) document after assigning a new value to XML (see page 7668), set the Active (see page 7661) property to true.

See Also

FileName (see page 7664)

Active (see page 7661)

DOMDocument (see page 7663)

DocumentElement (see page 7663)

Resync (see page 7655)

81.2.1.2.27 IXMLDocument.RegisterDocBinding Method

Registers an implementation class for child nodes with a specified tag name.

Pascal

```
procedure RegisterDocBinding(const TagName: DOMString; DocNodeClass: TClass; NamespaceURI:
DOMString = '');
```

C++

```
__fastcall RegisterDocBinding(const DOMString TagName, TClass DocNodeClass, DOMString
NamespaceURI = '');
```

Description

Call RegisterDocBinding to specify the implementation class for one of the child nodes of the document node. RegisterDocBinding replaces the specified node with an instance of the specified class.

TagName is the tag name of the child node to be replaced. Typically, this identifies the document element.

DocNodeClass is the implementation class to use for all child nodes with the specified tag name.

NamespaceURI is the URI of the namespace in which TagName is defined.

See Also

DocumentElement (see page 7663)

GetDocBinding (see page 7647)

ChildNodes (see page 7663)

81.2.1.2.28 IXMLDocument.Resync Method

Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.

Pascal

```
procedure Resync;
```

C++

```
__fastcall Resync();
```

Description

Resync forces the document to reread the values of its child nodes and attribute nodes, discarding any changes that have not been propagated to the underlying DOM implementation.

See Also

ChildNodes (see page 7663)

81.2.1.2.29 IXMLDocument.SaveToFile Method

Saves the XML (see page 7668) document to disk.

Pascal

```
procedure SaveToFile(const AFileName: DOMString);
```

C++

```
__fastcall SaveToFile(const DOMString AFileName);
```

Description

Call SaveToFile to save any modifications you have made to the parsed XML (see page 7668) document.

AFileName is the name of the file to save.

Tip: To save the modifications back to the file from which the document was originally read, use the value of the FileName (see page 7664) property for the AFileName parameter.

See Also

LoadFromFile (see page 7652)

XML (see page 7668)

FileName (see page 7664)

81.2.1.2.30 IXMLDocument.SaveToStream Method

Saves the XML (see page 7668) document to a stream.

Pascal

```
procedure SaveToStream(const Stream: TStream);
```

C++

```
__fastcall SaveToStream(const TStream Stream);
```

Description

Call SaveToStream to save the contents of the XML (see page 7668) document to the stream specified by Stream. Regardless of the encoding system of the original XML (see page 7668) document, SaveToStream always saves the stream in UTF-16.

See Also

LoadFromStream (see page 7653)

SaveToXML (see page 7656)

SaveToFile (see page 7655)

81.2.1.2.31 SaveToXML Method

This is the overview for the SaveToXML method overload.

Overload List

	Name	Description
	IXMLDocument.SaveToXML (DOMString) (see page 7656)	Saves the XML (see page 7668) document to a string-type variable.
	IXMLDocument.SaveToXML (UTF8String) (see page 7656)	Saves the XML (see page 7668) document to a string-type variable.
	IXMLDocument.SaveToXML (WideString) (see page 7656)	Saves the XML (see page 7668) document to a string-type variable.

81.2.1.2.31.1 IXMLDocument.SaveToXML Method (DOMString)

Saves the XML (see page 7668) document to a string-type variable.

Pascal

```
procedure SaveToXML(var XML: DOMString); overload;
procedure SaveToXML(var XML: WideString); overload;
procedure SaveToXML(var XML: UTF8String); overload;
```

C++

```
__fastcall SaveToXML(DOMString XML);
```

```
__fastcall SaveToXML(BSTR XML);
__fastcall SaveToXML(UTF8String XML);
```

Description

Call SaveToXML to save the contents of the XML (see page 7668) document to the string-type variable specified by XML (see page 7668). SaveToXML writes the contents of XML (see page 7668) document using UTF-8 or UTF-16 as an encoding system, depending on the type of the XML (see page 7668) parameter.

Unlike the XML (see page 7668) property, which lets you write individual lines from the XML (see page 7668) document, SaveToXML writes the entire text of the XML (see page 7668) document.

See Also

LoadFromXML (see page 7653)

SaveToStream (see page 7656)

SaveToFile (see page 7655)

XML (see page 7668)

81.2.1.2.32 IXMLDocument.SetActive Method

Sets the value of the Active (see page 7661) property.

Pascal

```
procedure SetActive(const Value: Boolean);
```

C++

```
__fastcall SetActive(const Boolean Value);
```

Description

SetActive is the write implementation of the Active (see page 7661) property.

Value is the new value to set.

See Also

Active (see page 7661)

81.2.1.2.33 IXMLDocument.SetDocumentElement Method

Sets the value of the DocumentElement (see page 7663) property.

Pascal

```
procedure SetDocumentElement(const Value: IXMLNode);
```

C++

```
__fastcall SetDocumentElement(const IXMLNode Value);
```

Description

SetDocumentElement is the write implementation of the DocumentElement (see page 7663) property.

Value is the interface for the node tree that replaces the current document element.

See Also

DocumentElement (see page 7663)

81.2.1.2.34 IXMLDocument.SetDOMDocument Method

Sets the value of the DOMDocument (see page 7663) property.

Pascal

```
procedure SetDOMDocument(const Value: IDOMDocument);
```

C++

```
__fastcall SetDOMDocument(const IDOMDocument Value);
```

Description

SetDOMDocument is the write implementation of the DOMDocument (see page 7663) property.

Value is the DOM interface for the document to assign.

See Also

DOMDocument (see page 7663)

81.2.1.2.35 IXMLDocument.SetEncoding Method

Sets the value of the Encoding (see page 7664) property.

Pascal

```
procedure SetEncoding(const Value: DOMString);
```

C++

```
__fastcall SetEncoding(const DOMString Value);
```

Description

SetEncoding is the write implementation of the Encoding (see page 7664) property.

Value is the value of the encoding attribute of the document type node.

See Also

Encoding (see page 7664)

81.2.1.2.36 IXMLDocument.SetFileName Method

Sets the value of the FileName (see page 7664) property.

Pascal

```
procedure SetFileName(const Value: DOMString);
```

C++

```
__fastcall SetFileName(const DOMString Value);
```

Description

SetFileName is the write implementation of the FileName (see page 7664) property.

Value is the name of an XML (see page 7668) document or, if the vendor supports it, an URL for the XML (see page 7668) document.

See Also

FileName (see page 7664)

81.2.1.2.37 IXMLDocument.SetNodeIndentStr Method

Sets the value of the NodeIndentStr (see page 7666) property.

Pascal

```
procedure SetNodeIndentStr(const Value: DOMString);
```

C++

```
__fastcall SetNodeIndentStr(const DOMString Value);
```

Description

SetNodeIndentStr is the write implementation of the NodeIndentStr (see page 7666) property.

Value is the string that is inserted before nested nodes to indicate a level of nesting.

See Also

NodeIndentStr (see page 7666)

81.2.1.2.38 IXMLDocument.SetOnAsyncLoad Method

Supplies an event handler that responds when the AsyncLoadState (see page 7662) property changes.

Pascal

```
procedure SetOnAsyncLoad(const Value: TAsyncEventHandler);
```

C++

```
__fastcall SetOnAsyncLoad(const TAsyncEventHandler Value);
```

Description

Use SetOnAsyncLoad to supply a callback that responds when the asynchronous parsing of an XML (see page 7668) document progresses to a certain point.

Value is a method that is called when the AsyncLoadState (see page 7662) property changes to reflect a new stage in the parsing process.

See Also

AsyncLoadState (see page 7662)

81.2.1.2.39 IXMLDocument.SetOptions Method

Sets the value of the Options (see page 7666) property.

Pascal

```
procedure SetOptions(const Value: TXMLDocOptions);
```

C++

```
__fastcall SetOptions(const TXMLDocOptions Value);
```

Description

GetOptions (see page 7650) is the write implementation of the Options (see page 7666) property.

Value is the set of options to assign.

See Also

Options (see page 7666)

81.2.1.2.40 IXMLDocument.SetParseOptions Method

Sets the value of the ParseOptions (see page 7667) property.

Pascal

```
procedure SetParseOptions(const Value: TParseOptions);
```

C++

```
__fastcall SetParseOptions(const TParseOptions Value);
```

Description

GetParseOptions (see page 7650) is the write implementation of the ParseOptions (see page 7667) property.

Value is the set of parser options to assign.

See Also

ParseOptions (see page 7667)

81.2.1.2.41 IXMLDocument.SetStandAlone Method

Sets the value of the StandAlone (see page 7668) property.

Pascal

```
procedure SetStandAlone(const Value: DOMString);
```

C++

```
__fastcall SetStandAlone(const DOMString Value);
```

Description

SetStandAlone is the write implementation of the StandAlone (see page 7668) property.

Value is the value of the stand-alone attribute of the document type node.

See Also

StandAlone (see page 7668)

81.2.1.2.42 IXMLDocument.SetVersion Method

Sets the value of the Version (see page 7668) property.

Pascal

```
procedure SetVersion(const Value: DOMString);
```

C++

```
__fastcall SetVersion(const DOMString Value);
```

Description

SetVersion is the write implementation of the Version (see page 7668) property.

Value is the value of the version attribute of the document type node.

See Also

Version (see page 7668)

81.2.1.2.43 IXMLDocument.SetXML Method

Sets the value of the XML (see page 7668) property.

Pascal

```
procedure SetXML(const Value: TStrings);
```

C++

```
__fastcall SetXML(const TStrings Value);
```

Description

SetXML is the write implementation of the XML (see page 7668) property.

Value contains the raw (unparsed) XML (see page 7668) to assign.

See Also

XML (see page 7668)

81.2.1.3 IXMLDocument Properties

The properties of the IXMLDocument class are listed here.

Public Properties

	Name	Description
	Active (see page 7661)	Specifies whether the XML (see page 7668) document has been parsed so that the DOM interfaces are available to examine or change its contents.
R	AsyncLoadState (see page 7662)	Indicates the state of the DOM parser when it parses the XML (see page 7668) document asynchronously.
R	ChildNodes (see page 7663)	Lists all of the child nodes of the document.
	DocumentElement (see page 7663)	Provides access to the root node of the XML (see page 7668) document.
	DOMDocument (see page 7663)	Provides access to the DOM interface for the parsed XML (see page 7668) document.
	Encoding (see page 7664)	Indicates the character set that the XML (see page 7668) document uses to encode characters.
	FileName (see page 7664)	Indicates the XML (see page 7668) document file, if any, that this interface represents.
R	Modified (see page 7665)	Indicates whether the XML (see page 7668) document has been modified.
R	Node (see page 7665)	Provides access to the document node for the XML (see page 7668) document.
	NodeIndentStr (see page 7666)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7668) text.
	Options (see page 7666)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7667)	Specifies implementation-specific options that are followed when parsing the XML (see page 7668) document.
R	SchemaRef (see page 7667)	Returns the name of the schema associated with this XML (see page 7668) document.
	StandAlone (see page 7668)	Indicates whether the XML (see page 7668) document includes any external markup declarations.
	Version (see page 7668)	Indicates the XML (see page 7668) version that the document uses.
	XML (see page 7668)	Specifies the content of the XML document associated with this IXMLDocument (see page 7640) interface.

81.2.1.3.1 IXMLDocument.Active Property

Specifies whether the XML (see page 7668) document has been parsed so that the DOM interfaces are available to examine or change its contents.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Before you can use IXMLDocument (see page 7640) to examine or change the contents of an XML (see page 7668) document, it must be active. Setting Active to true results in the parsing of the XML (see page 7668) document specified by the FileName (see page 7664) property or by the XML (see page 7668) property. If both FileName (see page 7664) and XML (see page 7668) are empty strings, Setting Active to true causes IXMLDocument (see page 7640) to represent an empty document.

Active must be true before you can access the DOMDocument (see page 7663) or DocumentElement (see page 7663) properties.

See Also

DOMDocument (see page 7663)

DocumentElement (see page 7663)

FileName (see page 7664)

XML (see page 7668)

81.2.1.3.2 IXMLDocument.AsyncLoadState Property

Indicates the state of the DOM parser when it parses the XML (see page 7668) document asynchronously.

Pascal

```
property AsyncLoadState: Integer;
```

C++

```
__property int AsyncLoadState;
```

Description

Use AsyncLoadState to determine that status of the DOM parser when it is parsing an XML (see page 7668) document asynchronously. The value of AsyncLoadState is vendor-specific. That is, each DOM parser that loads and parses an XML (see page 7668) document asynchronously supplies its own flags to indicate state information.

When the DOM vendor is MSXML, AsyncLoadState can have any of the following values:

Value	Meaning
0	Uninitialized: The AsyncLoadState is not assigned. (Usually indicates that the parser has not tried to parse a document or it is not parsing the document asynchronously.)
1	Loading: The parser is currently parsing the structure of the XML (see page 7668) document.
2	Loaded: The parser has finished reading and parsing the structure of the XML (see page 7668) document, but the corresponding DOM interfaces are not yet available.
3	Interactive: The parser has parsed the structure of the XML (see page 7668) document, the corresponding DOM interfaces are available, but the parser has not finished reading all the node values.
4	Complete: The parser has fully read and parsed the XML (see page 7668) document.

See Also

SetOnAsyncLoad (see page 7659)

81.2.1.3.3 IXMLDocument.ChildNodes Property

Lists all of the child nodes of the document.

Pascal

```
property ChildNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList ChildNodes;
```

Description

Use ChildNodes to access all of the nodes that are children of the document object. In addition to DocumentElement (see page 7663), which is the root of the data hierarchy, ChildNodes can include nodes for comments, processing instructions, and so on.

See Also

DocumentElement (see page 7663)

Node (see page 7665)

81.2.1.3.4 IXMLDocument.DocumentElement Property

Provides access to the root node of the XML (see page 7668) document.

Pascal

```
property DocumentElement: IXMLNode;
```

C++

```
__property IXMLNode DocumentElement;
```

Description

Use DocumentElement to access the root node of the XML (see page 7668) document. Because XML (see page 7668) documents are hierarchical in structure, DocumentElement is the entry point to all data in the XML (see page 7668) document. Setting DocumentElement replaces the entire data hierarchy with a new hierarchy of nodes.

The IXMLNode (see page 7669) interface includes properties and methods for examining and changing the text and attributes of a node, for adding and deleting child nodes, and for traversing the hierarchy of nodes rooted at that node.

See Also

DOMDocument (see page 7663)

ChildNodes (see page 7663)

81.2.1.3.5 IXMLDocument.DOMDocument Property

Provides access to the DOM interface for the parsed XML (see page 7668) document.

Pascal

```
property DOMDocument: IDOMDocument;
```

C++

```
__property IDOMDocument DOMDocument;
```

Description

Use DOMDocument to directly access the IDOMDocument (see page 7530) interface for the parsed XML (see page 7668) document. This is the interface supported by the DOM parser for the document.

Most applications do not need to use the DOMDocument property directly. Instead, it supplies the underlying support for parsing and manipulating the nodes accessed through DocumentElement (see page 7663). If you do want to make use of DOMDocument's low-level support, you must be familiar with the W3C Document Object Model (DOM) Specification.

See Also

DocumentElement (see page 7663)

81.2.1.3.6 IXMLDocument.Encoding Property

Indicates the character set that the XML (see page 7668) document uses to encode characters.

Pascal

```
property Encoding: DOMString;
```

C++

```
__property DOMString Encoding;
```

Description

Encoding is the encoding name that appears in the document type declaration of the XML (see page 7668) document. It is a string such as 'UTF-8', 'UTF-16', or 'ISO-10646-UCS-2' that indicates the character set used in the document.

See Also

FileName (see page 7664)

DOMDocument (see page 7663)

XML (see page 7668)

81.2.1.3.7 IXMLDocument.FileName Property

Indicates the XML (see page 7668) document file, if any, that this interface represents.

Pascal

```
property FileName: DOMString;
```

C++

```
__property DOMString FileName;
```

Description

Use FileName to get or set the name of the XML (see page 7668) file that this document represents. FileName is set automatically when an application calls the LoadFromFile (see page 7652) method or when this interface is obtained from the global LoadXMLDocument function.

When you set the value of FileName, the XML (see page 7668) property automatically changes (at runtime) to represent the contents of that file.

Note: The content of this XML (see page 7668) document, which is available as the value of the XML (see page 7668) property, may not be the same as the content of the specified file. If an application uses IXMLDocument (see page 7640) to

edit the document, those changes are not saved back to the XML (see page 7668) document file until you call the SaveToFile (see page 7655) method.

Tip: If the underlying DOM implementation supports it, you can use FileName to specify an URL rather than a file on disk.

See Also

SaveToFile (see page 7655)

LoadFromFile (see page 7652)

LoadXMLDocument (see page 7491)

XML (see page 7668)

81.2.1.3.8 IXMLDocument.Modified Property

Indicates whether the XML (see page 7668) document has been modified.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Read (see page 3634) Modified to determine whether the application has made any changes to the nodes in the XML (see page 7668) document. When Modified is true, the value of the XML (see page 7668) property may differ from the contents of the file specified by FileName (see page 7664). You can call the SaveToFile (see page 7655) method to update the XML (see page 7668) document file to reflect the changes.

See Also

Resync (see page 7655)

SaveToFile (see page 7655)

XML (see page 7668)

FileName (see page 7664)

81.2.1.3.9 IXMLDocument.Node Property

Provides access to the document node for the XML (see page 7668) document.

Pascal

```
property Node: IXMLNode;
```

C++

```
__property IXMLNode Node;
```

Description

Read (see page 3634) Node to access the document node for the XML (see page 7668) document. The document node represents information about the entire document. It may have several child nodes, which represent comments, processing instructions, and which include the DocumentElement (see page 7663) node that acts as the root of the data hierarchy.

See Also

DocumentElement (see page 7663)

ChildNodes (see page 7663)

81.2.1.3.10 IXMLDocument.NodeIndentStr Property

Indicates the string that is inserted before nested nodes in the formatted XML (see page 7668) text.

Pascal

```
property NodeIndentStr: DOMString;
```

C++

```
__property DOMString NodeIndentStr;
```

Description

Use NodeIndentStr to customize how the document formats nodes that are added. When the Options (see page 7666) property includes doNodeAutoIndent, this string is inserted in the generated XML (see page 7668) before any newly added node, once for each nesting level.

If you do not assign a value to NodeIndentStr, IXMLDocument (see page 7640) inserts two spaces to represent each nesting level.

See Also

Options (see page 7666)

NestingLevel (see page 7428)

FormatXMLData (see page 7490)

XML (see page 7668)

81.2.1.3.11 IXMLDocument.Options Property

Influences various aspects of the document's behavior.

Pascal

```
property Options: TXMLDocOptions;
```

C++

```
__property TXMLDocOptions Options;
```

Description

Set Options to configure how you want the document to respond when the application tries to read nodes or attributes that do not exist, when it creates a new namespace when adding a node, when it generates XML (see page 7668) text from the nodes in the document, or whether it saves its value automatically when you close the document. Options can include any of the following values:

Value	Meaning
doNodeAutoCreate	If the application tries to read a node by name, using the Nodes property of an IXMLNodeList (see page 7703) interface, and that node does not exist, then the application creates a new node using the specified name.
doNodeAutoIndent	When formatting the XML (see page 7668) text from the parsed set of nodes, child nodes are automatically indented from their parent nodes.

doAttrNull	When reading the value of an attribute that does not exist, the value is given as a Null Variant (see page 3421) (as opposed to a value of an empty string).
doAutoPrefix	When generating the name of a new node, the value is automatically given a namespace prefix if a namespace URI is supplied.
doNamespaceDecl	When the AddChild (see page 7643) method must create a new namespace for the node, it also adds a namespace attribute to declare that new namespace. If doNamespaceDecl is not included, AddChild (see page 7643) creates the new namespace but does not add an attribute to declare it.
doAutoSave	When you close the document (set Active (see page 7661) to false), any changes are automatically saved back to the file specified by FileName (see page 7664) or to the XML (see page 7668) property.

See Also

Nodes (see page 7714)

Attributes (see page 7688)

AddChild (see page 7672)

81.2.1.3.12 IXMLDocument.ParseOptions Property

Specifies implementation-specific options that are followed when parsing the XML (see page 7668) document.

Pascal

```
property ParseOptions: TParseOptions;
```

C++

```
__property TParseOptions ParseOptions;
```

Description

Set ParseOptions to influence the way the DOM implementation parses the XML (see page 7668) document. Different DOM implementations support different options. If you attempt to use an option that is not supported by your DOM implementation, IXMLDocument (see page 7640) raises an EXMLDocError (see page 7639) exception.

See Also

DOMImplementation (see page 7385)

EXMLDocError (see page 7639)

81.2.1.3.13 IXMLDocument.SchemaRef Property

Returns the name of the schema associated with this XML (see page 7668) document.

Pascal

```
property SchemaRef: DOMString;
```

C++

```
__property DOMString SchemaRef;
```

Description

Read (see page 3634) SchemaRef to determine the schema associated with this XML (see page 7668) document. If the document does not have an attribute that identifies an associated schema, the value of SchemaRef is an empty string.

See Also

DOMDocument (see page 7663)

81.2.1.3.14 IXMLDocument.StandAlone Property

Indicates whether the XML (see page 7668) document includes any external markup declarations.

Pascal

```
property StandAlone: DOMString;
```

C++

```
__property DOMString StandAlone;
```

Description

StandAlone is the value of the stand-alone attribute on the document type declaration of the XML (see page 7668) document. StandAlone has a value of 'yes' or 'no'.

When StandAlone is 'yes', the document contains no external markup declarations. It may, however, still contain references to external entities, as long as they are not declarations.

When StandAlone is 'no', the document may or may not contain external markup declarations.

See Also

DOMDocument (see page 7663)

81.2.1.3.15 IXMLDocument.Version Property

Indicates the XML (see page 7668) version that the document uses.

Pascal

```
property Version: DOMString;
```

C++

```
__property DOMString Version;
```

Description

Version indicates the XML (see page 7668) version number that the document uses. An XML (see page 7668) version number is a string of the form 'n.m', where n is the major version number and m is the minor version number.

See Also

XML (see page 7668)

81.2.1.3.16 IXMLDocument.XML Property

Specifies the content of the XML document associated with this IXMLDocument (see page 7640) interface.

Pascal

```
property XML: TStrings;
```

C++

```
__property TStrings XML;
```

Description

Read (see page 3634) XML to obtain the contents of the associated XML document. Set XML to specify the raw (unparsed)

XML you want to examine or manipulate.

XML is a TStrings object. This means you can manipulate the XML line by line. To read or write the XML in the document as a single string, use the LoadFromXML (see page 7653) or SaveToXML (see page 7656) method.

Note: If you call the LoadFromFile (see page 7652), LoadFromStream (see page 7653), or LoadFromXML (see page 7653) method, XML is automatically updated to reflect the contents of that file.

See Also

LoadFromFile (see page 7652)

DocumentElement (see page 7663)

TXMLDocument (see page 7347)

LoadFromXML (see page 7653)

SaveToXML (see page 7656)

LoadFromStream (see page 7653)

81.2.2 IXMLNode Interface

IXMLNode is the interface for a node in an XML (see page 7697) document.

Class Hierarchy

Pascal

```
IXMLNode = interface;
```

C++

```
__interface IXMLNode;
```

File

XMLIntf

Description

Use IXMLNode to work with a node in an XML (see page 7697) document. The IXMLNode interface is designed to work with TXMLDocument and the code generated by the Data Binding wizard.

IXMLNode is similar to the IDOMNode (see page 7557) interface that is defined as part of the Document Object Model (DOM) specification. However, IXMLNode is designed to simplify the task of navigating and editing XML (see page 7697) documents by

including some of the properties and methods from the IDOMElement (see page 7542) interface, resulting in a simpler model for examining an XML (see page 7697) node.

including additional properties and methods to simplify access to data in common XML (see page 7697) structures.

The Data Binding wizard generates descendants of IXMLNode that further simplify the task of working with XML (see page 7697) documents by converting the attributes and child nodes of a node into properties of the node interface.

Note: C++ method declarations that use IXMLNode use the _di_IXMLNode type instead. This type is a DelphiInterface (see page 3256) wrapper around the IXMLNode interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IXMLNode >  _di_IXMLNode;
```

See Also

TXMLNode (see page 7396)

TXMLDocument (see page 7347)

IXMLNodeCollection (see page 7698)

IDOMNode (see page 7557)

IXMLNodeList (see page 7703)

Working with XML Nodes

81.2.2.1 IXMLNode Members

The following tables list the members exposed by IXMLNode.

Public Methods

	Name	Description
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
	CloneNode (see page 7673)	Creates a copy of this node and returns its interface.
	DeclareNamespace (see page 7674)	Adds an attribute to the node that declares a specified namespace URI.
	FindNamespaceDecl (see page 7674)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7674)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7675)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7675)	Returns the value of the AttributeNodes (see page 7688) property.
	GetAttributeNS (see page 7676)	Returns the value of a specified attribute.
	GetChildNodes (see page 7676)	Returns the value of the ChildNodes (see page 7689) property.
	GetChildValue (see page 7676)	Returns the value of a specified child node.
	GetCollection (see page 7677)	Returns the value of the Collection (see page 7690) property.
	GetDOMNode (see page 7677)	Returns the value of the DOMNode (see page 7691) property.
	GetHasChildNodes (see page 7678)	Indicates whether the node has any child nodes.
	GetIsTextElement (see page 7678)	Indicates whether the node has a single text value.
	GetLocalName (see page 7678)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7679)	Returns the namespace URI for the node's qualified name.
	GetNodeName (see page 7679)	Returns the name of the node.
	GetNodeType (see page 7679)	Returns the type of the node.
	GetNodeValue (see page 7680)	Returns the value of the node.
	GetOwnerDocument (see page 7680)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7680)	Returns the interface for the node's parent node.
	GetPrefix (see page 7680)	Returns the namespace prefix from the node's name.
	GetReadOnly (see page 7681)	Returns the value of the ReadOnly (see page 7696) property.
	GetText (see page 7681)	Returns the text value of the node.
	GetXML (see page 7681)	Returns the value of the XML (see page 7697) property.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	NextSibling (see page 7682)	Returns the next child of this node's parent.
	Normalize (see page 7683)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7683)	Returns the previous child of this node's parent.
	Resync (see page 7684)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7684)	Sets the value of one of this node's attributes.
	SetAttributeNS (see page 7684)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.

	SetChildValue (see page 7685)	Sets the value of a specified child node.
	SetNodeValue (see page 7685)	Sets the value of this node.
	SetReadOnly (see page 7686)	Specifies whether the node can be modified.
	SetText (see page 7686)	Sets the text value of the node.
	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.

Public Properties

	Name	Description
R	AttributeNodes (see page 7688)	Lists the interfaces for nodes that represent attributes of this node.
	Attributes (see page 7688)	Represents the values of this node's attributes.
R	ChildNodes (see page 7689)	Represents the child nodes of the node.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	Collection (see page 7690)	Indicates the collection in which this node appears.
R	DOMNode (see page 7691)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.
R	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
R	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
R	NodeName (see page 7693)	Indicates the node name.
R	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
R	OwnerDocument (see page 7695)	Identifies the document in which this node appears.
R	ParentNode (see page 7695)	Identifies the interface of the node's parent node.
R	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
	Text (see page 7697)	Represents the Text of the node.
R	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

81.2.2.2 IXMLNode Methods

The methods of the IXMLNode class are listed here.

Public Methods

	Name	Description
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
	CloneNode (see page 7673)	Creates a copy of this node and returns its interface.
	DeclareNamespace (see page 7674)	Adds an attribute to the node that declares a specified namespace URI.
	FindNamespaceDecl (see page 7674)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7674)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7675)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7675)	Returns the value of the AttributeNodes (see page 7688) property.
	GetAttributeNS (see page 7676)	Returns the value of a specified attribute.
	GetChildNodes (see page 7676)	Returns the value of the ChildNodes (see page 7689) property.
	GetChildValue (see page 7676)	Returns the value of a specified child node.
	GetCollection (see page 7677)	Returns the value of the Collection (see page 7690) property.
	GetDOMNode (see page 7677)	Returns the value of the DOMNode (see page 7691) property.
	GetHasChildNodes (see page 7678)	Indicates whether the node has any child nodes.
	GetIsTextElement (see page 7678)	Indicates whether the node has a single text value.
	GetLocalName (see page 7678)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7679)	Returns the namespace URI for the node's qualified name.
	GetNodeName (see page 7679)	Returns the name of the node.
	GetNodeType (see page 7679)	Returns the type of the node.
	GetNodeValue (see page 7680)	Returns the value of the node.

	GetOwnerDocument (see page 7680)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7680)	Returns the interface for the node's parent node.
	GetPrefix (see page 7680)	Returns the namespace prefix from the node's name.
	GetReadOnly (see page 7681)	Returns the value of the ReadOnly (see page 7696) property.
	GetText (see page 7681)	Returns the text value of the node.
	GetXML (see page 7681)	Returns the value of the XML (see page 7697) property.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	NextSibling (see page 7682)	Returns the next child of this node's parent.
	Normalize (see page 7683)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7683)	Returns the previous child of this node's parent.
	Resync (see page 7684)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7684)	Sets the value of one of this node's attributes.
	SetAttributeNS (see page 7684)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
	SetChildValue (see page 7685)	Sets the value of a specified child node.
	SetNodeValue (see page 7685)	Sets the value of this node.
	SetReadOnly (see page 7686)	Specifies whether the node can be modified.
	SetText (see page 7686)	Sets the text value of the node.
	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.

81.2.2.2.1 AddChild Method

This is the overview for the AddChild method overload.

Overload List

	Name	Description
	IXMLNode.AddChild (DOMString, DOMString, Boolean, Integer) (see page 7672)	Adds a new child node to this node.
	IXMLNode.AddChild (DOMString, Integer) (see page 7672)	Adds a new child node to this node.

81.2.2.2.1.1 IXMLNode.AddChild Method (DOMString, DOMString, Boolean, Integer)

Adds a new child node to this node.

Pascal

```
function AddChild(const TagName: DOMString; Index: Integer = -1): IXMLNode; overload;
function AddChild(const TagName: DOMString; const NamespaceURI: DOMString; GenPrefix: Boolean
= False; Index: Integer = -1): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode AddChild(const DOMString TagName, int Index = -1);
__fastcall IXMLNode AddChild(const DOMString TagName, const DOMString NamespaceURI, Boolean
GenPrefix = False, int Index = -1);
```

Description

AddChild creates a new element node as the child of this node.

TagName provides the tag name of the newly created node.

NamespaceURI (see page 7693) identifies the namespace that includes the new node's definition. If NamespaceURI (see page 7693) is omitted (the second syntax), the namespace of the new node is deduced from the namespace prefix of TagName. If TagName has no namespace prefix and there is no NamespaceURI (see page 7693) parameter, the namespace is the

same as this node's NamespaceURI (see page 7693) property.

GenPrefix controls whether AddChild generates a namespace prefix for the namespace URI when the NamespaceURI (see page 7693) parameter identifies a URI that is not already declared in the document. Note that setting GenPrefix to true does not cause AddChild to add a declaration of the new namespace prefix unless the document's Options property includes doNamespaceDecl.

Index indicates the position of the child node in this node's list of children, where 0 is the first position, 1 is the second position, and so on. If Index is –1, the new node is added to the end.

AddChild returns the interface for the newly created child node.

Tip: AddChild only adds element nodes. To add other types of child nodes, use the XML (see page 7697) document's CreateNode method instead, and then add the resulting node to the ChildNodes (see page 7689) property array.

See Also

Delete (see page 7707)

ChildNodes (see page 7689)

CreateNode (see page 7645)

NamespaceURI (see page 7693)

Options (see page 7389)

Working with XML Nodes

81.2.2.2.2 IXMLNode.CloneNode Method

Creates a copy of this node and returns its interface.

Pascal

```
function CloneNode(Deep: Boolean): IXMLNode;
```

C++

```
__fastcall IXMLNode CloneNode(Boolean Deep);
```

Description

CloneNode returns a copy of this node that has no parent. Any attributes of this node are copied as well, including attribute nodes that represent default values.

Deep indicates whether the child nodes of this node should be cloned as well. For example, if an element node contains any text, CloneNode only copies then text when deep is true, because in the underlying DOM implementation, the text is contained in a child node.

After calling CloneNode to create a new node, you can add that node into the ChildNodes (see page 7689) property of another node (or, if this node represents an attribute, into the AttributeNodes (see page 7688) property) by calling ChildNodes (see page 7689). ->Add or ChildNodes (see page 7689). ->Insert (see page 3601).

See Also

ChildNodes (see page 7689)

AddChild (see page 7672)

ParentNode (see page 7695)

cloneNode (see page 7560)

Add (see page 7705)

Insert (see page 7712)

81.2.2.2.3 IXMLNode.DeclareNamespace Method

Adds an attribute to the node that declares a specified namespace URI.

Pascal

```
procedure DeclareNamespace(const Prefix: DOMString; const URI: DOMString);
```

C++

```
__fastcall DeclareNamespace(const DOMString Prefix, const DOMString URI);
```

Description

DeclareNamespace adds an attribute to this node that declares the specified namespace URI as the value of the specified prefix.

Prefix (see page 7696) is the namespace prefix that appears in tag names that reference the namespace.

URI is the corresponding namespace URI.

Note: This method is called automatically for newly created nodes when the document's Options property includes doNamespaceDecl.

See Also

Options (see page 7666)

Attributes (see page 7688)

FindNamespaceDecl (see page 7674)

81.2.2.2.4 IXMLNode.FindNamespaceDecl Method

Returns the attribute node that declares a specified Namespace URI.

Pascal

```
function FindNamespaceDecl(const NamespaceURI: DOMString): IXMLNode;
```

C++

```
__fastcall IXMLNode FindNamespaceDecl(const DOMString NamespaceURI);
```

Description

FindNamespaceDecl searches the node hierarchy that contains this node for an attribute that specifies the mapping between a namespace prefix and the namespace URI identified by NamespaceURI (see page 7693). If it finds such a mapping, FindNamespaceDecl returns the interface for the Attribute node. If it does not find a mapping, FindNamespaceDecl returns nil (Delphi) or NULL (C++).

NamespaceURI (see page 7693) is the namespace URI to locate.

See Also

FindNamespaceURI (see page 7674)

DeclareNamespace (see page 7674)

81.2.2.2.5 IXMLNode.FindNamespaceURI Method

Returns the namespace URI for a namespace prefix or qualified tag name.

Pascal

```
function FindNamespaceURI(const TagOrPrefix: DOMString): DOMString;
```

C++

```
__fastcall DOMString FindNamespaceURI(const DOMString TagOrPrefix);
```

Description

FindNamespaceDecl (see page 7674) searches the node hierarchy that contains this node for an attribute that specifies the mapping between the namespace prefix identified by TagOrPrefix and a namespace URI. If it finds such a mapping, FindNamespaceURI returns the namespace URI. If it does not find a mapping, FindNamespaceURI returns an empty string.

TagOrPrefix is the namespace prefix or a tag name that includes the namespace prefix.

See Also

GetNamespaceURI (see page 7679)

GetPrefix (see page 7680)

FindNamespaceDecl (see page 7674)

81.2.2.2.6 IXMLNode.GetAttribute Method

Returns the value of one of this node's attributes.

Pascal

```
function GetAttribute(const AttrName: DOMString): OleVariant;
```

C++

```
__fastcall OleVariant GetAttribute(const DOMString AttrName);
```

Description

GetAttribute is the read implementation of the Attributes (see page 7688) property.

AttrName is the name of the attribute.

GetAttribute returns the value of the specified attribute. Typically, this value is a string. If the node does not have an attribute with the name specified by AttrName, GetAttribute returns a Null Variant (see page 3421).

Note: Do not call GetAttribute unless this node is an element node. Only element nodes have attributes.

See Also

Attributes (see page 7688)

GetAttributeNS (see page 7676)

81.2.2.2.7 IXMLNode.GetAttributeNodes Method

Returns the value of the AttributeNodes (see page 7688) property.

Pascal

```
function GetAttributeNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetAttributeNodes();
```

Description

GetAttributeNodes is the read implementation of the AttributeNodes (see page 7688) property.

See Also

AttributeNodes (see page 7688)

81.2.2.2.8 IXMLNode.GetAttributeNS Method

Returns the value of a specified attribute.

Pascal

```
function GetAttributeNS(const AttrName: DOMString; const NamespaceURI: DOMString): OleVariant;
```

C++

```
__fastcall OleVariant GetAttributeNS(const DOMString AttrName, const DOMString NamespaceURI);
```

Description

Call GetAttributeNS to determine the value of an attribute when you must explicitly specify the namespace for the attribute.

AttrName is the name of the attribute whose value you want to fetch.

NamespaceURI (see page 7693) identifies the namespace in which the attribute resides.

GetAttributeNS returns the value of the attribute. If AttrName and NamespaceURI (see page 7693) do not identify an attribute of this node, GetAttributeNS returns a Null Variant (see page 3421).

See Also

AttributeNodes (see page 7688)

Attributes (see page 7688)

NamespaceURI (see page 7693)

SetAttributeNS (see page 7684)

81.2.2.2.9 IXMLNode.GetChildNodes Method

Returns the value of the ChildNodes (see page 7689) property.

Pascal

```
function GetChildNodes: IXMLNodeList;
```

C++

```
__fastcall IXMLNodeList GetChildNodes();
```

Description

GetChildNodes is the read implementation of the ChildNodes (see page 7689) property.

See Also

ChildNodes (see page 7689)

81.2.2.2.10 IXMLNode.GetChildValue Method

Returns the value of a specified child node.

Pascal

```
function GetChildValue(const IndexOrName: OleVariant): OleVariant;
```

C++

```
__fastcall OleVariant GetChildValue(const OleVariant IndexOrName);
```

Description

GetChildValue is the read implementation of the ChildValues (see page 7690) property.

IndexOrName identifies the desired child node by either its interface, or by a string that is the local name of the child node.

The return value depends on the type of the child node, as indicated in the following table:

NodeType (see page 7694)	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, reading the child's value causes an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntEntityRef	nil (Delphi) or NULL (C++)
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
ntDocFragment	nil (Delphi) or NULL (C++)

See Also

ChildValues (see page 7690)

81.2.2.2.11 IXMLNode.GetCollection Method

Returns the value of the Collection (see page 7690) property.

Pascal

```
function GetCollection: IXMLNodeCollection;
```

C++

```
__fastcall IXMLNodeCollection GetCollection();
```

Description

GetCollection is the read implementation of the Collection (see page 7690) property.

See Also

Collection (see page 7690)

81.2.2.2.12 IXMLNode.GetDOMNode Method

Returns the value of the DOMNode (see page 7691) property.

Pascal

```
function GetDOMNode: IDOMNode;
```

C++

```
__fastcall IDOMNode GetDOMNode();
```

Description

GetDOMNode is the read implementation of the DOMNode (see page 7691) property.

See Also

DOMNode (see page 7691)

81.2.2.2.13 IXMLNode.GetHasChildNodes Method

Indicates whether the node has any child nodes.

Pascal

```
function GetHasChildNodes: Boolean;
```

C++

```
__fastcall Boolean GetHasChildNodes();
```

Description

GetHasChildNodes is the read implementation of the HasChildNodes (see page 7691) property.

See Also

HasChildNodes (see page 7691)

81.2.2.2.14 IXMLNode.GetIsTextElement Method

Indicates whether the node has a single text value.

Pascal

```
function GetIsTextElement: Boolean;
```

C++

```
__fastcall Boolean GetIsTextElement();
```

Description

GetIsTextElement is the read implementation of the IsTextElement (see page 7692) property.

See Also

IsTextElement (see page 7692)

81.2.2.2.15 IXMLNode.GetLocalName Method

Returns the name of the node without any namespace prefix.

Pascal

```
function GetLocalName: DOMString;
```

C++

```
__fastcall DOMString GetLocalName();
```

Description

GetLocalName is the read implementation of the LocalName (see page 7692) property.

See Also

LocalName (see page 7692)

81.2.2.2.16 IXMLNode.GetNamespaceURI Method

Returns the namespace URI for the node's qualified name.

Pascal

```
function GetNamespaceURI: DOMString;
```

C++

```
__fastcall DOMString GetNamespaceURI();
```

Description

GetNamespaceURI is the read implementation of the NamespaceURI (see page 7693) property.

See Also

NamespaceURI (see page 7693)

81.2.2.2.17 IXMLNode.GetNodeName Method

Returns the name of the node.

Pascal

```
function GetNodeName: DOMString;
```

C++

```
__fastcall DOMString GetNodeName();
```

Description

GetNodeName is the read implementation of the NodeName (see page 7693) property.

See Also

NodeName (see page 7693)

81.2.2.2.18 IXMLNode.GetNodeType Method

Returns the type of the node.

Pascal

```
function GetNodeType: TNodeType;
```

C++

```
__fastcall TNodeType GetNodeType();
```

Description

GetNodeType is the read implementation of the NodeType (see page 7694) property.

See Also

NodeType (see page 7694)

81.2.2.2.19 IXMLNode.GetNodeValue Method

Returns the value of the node.

Pascal

```
function GetNodeValue: OleVariant;
```

C++

```
__fastcall OleVariant GetNodeValue();
```

Description

GetNodeValue is the read implementation of the NodeValue (see page 7695) property.

See Also

NodeValue (see page 7695)

81.2.2.2.20 IXMLNode.GetOwnerDocument Method

Returns the interface for the document in which this node appears.

Pascal

```
function GetOwnerDocument: IXMLDocument;
```

C++

```
__fastcall IXMLDocument GetOwnerDocument();
```

Description

GetOwnerDocument is the read implementation of the OwnerDocument (see page 7695) property.

See Also

OwnerDocument (see page 7695)

81.2.2.2.21 IXMLNode.GetParentNode Method

Returns the interface for the node's parent node.

Pascal

```
function GetParentNode: IXMLNode;
```

C++

```
__fastcall IXMLNode GetParentNode();
```

Description

GetParentNode is the read implementation of the ParentNode (see page 7695) property.

See Also

ParentNode (see page 7695)

81.2.2.2.22 IXMLNode.GetPrefix Method

Returns the namespace prefix from the node's name.

Pascal

```
function GetPrefix: DOMString;
```

C++

```
__fastcall DOMString GetPrefix();
```

Description

GetPrefix is the read implementation of the Prefix (see page 7696) property.

See Also

Prefix (see page 7696)

81.2.2.2.23 IXMLNode.GetReadOnly Method

Returns the value of the ReadOnly (see page 7696) property.

Pascal

```
function GetReadOnly: Boolean;
```

C++

```
__fastcall Boolean GetReadOnly();
```

Description

GetReadOnly is the read implementation of the ReadOnly (see page 7696) property.

See Also

ReadOnly (see page 7696)

81.2.2.2.24 IXMLNode.GetText Method

Returns the text value of the node.

Pascal

```
function GetText: DOMString;
```

C++

```
__fastcall DOMString GetText();
```

Description

GetText is the read implementation for the Text (see page 7697) property.

See Also

Text (see page 7697)

81.2.2.2.25 IXMLNode.GetXML Method

Returns the value of the XML (see page 7697) property.

Pascal

```
function GetXML: DOMString;
```

C++

```
__fastcall DOMString GetXML();
```

Description

GetXML is the read implementation of this node's XML (see page 7697) property.

See Also

XML (see page 7697)

81.2.2.2.26 HasAttribute Method

This is the overview for the HasAttribute method overload.

Overload List

	Name	Description
	IXMLNode.HasAttribute (DOMString) (see page 7682)	Indicates whether the node has an attribute with a specified name.
	IXMLNode.HasAttribute (DOMString, DOMString) (see page 7682)	Indicates whether the node has an attribute with a specified name.

81.2.2.2.26.1 IXMLNode.HasAttribute Method (DOMString)

Indicates whether the node has an attribute with a specified name.

Pascal

```
function HasAttribute(const Name: DOMString): Boolean; overload;
function HasAttribute(const Name: DOMString; const NamespaceURI: DOMString): Boolean; overload;
```

C++

```
__fastcall Boolean HasAttribute(const DOMString Name);
__fastcall Boolean HasAttribute(const DOMString Name, const DOMString NamespaceURI);
```

Description

Call HasAttribute to determine whether this node has a specified attribute.

Name is the name of the attribute about which you want to know.

NamespaceURI (see page 7693) is the namespace of the attribute.

HasAttribute returns true if this node has the specified attribute, false otherwise.

See Also

AttributeNodes (see page 7688)

Attributes (see page 7688)

81.2.2.2.27 IXMLNode.NextSibling Method

Returns the next child of this node's parent.

Pascal

```
function NextSibling: IXMLNode;
```

C++

```
__fastcall IXMLNode NextSibling();
```

Description

NextSibling returns the node that follows this one in the parent node's ChildNodes (see page 7689) property list.

If this node is the last node in its parent's child list, NextSibling raises an exception.

See Also

ParentNode (see page 7695)

PreviousSibling (see page 7683)

ChildNodes (see page 7689)

81.2.2.2.28 IXMLNode.Normalize Method

Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.

Pascal

```
procedure Normalize;
```

C++

```
__fastcall Normalize();
```

Description

Use the IXMLNode (see page 7669) interface to call the protected Normalize method. Normalize consolidates adjacent text nodes and remove any empty text nodes in the subtree beneath this node. This method ensures that for all child nodes of this node and of its attributes, only structure nodes (element nodes, comments, processing instructions, CDATA sections, and entity references) separate text nodes and that there are no empty text nodes.

See Also

ChildNodes (see page 7689)

AttributeNodes (see page 7688)

81.2.2.2.29 IXMLNode.PreviousSibling Method

Returns the previous child of this node's parent.

Pascal

```
function PreviousSibling: IXMLNode;
```

C++

```
__fastcall IXMLNode PreviousSibling();
```

Description

PreviousSibling returns the node that precedes this one in the parent node's ChildNodes (see page 7689) property list.

If this node is the first node in its parent's child list, PreviousSibling raises an exception.

See Also

ParentNode (see page 7695)

NextSibling (see page 7682)

ChildNodes (see page 7689)

81.2.2.2.30 IXMLNode.Resync Method

Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.

Pascal

```
procedure Resync;
```

C++

```
__fastcall Resync();
```

Description

Resync forces the node to reread the values of its child nodes and attribute nodes, discarding any changes that have not been propagated to the underlying DOM implementation.

See Also

ChildNodes (see page 7689)

AttributeNodes (see page 7688)

Refresh (see page 7371)

81.2.2.2.31 IXMLNode.SetAttribute Method

Sets the value of one of this node's attributes.

Pascal

```
procedure SetAttribute(const AttrName: DOMString; const Value: OleVariant);
```

C++

```
__fastcall SetAttribute(const DOMString AttrName, const OleVariant Value);
```

Description

SetAttribute is the write implementation for the Attributes (see page 7688) property.

AttrName is the name of the attribute. If the attribute already exists for the node, its value is changed. If the attribute does not already exist, a new attribute is created.

Value is the value to assign to the attribute. This value is a string that is not parsed. Any markup (for example, for an entity reference) is treated as literal text, and must include appropriate escape sequences. If Value is NULL, the attribute is removed from this node. If Value is an empty string, the attribute is assigned an empty value.

See Also

Attributes (see page 7688)

SetAttributeNS (see page 7684)

81.2.2.2.32 IXMLNode.SetAttributeNS Method

Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.

Pascal

```
procedure SetAttributeNS(const AttrName: DOMString; const NamespaceURI: DOMString; const
Value: OleVariant);
```

C++

```
__fastcall SetAttributeNS(const DOMString AttrName, const DOMString NamespaceURI, const
OleVariant Value);
```

Description

SetAttributeNS sets the value of a specified attribute of this node.

AttrName is the name of the attribute. If the attribute already exists for the node, its value is changed. If the attribute does not already exist, a new attribute is created.

NamespaceURI (see page 7693) is the namespace for the attribute.

Value is the value to assign to the attribute. This value is a string that is not parsed. Any markup (for example, for an entity reference) is treated as literal text, and must include appropriate escape sequences. If Value is NULL, the attribute is removed from this node. If Value is an empty string, the attribute is assigned an empty value.

See Also

SetAttribute (see page 7684)

GetAttributeNS (see page 7676)

AttributeNodes (see page 7688)

81.2.2.2.33 IXMLNode.SetChildValue Method

Sets the value of a specified child node.

Pascal

```
procedure SetChildValue(const IndexOrName: OleVariant; const Value: OleVariant);
```

C++

```
__fastcall SetChildValue(const OleVariant IndexOrName, const OleVariant Value);
```

Description

SetChildValue is the write implementation of the ChildValues (see page 7690) property.

IndexOrName identifies the desired child node by either its interface, or by a string that is the local name of the child node.

Value is the value to assign.

See Also

ChildValues (see page 7690)

81.2.2.2.34 IXMLNode.SetNodeValue Method

Sets the value of this node.

Pascal

```
procedure SetNodeValue(const Value: OleVariant);
```

C++

```
__fastcall SetNodeValue(const OleVariant Value);
```

Description

SetNodeValue is the write implementation of the NodeValue (see page 7695) property.

Value is the value to assign.

See Also

NodeValue (see page 7695)

81.2.2.2.35 IXMLNode.SetReadOnly Method

Specifies whether the node can be modified.

Pascal

```
procedure SetReadOnly(const Value: Boolean);
```

C++

```
__fastcall SetReadOnly(const Boolean Value);
```

Description

SetReadOnly is the write implementation of the ReadOnly (see page 7696) property.

Value is the new read-only status of the node.

See Also

ReadOnly (see page 7696)

81.2.2.2.36 IXMLNode.SetText Method

Sets the text value of the node.

Pascal

```
procedure SetText(const Value: DOMString);
```

C++

```
__fastcall SetText(const DOMString Value);
```

Description

SetText is the write implementation for the Text (see page 7697) property.

Value is the new text value for the node.

See Also

Text (see page 7697)

81.2.2.2.37 TransformNode Method

This is the overview for the TransformNode method overload.

Overload List

	Name	Description
	IXMLNode.TransformNode (IXMLNode, IXMLDocument) (see page 7687)	Transforms the subtree rooted at this node, using a specified XSL interface.
	IXMLNode.TransformNode (IXMLNode, WideString) (see page 7687)	Transforms the subtree rooted at this node, using a specified XSL interface.

81.2.2.2.37.1 IXMLNode.TransformNode Method (IXMLNode, IXMLDocument)

Transforms the subtree rooted at this node, using a specified XSL interface.

Pascal

```
procedure TransformNode(const stylesheet: IXMLNode; var output: WideString); overload;
procedure TransformNode(const stylesheet: IXMLNode; const output: IXMLDocument); overload;
```

C++

```
__fastcall TransformNode(const IXMLNode stylesheet, BSTR output);
__fastcall TransformNode(const IXMLNode stylesheet, const IXMLDocument output);
```

Description

Call TransformNode to transform the XML (see page 7697) that is the value of the XML (see page 7697) property using the transformation specified by an XSL document.

stylesheet is a node in an XML (see page 7697) document that represents an XSL transformation. Typically, it is the document element of that document.

output represents the result of the transformation. If output is a WideString (see page 3467), TransformNode returns a string of XML (see page 7697). If output is the interface to an XML (see page 7697) document, TransformNode replaces the content of that document with the results of the transformation.

Note: TransformNode is only available when the DOMVendor used to parse this node's XML (see page 7697) document is MSXML.

See Also

XML (see page 7697)

81.2.2.3 IXMLNode Properties

The properties of the IXMLNode class are listed here.

Public Properties

	Name	Description
R	AttributeNodes (see page 7688)	Lists the interfaces for nodes that represent attributes of this node.
	Attributes (see page 7688)	Represents the values of this node's attributes.
R	ChildNodes (see page 7689)	Represents the child nodes of the node.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	Collection (see page 7690)	Indicates the collection in which this node appears.
R	DOMNode (see page 7691)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.
R	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
R	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
R	NodeName (see page 7693)	Indicates the node name.
R	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
R	OwnerDocument (see page 7695)	Identifies the document in which this node appears.
R	ParentNode (see page 7695)	Identifies the interface of the node's parent node.
R	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
	Text (see page 7697)	Represents the Text of the node.
R	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

81.2.2.3.1 IXMLNode.AttributeNodes Property

Lists the interfaces for nodes that represent attributes of this node.

Pascal

```
property AttributeNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList AttributeNodes;
```

Description

Use AttributeNodes to access the attributes of this node using an IXMLNode (see page 7669) interface. Attributes (see page 7688) modify a node in an XML (see page 7697) document. For example, given the node for

```
<Movie genre="scifi" title="Star Wars"> ... </Movie>
```

both genre and title are attributes of the node, with values of "scifi" and "Star Wars", respectively.

If an attribute consists of a simple Name=Value pair, it is simpler to use the Attributes (see page 7688) property to read or set attribute values. AttributeNodes is an IXMLNodeList (see page 7703) interface, which can be used to

Read (see page 3634) the count of attributes before iterating over all the attributes of this node.

Add or delete attribute nodes from this node.

Access attributes through an XML (see page 7697) node interface (for example, to read the attribute names from the nodes).

Only element nodes have attributes, and not every element node has them. If the node does not have any attributes, AttributeNodes is the interface for an empty list.

Note: Attributes (see page 7688) are not considered child nodes of a node and can't be accessed using the ChildNodes (see page 7689) property.

See Also

ChildNodes (see page 7689)

Attributes (see page 7688)

81.2.2.3.2 IXMLNode.Attributes Property

Represents the values of this node's attributes.

Pascal

```
property Attributes [const AttrName: DOMString]: OleVariant;
```

C++

```
__property OleVariant Attributes[DOMString const AttrName];
```

Description

Use Attributes to read or set the values of this node's attributes. Attributes modify a node in an XML (see page 7697) document. For example, given the node for

```
<Movie genre="scifi" title="Star Wars"> ... </Movie>
```

both genre and title are attributes of the node, with values of "scifi" and "Star Wars", respectively.

The AttrName index gives the name of the attribute to access. In the previous example, "genre" and "title" are the names of the attributes. When setting Attributes, if you specify the name of an attribute that already exists for a node, you change that attribute's value. If you specify an attribute name that does not correspond to an existing attribute of the node, a new attribute is

created.

When reading Attributes, if you specify the name of an attribute that does not exist for the node, the value depends on the Options property of the document that contains the node. If Options includes doAttrNull, reading an attribute that does not exist for the node results in a Null Variant (see page 3421). When Options does not include doAttrNull, reading an attribute that does not exist results in an empty string.

The value of Attributes is the text of the specified attribute. When setting attributes, the value string is not parsed. Any markup in the supplied value (for example, an entity reference) is treated as literal text. If you set an attribute to nil (Delphi) or NULL (C++), it is removed from this node. Note that you can set an attribute's value to an empty string.

See Also

AttributeNodes (see page 7688)

GetAttributeNS (see page 7676)

SetAttributeNS (see page 7684)

Options (see page 7389)

Working with XML Nodes

81.2.2.3.3 IXMLNode.ChildNodes Property

Represents the child nodes of the node.

Pascal

```
property ChildNodes: IXMLNodeList;
```

C++

```
__property IXMLNodeList ChildNodes;
```

Description

Use ChildNodes to access the children of a node. ChildNodes is an IXMLNodeList (see page 7703) interface, which can be used to access individual child nodes or to add child nodes to or delete them from this node. Each child node specifies this node as its parent node.

Tip: To get or set the values of the child nodes rather than their interfaces, use the ChildValues (see page 7690) property instead.

Note: Attributes (see page 7688) are not considered child nodes of a node. To get the values of this node's attributes, use the Attributes (see page 7688) or AttributeNodes (see page 7688) property instead.

See Also

ChildValues (see page 7690)

AttributeNodes (see page 7688)

ParentNode (see page 7695)

Attributes (see page 7688)

Working with XML Nodes

81.2.2.3.4 IXMLNode.ChildValues Property

Represents the values of this node's child nodes.

Pascal

```
property ChildValues [const IndexOrName: OleVariant]: OleVariant;
```

C++

```
__property OleVariant ChildValues[OleVariant const IndexOrName];
```

Description

Use ChildValues to access the values of this node's children.

IndexOrName identifies the desired child node either by its interface, or by a string that is the local name of the child node. If IndexOrName does not identify a child of this node, trying to get or set ChildValues causes an exception.

The value of a child node depends on the type of the child node, as indicated in the following table:

NodeType (see page 7694)	Value
ntElement	If the element contains only text, this is that text value. Otherwise, it is the Value of the first child node.
ntText	The text
ntCData	The content of the CDATA section.
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.
If the child node is any other node type, reading or setting ChildValues causes an exception.	

Note: In Delphi, ChildValues is the default property for IXMLNode (see page 7669). That means that you can omit the property name when using this property. For example

```
Edit1.Text := XMLDocument1.DocumentElement.ChildValues['Name'];
```

can also be written

```
Edit1.Text := XMLDocument1.DocumentElement['Name'];
```

Note: Attributes (see page 7688) are not considered child nodes of a node. To get or set the values of this node's attributes, use the Attributes (see page 7688) property instead.

See Also

ChildNodes (see page 7689)

ParentNode (see page 7695)

Attributes (see page 7688)

81.2.2.3.5 IXMLNode.Collection Property

Indicates the collection in which this node appears.

Pascal

```
property Collection: IXMLNodeCollection;
```

C++

```
__property IXMLNodeCollection Collection;
```

Description

Read (see page 3634) Collection to determine whether this node is one of a repeating set of child nodes. The node specified by Collection represents the same node in the XML (see page 7697) document as this node's ParentNode (see page 7695) property, but it is specialized to work with this node and any other child nodes of the same type.

For example, consider the following XML (see page 7697) fragment:

```
<students>
  <student name="John Smith">
    <grade>incomplete</grade>
  </student>
  <student name="Jane Doe">
    <grade>B+</grade>
  </student>
  <auditor name="Bill Jones"></auditor>
</students>
```

If this node represents one of the <student> nodes, then ParentNode (see page 7695) represents the <students> node, and Collection represents a copy of the <students> node that is used for only those children that are <student> nodes, and not the <auditor> nodes.

If this node does not represent one of a set of repeating child elements, Collection is nil (Delphi) or NULL (C++).

See Also

ParentNode (see page 7695)

81.2.2.3.6 IXMLNode.DOMNode Property

Provides access to the IDOMNode (see page 7557) interface for this node.

Pascal

```
property DOMNode: IDOMNode;
```

C++

```
__property IDOMNode DOMNode;
```

Description

IDOMNode (see page 7557) is the interface for this node provided by the DOM implementation that parsed the XML (see page 7697) document. You can use this interface to work with the node using the lower-level properties and methods of the DOM.

Typically, applications use the IXMLNode (see page 7669) interface to work with a node rather than the IDOMNode (see page 7557) interface. For more information on DOM interfaces, see the DOM specification on the W3 website or the documentation provided by your DOM vendor.

81.2.2.3.7 IXMLNode.HasChildNodes Property

Indicates whether this node has any child nodes.

Pascal

```
property HasChildNodes: Boolean;
```

C++

```
__property Boolean HasChildNodes;
```

Description

HasChildNodes is true if the underlying DOM node has any child nodes, false if it has no children.

Note that in the underlying DOM implementation, given the following XML (see page 7697)

```
<Title> Understanding XML </Title>
```

the "Title" node has a single child (a text node with the value 'Understanding XML (see page 7697)').

See Also

ChildNodes (see page 7689)

DOMNode (see page 7691)

81.2.2.3.8 IXMLNode.IsTextElement Property

Indicates whether the node has a single text value.

Pascal

```
property IsTextElement: Boolean;
```

C++

```
__property Boolean IsTextElement;
```

Description

Read (see page 3634) IsTextElement to determine whether this node represents a single text value. For example, if the node represents the following:

```
<Title> Understanding XML </Title>
```

IsTextElement is true, because the node represents a tagged element and the text that is its value.

Note: In the underlying DOM implementation, nodes for which IsTextElement is true are element nodes that have a single child node that is a text node. IXMLNode (see page 7669) flattens this out so that you can use the element node to work with the text value (through the Text (see page 7697) property), rather than requiring you to use a separate node for the text value.

See Also

NodeType (see page 7694)

Text (see page 7697)

Working with XML Nodes

81.2.2.3.9 IXMLNode.LocalName Property

Indicates the name of the node without any namespace prefix.

Pascal

```
property LocalName: DOMString;
```

C++

```
__property DOMString LocalName;
```

Description

Read (see page 3634) LocalName to determine the local name of the underlying DOM node. LocalName is only defined for

nodes of type ntElement or ntAttrribute.

For element nodes, LocalName is derived from the name that appears in the XML (see page 7697) tag. For example, the local name for <xsi:Name First="John" Last="Doe"> is 'Name'. (The string "xsi" is called the prefix).

For attribute nodes, the local name is derived from the string that appears to the left of the equals sign in the attribute declaration. For example, the element <xsi:Name xsi:First="John" xsi:Last="Doe"> results in two attribute nodes, with the local names 'First' and 'Last'.

For any other node types, localName is nil (Delphi) or NULL (C++).

To get the name of a node when localName is not defined, use the NodeName (see page 7693) property instead. If the node's name has no namespace prefix, LocalName has the same value as NodeName (see page 7693).

See Also

NamespaceURI (see page 7693)

Prefix (see page 7696)

NodeName (see page 7693)

81.2.2.3.10 IXMLNode.NamespaceURI Property

Identifies the URI for the namespace used in the qualified node name.

Pascal

```
property NamespaceURI: DOMString;
```

C++

```
__property DOMString NamespaceURI;
```

Description

NamespaceURI is the URI for the namespace that should be used to interpret the node's name.

Only element and attribute nodes can have a namespace URI value. For any other node type, NamespaceURI is an empty string.

The namespace URI is only available if it is explicitly assigned when the node is created. By default, IXMLNode (see page 7669) does not assign namespaces to the new nodes it creates.

See Also

NodeName (see page 7693)

NodeType (see page 7694)

Prefix (see page 7696)

LocalName (see page 7692)

CreateDOMNode (see page 7488)

namespaceURI (see page 7571)

81.2.2.3.11 IXMLNode.NodeName Property

Indicates the node name.

Pascal

```
property NodeName: DOMstring;
```

C++

```
__property DOMstring NodeName;
```

Description

NodeName is the name of the underlying DOM node.

The node's name depends on the type of the node, as indicated in the following table:

NodeType (see page 7694)	NodeName
ntAttribute	The attribute name
ntElement	The tag name
ntText	'#text'
ntCData	'#cdata-section'
ntEntityRef	The name of the entity reference.
ntEntity	The entity name
ntProcessingInstr	the target of the processing instruction
ntComment	'#comment'
ntDocument	'#document'
ntDocType	The document type name
ntDocFragment	'#document-fragment'
ntNotation	The notation name

Note: If Prefix (see page 7696) and LocalName (see page 7692) are both defined for a node, the node name is the combination of these two values.

See Also

NodeType (see page 7694)

Prefix (see page 7696)

LocalName (see page 7692)

81.2.2.3.12 IXMLNode.NodeType Property

Indicates the type of the node.

Pascal

```
property NodeType: TNodeType;
```

C++

```
__property TNodeType NodeType;
```

Description

Read (see page 3634) NodeType to determine the type of the node. The type reflects the way the node is used in the XML (see page 7697) document.

See Also

IsTextElement (see page 7692)

81.2.2.3.13 IXMLNode.NodeValue Property

Specifies the value of this node.

Pascal

```
property NodeValue: OleVariant;
```

C++

```
__property OleVariant NodeValue;
```

Description

Use NodeValue to get or set the value of the node. The meaning of a node's value depends on the type of the node, as indicated in the following table:

NodeType (see page 7694)	Value
ntAttribute	The attribute value
ntElement	If the element contains only text, this is that text value. Otherwise, trying to read or set NodeValue causes an exception.
ntText	The text
ntCData	The content of the CDATA section.
ntProcessingInstr	The content of the processing instruction except for the target.
ntComment	The value (text) of the comment.

Trying to read or set the value of any other node type causes an exception.

See Also

ChildValues (see page 7690)

Text (see page 7697)

81.2.2.3.14 IXMLNode.OwnerDocument Property

Identifies the document in which this node appears.

Pascal

```
property OwnerDocument: IXMLDocument;
```

C++

```
__property IXMLDocument OwnerDocument;
```

Description

Read (see page 3634) OwnerDocument to obtain the IXMLDocument (see page 7640) interface of the document to which this node belongs.

See Also

ParentNode (see page 7695)

81.2.2.3.15 IXMLNode.ParentNode Property

Identifies the interface of the node's parent node.

Pascal

```
property ParentNode: IXMLNode;
```

C++

```
__property IXMLNode ParentNode;
```

Description

Read (see page 3634) ParentNode to access the node's parent node.

See Also

ChildNodes (see page 7689)

81.2.2.3.16 IXMLNode.Prefix Property

Identifies the namespace prefix of the node's name.

Pascal

```
property Prefix: DOMString;
```

C++

```
__property DOMString Prefix;
```

Description

Prefix is the namespace prefix of an element or attribute node's name. A namespace prefix is a symbolic name for a namespace URI.

For element nodes, the namespace prefix is derived from the name that appears in the XML (see page 7697) tag. For example, the namespace prefix for <xsi:Name First="John" Last="Doe"> is 'xsi'.

For attribute nodes, the namespace prefix is derived from the string that appears to the left of the equals sign in the attribute declaration. For example the element <xsi:Name xsn:First="John" Last="Doe"> results in two attribute nodes, with namespace prefixes of 'xsn' and '', respectively. Note that the attribute never inherits a namespace prefix from the node to which it is attached.

For any other node types, the namespace prefix is nil (Delphi) or NULL (C++).

See Also

LocalName (see page 7692)

NodeType (see page 7694)

NamespaceURI (see page 7693)

81.2.2.3.17 IXMLNode.ReadOnly Property

Specifies whether the node can be modified.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

ReadOnly specifies whether the value, child nodes, or attributes of the node can be changed. When ReadOnly is true, the node can't be modified. Read (see page 3634)-only nodes raise an exception when an attempt is made to modify them.

When ReadOnly is false, the node can be modified.

See Also

AttributeNodes (see page 7688)

ChildNodes (see page 7689)

NodeValue (see page 7695)

81.2.2.3.18 IXMLNode.Text Property

Represents the Text of the node.

Pascal

```
property Text: DOMString;
```

C++

```
__property DOMString Text;
```

Description

Text represents the text of the node. For example, if the node corresponds to

```
<Title> Understanding XML </Title>
```

The text of the node is the string 'Understanding XML (see page 7697)'.

Text is intended for use nodes where the IsTextElement (see page 7692) property is true. If IsTextElement (see page 7692) is false, then

If the node has no children, the value of Text is an empty string. Setting Text is this case result in a node where IsTextElement (see page 7692) istrue.

If the node has children (other than a single DOM text node), reading or setting Text causes an exception.

See Also

IsTextElement (see page 7692)

NodeValue (see page 7695)

Working with XML Nodes

81.2.2.3.19 IXMLNode.XML Property

Indicates the XML that corresponds to the subtree rooted at this node.

Pascal

```
property XML: DOMString;
```

C++

```
__property DOMString XML;
```

Description

XML is the XML that corresponds to the document fragment that consists of this node and any child nodes it contains.

Note: XML is only available when the DOMVendor used to parse this node's XML document is MSXML.

See Also

Text (see page 7697)

ChildValues (see page 7690)

DOMVendor (see page 7386)

81.2.3 IXMLNodeCollection Interface

IXMLNodeCollection is the interface for a set of child nodes that are all the same type.

Class Hierarchy

Pascal

```
IXMLNodeCollection = interface(IXMLNode);
```

C++

```
__interface IXMLNodeCollection : public IXMLNode;
```

File

XMLIntf

Description

Use IXMLNodeCollection to work with repeating elements in an XML (see page 7697) document. The XML (see page 7697) Data Binding wizard generates descendants of IXMLNodeCollection interface to represent sets of child nodes that are all of a particular type.

IXMLNodeCollection is a descendant of IXMLNode (see page 7669). As such, it provides generic support for working with a node in an XML (see page 7697) document. In addition, IXMLNodeCollection introduces properties and methods that manage a set of child nodes that are all the same type of node (that all have the same tag names or that are defined as the same type in an XML (see page 7697) schema).

Note: C++ method declarations that use IXMLNodeCollection use the _di_IXMLNodeCollection type instead. This type is a DelphiInterface (see page 3256) wrapper around the IXMLNodeCollection interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IXMLNodeCollection >
_di_IXMLNodeCollection;
```

See Also

TXMLDocument (see page 7347)

IXMLNode (see page 7669)

TXMLNodeCollection (see page 7444)

81.2.3.1 IXMLNodeCollection Members

The following tables list the members exposed by IXMLNodeCollection.

Public Methods

	Name	Description
	AddChild (see page 7672)	This is the overview for the AddChild method overload.
	Clear (see page 7700)	Removes all child nodes in the Nodes (see page 7703) property from the ChildList and Nodes (see page 7703) properties.

	CloneNode (see page 7673)	Creates a copy of this node and returns its interface.
	DeclareNamespace (see page 7674)	Adds an attribute to the node that declares a specified namespace URI.
	Delete (see page 7700)	Removes one of the repeating child nodes from this node.
	FindNamespaceDecl (see page 7674)	Returns the attribute node that declares a specified Namespace URI.
	FindNamespaceURI (see page 7674)	Returns the namespace URI for a namespace prefix or qualified tag name.
	GetAttribute (see page 7675)	Returns the value of one of this node's attributes.
	GetAttributeNodes (see page 7675)	Returns the value of the AttributeNodes (see page 7688) property.
	GetAttributeNS (see page 7676)	Returns the value of a specified attribute.
	GetChildNodes (see page 7676)	Returns the value of the ChildNodes (see page 7689) property.
	GetChildValue (see page 7676)	Returns the value of a specified child node.
	GetCollection (see page 7677)	Returns the value of the Collection (see page 7690) property.
	GetCount (see page 7701)	Returns the value of the Count (see page 7702) property.
	GetDOMNode (see page 7677)	Returns the value of the DOMNode (see page 7691) property.
	GetHasChildNodes (see page 7678)	Indicates whether the node has any child nodes.
	GetIsTextElement (see page 7678)	Indicates whether the node has a single text value.
	GetLocalName (see page 7678)	Returns the name of the node without any namespace prefix.
	GetNamespaceURI (see page 7679)	Returns the namespace URI for the node's qualified name.
	GetNode (see page 7701)	Returns the interface for one of the repeating child nodes.
	GetNodeName (see page 7679)	Returns the name of the node.
	GetNodeType (see page 7679)	Returns the type of the node.
	GetNodeValue (see page 7680)	Returns the value of the node.
	GetOwnerDocument (see page 7680)	Returns the interface for the document in which this node appears.
	GetParentNode (see page 7680)	Returns the interface for the node's parent node.
	GetPrefix (see page 7680)	Returns the namespace prefix from the node's name.
	GetReadOnly (see page 7681)	Returns the value of the ReadOnly (see page 7696) property.
	GetText (see page 7681)	Returns the text value of the node.
	GetXML (see page 7681)	Returns the value of the XML (see page 7697) property.
	HasAttribute (see page 7682)	This is the overview for the HasAttribute method overload.
	NextSibling (see page 7682)	Returns the next child of this node's parent.
	Normalize (see page 7683)	Converts the subtree beneath this node to the structure it would have if it were just loaded from a document.
	PreviousSibling (see page 7683)	Returns the previous child of this node's parent.
	Remove (see page 7702)	Removes one of the repeating child nodes from this node.
	Resync (see page 7684)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SetAttribute (see page 7684)	Sets the value of one of this node's attributes.
	SetAttributeNS (see page 7684)	Sets the value of one of this node's attributes when you must explicitly specify the attribute's namespace.
	SetChildValue (see page 7685)	Sets the value of a specified child node.
	SetNodeValue (see page 7685)	Sets the value of this node.
	SetReadOnly (see page 7686)	Specifies whether the node can be modified.
	SetText (see page 7686)	Sets the text value of the node.
	TransformNode (see page 7686)	This is the overview for the TransformNode method overload.

Public Properties

	Name	Description
R	AttributeNodes (see page 7688)	Lists the interfaces for nodes that represent attributes of this node.
	Attributes (see page 7688)	Represents the values of this node's attributes.
R	ChildNodes (see page 7689)	Represents the child nodes of the node.
	ChildValues (see page 7690)	Represents the values of this node's child nodes.
R	Collection (see page 7690)	Indicates the collection in which this node appears.
R	Count (see page 7702)	Indicates the number of repeating child nodes.
R	DOMNode (see page 7691)	Provides access to the IDOMNode (see page 7557) interface for this node.
R	HasChildNodes (see page 7691)	Indicates whether this node has any child nodes.
R	IsTextElement (see page 7692)	Indicates whether the node has a single text value.

	LocalName (see page 7692)	Indicates the name of the node without any namespace prefix.
	NamespaceURI (see page 7693)	Identifies the URI for the namespace used in the qualified node name.
	NodeName (see page 7693)	Indicates the node name.
	Nodes (see page 7703)	Lists the interfaces of the repeating child nodes.
	NodeType (see page 7694)	Indicates the type of the node.
	NodeValue (see page 7695)	Specifies the value of this node.
	OwnerDocument (see page 7695)	Identifies the document in which this node appears.
	ParentNode (see page 7695)	Identifies the interface of the node's parent node.
	Prefix (see page 7696)	Identifies the namespace prefix of the node's name.
	ReadOnly (see page 7696)	Specifies whether the node can be modified.
	Text (see page 7697)	Represents the Text of the node.
	XML (see page 7697)	Indicates the XML that corresponds to the subtree rooted at this node.

81.2.3.2 IXMLNodeCollection Methods

The methods of the IXMLNodeCollection class are listed here.

Public Methods

	Name	Description
	Clear (see page 7700)	Removes all child nodes in the Nodes (see page 7703) property from the ChildList and Nodes (see page 7703) properties.
	Delete (see page 7700)	Removes one of the repeating child nodes from this node.
	GetCount (see page 7701)	Returns the value of the Count (see page 7702) property.
	GetNode (see page 7701)	Returns the interface for one of the repeating child nodes.
	Remove (see page 7702)	Removes one of the repeating child nodes from this node.

81.2.3.2.1 IXMLNodeCollection.Clear Method

Removes all child nodes in the Nodes (see page 7703) property from the ChildList and Nodes (see page 7703) properties.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Clear deletes every child node from the collection (all the nodes in the Nodes (see page 7703) property), along with the corresponding nodes in the ChildNodes (see page 7689) property.

See Also

Nodes (see page 7703)

Delete (see page 7700)

Remove (see page 7702)

ChildNodes (see page 7689)

81.2.3.2.2 IXMLNodeCollection.Delete Method

Removes one of the repeating child nodes from this node.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Delete removes a specified child node from this node.

Index identifies the child to remove. It is the index of the child in the Nodes (see page 7703) property list of repeating child nodes. The index 0 represents the first repetition, 1 represents the second repetition, and so on.

See Also

Remove (see page 7702)

AddChild (see page 7672)

Nodes (see page 7703)

Clear (see page 7700)

81.2.3.2.3 IXMLNodeCollection.GetCount Method

Returns the value of the Count (see page 7702) property.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the read implementation of the Count (see page 7702) property.

See Also

Count (see page 7702)

81.2.3.2.4 IXMLNodeCollection.GetNode Method

Returns the interface for one of the repeating child nodes.

Pascal

```
function GetNode(Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode GetNode(int Index);
```

Description

GetNode is the read implementation of the Nodes (see page 7703) property.

Index identifies which repetition of the child node is desired, where 0 is the first repetition, 1 is the second repetition, and so on.

See Also

Nodes (see page 7703)

81.2.3.2.5 IXMLNodeCollection.Remove Method

Removes one of the repeating child nodes from this node.

Pascal

```
function Remove(const Node: IXMLNode): Integer;
```

C++

```
__fastcall int Remove(const IXMLNode Node);
```

Description

Remove removes a specified child node from the collection of repeating child nodes. It removes the node from both the collection, and from the ChildNodes (see page 7689) property, which lists all children of this node.

Node is the interface of the child to remove. It must represent on of the repeating child nodes.

To remove a child that is not one of the repeating child nodes, use the ChildNodes (see page 7689) property instead.

See Also

Delete (see page 7700)

ChildNodes (see page 7689)

Nodes (see page 7703)

81.2.3.3 IXMLNodeCollection Properties

The properties of the IXMLNodeCollection class are listed here.

Public Properties

	Name	Description
	Count (see page 7702)	Indicates the number of repeating child nodes.
	Nodes (see page 7703)	Lists the interfaces of the repeating child nodes.

81.2.3.3.1 IXMLNodeCollection.Count Property

Indicates the number of repeating child nodes.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read (see page 3634) Count to obtain the number of repeating children of this node. Use Count to obtain an upper limit when addressing child nodes by index (for example, when iterating over all nodes in the Nodes (see page 7703) property list).

Count is changed when you add child nodes using the AddChild (see page 7672) method or delete them using the Delete (see page 7700) or Remove (see page 7702) method. You can access the individual repeating child nodes using the Nodes (see page 7703) property.

See Also

Nodes (see page 7703)

AddChild (see page 7672)

Remove (see page 7702)

Delete (see page 7700)

81.2.3.3.2 IXMLNodeCollection.Nodes Property

Lists the interfaces of the repeating child nodes.

Pascal

```
property Nodes [Index: Integer]: IXMLNode;
```

C++

```
__property IXMLNode Nodes[int Index];
```

Description

Use Nodes to access nodes from the set of repeating child nodes. The value of Nodes is the IXMLNode (see page 7669) interface that represents a specified child node.

Index identifies which repetition of the child node is desired, where 0 is the first repetition, 1 is the second repetition, and so on.

Note: The XML (see page 7697) Data Binding wizard generates a nearly identical property in IXMLNodeCollection (see page 7698) descendants called Items. Items differs from Nodes in that the value is an IXMLNode (see page 7669) descendant specific to the type of the repeating element, rather than the generic IXMLNode (see page 7669) interface.

Note: In Delphi, ChildNodes (see page 7689) is the default property for IXMLNodeCollection (see page 7698). That means that you can omit the property name when using this property. In IXMLNodeCollection (see page 7698) descendants that are generated by the XML (see page 7697) Data Binding wizard, the Items property is the default property instead.

Note: As a descendant of IXMLNode (see page 7669), IXMLNodeCollection (see page 7698) also inherits the ChildNodes (see page 7689) property, which lists all the child nodes for this node. Nodes differs from ChildNodes (see page 7689) in that it contains only those child nodes that are in the repeating collection.

See Also

Count (see page 7702)

ChildNodes (see page 7689)

81.2.4 IXMLNodeList Interface

IXMLNodeList represents a set of nodes in an XML document.

Class Hierarchy

Pascal

```
IXMLNodeList = interface;
```

C++

```
__interface IXMLNodeList;
```

File

XMLIntf

Description

Use IXMLNodeList to work with a set of related nodes in an XML document. IXMLNodeList can be used to add or delete nodes from the set, or to access specific nodes.

Note: C++ method declarations that use IXMLNodeList use the _di_IXMLNodeList type instead. This type is a DelphiInterface (see page 3256) wrapper around the IXMLNodeList interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IXMLNodeList >  _di_IXMLNodeList;
```

See Also

TXMLNodeList (see page 7460)

IXMLNode (see page 7669)

TXMLDocument (see page 7347)

81.2.4.1 IXMLNodeList Members

The following tables list the members exposed by IXMLNodeList.

Public Methods

	Name	Description
	Add (see page 7705)	Adds a new node to the end of the list.
	BeginUpdate (see page 7705)	Increments the value of UpdateCount (see page 7715).
	Clear (see page 7706)	Removes all nodes from the list.
	Delete (see page 7706)	This is the overview for the Delete method overload.
	EndUpdate (see page 7707)	Decrements the value of UpdateCount (see page 7715).
	FindNode (see page 7708)	This is the overview for the FindNode method overload.
	FindSibling (see page 7709)	Returns a node that appears a specified amount before or after another node.
	First (see page 7709)	Returns the first node in the list.
	Get (see page 7710)	Returns a specified node in the list.
	GetCount (see page 7710)	Returns the number of nodes in the list.
	GetNode (see page 7710)	Returns a specified node from the list.
	GetUpdateCount (see page 7711)	Returns the value of the UpdateCount (see page 7715) property.
	IndexOf (see page 7711)	This is the overview for the IndexOf method overload.
	Insert (see page 7712)	Inserts a new node into a specified position in the list.
	Last (see page 7712)	Returns the last node in the list.
	Remove (see page 7713)	Removes a specified node from the list.
	ReplaceNode (see page 7713)	Replaces a specified node in the list with another node.

Public Properties

	Name	Description
R	Count (see page 7714)	Indicates the number of nodes in the list.
R	Nodes (see page 7714)	Provides access to the nodes in the list.
R	UpdateCount (see page 7715)	Indicates the number of times an application has called BeginUpdate (see page 7705) without a matching call to EndUpdate (see page 7707).

81.2.4.2 IXMLNodeList Methods

The methods of the IXMLNodeList class are listed here.

Public Methods

	Name	Description
	Add (see page 7705)	Adds a new node to the end of the list.
	BeginUpdate (see page 7705)	Increments the value of UpdateCount (see page 7715).
	Clear (see page 7706)	Removes all nodes from the list.
	Delete (see page 7706)	This is the overview for the Delete method overload.
	EndUpdate (see page 7707)	Decrements the value of UpdateCount (see page 7715).
	FindNode (see page 7708)	This is the overview for the FindNode method overload.
	FindSibling (see page 7709)	Returns a node that appears a specified amount before or after another node.
	First (see page 7709)	Returns the first node in the list.
	Get (see page 7710)	Returns a specified node in the list.
	GetCount (see page 7710)	Returns the number of nodes in the list.
	GetNode (see page 7710)	Returns a specified node from the list.
	GetUpdateCount (see page 7711)	Returns the value of the UpdateCount (see page 7715) property.
	IndexOf (see page 7711)	This is the overview for the IndexOf method overload.
	Insert (see page 7712)	Inserts a new node into a specified position in the list.
	Last (see page 7712)	Returns the last node in the list.
	Remove (see page 7713)	Removes a specified node from the list.
	ReplaceNode (see page 7713)	Replaces a specified node in the list with another node.

81.2.4.2.1 IXMLNodeList.Add Method

Adds a new node to the end of the list.

Pascal

```
function Add(const Node: IXMLNode): Integer;
```

C++

```
__fastcall int Add(const IXMLNode Node);
```

Description

Call Add to add a node to the end of the list. Add returns the index of the node once it is added, where 0 is the index of the first node in the list, 1 is the index of the second node, and so on.

Node is the node to add to the list.

See Also

Delete (see page 7707)

Remove (see page 7713)

IndexOf (see page 7711)

Insert (see page 7712)

Nodes (see page 7714)

81.2.4.2.2 IXMLNodeList.BeginUpdate Method

Increments the value of UpdateCount (see page 7715).

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

Call BeginUpdate before making several changes to the nodes in the list (such as adding or removing several nodes). BeginUpdate increments the UpdateCount (see page 7715) property, to keep track of the fact that the list is in the middle of an update. When the update is complete, call EndUpdate (see page 7707) to decrement the UpdateCount (see page 7715) property.

Every call to BeginUpdate should be matched by a call to EndUpdate (see page 7707), so that the UpdateCount (see page 7715) property accurately reflects whether an update operation is underway.

See Also

UpdateCount (see page 7715)

EndUpdate (see page 7707)

81.2.4.2.3 IXMLNodeList.Clear Method

Removes all nodes from the list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the list.

Note: Clear does not call the BeginUpdate (see page 7705) and EndUpdate (see page 7707) methods, even though it may result in the deletion of more than one node.

See Also

Delete (see page 7707)

Remove (see page 7713)

Nodes (see page 7714)

81.2.4.2.4 Delete Method

This is the overview for the Delete method overload.

Overload List

	Name	Description
	IXMLNodeList.Delete (DOMString) (see page 7707)	Removes a specified node from the list.
	IXMLNodeList.Delete (DOMString, DOMString) (see page 7707)	Removes a specified node from the list.

	IXMLNodeList.Delete (Integer) (see page 7707)	Removes a specified node from the list.

81.2.4.2.4.1 IXMLNodeList.Delete Method (DOMString)

Removes a specified node from the list.

Pascal

```
function Delete(const Index: Integer): Integer; overload;
function Delete(const Name: DOMString): Integer; overload;
function Delete(const Name: DOMString; const NamespaceURI: DOMString): Integer; overload;
```

C++

```
__fastcall int Delete(const int Index);
__fastcall int Delete(const DOMString Name);
__fastcall int Delete(const DOMString Name, const DOMString NamespaceURI);
```

Description

Delete removes the node specified by the Index or Name parameter.

Name identifies the node to remove from the list. This is the local name of the node to remove.

NamespaceURI identifies the namespace to use when interpreting Name (if necessary).

Index identifies the node to remove by index rather than name. Index ranges from 0 to one less than the value of the Count (see page 7714) property.

Delete returns the index of the node that was removed. If there was no node that matched the value of Index or Name, Delete returns –1.

See Also

Remove (see page 7713)

Clear (see page 7706)

IndexOf (see page 7711)

LocalName (see page 7692)

NamespaceURI (see page 7693)

Working with XML Nodes

81.2.4.2.5 IXMLNodeList.EndUpdate Method

Decrements the value of UpdateCount (see page 7715).

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Call EndUpdate after making several changes to the nodes in the list (such as adding or removing several nodes). EndUpdate decrements the UpdateCount (see page 7715) property, which was incremented by a previous call to BeginUpdate (see page 7705).

Every call to BeginUpdate (see page 7705) should be matched by a call to EndUpdate, so that the UpdateCount (see page

7715) property accurately reflects whether an update operation is underway.

See Also

UpdateCount (see page 7715)

BeginUpdate (see page 7705)

81.2.4.2.6 FindNode Method

This is the overview for the FindNode method overload.

Overload List

	Name	Description
	IXMLNodeList.FindNode (DOMString) (see page 7708)	Returns a specified node from the list.
	IXMLNodeList.FindNode (DOMString, DOMString) (see page 7708)	Returns a specified node from the list.
	IXMLNodeList.FindNode (TGuid) (see page 7708)	Returns a specified node from the list.

81.2.4.2.6.1 IXMLNodeList.FindNode Method (DOMString)

Returns a specified node from the list.

Pascal

```
function FindNode(NodeName: DOMString): IXMLNode; overload;
function FindNode(NodeName: DOMString; NamespaceURI: DOMString): IXMLNode; overload;
function FindNode(ChildNodeType: TGuid): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode FindNode(DOMString NodeName);
__fastcall IXMLNode FindNode(DOMString NodeName, DOMString NamespaceURI);
__fastcall IXMLNode FindNode(TGuid ChildNodeType);
```

Description

Call FindNode to access a particular node in the list.

NodeName is the node to access. It specifies the LocalName property of the desired node.

NamespaceURI identifies the namespace that qualifies NodeName. It is the same as the NamespaceURI property of the desired node.

ChildNodeType identifies the node to access by its interface type (GUID), rather than by name.

FindNode returns the interface for the node if it is in the list. If NodeName or ChildNodeType does not specify a node in the list, FindNode returns nil (Delphi) or NULL (C++).

See Also

FindSibling (see page 7709)

First (see page 7709)

Last (see page 7712)

IndexOf (see page 7711)

LocalName (see page 7692)

Nodes (see page 7714)

NamespaceURI (see page 7693)

81.2.4.2.7 IXMLNodeList.FindSibling Method

Returns a node that appears a specified amount before or after another node.

Pascal

```
function FindSibling(const Node: IXMLNode; Delta: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode FindSibling(const IXMLNode Node, int Delta);
```

Description

Call FindSibling to access the node whose position has a specified relationship to another node.

Node is a node in the list to use as a reference point.

Delta indicates where the desired node appears, relative to Node. If Delta is positive, FindSibling returns the node that appears Delta positions after Node. If Delta is negative, FindSibling returns a node that appears before Node.

FindSibling returns the node that appears at the position offset by Delta, relative to the position of Node. If Delta specifies a position before the first node or after the last node in the list, FindSibling returns nil (Delphi) or NULL (C++).

See Also

FindNode (see page 7708)

First (see page 7709)

Last (see page 7712)

IndexOf (see page 7711)

81.2.4.2.8 IXMLNodeList.First Method

Returns the first node in the list.

Pascal

```
function First: IXMLNode;
```

C++

```
__fastcall IXMLNode First();
```

Description

Call First to access the first node in the list. If the list is empty, First raises an exception.

See Also

FindNode (see page 7708)

FindSibling (see page 7709)

Last (see page 7712)

Nodes (see page 7714)

81.2.4.2.9 IXMLNodeList.Get Method

Returns a specified node in the list.

Pascal

```
function Get(Index: Integer): IXMLNode;
```

C++

```
__fastcall IXMLNode Get(int Index);
```

Description

Call Get to retrieve a node from the list, given its index.

Index specifies the node to fetch, where 0 identifies the first node, 1 identifies the second node, and so on. Index should be less than the value of the Count (see page 7714) property.

See Also

Nodes (see page 7714)

GetNode (see page 7710)

Count (see page 7714)

81.2.4.2.10 IXMLNodeList.GetCount Method

Returns the number of nodes in the list.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the read implementation of the Count (see page 7714) property.

See Also

Count (see page 7714)

81.2.4.2.11 IXMLNodeList.GetNode Method

Returns a specified node from the list.

Pascal

```
function GetNode(const IndexOrName: OleVariant): IXMLNode;
```

C++

```
__fastcall IXMLNode GetNode(const OleVariant IndexOrName);
```

Description

GetNode is the read implementation of the Nodes (see page 7714) property.

IndexOrName identifies the desired node. It can be

The index of the node, where 0 is the index of the first node, 1 is the index of the second node, and so on.

The LocalName property of a node in the list.

If IndexOrName does not identify a node in the list, GetNode tries to create a new node with the name specified by IndexOrName. If it can't create the new node, GetNode raises an exception.

See Also

FindNode (see page 7708)

Nodes (see page 7714)

LocalName (see page 7692)

Get (see page 7710)

81.2.4.2.12 IXMLNodeList.GetUpdateCount Method

Returns the value of the UpdateCount (see page 7715) property.

Pascal

```
function GetUpdateCount: Integer;
```

C++

```
__fastcall int GetUpdateCount();
```

Description

GetUpdateCount is the read implementation of the UpdateCount (see page 7715) property.

See Also

UpdateCount (see page 7715)

81.2.4.2.13 IndexOf Method

This is the overview for the IndexOf method overload.

Overload List

	Name	Description
	IXMLNodeList.IndexOf (DOMString) (see page 7711)	Returns the index of a specified node.
	IXMLNodeList.IndexOf (DOMString, DOMString) (see page 7711)	Returns the index of a specified node.
	IXMLNodeList.IndexOf (IXMLNode) (see page 7711)	Returns the index of a specified node.

81.2.4.2.13.1 IXMLNodeList.IndexOf Method (DOMString)

Returns the index of a specified node.

Pascal

```
function IndexOf(const Node: IXMLNode): Integer; overload;
function IndexOf(const Name: DOMString): Integer; overload;
function IndexOf(const Name: DOMString; const NamespaceURI: DOMString): Integer; overload;
```

C++

```
__fastcall int IndexOf(const IXMLNode Node);
```

```
__fastcall int IndexOf(const DOMString Name);
__fastcall int IndexOf(const DOMString Name, const DOMString NamespaceURI);
```

Description

Call IndexOf to locate a node in the list. You can specify which node to locate using its name or its interface.

Name is the LocalName property of the node to locate.

NamespaceURI identifies the namespace to use when interpreting LocalName (if necessary).

Node is the interface of the node to locate.

IndexOf returns the index of the specified node, where 0 is the index of the first node, 1 is the index of the second node, and so on. If the specified node is not in the list, IndexOf returns -1.

See Also

FindNode (see page 7708)

LocalName (see page 7692)

Nodes (see page 7714)

NamespaceURI (see page 7693)

81.2.4.2.14 IXMLNodeList.Insert Method

Inserts a new node into a specified position in the list.

Pascal

```
procedure Insert(Index: Integer; const Node: IXMLNode);
```

C++

```
__fastcall Insert(int Index, const IXMLNode Node);
```

Description

Call Insert to add a node at the position specified by Index.

Index specifies where to insert the node, where 0 is the first position, 1 is second position, and so on. If Index does not specify a valid index, Insert raises an exception.

Node is the node to add to the list.

See Also

Delete (see page 7707)

Remove (see page 7713)

IndexOf (see page 7711)

Add (see page 7705)

Nodes (see page 7714)

81.2.4.2.15 IXMLNodeList.Last Method

Returns the last node in the list.

Pascal

```
function Last: IXMLNode;
```

C++

```
__fastcall IXMLNode Last();
```

Description

Call Last to access the last node in the list. If the list is empty, Last raises an exception.

See Also

FindNode (see page 7708)

FindSibling (see page 7709)

First (see page 7709)

Nodes (see page 7714)

81.2.4.2.16 IXMLNodeList.Remove Method

Removes a specified node from the list.

Pascal

```
function Remove(const Node: IXMLNode): Integer;
```

C++

```
__fastcall int Remove(const IXMLNode Node);
```

Description

Remove removes the specified node from the list.

Node is the node to remove from the list.

Remove returns the index of Node before it was removed. If node is not a node in the list, Remove returns -1.

See Also

Delete (see page 7707)

Clear (see page 7706)

81.2.4.2.17 IXMLNodeList.ReplaceNode Method

Replaces a specified node in the list with another node.

Pascal

```
function ReplaceNode(const OldNode: IXMLNode; const NewNode: IXMLNode): IXMLNode;
```

C++

```
__fastcall IXMLNode ReplaceNode(const IXMLNode OldNode, const IXMLNode NewNode);
```

Description

Call ReplaceNode to replace the node specified by OldNode with the node specified by NewNode.

OldNode is the node to replace. If OldNode does not appear in the list, then ReplaceNode adds the new node to the end of the list.

NewNode is the node to add to the list in place of OldNode.

ReplaceNode returns OldNode (even if OldNode did not appear in the list).

See Also

Remove (see page 7713)

Insert (see page 7712)

81.2.4.3 IXMLNodeList Properties

The properties of the IXMLNodeList class are listed here.

Public Properties

	Name	Description
	Count (see page 7714)	Indicates the number of nodes in the list.
	Nodes (see page 7714)	Provides access to the nodes in the list.
	UpdateCount (see page 7715)	Indicates the number of times an application has called BeginUpdate (see page 7705) without a matching call to EndUpdate (see page 7707).

81.2.4.3.1 IXMLNodeList.Count Property

Indicates the number of nodes in the list.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read (see page 3634) Count to determine the number of nodes in the list. Count provides an upper limit to the indexes that can be used with the Nodes (see page 7714) property.

To change the value of Count, add nodes using the Add (see page 7705) or Insert (see page 7712) method, or remove them using the Delete (see page 7707) or Remove (see page 7713) method.

See Also

Nodes (see page 7714)

Add (see page 7705)

Delete (see page 7707)

Remove (see page 7713)

Insert (see page 7712)

81.2.4.3.2 IXMLNodeList.Nodes Property

Provides access to the nodes in the list.

Pascal

```
property Nodes [const IndexOrName: OleVariant]: IXMLNode;
```

C++

```
__property IXMLNode Nodes[OleVariant const IndexOrName];
```

Description

Read (see page 3634) Nodes to access a specified node in the list.

IndexOrName identifies the desired node. It can be

The index of the node, where 0 is the index of the first node, 1 is the index of the second node, and so on. The Count (see page 7714) property provides an upper bound on the indexes you can specify.

The LocalName property of a node in the list.

If IndexOrName does not identify a node in the list, and if the document that contains this node list's parent includes doNodeAutoCreate in its Options property, then the node list tries to create a new node with the name specified by IndexOrName. If the node list can't create the new node, it raises an exception.

See Also

Count (see page 7714)

FindNode (see page 7708)

LocalName (see page 7692)

Options (see page 7389)

81.2.4.3.3 IXMLNodeList.UpdateCount Property

Indicates the number of times an application has called BeginUpdate (see page 7705) without a matching call to EndUpdate (see page 7707).

Pascal

```
property UpdateCount: Integer;
```

C++

```
__property int UpdateCount;
```

Description

UpdateCount keeps track of whether all update operations have been completed. When an application starts making changes to the list, it calls BeginUpdate (see page 7705), which increments UpdateCount. When those changes are complete, it calls EndUpdate (see page 7707), which decrements UpdateCount. Thus, UpdateCount allows calls to BeginUpdate (see page 7705) and EndUpdate (see page 7707) to be nested.

Applications can avoid responding to updates in a piecemeal fashion by checking UpdateCount and only responding when it is 0.

See Also

BeginUpdate (see page 7705)

EndUpdate (see page 7707)

81.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TNodeType (see page 7716)	TNodeType identifies the type of a node in an XML document.
	TParseOption (see page 7718)	TParseOption and TParseOptions (see page 7721) represent implementation-specific options that are followed when parsing the XML document.
	TXMLDocOption (see page 7718)	TXMLDocOption and TXMLDocOptions (see page 7722) indicate types of information that an XML document automatically supplies.
	TXMLEncodingType (see page 7719)	TXMLEncodingType indicates the character set used to encode characters in an XML document.

81.3.1 XMLIntf.TNodeType Enumeration

TNodeType identifies the type of a node in an XML document.

Pascal

```
TNodeType = (
  ntReserved,
  ntElement,
  ntAttribute,
  ntText,
  ntCData,
  ntEntityRef,
  ntEntity,
  ntProcessingInstr,
  ntComment,
  ntDocument,
  ntDocType,
  ntDocFragment,
  ntNotation
);
```

C++

```
enum TNodeType {
  ntReserved,
  ntElement,
  ntAttribute,
  ntText,
  ntCData,
  ntEntityRef,
  ntEntity,
  ntProcessingInstr,
  ntComment,
  ntDocument,
  ntDocType,
  ntDocFragment,
  ntNotation
};
```

File

XMLIntf

Description

TNodeType identifies the type of a node in an XML document. The following table lists the possible values:

Value	Meaning
ntReserved	Not used
ntElement	The node represents an element. Element nodes represent simple tags that have child nodes. (Note that sometimes these child nodes do not appear when using IXMLNode (see page 7669). For example child nodes of type ntText are typically hidden by IXMLNode (see page 7669) and appear only as the value of the Text property). The child nodes of an element node can have the following node types: ntElement, ntText, ntCData, ntEntityRef, ntProcessingInstr, and ntComment. Element nodes can also have attributes (ntAttribute). Element nodes can be the child of a node of type ntDocument, ntDocFragment, ntEntityRef, and ntElement.
ntAttribute	The node represents an attribute of an element. It is not the child of another node, but its value can be accessed using the Attribute property of the element node's IXMLNode (see page 7669) interface. An attribute node can have child nodes of type ntText and ntEntityRef.
ntText	The node represents the text content of a tag. A text node cannot have any child nodes, but can appear as the child node of a node of type ntAttribute, ntDocFragment, ntElement, or ntEntityRef.
ntCData	The node represents a CDATA section in the XML source. CDATA sections identify blocks of text that would otherwise be interpreted as markup. An ntCData node can't have any child nodes. They can appear as the child of an ntDocFragment, ntEntityRef, or ntElement node.
ntEntityRef	The node represents a reference to an entity in the XML document. This can be any type of entity, including character entity references. The children of an entity reference node can be of the following types: ntElement, ntProcessingInstr, ntComment, ntText, ntCData, and ntEntityRef. The entity reference node can appear as the child of an ntAttribute, ntDocFragment, ntElement, or ntEntityRef node.
ntEntity	The node represents an expanded entity. Entity nodes can have child nodes that represent the expanded entity (for example, ntText and ntEntityRef nodes). Entity nodes only appear as the child of an ntDocType node.
ntProcessingInstr	The node represents a processing instruction (PI) from the XML document. A PI node cannot have any child nodes, but can appear as the child node of a node of type ntDocument, ntDocFragment, ntElement, or ntEntityRef.
ntComment	The node represents a comment in the XML document. Comment nodes do not have child nodes. They appear as the child of an ntDocument, ntDocFragment, ntElement, or ntEntityRef node.
ntDocument	The node represents a document object, which is the root of the entire XML document. Document nodes have a single ntElement node as a child (the DocumentElement). In addition, they can have child nodes of type ntProcessingInstr, ntComment, and ntDocType. Because the document is the root of the XML document, it never appears as a child node.
ntDocType	The node represents the document type declaration, indicated by the <!DOCTYPE > tag. The document type node can child nodes of type ntNotation and ntEntity. It always appears as the child of the document node.
ntDocFragment	The node represents a document fragment. A document fragment node associates a node or subtree with a document without actually being contained in the document. Document fragment nodes can have child nodes of type ntElement, ntProcessingInstr, ntComment, ntText, ntCData, and ntEntityRef. It never appears as the child of another node.
ntNotation	A node represents a notation in the document type declaration. It always appears as the child of an ntDocType node and never has any child nodes.

81.3.2 XMLIntf.TParseOption Enumeration

TParseOption and TParseOptions (see page 7721) represent implementation-specific options that are followed when parsing the XML document.

Pascal

```
TParseOption = (
  poResolveExternals,
  poValidateOnParse,
  poPreserveWhiteSpace,
  poAsyncLoad
);
```

C++

```
enum TParseOption {
  poResolveExternals,
  poValidateOnParse,
  poPreserveWhiteSpace,
  poAsyncLoad
};
```

File

XMLIntf

Description

TParseOptions (see page 7721) is a set of TParseOption values. Each TParseOption value provides information about how a DOM parser should parse an XML document. Different DOM implementations support different options.

The following table lists the possible values:

OptionDOM VendorMeaning

Option	DOM Vendor	Meaning
poResolveExternals	MSXML	External definitions (resolvable namespaces, DTD external subsets, and external entity references) are resolved at parse time.
poValidateOnParse	MSXML	The DOM parser validates the XML document against its schema information as well as verifying that it is well-formed XML.
poPreserveWhiteSpace	MSXML	White space in the text of the XML document is not stripped off.
poAsyncLoad	MSXML	The DOM parser works asynchronously. This can speed up performance, especially when parsing a large XML document, but can also lead to exceptions if the application tries to access nodes in the document before it is completely parsed.

81.3.3 XMLIntf.TXMLDocOption Enumeration

TXMLDocOption and TXMLDocOptions (see page 7722) indicate types of information that an XML document automatically supplies.

Pascal

```
TXMLDocOption = (
```

```
    doNodeAutoCreate,
    doNodeAutoIndent,
    doAttrNull,
    doAutoPrefix,
    doNamespaceDecl,
    doAutoSave
  );
```

C++

```
  enum TXMLDocOption {
    doNodeAutoCreate,
    doNodeAutoIndent,
    doAttrNull,
    doAutoPrefix,
    doNamespaceDecl,
    doAutoSave
  };
```

File

XMLIntf

Description

TXMLDocOptions (see page 7722) is a set of TXMLDocOption values. The following table lists the TXMLDocOption values:

Value	Meaning
doNodeAutoCreate	If the application tries to read a node by name, using the Nodes property of an IXMLNodeList (see page 7703) interface, and that node does not exist, then the application creates a new node using the specified name.
doNodeAutoIndent	When formatting the XML text from the parsed set of nodes, child nodes are automatically indented from their parent nodes.
doAttrNull	When reading the value of an attribute that does not exist, the value is given as a Null Variant (see page 3421) (as opposed to a value of an empty string).
doAutoPrefix	When generating the name of a new node, the value is automatically given a namespace prefix if a namespace URI is supplied.
doNamespaceDecl	When the AddChild method must create a new namespace for the node, it also adds a namespace attribute to declare that new namespace. If doNamespaceDecl is not included, AddChild creates the new namespace but does not add an attribute to declare it.
doAutoSave	When the XML document closes, any changes are automatically saved back to the XML document file or to the XML property.

81.3.4 XMLIntf.TXMLEncodingType Enumeration

TXMLEncodingType indicates the character set used to encode characters in an XML document.

Pascal

```
  TXMLEncodingType = (
    xetUnknown,
    xetUCS_4BE,
    xetUCS_4LE,
    xetUCS_4Order2134,
    xetUCS_4Order3412,
    xetUTF_16BE,
    xetUTF_16LE,
    xetUTF_8,
```

```
    xetUCS_4Like,
    xetUTF_16BELike,
    xetUTF_16LELike,
    xetUTF_8Like,
    xetEBCDICLike
  );
```

C++

```
  enum TXMLEncodingType {
    xetUnknown,
    xetUCS_4BE,
    xetUCS_4LE,
    xetUCS_4Order2134,
    xetUCS_4Order3412,
    xetUTF_16BE,
    xetUTF_16LE,
    xetUTF_8,
    xetUCS_4Like,
    xetUTF_16BELike,
    xetUTF_16LELike,
    xetUTF_8Like,
    xetEBCDICLike
  };
```

File

XMLIntf

Description

The following table lists the possible TXMLEncodingType values:

Value	Character encoding
xetUnknown	The character set is unknown.
xetUCS_4BE	UCS-4, big-endian (1234).
xetUCS_4LE	UCS-4, little-endian (4321).
xetUCS_4Order2134	UCS-4, unusual octet order (2134)
xetUCS_4Order3412	UCS-4, unusual octet order (3412)
xetUTF_16BE	UTF-16, big-endian order
xetUTF_16LE	UTF-16, little-endian order
xetUTF_8	UTF-8
xetUCS_4Like	Any UCS-4 encoding
xetUTF_16BELike	Any UTF-16, big-endian encoding, may be without byte order mark
xetUTF_16LELike	Any UTF-16, little-endian encoding, my be without byte order mark
xetUTF_8Like	UTF-8, ISO 646, ASCII, or other 7- or 8-bit encoding, including multi-byte character sets such as Shift-JIS.
xetEBCDICLike	EBCDIC

81.4 Types

The following table lists types in this documentation.

Types

Name	Description
TParseOptions (see page 7721)	TParseOptions and TParseOption (see page 7718) represent implementation-specific options that are followed when parsing the XML document.
TXMLDocOptions (see page 7722)	This is type XMLIntf.TXMLDocOptions.

81.4.1 XMLIntf.TParseOptions Type

TParseOptions and TParseOption (see page 7718) represent implementation-specific options that are followed when parsing the XML document.

Pascal

```
TParseOptions = set of TParseOption;
```

C++

```
TParseOption TParseOptions;
```

File

XMLIntf

Description

TParseOptions is a set of TParseOption (see page 7718) values. Each TParseOption (see page 7718) value provides information about how a DOM parser should parse an XML document. Different DOM implementations support different options.

The following table lists the possible values:

OptionDOM VendorMeaning

Option	DOM Vendor	Meaning
poResolveExternals	MSXML	External definitions (resolvable namespaces, DTD external subsets, and external entity references) are resolved at parse time.
poValidateOnParse	MSXML	The DOM parser validates the XML document against its schema information as well as verifying that it is well-formed XML.
poPreserveWhiteSpace	MSXML	White space in the text of the XML document is not stripped off.
poAsyncLoad	MSXML	The DOM parser works asynchronously. This can speed up performance, especially when parsing a large XML document, but can also lead to exceptions if the application tries to access nodes in the document before it is completely parsed.

See Also

TParseOption (see page 7718)

81.4.2 XMLIntf.TXMLDocOptions Type

Pascal

```
TXMLDocOptions = set of TXMLDocOption;
```

C++

```
TXMLDocOption TXMLDocOptions;
```

File

XMLIntf

Description

This is type XMLIntf.TXMLDocOptions.

81.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
NodeTypeNames (see page 7723)	This is constant XMLIntf.NodeTypeNames.

81.5.1 XMLIntf.NodeTypeNames Constant

Pascal

```
NodeTypeNames: array[TNodeType] of string = ('', 'Element','Attribute','Text','CDATASection',
'EntityRef','Entity', 'ProcessingInstr', 'Comment','Document','DocumentType',
'DocumentFragment','Notation');
```

C++

```
array[TNodeType] of string NodeTypeNames = ('', 'Element','Attribute','Text','CDATASection',
'EntityRef','Entity', 'ProcessingInstr', 'Comment','Document','DocumentType',
'DocumentFragment','Notation');
```

File

XMLIntf

Description

This is constant XMLIntf.NodeTypeNames.

82 Xmlxform Namespace

This is namespace Xmlxform.

Topics

Name	Description
Classes (see page 7726)	The following table lists classes in this documentation.
Types (see page 7761)	The following table lists types in this documentation.

Classes

	Name	Description
	TranslateException (see page 7726)	TranslateException is the exception class for errors that occur when converting an XML document to a data packet or a data packet to an XML document.
	TXMLTransform (see page 7727)	TXMLTransform converts an XML document into a data packet or an XML data packet into an XML document with another structure.
	TXMLTransformClient (see page 7739)	TXMLTransformClient acts as an adapter between an XML document and a provider component.
	TXMLTransformProvider (see page 7747)	TXMLTransformProvider provides data from and resolves updates to an XML document.

Types

Name	Description
TRowEvent (see page 7761)	TRowEvent is the type for event handlers of events that occur at discrete points during an XML transformation.
TTranslateEvent (see page 7762)	TTranslateEvent is the type for the OnTranslate event handler.

82.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TranslateException (see page 7726)	TranslateException is the exception class for errors that occur when converting an XML document to a data packet or a data packet to an XML document.
	TXMLTransform (see page 7727)	TXMLTransform converts an XML document into a data packet or an XML data packet into an XML document with another structure.
	TXMLTransformClient (see page 7739)	TXMLTransformClient acts as an adapter between an XML document and a provider component.
	TXMLTransformProvider (see page 7747)	TXMLTransformProvider provides data from and resolves updates to an XML document.

82.1.1 TranslateException Class

TranslateException is the exception class for errors that occur when converting an XML document to a data packet or a data packet to an XML document.

Class Hierarchy

Pascal

```
TranslateException = class(Exception);
```

C++

```
class TranslateException : public Exception;
```

File

Xmlxform

Description

TranslateException is raised by the transform components (TXMLTransform (see page 7727), TXMLTransformClient (see page 7739), and TXMLTransformProvider (see page 7747)) when they can't find a file that is needed to perform a transformation. The missing file can be the XML document that is to be translated into a data packet, or a transformation file that contains instructions on how to map between a data packet and an XML document.

See Also

TXMLTransform (see page 7727)

TXMLTransformClient (see page 7739)

TXMLTransformProvider (see page 7747)

82.1.2 TXMLTransform Class

TXMLTransform converts an XML document into a data packet or an XML data packet into an XML document with another structure.

Class Hierarchy

Pascal

```
TXMLTransform = class(TComponent);
```

C++

```
class TXMLTransform : public TComponent;
```

File

Xmlxform

Description

Use TXMLTransform to convert an XML document into a data packet or an XML data packet into an XML document that is not a data packet. You can use a TXMLTransform component by itself, or specify the transformation to be performed on a TXMLTransform component that is part of another component such as TXMLTransformClient (see page 7739) or TXMLTransformProvider (see page 7747).

TXMLTransform uses a special XML document called a transformation, which indicates how to perform the conversion. This transformation is specified by the TransformationFile (see page 7736) or TransformationDocument (see page 7735) property. You can generate a transformation file using the xmlmapper.exe utility.

There are three ways to specify the source document or data packet that TXMLTransform converts:

Use the SourceXmlFile (see page 7735) property if the source document is a file on disk.

Use the SourceXml (see page 7734) property if the source document is an in-memory string of XML.

Use the SourceXmlDocument (see page 7734) property if the source document is available through a DOM interface (IDOMDocument (see page 7530)).

TXMLTransform performs its transformation when you read the Data (see page 7731) property or call the TransformXML (see page 7730) method. Once the source XML has been transformed, you can access the DOM interface for the resulting XML document or data packet using the ResultDocument (see page 7733) property, or read the Data (see page 7731) property to directly access the string of XML.

Converting XML Documents into Data Packets

82.1.2.1 TXMLTransform Members

The following tables list the members exposed by TXMLTransform.

Protected Methods

	Name	Description
	DoTransform (see page 7729)	This is DoTransform, a member of class TXMLTransform.
	GetData (see page 7729)	This is GetData, a member of class TXMLTransform.
	GetResultString (see page 7729)	This is GetResultString, a member of class TXMLTransform.
	Transform (see page 7729)	This is Transform, a member of class TXMLTransform.
	Translate (see page 7730)	This is Translate, a member of class TXMLTransform.

Public Methods

	Name	Description
	TransformXML (see page 7730)	Converts an XML document using the specifications in a transformation file.

Public Properties

	Name	Description
R	Data (see page 7731)	Represents the translated string of XML.
	EmptyDestinationDocument (see page 7732)	Specifies the DOM interface for an XML document that defines the structure of the transformation result.
R	ResultDocument (see page 7733)	Specifies the DOM interface for the results of the transformation.
R	ResultString (see page 7733)	Specifies the results of the transformation.
	SourceXml (see page 7734)	Specifies a string of XML to be translated.
	SourceXmlDocument (see page 7734)	Specifies the DOM interface for the XML document to be converted.
	SourceXmlFile (see page 7735)	Specifies an XML document or XML data packet file to be translated.
	TransformationDocument (see page 7735)	Specifies the transformation that indicates how to convert the source XML document.

Published Events

	Name	Description
	AfterEachRow (see page 7737)	Occurs after TXMLTransform (see page 7727) has finished transforming a record in the XML data packet.
	AfterEachRowSet (see page 7737)	Occurs after TXMLTransform (see page 7727) has finished transforming the entire XML data packet or a nested detail set.
	BeforeEachRow (see page 7738)	Occurs immediately before TXMLTransform (see page 7727) starts transforming a record in the XML data packet.
	BeforeEachRowSet (see page 7738)	Occurs immediately before TXMLTransform (see page 7727) starts transforming the entire XML data packet or a nested detail set.
	OnTranslate (see page 7739)	Occurs when the TXMLTransform (see page 7727) component needs to translate a user-defined node.

Published Properties

	Name	Description
	TransformationFile (see page 7736)	Specifies the transformation file that indicates how to convert the source XML document.

82.1.2.2 TXMLTransform Methods

The methods of the TXMLTransform class are listed here.

Protected Methods

	Name	Description
	DoTransform (see page 7729)	This is DoTransform, a member of class TXMLTransform.
	GetData (see page 7729)	This is GetData, a member of class TXMLTransform.
	GetResultString (see page 7729)	This is GetResultString, a member of class TXMLTransform.
	Transform (see page 7729)	This is Transform, a member of class TXMLTransform.
	Translate (see page 7730)	This is Translate, a member of class TXMLTransform.

Public Methods

	Name	Description
	TransformXML (see page 7730)	Converts an XML document using the specifications in a transformation file.

82.1.2.2.1 TXMLTransform.DoTransform Method

Pascal

```
function DoTransform(const XMLSrc: IDOMDocument; const XMLExtract: IDOMDocument; const XMLOut:
IDOMDocument): string;
```

C++

```
__fastcall UnicodeString DoTransform(const IDOMDocument XMLSrc, const IDOMDocument XMLExtract,
const IDOMDocument XMLOut);
```

Description

This is DoTransform, a member of class TXMLTransform.

82.1.2.2.2 TXMLTransform.GetData Method

Pascal

```
function GetData: string;
```

C++

```
__fastcall UnicodeString GetData();
```

Description

This is GetData, a member of class TXMLTransform.

82.1.2.2.3 TXMLTransform.GetResultString Method

Pascal

```
function GetResultString: string;
```

C++

```
__fastcall UnicodeString GetResultString();
```

Description

This is GetResultString, a member of class TXMLTransform.

82.1.2.2.4 TXMLTransform.Transform Method

Pascal

```
procedure Transform(TransNode: IDOMNode; SrcNode: IDOMNode; DestNode: IDOMNode; Count:
Integer; InFromList: TStringList; InDestList: TStringList; InIdStrList: TStringList;
InValueList: TStringList; InOptionalList: TStringList; InDateFormatList: TStringList;
InDateFormatTypeList: TStringList; InMapValuesList: TStringList);
```

C++

```
__fastcall Transform(IDOMNode TransNode, IDOMNode SrcNode, IDOMNode DestNode, int Count,
TStringList InFromList, TStringList InDestList, TStringList InIdStrList, TStringList
InValueList, TStringList InOptionalList, TStringList InDateFormatList, TStringList
InDateFormatTypeList, TStringList InMapValuesList);
```

Description

This is Transform, a member of class TXMLTransform.

82.1.2.2.5 TXMLTransform.TransformXML Method

Converts an XML document using the specifications in a transformation file.

Pascal

```
function TransformXML(const SourceXml: string; const ATransformationFile: string = ''): string;
```

C++

```
__fastcall UnicodeString TransformXML(const UnicodeString SourceXml, const UnicodeString
ATransformationFile = '');
```

Description

Call TransformXML to convert an XML document when the source XML is an in-memory string.

SourceXml (see page 7734) is a string of XML to be transformed. It can be any type of XML document, including an XML data packet. It must, however, conform to the schema expected by the transformation document used to perform the transformation. If the transformation converts a specific type of XML document into a data packet, SourceXml (see page 7734) must conform to the expected schema. If the transformation converts a data packet into an XML document, SourceXml (see page 7734) must be an XML data packet with the expected metadata.

ATransformationFile is the transformation file to use when performing the translation. A transformation file is a special type of XML file with the .xtr extension. Each transformation file is specific to a particular XML schema and data packet format and represents a one-way transformation. Use the xmlmapper utility to create transformation files.

If the ATransformationFile parameter is omitted, TransformXML uses the file specified by the TransformationFile (see page 7736) property, or the document specified by the TransformationDocument (see page 7735) property.

TransformXML returns the results of the conversion as a string of XML.

See Also

Data (see page 7731)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

82.1.2.2.6 TXMLTransform.Translate Method

Pascal

```
procedure Translate(const Id: string; const SrcNode: IDOMNode; var SrcValue: string; const
DestNode: IDOMNode); dynamic;
```

C++

```
__fastcall Translate(const UnicodeString Id, const IDOMNode SrcNode, UnicodeString SrcValue,
const IDOMNode DestNode);
```

Description

This is Translate, a member of class TXMLTransform.

82.1.2.3 TXMLTransform Properties

The properties of the TXMLTransform class are listed here.

Public Properties

	Name	Description
	Data (see page 7731)	Represents the translated string of XML.
	EmptyDestinationDocument (see page 7732)	Specifies the DOM interface for an XML document that defines the structure of the transformation result.
	ResultDocument (see page 7733)	Specifies the DOM interface for the results of the transformation.
	ResultString (see page 7733)	Specifies the results of the transformation.
	SourceXml (see page 7734)	Specifies a string of XML to be translated.
	SourceXmlDocument (see page 7734)	Specifies the DOM interface for the XML document to be converted.
	SourceXmlFile (see page 7735)	Specifies an XML document or XML data packet file to be translated.
	TransformationDocument (see page 7735)	Specifies the transformation that indicates how to convert the source XML document.

Published Properties

	Name	Description
	TransformationFile (see page 7736)	Specifies the transformation file that indicates how to convert the source XML document.

82.1.2.3.1 TXMLTransform.Data Property

Represents the translated string of XML.

Pascal

```
property Data: string;
```

C++

```
__property UnicodeString Data;
```

Description

Read (see page 3634) Data to obtain the results of the transformation. Reading the Data property causes TXMLTransform (see page 7727) to translate its source XML document or data packet into the destination format, which becomes the value of the Data property. The resulting XML string is not cached in memory: reading Data a second time causes TXMLTransform (see page 7727) to perform its transformation a second time.

If the source XML is an XML document and the transformation indicates how to convert it into a data packet, Data is the contents of a data packet in XML format.

If the source XML is an XML data packet and the transformation indicates how to convert it into another type of XML document, Data is the contents of the resulting document.

There are three ways to specify the source document or data packet that is converted to produce Data:

- Use the SourceXmlFile (see page 7735) property if the source document is a file on disk.
- Use the SourceXml (see page 7734) property if the source document is an in-memory string of XML.
- Use the SourceXmlDocument (see page 7734) property if the source document is available through a DOM interface (IDOMDocument (see page 7530)).
- If SourceXmlFile (see page 7735) is set to an invalid file name or SourceXmlFile (see page 7735) is an empty string and SourceXml (see page 7734) is not a valid string of XML, or SourceXmlFile (see page 7735) and SourceXml (see page 7734) are both empty strings and SourceXmlDocument (see page 7734) is not set, TXMLTransform (see page 7727) raises a TranslateException (see page 7726) when you try to read Data.

- There are two ways to specify the transformation that converts the source XML into Data:
- Use the TransformationFile (see page 7736) property if the transformation is stored in a file on disk.
- Use the TransformationDocument (see page 7735) method if the transformation is available through a DOM interface (IDOMDocument (see page 7530)).
- If TransformationFile (see page 7736) is set to an invalid file name or TransformationFile (see page 7736) is an empty string and TransformationDocument (see page 7735) is not set, TXMLTransform (see page 7727) raises a TranslateException (see page 7726) when you try to read Data.
- You can augment the transformation by using the EmptyDestinationDocument (see page 7732) property to supply a skeleton document that gives the form for the resulting XML document.
- When you read Data, for every user-defined node in the source XML document, TXMLTransform (see page 7727) generates an OnTranslate (see page 7739) event to convert the node.

Tip: When converting an XML document into a data packet, the value of Data can be assigned to a client dataset's XMLData property.

Converting XML Documents into Data Packets

82.1.2.3.2 TXMLTransform.EmptyDestinationDocument Property

Specifies the DOM interface for an XML document that defines the structure of the transformation result.

Pascal

```
property EmptyDestinationDocument: IDOMDocument;
```

C++

```
__property IDOMDocument EmptyDestinationDocument;
```

Description

The transformation defined by TransformationFile (see page 7736) or TransformationDocument (see page 7735) contains a default structure for the results of transforming the source document in addition to the mappings between nodes in the source document and nodes in the destination. You can override this default structure, however, by setting EmptyDestinationDocument. This is the DOM interface for an XML document that has the desired structure, but with no values in the nodes that should be filled in using values in the source document. This is useful, for example, when you want to add additional information that does not come from the source document.

EmptyDestinationDocument is not changed when TXMLTransform (see page 7727) performs its transformation. To obtain a DOM interface for the resulting document, use the ResultDocument (see page 7733) property.

See Also

ResultDocument (see page 7733)

Data (see page 7731)

TransformXML (see page 7730)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

82.1.2.3.3 TXMLTransform.ResultDocument Property

Specifies the DOM interface for the results of the transformation.

Pascal

```
property ResultDocument: IDOMDocument;
```

C++

```
__property IDOMDocument ResultDocument;
```

Description

Read (see page 3634) ResultDocument to work with the results of the transformation using a DOM interface. ResultDocument is created when you call the TransformXML (see page 7730) method to perform the transformation.

See Also

SourceXmlDocument (see page 7734)

Data (see page 7731)

TransformXML (see page 7730)

EmptyDestinationDocument (see page 7732)

ResultString (see page 7733)

82.1.2.3.4 TXMLTransform.ResultString Property

Specifies the results of the transformation.

Pascal

```
property ResultString: string;
```

C++

```
__property UnicodeString ResultString;
```

Description

Read (see page 3634) ResultString to obtain the results of the transformation as a string of XML. ResultString is created when you call the TransformXML (see page 7730) method to perform the transformation.

See Also

SourceXmlDocument (see page 7734)

Data (see page 7731)

TransformXML (see page 7730)

EmptyDestinationDocument (see page 7732)

82.1.2.3.5 TXMLTransform.SourceXml Property

Specifies a string of XML to be translated.

Pascal

```
property SourceXml: string;
```

C++

```
__property UnicodeString SourceXml;
```

Description

Specify the XML to be translated as the value of SourceXml. SourceXml can be the text of any XML document, including an XML data packet. It must, however, conform to the schema expected by the transformation specified by TransformationFile (see page 7736) or TransformationDocument (see page 7735). If the transformation converts a specific type of XML document into a data packet, SourceXml must conform to the expected schema. If the transformation converts a data packet into an XML document, SourceXml is an XML data packet with the expected metadata.

SourceXmlDocument (see page 7734) is used only if the SourceXmlFile (see page 7735) property has not been set. If both SourceXmlFile (see page 7735) and SourceXml are empty strings, TXMLTransform (see page 7727) uses the SourceXmlDocument (see page 7734) property instead. SourceXml takes precedence over SourceXmlDocument (see page 7734): If SourceXmlDocument (see page 7734) is set, TXMLTransform (see page 7727) still uses SourceXml (even if its value is not a valid string of XML).

SourceXmlFile (see page 7735)

Converting XML Documents into Data Packets

82.1.2.3.6 TXMLTransform.SourceXmlDocument Property

Specifies the DOM interface for the XML document to be converted.

Pascal

```
property SourceXmlDocument: IDOMDocument;
```

C++

```
__property IDOMDocument SourceXmlDocument;
```

Description

Specify the document to be translated as the value of SourceXmlDocument. SourceXmlDocument can be any type of XML document, including an XML data packet. It must, however, conform to the schema expected by the transformation specified by TransformationFile (see page 7736) or TransformationDocument (see page 7735). If the transformation converts a specific type of XML document into a data packet, then SourceXmlDocument is a document with the expected schema. If the transformation converts a data packet into an XML document, SourceXmlDocument is the interface to an XML data packet with the expected metadata.

SourceXmlDocument is used only if the SourceXmlFile (see page 7735) and SourceXml (see page 7734) properties have not been set.

SourceXmlFile (see page 7735)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

SourceXml (see page 7734)

Converting XML Documents into Data Packets

82.1.2.3.7 TXMLTransform.SourceXmlFile Property

Specifies an XML document or XML data packet file to be translated.

Pascal

```
property SourceXmlFile: string;
```

C++

```
__property UnicodeString SourceXmlFile;
```

Description

Specify the file to be translated as the value of SourceXmlFile. SourceXmlFile can be any type of XML document, including an XML data packet. It must, however, conform to the schema expected by the transformation specified by TransformationFile (see page 7736) or TransformationDocument (see page 7735). If the transformation converts a specific type of XML document into a data packet, SourceXmlFile is a document with the expected schema. If the transformation converts a data packet into an XML document, SourceXmlFile is an XML data packet with the expected metadata.

If SourceXmlFile is an empty string, TXMLTransform (see page 7727) uses the SourceXml (see page 7734) or SourceXmlDocument (see page 7734) property instead. SourceXmlFile takes precedence over both of these other properties. If SourceXml (see page 7734) or SourceXmlDocument (see page 7734) is set, TXMLTransform (see page 7727) still uses SourceXmlFile (even if it does not specify a valid file name).

SourceXmlDocument (see page 7734)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

SourceXml (see page 7734)

Converting XML Documents into Data Packets

82.1.2.3.8 TXMLTransform.TransformationDocument Property

Specifies the transformation that indicates how to convert the source XML document.

Pascal

```
property TransformationDocument: IDOMDocument;
```

C++

```
__property IDOMDocument TransformationDocument;
```

Description

TransformationDocument is the DOM interface for the transformation that contains instructions for converting the source XML

document into the XML that is the value of Data (see page 7731) and ResultDocument (see page 7733).

A transformation is a special type of XML document that defines the mapping between the nodes of a source document and a destination document and the structure of the destination document. Each transformation is specific to a particular XML schema and data packet format and represents a one-way transformation. Use the xmlmapper utility to create transformations.

If the EmptyDestinationDocument (see page 7732) property is set, TXMLTransform (see page 7727) uses that to override the default structure for the destination document that is defined in TransformationDocument.

TransformationDocument is used only if the value of TransformationFile (see page 7736) is an empty string.

Converting XML Documents into Data Packets

Using an XML Document as the Client of a Provider

Using an XML Document as the Source for a Provider

82.1.2.3.9 TXMLTransform.TransformationFile Property

Specifies the transformation file that indicates how to convert the source XML document.

Pascal

```
property TransformationFile: string;
```

C++

```
__property UnicodeString TransformationFile;
```

Description

TransformationFile is a file that contains instructions for converting the source XML document into the XML that is the value of Data (see page 7731) and ResultDocument (see page 7733). If the source document is a general XML document, TransformationFile represents a transformation from that document's schema into a data packet. If the source document is an XML data packet, TransformationFile represents a transformation from that data packet into another type of XML document.

A transformation file is a special type of XML file with the .xtr extension. Each transformation file is specific to a particular XML schema and data packet format and represents a one-way transformation. Use the xmlmapper utility to create transformation files.

If the EmptyDestinationDocument (see page 7732) property is set, TXMLTransform (see page 7727) uses that to override the default structure for the destination document that is defined in the transformation file.

TransformationFile takes precedence over the TransformationDocument (see page 7735) property. That is, TXMLTransform (see page 7727) only uses TransformationDocument (see page 7735) if TransformationFile is an empty string.

82.1.2.4 TXMLTransform Events

The events of the TXMLTransform class are listed here.

Published Events

	Name	Description
	AfterEachRow (see page 7737)	Occurs after TXMLTransform (see page 7727) has finished transforming a record in the XML data packet.
	AfterEachRowSet (see page 7737)	Occurs after TXMLTransform (see page 7727) has finished transforming the entire XML data packet or a nested detail set.
	BeforeEachRow (see page 7738)	Occurs immediately before TXMLTransform (see page 7727) starts transforming a record in the XML data packet.
	BeforeEachRowSet (see page 7738)	Occurs immediately before TXMLTransform (see page 7727) starts transforming the entire XML data packet or a nested detail set.
	OnTranslate (see page 7739)	Occurs when the TXMLTransform (see page 7727) component needs to translate a user-defined node.

82.1.2.4.1 TXMLTransform.AfterEachRow Event

Occurs after TXMLTransform (see page 7727) has finished transforming a record in the XML data packet.

Pascal

```
property AfterEachRow: TRowEvent;
```

C++

```
__property TRowEvent AfterEachRow;
```

Description

Write (see page 3707) an AfterEachRow event handler to take specific action after the XML transform component has translated each row in the data packet. For example, you can use AfterEachRow to read the data from the generated row and use it to compute the value of an internally calculated field.

See Also

TransformXML (see page 7730)

AfterEachRowSet (see page 7737)

BeforeEachRow (see page 7738)

Data (see page 7731)

82.1.2.4.2 TXMLTransform.AfterEachRowSet Event

Occurs after TXMLTransform (see page 7727) has finished transforming the entire XML data packet or a nested detail set.

Pascal

```
property AfterEachRowSet: TRowEvent;
```

C++

```
__property TRowEvent AfterEachRowSet;
```

Description

Write (see page 3707) an AfterEachRowSet event handler to take specific action after the XML transform component has translated an entire dataset. This can be a nested detail set, or the entire XML data packet.

For example, you can use AfterEachRowSet with the BeforeEachRowSet (see page 7738) and OnTranslate (see page 7739) methods to compute summary values: initialize a variable in the BeforeEachRowSet (see page 7738) method, update it for every OnTranslate (see page 7739) event, and use the result in the AfterEachRowSet event.

See Also

TransformXML (see page 7730)

AfterEachRow (see page 7737)

BeforeEachRow (see page 7738)

Data (see page 7731)

82.1.2.4.3 TXMLTransform.BeforeEachRow Event

Occurs immediately before TXMLTransform (see page 7727) starts transforming a record in the XML data packet.

Pascal

```
property BeforeEachRow: TRowEvent;
```

C++

```
__property TRowEvent BeforeEachRow;
```

Description

Write (see page 3707) a BeforeEachRow event handler to take specific action before the XML transform component starts translating each row in the data packet.

See Also

TransformXML (see page 7730)

BeforeEachRowSet (see page 7738)

AfterEachRow (see page 7737)

Data (see page 7731)

82.1.2.4.4 TXMLTransform.BeforeEachRowSet Event

Occurs immediately before TXMLTransform (see page 7727) starts transforming the entire XML data packet or a nested detail set.

Pascal

```
property BeforeEachRowSet: TRowEvent;
```

C++

```
__property TRowEvent BeforeEachRowSet;
```

Description

Write (see page 3707) an BeforeEachRowSet event handler to take specific action before the XML transform component

starts translating a dataset. This can be a nested detail set, or the entire XML data packet.

For example, you can use BeforeEachRowSet with the AfterEachRowSet (see page 7737) and OnTranslate (see page 7739) methods to compute summary values: initialize a variable in the BeforeEachRowSet method, update it for every OnTranslate (see page 7739) event, and use the result in the AfterEachRowSet (see page 7737) event.

See Also

TransformXML (see page 7730)

AfterEachRowSet (see page 7737)

BeforeEachRow (see page 7738)

Data (see page 7731)

82.1.2.4.5 TXMLTransform.OnTranslate Event

Occurs when the TXMLTransform (see page 7727) component needs to translate a user-defined node.

Pascal

```
property OnTranslate: TTranslateEvent;
```

C++

```
__property TTranslateEvent OnTranslate;
```

Description

Write (see page 3707) an OnTranslate event handler to provide the translation for user-defined nodes.

TXMLTransform (see page 7727) performs a translation when an application reads the Data (see page 7731) property or calls the TransformXML (see page 7730) method. If the transformation document that governs how to perform that translation indicates that a node in the XML document is user defined, TXMLTransform (see page 7727) generates an OnTranslate event when it needs to translate to or from that node. OnTranslate only occurs for nodes that are marked as user defined.

If you do not translate a user-defined node in an OnTranslate event handler, the corresponding node in the translated XML is assigned the source XML node's value, if available. Otherwise, it is left blank.

TransformationDocument (see page 7735)

Data (see page 7731)

Converting XML Documents into Data Packets

Using an XML Document as the Client of a Provider

Using an XML Document as the Source for a Provider

82.1.3 TXMLTransformClient Class

TXMLTransformClient acts as an adapter between an XML document and a provider component.

Class Hierarchy

Pascal

```
TXMLTransformClient = class(TComponent);
```

C++

```
class TXMLTransformClient : public TComponent;
```

File

Xmlxform

Description

Use TXMLTransformClient to convert the data from a provider into an XML document or to apply updates in the form of an XML document to a provider component. TXMLTransformClient can act as the client of any provider component, local or remote. It uses a transformation file that is generated using the xmlmapper utility to convert between XML documents and the data packets and delta packets used by the provider.

See Also

TXMLTransform (see page 7727)

TXMLTransformProvider (see page 7747)

Using an XML Document as the Client of a Provider

82.1.3.1 TXMLTransformClient Members

The following tables list the members exposed by TXMLTransformClient.

Protected Methods

	Name	Description
	SetupAppServer (see page 7744)	This is SetupAppServer, a member of class TXMLTransformClient.

Public Methods

	Name	Description
V	ApplyUpdates (see page 7742)	Inserts or deletes the records corresponding to the data in an XML document.
V	Create (see page 7741)	Creates and initializes a TXMLTransformClient (see page 7739) object.
V	Destroy (see page 7741)	Destroys the instance of a TXMLTransformClient (see page 7739) component.
V	GetDataAsXml (see page 7742)	Fetches a data packet from the provider and converts it to an XML document.
	SetParams (see page 7743)	Sets input parameters to values supplied in an XML document.

Published Properties

	Name	Description
	ProviderName (see page 7745)	Specifies the name of a provider component that supplies data to and applies updates from the XML transform client.
	RemoteServer (see page 7745)	Specifies the connection component that this XML transform client uses to connect to an application server.
R	TransformApplyUpdates (see page 7746)	Specifies the TXMLTransform (see page 7727) component that converts XML into delta packets that are then sent to the provider to apply updates.
R	TransformGetData (see page 7746)	Specifies the TXMLTransform (see page 7727) component that converts data packets from the provider into XML.
R	TransformSetParams (see page 7747)	Specifies the TXMLTransform (see page 7727) component that converts the XML supplied to the SetParams (see page 7743) method into a data packet format.

82.1.3.2 TXMLTransformClient.Create Constructor

Creates and initializes a TXMLTransformClient (see page 7739) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXMLTransformClient(TComponent * AOwner);
```

Description

Call Create to instantiate an XML transform client at runtime. XML transform clients placed in forms or data modules at design time are created automatically.

The AOwner parameter specifies another component (typically a form or data module) that is responsible for freeing the TXMLTransformClient (see page 7739) object.

See Also

Owner

82.1.3.3 TXMLTransformClient.Destroy Destructor

Destroys the instance of a TXMLTransformClient (see page 7739) component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLTransformClient();
```

Description

Do not call Destroy directly in an application. Usually destruction of TXMLTransformClient (see page 7739) objects is handled automatically. If an application creates its own instances of TXMLTransformClient (see page 7739) without assigning an Owner, however, it should call Free, which verifies that the dataset component is not nil before calling Destroy.

See Also

Owner

Create (see page 7741)

System::TObject::Free (see page 3372)

82.1.3.4 TXMLTransformClient Methods

The methods of the TXMLTransformClient class are listed here.

Protected Methods

	Name	Description
	SetupAppServer (see page 7744)	This is SetupAppServer, a member of class TXMLTransformClient.

Public Methods

	Name	Description
	ApplyUpdates (see page 7742)	Inserts or deletes the records corresponding to the data in an XML document.
	GetDataAsXml (see page 7742)	Fetches a data packet from the provider and converts it to an XML document.
	SetParams (see page 7743)	Sets input parameters to values supplied in an XML document.

82.1.3.4.1 TXMLTransformClient.ApplyUpdates Method

Inserts or deletes the records corresponding to the data in an XML document.

Pascal

```
function ApplyUpdates(const UpdateXML: string; const UpdateTransformFile: string; MaxErrors:
Integer): Integer; virtual;
```

C++

```
virtual __fastcall int ApplyUpdates(const UnicodeString UpdateXML, const UnicodeString
UpdateTransformFile, int MaxErrors);
```

Description

Call ApplyUpdates to transform an XML document into a delta packet that inserts or deletes all of the resulting records and send it to the associated provider so that it can be applied. Before you can call ApplyUpdates, you must define the transformation to use by setting properties on the XML transform component specified by TransformApplyUpdates (see page 7746).

UpdateXML is the XML document that can be transformed into a delta packet. Typically, it contains the contents of an XML document file.

UpdateTransformFile is the name of a transformation file that converts UpdateXML into an insert or delete delta packet. A transformation file is a special type of XML file with the .xtr extension. The transformation file is specific to a particular XML schema, data packet format, and update operation (insert or delete). Use the xmlmapper utility to create the transformation file.

Note: If UpdateTransformFile includes any user-defined conversions, ApplyUpdates generates an OnTranslate event on TransformApplyUpdates (see page 7746) when it needs to transform user-defined nodes in the UpdateXML string into corresponding field values.

MaxErrors indicates the maximum number of errors that the provider should allow before prematurely stopping the update operation. Set MaxErrors to –1 to indicate that there is no limit to the number of errors.

ApplyUpdates returns the number of errors it encountered.

See Also

ProviderName (see page 7745)

TransformApplyUpdates (see page 7746)

Using an XML Document as the Client of a Provider

82.1.3.4.2 TXMLTransformClient.GetDataAsXml Method

Fetches a data packet from the provider and converts it to an XML document.

Pascal

```
function GetDataAsXml(const PublishTransformFile: string): string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDataAsXml(const UnicodeString PublishTransformFile);
```

Description

Call GetDataAsXml to obtain an XML document that is the translation of a data packet from the associated provider. GetDataAsXml

1. Passes any parameters supplied to the SetParams (see page 7743) method to the provider specified by ProviderName (see page 7745).
2. Obtains a data packet that the provider returns.
3. Uses the transform component specified by TransformGetData (see page 7746) to convert the data packet to an XML document. If the PublishTransformFile parameter is not an empty string, GetDataAsXml uses the file specified by this parameter as the transformation file. Otherwise, it uses the transformation file specified on the TransformGetData (see page 7746) property.
4. Generates an OnTranslate event for every user-defined conversion in its transformation. The application can use this event to perform the user-defined conversion that converts field values into XML nodes.
5. Returns the resulting XML document as a string.

Once you have obtained the resulting, translated XML document, you can assign it to a TXMLDocument component or save it to a file.

Note: Before you can call GetDataAsXml, you must supply any input parameters using the SetParams (see page 7743) method and set properties on TransformGetData (see page 7746) to indicate what transformation to perform.

See Also

ProviderName (see page 7745)

TransformGetData (see page 7746)

XML (see page 7392)

OnTranslate (see page 7739)

SetParams (see page 7743)

Using an XML Document as the Client of a Provider

82.1.3.4.3 TXMLTransformClient.SetParams Method

Sets input parameters to values supplied in an XML document.

Pascal

```
procedure SetParams(const ParamsXml: string; const ParamsTransformFile: string);
```

C++

```
__fastcall SetParams(const UnicodeString ParamsXml, const UnicodeString ParamsTransformFile);
```

Description

Call SetParams to supply input parameter values before fetching data from the provider. Parameter values can represent the input parameters to a query or stored procedure, or they can represent field values that filter the data when the provider represents the data in a TTable or TSQLTable component.

ParamsXML is the XML document that represents the parameter values to set. Typically, it contains the contents of an XML document file.

ParamsTransformFile is the name of a transformation file that converts ParamsXml into a data packet. A transformation file is a special type of XML file with the .xtr extension. The transformation file is specific to a particular XML schema and data packet format. Use the xmlmapper.exe utility to create the transformation file.

Note: If ParamsTransformFile includes any user-defined conversions, the component specified by TransformSetParams (see page 7747) generates an OnTranslate event when it needs to transform user-defined nodes in the ParamsXml string into corresponding parameter values.

The TXMLTransformClient (see page 7739) component stores parameter values internally. Each time you call SetParams, you update those internally stored values. Parameter values from previous calls are not cleared, so be sure to set every parameter value you want to change.

The next the GetDataAsXml (see page 7742) method is called, TXMLTransformClient (see page 7739) sends the currently stored parameter values to the provider.

82.1.3.4.4 TXMLTransformClient.SetupAppServer Method

Pascal

```
procedure SetupAppServer;
```

C++

```
__fastcall SetupAppServer();
```

Description

This is SetupAppServer, a member of class TXMLTransformClient.

82.1.3.5 TXMLTransformClient Properties

The properties of the TXMLTransformClient class are listed here.

Published Properties

	Name	Description
	ProviderName (see page 7745)	Specifies the name of a provider component that supplies data to and applies updates from the XML transform client.
	RemoteServer (see page 7745)	Specifies the connection component that this XML transform client uses to connect to an application server.
R	TransformApplyUpdates (see page 7746)	Specifies the TXMLTransform (see page 7727) component that converts XML into delta packets that are then sent to the provider to apply updates.
R	TransformGetData (see page 7746)	Specifies the TXMLTransform (see page 7727) component that converts data packets from the provider into XML.
R	TransformSetParams (see page 7747)	Specifies the TXMLTransform (see page 7727) component that converts the XML supplied to the SetParams (see page 7743) method into a data packet format.

82.1.3.5.1 TXMLTransformClient.ProviderName Property

Specifies the name of a provider component that supplies data to and applies updates from the XML transform client.

Pascal

```
property ProviderName: string;
```

C++

```
__property UnicodeString ProviderName;
```

Description

Use ProviderName to specify the provider object that supplies the XML transform client with data packets and applies updates on its behalf. This property is passed as a parameter to IAppServer interface calls when the client fetches data from or applies updates to the source dataset, its database server, or the source XML document.

The provider specified by ProviderName can reside in the same application as the XML transform client or in an application server running on another system.

If the provider is in the same application as the XML transform client, it must have the same Owner as the client.

If the provider is on a remote application server, it must be exported by that application server. If the application server contains multiple provider objects, you can set ProviderName to any of them once the XML transform client establishes an initial connection to the application server through its RemoteServer (see page 7745) property.

ProviderName can be set from a drop-down in the Object Inspector once the RemoteServer (see page 7745) property is set if

The connection component is a SOAP connection.

The connection component is a Web connection or socket connection (Windows only).

The application server is COM-based and registered on the client system using TRegsvr.exe (Windows only).

RemoteServer (see page 7745)

GetDataAsXml (see page 7742)

IAppServer

ApplyUpdates (see page 7742)

Using an XML Document as the Client of a Provider

82.1.3.5.2 TXMLTransformClient.RemoteServer Property

Specifies the connection component that this XML transform client uses to connect to an application server.

Pascal

```
property RemoteServer: TCustomRemoteServer;
```

C++

```
__property TCustomRemoteServer RemoteServer;
```

Description

If the XML transform client is in the client portion of a multi-tiered application, use RemoteServer to specify the connection component that connects to the application server. The connection component locates the application server and obtains its IAppServer interface, which the XML transform client can use for communicating with a remote provider.

If a client application uses more than connection component, the application can change which connection an XML transform client uses by changing the value for this property.

TSoapConnection (see page 1188)

AppServer

IAppServer

Using an XML Document as the Client of a Provider

82.1.3.5.3 TXMLTransformClient.TransformApplyUpdates Property

Specifies the TXMLTransform (see page 7727) component that converts XML into delta packets that are then sent to the provider to apply updates.

Pascal

```
property TransformApplyUpdates: TXMLTransform;
```

C++

```
__property TXMLTransform TransformApplyUpdates;
```

Description

Use TransformApplyUpdates to access the subcomponent that transforms the XML passed as the UpdateXML parameter of the ApplyUpdates (see page 7742) method into a delta packet, which is then forwarded to the provider. If the transformation passed to the ApplyUpdates (see page 7742) method includes any user-defined nodes, you must supply TransformApplyUpdates with an OnTranslate event handler.

See Also

ApplyUpdates (see page 7742)

ProviderName (see page 7745)

OnTranslate (see page 7739)

82.1.3.5.4 TXMLTransformClient.TransformGetData Property

Specifies the TXMLTransform (see page 7727) component that converts data packets from the provider into XML.

Pascal

```
property TransformGetData: TXMLTransform;
```

C++

```
__property TXMLTransform TransformGetData;
```

Description

Use TransformGetData to access the subcomponent that performs the transformation of data packets from the provider into another XML format. When an application calls the GetDataAsXml (see page 7742) method, this subcomponent converts the

data packet from the provider into XML.

Before you can call GetDataAsXml (see page 7742), you must specify the transformation that this subcomponent uses by setting its TransformationFile or TransformationDocument property. In addition, if the transformation includes any user-defined nodes, you must supply TransformGetData with an OnTranslate event handler.

See Also

GetDataAsXml (see page 7742)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

OnTranslate (see page 7739)

Using an XML Document as the Client of a Provider

82.1.3.5.5 TXMLTransformClient.TransformSetParams Property

Specifies the TXMLTransform (see page 7727) component that converts the XML supplied to the SetParams (see page 7743) method into a data packet format.

Pascal

```
property TransformSetParams: TXMLTransform;
```

C++

```
__property TXMLTransform TransformSetParams;
```

Description

Use TransformSetParams to directly access the subcomponent that performs the transformation of an XML document into a set of parameter values. When an application calls the SetParams (see page 7743) method, this subcomponent converts the XML supplied as the ParamsXml parameter into a data packet, which it then uses to read and store parameter values. These parameter values are later passed to the provider when you call GetDataAsXml (see page 7742).

If the transformation passed to the SetParams (see page 7743) method includes any user-defined nodes, you must supply TransformSetParams with an OnTranslate event handler.

82.1.4 TXMLTransformProvider Class

TXMLTransformProvider provides data from and resolves updates to an XML document.

Class Hierarchy

Pascal

```
TXMLTransformProvider = class(TCustomProvider);
```

C++

```
class TXMLTransformProvider : public TCustomProvider;
```

File

Xmlxform

Description

Use TXMLTransformProvider to provide data from an XML document to a client dataset or XML broker and to resolve updates from that client dataset or XML broker back to the source XML document. TXMLTransformProvider can be a part of the same application as the client dataset or XML broker, or it can be placed in the application server of a multi-tiered application. It serves as a translator between an XML document and a client dataset.

TDataSetProvider packages data from the source XML document and passes it in one or more transportable data packets to the client dataset or XML broker.

When the provider supplies data to a client dataset, the client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the source XML document.

When the provider supplies data to an XML broker, the XML broker adds the data packet, in XML format, to an HTML document that is downloaded by a Web client. When the XML broker receives updates from the Web client, it sends the updates to the provider, which applies them to the source XML document.

Client datasets and XML brokers communicate with a provider through the IAppServer interface. In multi-tiered applications, this is the interface of the remote data module that contains the provider. To enable the remote data module to pass calls to the provider, the provider's Exported property must be true, and its Owner property must specify the remote data module.

Determining the Source of Data

Using Provider Components

Using an XML Document as the Source for a Provider

82.1.4.1 TXMLTransformProvider Members

The following tables list the members exposed by TXMLTransformProvider.

Protected Methods

	Name	Description
	InternalApplyUpdates (see page 7750)	Provides the underlying implementation of the ApplyUpdates method.
	InternalGetRecords (see page 7750)	Provides the underlying implementation of the GetRecords method.

Public Methods

	Name	Description
	Create (see page 7749)	Creates and initializes a TXMLTransformProvider (see page 7747) object.
	Destroy (see page 7749)	Frees an instance of a provider object.

Published Events

	Name	Description
	AfterApplyUpdates (see page 7754)	Occurs after the provider applies updates.
	AfterGetRecords (see page 7755)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 7756)	Occurs after the provider fetches new information about the current record.
	BeforeApplyUpdates (see page 7756)	Occurs before the provider applies updates from a client dataset.
	BeforeGetRecords (see page 7757)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 7758)	Occurs before the provider creates a delta packet with information about the current record.
	OnDataRequest (see page 7759)	Occurs when a provider calls its DataRequest method.

Published Properties

	Name	Description
	CacheData (see page 7751)	Specifies whether the provider caches the data packet internally in memory.
R	TransformRead (see page 7752)	Specifies the TXMLTransform (see page 7727) component that converts the source XML document into data packets.
R	TransformWrite (see page 7753)	Specifies the TXMLTransform (see page 7727) component that generates the new value of the source XML document when updates are applied.
	XMLDataFile (see page 7753)	Specifies the XML document from which the provider creates data packets and to which it applies updates.

82.1.4.2 TXMLTransformProvider.Create Constructor

Creates and initializes a TXMLTransformProvider (see page 7747) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXMLTransformProvider(TComponent * AOwner);
```

Description

Call Create to instantiate an XML transform provider at runtime. Providers placed in forms or data modules at design time are created automatically.

The AOwner parameter specifies another component (typically a form or data module) that is responsible for freeing the provider.

See Also

Owner

82.1.4.3 TXMLTransformProvider.Destroy Destructor

Frees an instance of a provider object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLTransformProvider();
```

Description

Do not call Destroy directly. Instead, use the delete keyword, which indirectly calls Destroy.

See Also

delete

82.1.4.4 TXMLTransformProvider Methods

The methods of the TXMLTransformProvider class are listed here.

Protected Methods

	Name	Description
	InternalApplyUpdates (see page 7750)	Provides the underlying implementation of the ApplyUpdates method.
	InternalGetRecords (see page 7750)	Provides the underlying implementation of the GetRecords method.

82.1.4.4.1 TXMLTransformProvider.InternalApplyUpdates Method

Provides the underlying implementation of the ApplyUpdates method.

Pascal

```
function InternalApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount:
Integer): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount);
```

Description

The ApplyUpdates method calls InternalApplyUpdates to apply the updates contained in a delta packet after generating the BeforeApplyUpdates event and before generating the AfterApplyUpdates event. The InternalApplyUpdates method of TCustomProvider is abstract (Delphi) or pure virtual (C++), meaning that it has no implementation. Descendant classes override this method to apply updates, resolve update errors, and return any updates that could not be applied.

Delta is the delta packet containing insertions, deletions, and modifications to be applied.

MaxErrors indicates the maximum number of errors that can be applied before stopping the update operation. If MaxErrors is –1, the provider tries to apply all updates.

ErrorCount returns the number of errors encountered during the update operation.

InternalApplyUpdates returns a data packet of updates that could not be applied to the database as an OleVariant.

See Also

ApplyUpdates

82.1.4.4.2 TXMLTransformProvider.InternalGetRecords Method

Provides the underlying implementation of the GetRecords method.

Pascal

```
function InternalGetRecords(Count: Integer; out RecsOut: Integer; Options: TGetRecordOptions;
const CommandText: WideString; var Params: OleVariant): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalGetRecords(int Count, int RecsOut, TGetRecordOptions
Options, const BSTR CommandText, OleVariant Params);
```

Description

The GetRecords method calls InternalGetRecords to assemble a data packet after calling DoBeforeGetRecords to apply the CommandText and Params and generate a BeforeGetRecords event. As implemented in TCustomProvider, InternalGetRecords always returns NULL. Descendant classes override this method to fetch the requested records and assemble them into a data packet.

Count indicates the number of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only the specified number of records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It can include grMetaData (include metadata), grReset (start providing records with the first one in the dataset), and grXML (encode the datapacket in XML rather than as an OleVariant) or grXMLUTF8 (same as grXML except extended characters are encoded using UTF8).

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText or if the provider does not have an Options property.

Params specifies any parameter values that should be applied to CommandText or to an associated query or stored procedure. If the provider is associated with a TTable object, Params specifies field values that filter the result set. On exit from GetRecords, Params returns any output parameters.

Records are returned as a data packet in a Variant.

DoBeforeGetRecords

82.1.4.5 TXMLTransformProvider Properties

The properties of the TXMLTransformProvider class are listed here.

Published Properties

	Name	Description
	CacheData (see page 7751)	Specifies whether the provider caches the data packet internally in memory.
R	TransformRead (see page 7752)	Specifies the TXMLTransform (see page 7727) component that converts the source XML document into data packets.
R	TransformWrite (see page 7753)	Specifies the TXMLTransform (see page 7727) component that generates the new value of the source XML document when updates are applied.
	XMLDataFile (see page 7753)	Specifies the XML document from which the provider creates data packets and to which it applies updates.

82.1.4.5.1 TXMLTransformProvider.CacheData Property

Specifies whether the provider caches the data packet internally in memory.

Pascal

```
property CacheData: Boolean;
```

C++

```
__property Boolean CacheData;
```

Description

Set CacheData to true to specify that the provider should cache its data packet in memory after the first time it is read from the source XML document. When CacheData is false, every time the Data property is read, the GetRecords method is called, or updates are applied, the provider must reread the source document specified by XMLDataFile (see page 7753).

Caching the data improves performance on subsequent data fetches or when applying updates, but consumes additional resources.

See Also

Data

TransformRead (see page 7752)

GetRecords

XMLDataFile (see page 7753)

82.1.4.5.2 TXMLTransformProvider.TransformRead Property

Specifies the TXMLTransform (see page 7727) component that converts the source XML document into data packets.

Pascal

```
property TransformRead: TXMLTransform;
```

C++

```
__property TXMLTransform TransformRead;
```

Description

Use TransformRead to access the subcomponent that transforms the source XML document into the data packet that is the value of the Data property. Before you can use TXMLTransformProvider (see page 7747), you must specify the transformation that this subcomponent uses by setting its TransformationFile or TransformationDocument property. In addition, if the transformation includes any user-defined nodes, you must supply TransformRead with an OnTranslate event handler.

Determining the Source of Data

Using an XML Document as the Source for a Provider

82.1.4.5.3 TXMLTransformProvider.TransformWrite Property

Specifies the TXMLTransform (see page 7727) component that generates the new value of the source XML document when updates are applied.

Pascal

```
property TransformWrite: TXMLTransform;
```

C++

```
__property TXMLTransform TransformWrite;
```

Description

Use TransformWrite to access the subcomponent that transforms a data packet back into the format required by the source XML document. When a client calls the ApplyUpdates method, the delta packet is merged into the transformed data from the XML document, and then TransformWrite converts the resulting dataset into the format of the source XML document.

Before you can use TXMLTransformProvider (see page 7747) to apply updates, you must specify the transformation that this subcomponent uses by setting its TransformationFile or TransformationDocument property. In addition, if the transformation includes any user-defined nodes, you must supply TransformWrite with an OnTranslate event handler.

TransformRead (see page 7752)

TransformationFile (see page 7736)

TransformationDocument (see page 7735)

OnTranslate (see page 7739)

Using an XML Document as the Source for a Provider

82.1.4.5.4 TXMLTransformProvider.XMLDataFile Property

Specifies the XML document from which the provider creates data packets and to which it applies updates.

Pascal

```
property XMLDataFile: string;
```

C++

```
__property UnicodeString XMLDataFile;
```

Description

Use XMLDataFile to specify the XML document whose data the provider represents. When the Data property is read or the GetRecords method is called, TXMLTransformProvider (see page 7747) reads the contents of XMLDataFile and converts it into a data packet using the transform component specified by TransformRead (see page 7752). When the ApplyUpdates method is called, TXMLTransformProvider (see page 7747) uses the transform component specified by TransformWrite (see page 7753) to convert the data into the proper format for XMLDataFile and updates this XML document accordingly.

XMLDataFile is the same as the SourceXmlFile property of TransformRead (see page 7752).

82.1.4.6 TXMLTransformProvider Events

The events of the TXMLTransformProvider class are listed here.

Published Events

	Name	Description
	AfterApplyUpdates (see page 7754)	Occurs after the provider applies updates.
	AfterGetRecords (see page 7755)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 7756)	Occurs after the provider fetches new information about the current record.
	BeforeApplyUpdates (see page 7756)	Occurs before the provider applies updates from a client dataset.
	BeforeGetRecords (see page 7757)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 7758)	Occurs before the provider creates a delta packet with information about the current record.
	OnDataRequest (see page 7759)	Occurs when a provider calls its DataRequest method.

82.1.4.6.1 TXMLTransformProvider.AfterApplyUpdates Event

Occurs after the provider applies updates.

Pascal

```
property AfterApplyUpdates;
```

C++

```
__property AfterApplyUpdates;
```

Description

Write an AfterApplyUpdates event handler to return custom information to a client dataset after applying updates. AfterApplyUpdates is part of the mechanism by which a client dataset and a provider communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_ApplyUpdates method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeApplyUpdates event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnUpdateData event where it can edit the updates before they are applied.

3. The provider applies the updates, and attempts to resolve problems.

4.The provider receives an AfterApplyUpdates event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeApplyUpdates event handler.

5.The client dataset receives an AfterApplyUpdates event, where it can respond to the custom information returned by the

provider in its AfterApplyUpdates event handler.

Note: If ApplyUpdates is called without the OwnerData parameter, on entry to the event handler the OwnerData parameter contains the value set in the BeforeApplyUpdates event handler and it is ignored on exit from the AfterApplyUpdates event handler.

82.1.4.6.2 TXMLTransformProvider.AfterGetRecords Event

Occurs after the provider creates a data packet to send to the client dataset.

Pascal

```
property AfterGetRecords;
```

C++

```
__property AfterGetRecords;
```

Description

Write an AfterGetRecords event handler to send custom information to a client dataset when providing a data packet. AfterGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_GetRecords method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeGetRecords event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnGetData event where it can edit the data before creating a data packet, and then generates the data packet.

3.The provider receives an AfterGetRecords event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeGetRecords event handler.

4.The client dataset receives an AfterGetRecords event, where it can respond to the custom information returned by the provider in its AfterGetRecords event handler.

Responding to Client Data Requests

82.1.4.6.3 TXMLTransformProvider.AfterRowRequest Event

Occurs after the provider fetches new information about the current record.

Pascal

```
property AfterRowRequest;
```

C++

```
__property AfterRowRequest;
```

Description

Write an AfterRowRequest event handler to send custom information to a client dataset along with information about the current record. AfterRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_RowRequest method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeRowRequest event, where it can respond to or change custom information that the client dataset sends.

2.The provider creates a delta packet that contains the requested information.

3.The provider receives an AfterRowRequest event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeRowRequest event handler.

4.The client dataset receives an AfterRowRequest event, where it can respond to the custom information returned by the provider in its AfterRowRequest event handler.

Communicating with the Client Dataset

82.1.4.6.4 TXMLTransformProvider.BeforeApplyUpdates Event

Occurs before the provider applies updates from a client dataset.

Pascal

```
property BeforeApplyUpdates;
```

C++

```
__property BeforeApplyUpdates;
```

Description

Write a BeforeApplyUpdates event handler to respond to custom information from a client dataset. BeforeApplyUpdates is part of the mechanism by which a provider and a client dataset communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset's ApplyUpdates method is called, the following events occur:

1.The client dataset receives a BeforeApplyUpdates event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeApplyUpdates event, where the OleVariant from the client dataset appears as the OwnerData parameter. The provider can respond to or change that information before applying the updates.

3.If it is a dataset provider, the provider applies the updates, and receives an OnUpdateError event for any problem records.

4.The provider receives an AfterApplyUpdates event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeApplyUpdates event handler.

5.The client dataset receives an AfterApplyUpdates event, where it can respond to the custom information returned by the provider in its AfterApplyUpdates event handler.

Note: If ApplyUpdates is called without the OwnerData parameter, the OwnerData parameter is nil (Delphi) or NULL (C++) on entry to the event handler and its value (on exit) is only passed to the AfterApplyUpdates event handler but not returned to the caller.

Responding to Client Update Requests

Communicating with the Client Dataset

82.1.4.6.5 TXMLTransformProvider.BeforeGetRecords Event

Occurs before the provider creates a data packet and sends it to a client dataset.

Pascal

```
property BeforeGetRecords;
```

C++

```
__property BeforeGetRecords;
```

Description

Write a BeforeGetRecords event handler to respond to custom information from a client dataset. BeforeGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches data from the provider, the following events occur:

1.The client dataset receives a BeforeGetRecords event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeGetRecords event, where the OleVariant from the client dataset appears as the OwnerData parameter. The provider can respond to or change that information before it creates a data packet.

3.The provider generates the data packet.

4.The provider receives an AfterGetRecords event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeGetRecords event handler.

5.The client dataset receives an AfterGetRecords event, where it can respond to the custom information returned by the provider in its AfterGetRecords event handler.

Delphi Examples:

```
{
This example shows the implementation of a provider BeforeGetRecords
event handler and a RemoteDataModule UpdateRegistry method.  The
complete project using this code example is in
Demos/DelphiWin32/VCLWin32/MIDAS/Pooler.
}
procedure TPooledRDM.DataSetProvider1BeforeGetRecords(Sender: TObject;
  var OwnerData: OleVariant);
begin
  try
    Query1.Close;
    Query1.SQL.Text := OwnerData[0];
    if not VarIsNull(OwnerData[1]) and not VarIsEmpty(OwnerData[1]) then
    begin
      Query1.Open;
      if not Query1.Locate(Query1.Fields[0].FieldName, OwnerData[1], []) then
        raise Exception.Create('Record not found');
      Query1.Next;
    end;
  finally
    OwnerData := NULL;
  end;
end;
```

AfterGetRecords

Communicating with the Client Dataset

Responding to Client Data Requests

82.1.4.6.6 TXMLTransformProvider.BeforeRowRequest Event

Occurs before the provider creates a delta packet with information about the current record.

Pascal

```
property BeforeRowRequest;
```

C++

```
__property BeforeRowRequest;
```

Description

Write a BeforeRowRequest event handler to respond to custom information from a client dataset. BeforeRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches detail information about the current record or refreshes the current record, the following events occur:

1.The client dataset receives a BeforeRowRequest event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeRowRequest event, where the custom information appears as the OwnerData parameter. The provider can respond to or change that information before it looks up the requested information.

3.The provider creates a delta packet that contains the requested information.

4.The provider receives an AfterRowRequest event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeRowRequest event handler.

5.The client dataset receives an AfterRowRequest event, where it can respond to the custom information returned by the provider in its AfterRowRequest event handler.

Communicating with the Client Dataset

82.1.4.6.7 TXMLTransformProvider.OnDataRequest Event

Occurs when a provider calls its DataRequest method.

Pascal

```
property OnDataRequest;
```

C++

```
__property OnDataRequest;
```

Description

Write an OnDataRequest event handler to do custom processing of data. OnDataRequest has no built-in use. Instead, it allows developers to augment the IAppServer interface so that clients in a multi-tiered application can communicate directly with an individual provider.

If an application does not provide an OnDataRequest event handler, calls to DataRequest return NULL.

Note: To provide the same sort of custom processing on the client side, use an automation method on the connection component.

82.2 Types

The following table lists types in this documentation.

Types

Name	Description
TRowEvent (see page 7761)	TRowEvent is the type for event handlers of events that occur at discrete points during an XML transformation.
TTranslateEvent (see page 7762)	TTranslateEvent is the type for the OnTranslate event handler.

82.2.1 Xmlxform.TRowEvent Type

TRowEvent is the type for event handlers of events that occur at discrete points during an XML transformation.

Pascal

```
TRowEvent = procedure (Sender: TObject; Id: string; SrcNode: IDOMNode; DestNode: IDOMNode) of object;
```

C++

```
(Sender: TObject; Id: string; SrcNode: IDOMNode; DestNode: IDOMNode) ( TRowEvent)();
```

File

Xmlxform

Description

TRowEvent is the type for the event handlers of events that occur while TXMLTransform (see page 7727) is converting an XML document into an XML data packet, or vice versa.

Sender is the XML transform component that generates the event.

Id is a string that identifies the node in the XML document that is about to be translated. This identifier is assigned using the Node Repository page of the Xmlmapper utility when the transformation file is generated. If the node does not have an assigned identifier, Id is an empty string.

SrcNode is the DOM interface for the node that is about to be translated. This node may correspond to the entire XML data packet, a dataset field in the XML data packet, or a record in the XML data packet.

DestNode is the DOM interface for the translated value of SrcNode.

See Also

TXMLTransform (see page 7727)

Procedural types

Creating events

82.2.2 Xmlxform.TTranslateEvent Type

TTranslateEvent is the type for the OnTranslate event handler.

Pascal

```
TTranslateEvent = procedure (Sender: TObject; Id: string; SrcNode: IDOMNode; var Value:
string; DestNode: IDOMNode) of object;
```

C++

```
(Sender: TObject; Id: string; SrcNode: IDOMNode; var Value: string; DestNode: IDOMNode) (
TTranslateEvent)();
```

File

Xmlxform

Description

TTranslateEvent is the type of the OnTranslate event handler. OnTranslate occurs when an XML transform component needs to translate user-defined nodes. This event can occur when translating XML documents into data packets or when translating data packets into XML documents.

Sender is the XML transform component that generates the event.

Id is a string that identifies the node in the XML document. This identifier is assigned using the Node Repository page of Xmlmapper.exe when the transformation file is generated.

SrcNode is the DOM interface for the node being translated. If the current translation is from XML document to data packet, this is the node with the Id specified by Id. If the current translation is from a data packet to an XML document, this is a node in the XML form of the data packet.

Value returns the translation of SrcNode. If the current translation is from XML document to data packet, on entry to the event handler this is the value of SrcNode, if available. On exit, this is a string representation of the value to be assigned to the corresponding field in the data packet. If the current translation is from data packet to XML document, on entry to the event handler this is a string representation of the field (or parameter) value. On exit, it should be the value of the XML node that has the identifier Id (including any subnodes, if appropriate).

DestNode is the DOM interface for the translated node. If the current translation is from XML document to data packet, this is the node for the field in the XML data packet. If the current translation is from data packet to XML document, this is the XML node that has the identifier ID.

83.1.1.1 TXPStyleAddRemoveItem Members

The following tables list the members exposed by TXPStyleAddRemoveItem.

Protected Methods

	Name	Description
	DrawBackground (see page 7765)	Draws a background image on the control.
	DrawGlyph (see page 7766)	Draws a symbol on the control.
	DrawSeparator (see page 7766)	This is DrawSeparator, a member of class TXPStyleAddRemoveItem.
	DrawText (see page 7766)	This is DrawText, a member of class TXPStyleAddRemoveItem.
	DrawUnusedEdges (see page 7766)	This is DrawUnusedEdges, a member of class TXPStyleAddRemoveItem.

Public Methods

	Name	Description
	CalcBounds (see page 7765)	Calculates the size of the add/remove menu item.

83.1.1.2 TXPStyleAddRemoveItem Methods

The methods of the TXPStyleAddRemoveItem class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7765)	Draws a background image on the control.
	DrawGlyph (see page 7766)	Draws a symbol on the control.
	DrawSeparator (see page 7766)	This is DrawSeparator, a member of class TXPStyleAddRemoveItem.
	DrawText (see page 7766)	This is DrawText, a member of class TXPStyleAddRemoveItem.
	DrawUnusedEdges (see page 7766)	This is DrawUnusedEdges, a member of class TXPStyleAddRemoveItem.

Public Methods

	Name	Description
	CalcBounds (see page 7765)	Calculates the size of the add/remove menu item.

83.1.1.2.1 TXPStyleAddRemoveItem.CalcBounds Method

Calculates the size of the add/remove menu item.

Pascal

```
procedure CalcBounds; override;
```

C++

```
virtual __fastcall CalcBounds();
```

Description

CalcBounds updates the Height, Width, and TextBounds properties to reflect current conditions (such as the item's caption and the current font).

See Also

Height

Width

TextBounds

83.1.1.2.2 TXPStyleAddRemoveItem.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.1.2.3 TXPStyleAddRemoveItem.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

83.1.1.2.4 TXPStyleAddRemoveItem.DrawSeparator Method

Pascal

```
procedure DrawSeparator(const Offset: Integer); override;
```

C++

```
virtual __fastcall DrawSeparator(const int Offset);
```

Description

This is DrawSeparator, a member of class TXPStyleAddRemoveItem.

83.1.1.2.5 TXPStyleAddRemoveItem.DrawText Method

Pascal

```
procedure DrawText(var Rect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect Rect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TXPStyleAddRemoveItem.

83.1.1.2.6 TXPStyleAddRemoveItem.DrawUnusedEdges Method

Pascal

```
procedure DrawUnusedEdges; override;
```

C++

```
virtual __fastcall DrawUnusedEdges();
```

Description

This is DrawUnusedEdges, a member of class TXPStyleAddRemoveItem.

83.1.2 TXPStyleButton Class

Class Hierarchy

Pascal

```
TXPStyleButton = class(TCustomButtonControl);
```

C++

```
class TXPStyleButton : public TCustomButtonControl;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleButton.

83.1.2.1 TXPStyleButton Members

The following tables list the members exposed by TXPStyleButton.

Protected Methods

	Name	Description
	DrawBackground (see page 7767)	Draws a background image on the control.
	DrawFrame (see page 7768)	This is DrawFrame, a member of class TXPStyleButton.
	DrawGlyph (see page 7768)	Draws a symbol on the control.
	DrawText (see page 7768)	This is DrawText, a member of class TXPStyleButton.

83.1.2.2 TXPStyleButton Methods

The methods of the TXPStyleButton class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7767)	Draws a background image on the control.
	DrawFrame (see page 7768)	This is DrawFrame, a member of class TXPStyleButton.
	DrawGlyph (see page 7768)	Draws a symbol on the control.
	DrawText (see page 7768)	This is DrawText, a member of class TXPStyleButton.

83.1.2.2.1 TXPStyleButton.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.2.2.2 TXPStyleButton.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TXPStyleButton.

83.1.2.2.3 TXPStyleButton.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

83.1.2.2.4 TXPStyleButton.DrawText Method

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TXPStyleButton.

83.1.3 TXPStyleCustomizePopup Class

Class Hierarchy

Pascal

```
TXPStyleCustomizePopup = class(TCustomizeActionToolBar);
```

C++

```
class TXPStyleCustomizePopup : public TCustomizeActionToolBar;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleCustomizePopup.

83.1.3.1 TXPStyleCustomizePopup Members

The following tables list the members exposed by TXPStyleCustomizePopup.

Protected Methods

	Name	Description
	GetAddRemoveItemClass (see page 7770)	This is GetAddRemoveItemClass, a member of class TXPStyleCustomizePopup.
	GetDefaultColorMapClass (see page 7770)	This is GetDefaultColorMapClass, a member of class TXPStyleCustomizePopup.
	NCPaint (see page 7770)	This is NCPaint, a member of class TXPStyleCustomizePopup.

Public Methods

	Name	Description
	Create (see page 7769)	Creates and initializes a TCustomActionPopupMenu instance.

83.1.3.2 TXPStyleCustomizePopup.Create Constructor

Creates and initializes a TCustomActionPopupMenu instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXPStyleCustomizePopup(TComponent * AOwner);
```

Description

Create generates a TCustomActionPopupMenu and initializes its properties.

```
__fastcall virtual TCustomActionMenuBar (Classes::TComponentTComponent_Object* AOwner);
__fastcall TCustomActionMenuBar (HWND ParentWindow) :
Controls::TWinControlTWinControl_Create(ParentWindow) { }
```

83.1.3.3 TXPStyleCustomizePopup Methods

The methods of the TXPStyleCustomizePopup class are listed here.

Protected Methods

	Name	Description
	GetAddRemoveItemClass (see page 7770)	This is GetAddRemoveItemClass, a member of class TXPStyleCustomizePopup.
	GetDefaultColorMapClass (see page 7770)	This is GetDefaultColorMapClass, a member of class TXPStyleCustomizePopup.
	NCPaint (see page 7770)	This is NCPaint, a member of class TXPStyleCustomizePopup.

83.1.3.3.1 TXPStyleCustomizePopup.GetAddRemoveItemClass Method

Pascal

```
function GetAddRemoveItemClass: TCustomAddRemoveItemClass; override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass();
```

Description

This is GetAddRemoveItemClass, a member of class TXPStyleCustomizePopup.

83.1.3.3.2 TXPStyleCustomizePopup.GetDefaultColorMapClass Method

Pascal

```
function GetDefaultColorMapClass: TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetDefaultColorMapClass();
```

Description

This is GetDefaultColorMapClass, a member of class TXPStyleCustomizePopup.

83.1.3.3.3 TXPStyleCustomizePopup.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TXPStyleCustomizePopup.

83.1.4 TXPStyleDropDownBtn Class

Class Hierarchy

Pascal

```
TXPStyleDropDownBtn = class(TCustomDropDownButton);
```

C++

```
class TXPStyleDropDownBtn : public TCustomDropDownButton;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleDropDownBtn.

83.1.4.1 TXPStyleDropDownBtn Members

The following tables list the members exposed by TXPStyleDropDownBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 7771)	Draws a background image on the control.
	DrawFrame (see page 7772)	This is DrawFrame, a member of class TXPStyleDropDownBtn.
	DrawGlyph (see page 7772)	Draws a symbol on the control.
	GetPopupClass (see page 7772)	This is GetPopupClass, a member of class TXPStyleDropDownBtn.

83.1.4.2 TXPStyleDropDownBtn Methods

The methods of the TXPStyleDropDownBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7771)	Draws a background image on the control.
	DrawFrame (see page 7772)	This is DrawFrame, a member of class TXPStyleDropDownBtn.
	DrawGlyph (see page 7772)	Draws a symbol on the control.
	GetPopupClass (see page 7772)	This is GetPopupClass, a member of class TXPStyleDropDownBtn.

83.1.4.2.1 TXPStyleDropDownBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.4.2.2 TXPStyleDropDownBtn.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TXPStyleDropDownBtn.

83.1.4.2.3 TXPStyleDropDownBtn.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

83.1.4.2.4 TXPStyleDropDownBtn.GetPopupClass Method

Pascal

```
function GetPopupClass: TCustomActionBarClass; override;
```

C++

```
virtual __fastcall TCustomActionBarClass GetPopupClass();
```

Description

This is GetPopupClass, a member of class TXPStyleDropDownBtn.

83.1.5 TXPStyleExpandBtn Class

Class Hierarchy

Pascal

```
TXPStyleExpandBtn = class(TCustomMenuExpandBtn);
```

C++

```
class TXPStyleExpandBtn : public TCustomMenuExpandBtn;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleExpandBtn.

83.1.5.1 TXPStyleExpandBtn Members

The following tables list the members exposed by TXPStyleExpandBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 7773)	Draws a background image on the control.
	DrawFrame (see page 7773)	This is DrawFrame, a member of class TXPStyleExpandBtn.

83.1.5.2 TXPStyleExpandBtn Methods

The methods of the TXPStyleExpandBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7773)	Draws a background image on the control.
	DrawFrame (see page 7773)	This is DrawFrame, a member of class TXPStyleExpandBtn.

83.1.5.2.1 TXPStyleExpandBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.5.2.2 TXPStyleExpandBtn.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TXPStyleExpandBtn.

83.1.6 TXPStyleMenuButton Class

Class Hierarchy

Pascal

```
TXPStyleMenuButton = class(TCustomMenuButton);
```

C++

```
class TXPStyleMenuButton : public TCustomMenuButton;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleMenuButton.

83.1.6.1 TXPStyleMenuButton Members

The following tables list the members exposed by TXPStyleMenuButton.

Protected Methods

	Name	Description
	DrawBackground (see page 7774)	Draws a background image on the control.
	DrawText (see page 7775)	This is DrawText, a member of class TXPStyleMenuButton.

83.1.6.2 TXPStyleMenuButton Methods

The methods of the TXPStyleMenuButton class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7774)	Draws a background image on the control.
	DrawText (see page 7775)	This is DrawText, a member of class TXPStyleMenuButton.

83.1.6.2.1 TXPStyleMenuButton.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.6.2.2 TXPStyleMenuButton.DrawText Method

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TXPStyleMenuButton.

83.1.7 TXPStyleMenuItem Class

Class Hierarchy

Pascal

```
TXPStyleMenuItem = class(TCustomMenuItem);
```

C++

```
class TXPStyleMenuItem : public TCustomMenuItem;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleMenuItem.

83.1.7.1 TXPStyleMenuItem Members

The following tables list the members exposed by TXPStyleMenuItem.

Protected Methods

	Name	Description
	CalcLayout (see page 7776)	This is CalcLayout, a member of class TXPStyleMenuItem.
	DrawBackground (see page 7777)	Draws a background image on the control.
	DrawGlyph (see page 7777)	Draws a symbol on the control.
	DrawSeparator (see page 7777)	This is DrawSeparator, a member of class TXPStyleMenuItem.
	DrawShadowedText (see page 7777)	This is DrawShadowedText, a member of class TXPStyleMenuItem.
	DrawSubMenuGlyph (see page 7778)	This is DrawSubMenuGlyph, a member of class TXPStyleMenuItem.
	DrawText (see page 7778)	This is DrawText, a member of class TXPStyleMenuItem.

	DrawUnusedEdges (see page 7778)	This is DrawUnusedEdges, a member of class TXPStyleMenuItem.

Public Methods

	Name	Description
	CalcBounds (see page 7776)	Calculates the size of the menu item.

83.1.7.2 TXPStyleMenuItem Methods

The methods of the TXPStyleMenuItem class are listed here.

Protected Methods

	Name	Description
	CalcLayout (see page 7776)	This is CalcLayout, a member of class TXPStyleMenuItem.
	DrawBackground (see page 7777)	Draws a background image on the control.
	DrawGlyph (see page 7777)	Draws a symbol on the control.
	DrawSeparator (see page 7777)	This is DrawSeparator, a member of class TXPStyleMenuItem.
	DrawShadowedText (see page 7777)	This is DrawShadowedText, a member of class TXPStyleMenuItem.
	DrawSubMenuGlyph (see page 7778)	This is DrawSubMenuGlyph, a member of class TXPStyleMenuItem.
	DrawText (see page 7778)	This is DrawText, a member of class TXPStyleMenuItem.
	DrawUnusedEdges (see page 7778)	This is DrawUnusedEdges, a member of class TXPStyleMenuItem.

Public Methods

	Name	Description
	CalcBounds (see page 7776)	Calculates the size of the menu item.

83.1.7.2.1 TXPStyleMenuItem.CalcBounds Method

Calculates the size of the menu item.

Pascal

```
procedure CalcBounds; override;
```

C++

```
virtual __fastcall CalcBounds();
```

Description

The size of the control depends on many factors, such as whether or not the menu item is a separator or not. CalcBounds computes the boundaries of the menu item considering these kinds of factors. At the end, it calls SetBounds and other routines to ensure that the values are set properly.

See Also

SetBounds

83.1.7.2.2 TXPStyleMenuItem.CalcLayout Method

Pascal

```
procedure CalcLayout; override;
```

C++

```
virtual __fastcall CalcLayout();
```

Description

This is CalcLayout, a member of class TXPStyleMenuItem.

83.1.7.2.3 TXPStyleMenuItem.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

83.1.7.2.4 TXPStyleMenuItem.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

83.1.7.2.5 TXPStyleMenuItem.DrawSeparator Method

Pascal

```
procedure DrawSeparator(const Offset: Integer); override;
```

C++

```
virtual __fastcall DrawSeparator(const int Offset);
```

Description

This is DrawSeparator, a member of class TXPStyleMenuItem.

83.1.7.2.6 TXPStyleMenuItem.DrawShadowedText Method

Pascal

```
procedure DrawShadowedText(Rect: TRect; Flags: Cardinal; Text: String; TextColor: TColor;
ShadowColor: TColor); override;
```

C++

```
virtual __fastcall DrawShadowedText(TRect Rect, unsigned Flags, UnicodeString Text, TColor
TextColor, TColor ShadowColor);
```

Description

This is DrawShadowedText, a member of class TXPStyleMenuItem.

83.1.7.2.7 TXPStyleMenuItem.DrawSubMenuGlyph Method

Pascal

```
procedure DrawSubMenuGlyph; override;
```

C++

```
virtual __fastcall DrawSubMenuGlyph();
```

Description

This is DrawSubMenuGlyph, a member of class TXPStyleMenuItem.

83.1.7.2.8 TXPStyleMenuItem.DrawText Method

Pascal

```
procedure DrawText(var Rect: TRect; var Flags: Cardinal; Text: String); override;
```

C++

```
virtual __fastcall DrawText(TRect Rect, unsigned Flags, UnicodeString Text);
```

Description

This is DrawText, a member of class TXPStyleMenuItem.

83.1.7.2.9 TXPStyleMenuItem.DrawUnusedEdges Method

Pascal

```
procedure DrawUnusedEdges; override;
```

C++

```
virtual __fastcall DrawUnusedEdges();
```

Description

This is DrawUnusedEdges, a member of class TXPStyleMenuItem.

83.1.8 TXPStylePopupMenu Class

Class Hierarchy

Pascal

```
TXPStylePopupMenu = class(TCustomActionPopupMenu);
```

C++

```
class TXPStylePopupMenu : public TCustomActionPopupMenu;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStylePopupMenu.

83.1.8.1 TXPStylePopupMenu Members

The following tables list the members exposed by TXPStylePopupMenu.

Protected Methods

	Name	Description
	DisplayShadow (see page 7780)	This is DisplayShadow, a member of class TXPStylePopupMenu.
	GetExpandBtnClass (see page 7780)	This is GetExpandBtnClass, a member of class TXPStylePopupMenu.
	HideShadow (see page 7781)	This is HideShadow, a member of class TXPStylePopupMenu.
	NCPaint (see page 7781)	This is NCPaint, a member of class TXPStylePopupMenu.
	PositionPopup (see page 7781)	This is PositionPopup, a member of class TXPStylePopupMenu.
	VisibleChanging (see page 7781)	Provides the interface for a method that responds to changes in the control's visibility.

Public Methods

	Name	Description
	Create (see page 7779)	Creates and initializes a TCustomActionPopupMenu instance.
	Destroy (see page 7779)	Destroys an instance of TCustomActionMenuBar.

83.1.8.2 TXPStylePopupMenu.Create Constructor

Creates and initializes a TCustomActionPopupMenu instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXPStylePopupMenu(TComponent * AOwner);
```

Description

Create generates a TCustomActionPopupMenu and initializes its properties.

```
__fastcall virtual TCustomActionMenuBar (Classes::TComponentTComponent_Object* AOwner);
__fastcall TCustomActionMenuBar (HWND ParentWindow) :
Controls::TWinControlTWinControl_Create(ParentWindow) { }
```

83.1.8.3 TXPStylePopupMenu.Destroy Destructor

Destroys an instance of TCustomActionMenuBar.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXPStylePopupMenu();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TCustomActionMenuBar reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

Destroy

83.1.8.4 TXPStylePopupMenu Methods

The methods of the TXPStylePopupMenu class are listed here.

Protected Methods

	Name	Description
	DisplayShadow (see page 7780)	This is DisplayShadow, a member of class TXPStylePopupMenu.
	GetExpandBtnClass (see page 7780)	This is GetExpandBtnClass, a member of class TXPStylePopupMenu.
	HideShadow (see page 7781)	This is HideShadow, a member of class TXPStylePopupMenu.
	NCPaint (see page 7781)	This is NCPaint, a member of class TXPStylePopupMenu.
	PositionPopup (see page 7781)	This is PositionPopup, a member of class TXPStylePopupMenu.
	VisibleChanging (see page 7781)	Provides the interface for a method that responds to changes in the control's visibility.

83.1.8.4.1 TXPStylePopupMenu.DisplayShadow Method

Pascal

```
procedure DisplayShadow; override;
```

C++

```
virtual __fastcall DisplayShadow();
```

Description

This is DisplayShadow, a member of class TXPStylePopupMenu.

83.1.8.4.2 TXPStylePopupMenu.GetExpandBtnClass Method

Pascal

```
function GetExpandBtnClass: TCustomMenuExpandBtnClass; override;
```

C++

```
virtual __fastcall TCustomMenuExpandBtnClass GetExpandBtnClass();
```

Description

This is GetExpandBtnClass, a member of class TXPStylePopupMenu.

83.1.8.4.3 TXPStylePopupMenu.HideShadow Method

Pascal

```
procedure HideShadow; override;
```

C++

```
virtual __fastcall HideShadow();
```

Description

This is HideShadow, a member of class TXPStylePopupMenu.

83.1.8.4.4 TXPStylePopupMenu.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TXPStylePopupMenu.

83.1.8.4.5 TXPStylePopupMenu.PositionPopup Method

Pascal

```
procedure PositionPopup(AnOwner: TCustomActionBar; ParentItem: TCustomActionControl); override;
```

C++

```
virtual __fastcall PositionPopup(TCustomActionBar AnOwner, TCustomActionControl ParentItem);
```

Description

This is PositionPopup, a member of class TXPStylePopupMenu.

83.1.8.4.6 TXPStylePopupMenu.VisibleChanging Method

Provides the interface for a method that responds to changes in the control's visibility.

Pascal

```
procedure VisibleChanging; override;
```

C++

```
virtual __fastcall VisibleChanging();
```

Description

VisibleChanging is called before the value of a control's Visible property changes. As implemented in TControl, it does nothing. Override VisibleChanging to respond to changes in the control's visibility. For example, if a control should not change its visibility, override VisibleChanging to raise an exception when an attempt is made to alter the control's visibility.

83.1.9 TXPStyleToolScrollBtn Class

Class Hierarchy

Pascal

```
TXPStyleToolScrollBtn = class(TCustomToolScrollBtn);
```

C++

```
class TXPStyleToolScrollBtn : public TCustomToolScrollBtn;
```

File

XPActnCtrls

Description

This is class XPActnCtrls.TXPStyleToolScrollBtn.

83.1.9.1 TXPStyleToolScrollBtn Members

The following tables list the members exposed by TXPStyleToolScrollBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 7782)	Draws a background image on the control.

83.1.9.2 TXPStyleToolScrollBtn Methods

The methods of the TXPStyleToolScrollBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 7782)	Draws a background image on the control.

83.1.9.2.1 TXPStyleToolScrollBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

Variables

Name	Description
XPStyle (see page 7791)	This is variable XPStyleActnCtrls.XPStyle.

85.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TXPStyleActionBars (see page 7788)	This is class XPStyleActnCtrls.TXPStyleActionBars.

85.1.1 TXPStyleActionBars Class

Class Hierarchy

Pascal

```
TXPStyleActionBars = class(TActionBarStyleEx);
```

C++

```
class TXPStyleActionBars : public TActionBarStyleEx;
```

File

XPStyleActnCtrls

Description

This is class XPStyleActnCtrls.TXPStyleActionBars.

85.1.1.1 TXPStyleActionBars Members

The following tables list the members exposed by TXPStyleActionBars.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 7789)	Returns the base class for ActionBand menus for customizing action bands.
	GetColorMapClass (see page 7789)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 7789)	Returns the control class type on an action bar item.
	GetPopupClass (see page 7790)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 7790)	This is GetScrollBtnClass, a member of class TXPStyleActionBars.
	GetStyleName (see page 7790)	Returns the style associated with action manager.

85.1.1.2 TXPStyleActionBars Methods

The methods of the TXPStyleActionBars class are listed here.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 7789)	Returns the base class for ActionBand menus for customizing action bands.

	GetColorMapClass (see page 7789)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 7789)	Returns the control class type on an action bar item.
	GetPopupClass (see page 7790)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 7790)	This is GetScrollBtnClass, a member of class TXPStyleActionBars.
	GetStyleName (see page 7790)	Returns the style associated with action manager.

85.1.1.2.1 TXPStyleActionBars.GetAddRemoveItemClass Method

Returns the base class for ActionBand menus for customizing action bands.

Pascal

```
function GetAddRemoveItemClass(ActionBar: TCustomActionBar): TCustomAddRemoveItemClass;
override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass(TCustomActionBar ActionBar);
```

Description

Call GetAddRemoveItemClass to customize action bands.

See Also

TCustomAddRemoveItem

85.1.1.2.2 TXPStyleActionBars.GetColorMapClass Method

Returns the class type of the colormap for an action bar.

Pascal

```
function GetColorMapClass(ActionBar: TCustomActionBar): TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetColorMapClass(TCustomActionBar ActionBar);
```

Description

Returns the class type TCustomActionBarColorMap, which is a colormap associated with an action bar. Override this method to customize the appearance of your applications.

85.1.1.2.3 TXPStyleActionBars.GetControlClass Method

Returns the control class type on an action bar item.

Pascal

```
function GetControlClass(ActionBar: TCustomActionBar; AnItem: TActionClientItem):
TCustomActionControlClass; override;
```

C++

```
virtual __fastcall TCustomActionControlClass GetControlClass(TCustomActionBar ActionBar,
TActionClientItem AnItem);
```

Description

Returns the control class type on an item in the action bar, such as a button or menu item.

85.1.1.2.4 TXPStyleActionBars.GetPopupClass Method

Returns the popup class added to a menu action band.

Pascal

```
function GetPopupClass(ActionBar: TCustomActionBar): TCustomPopupClass; override;
```

C++

```
virtual __fastcall TCustomPopupClass GetPopupClass(TCustomActionBar ActionBar);
```

Description

Call GetPopupClass to find the popup menu associated with a menu action band. Override GetPopupClass to change which popup class is associated with a menu action band depending on the state of the control.

See Also

TCustomActionPopupMenu

85.1.1.2.5 TXPStyleActionBars.GetScrollBtnClass Method

Pascal

```
function GetScrollBtnClass: TCustomToolScrollBtnClass; override;
```

C++

```
virtual __fastcall TCustomToolScrollBtnClass GetScrollBtnClass();
```

Description

This is GetScrollBtnClass, a member of class TXPStyleActionBars.

85.1.1.2.6 TXPStyleActionBars.GetStyleName Method

Returns the style associated with action manager.

Pascal

```
function GetStyleName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetStyleName();
```

Description

Returns the value of the Style property.

85.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
XPStyle (see page 7791)	This is variable XPStyleActnCtrls.XPStyle.

85.2.1 XPStyleActnCtrls.XPStyle Variable

Pascal

```
XPStyle: TXPStyleActionBars;
```

C++

```
TXPStyleActionBars XPStyle;
```

File

XPStyleActnCtrls

Description

This is variable XPStyleActnCtrls.XPStyle.

86 XSBuiltIns Namespace

This is namespace XSBuiltIns.

Topics

Name	Description
Classes (see page 7795)	The following table lists classes in this documentation.
Functions (see page 7861)	The following table lists functions in this documentation.
Types (see page 7865)	The following table lists types in this documentation.
Constants (see page 7866)	The following table lists constants in this documentation.

Classes

	Name	Description
	EXSDateTimeException (see page 7795)	EXSDateTimeException is the exception class for errors encountered by the remotable objects that represent XML schema date and time values.
	EXSDecimalException (see page 7796)	EXSDecimalException is the exception class for errors encountered by the remotable objects that represent decimal values.
	EXSHexBinaryException (see page 7796)	EXSHexBinaryException is the exception class for errors encountered by the remotable objects that represent hexadecimal values.
	TXMLData (see page 7797)	This is class XSBuiltIns.TXMLData.
	TXSBoolean (see page 7801)	This is class XSBuiltIns.TXSBoolean.
	TXSCustomDateTime (see page 7803)	TXSCustomDateTime is the base class for classes that represent both date and time values for an invokable interface.
	TXSDate (see page 7822)	TXSDate implements the XML schema date type so that it can be used on invokable interfaces.
	TXSDateTime (see page 7828)	TXSDateTime implements the XML schema datetime type so that it can be used on invokable interfaces.
	TXSDecimal (see page 7832)	TXSDecimal implements the XML schema decimal type so that it can be used on invokable interfaces.
	TXSDuration (see page 7836)	TXSDuration implements the XML schema duration type so that it can be used on invokable interfaces.
	TXSHexBinary (see page 7840)	TXSHexBinary implements the XML schema hexBinary type so that it can be used on invokable interfaces.
	TXSInteger (see page 7843)	This is class XSBuiltIns.TXSInteger.
	TXSLong (see page 7845)	This is class XSBuiltIns.TXSLong.
	TXSString (see page 7847)	This is class XSBuiltIns.TXSString.
	TXSTime (see page 7849)	TXSTime implements the XML schema time type so that it can be used on invokable interfaces.

Constants

Name	Description
IncrementAmount (see page 7866)	This is constant XSBuiltIns.IncrementAmount.
MaxDay (see page 7867)	This is constant XSBuiltIns.MaxDay.
MaxMonth (see page 7867)	This is constant XSBuiltIns.MaxMonth.
MinDay (see page 7867)	This is constant XSBuiltIns.MinDay.
MinMonth (see page 7868)	This is constant XSBuiltIns.MinMonth.
SDecimal (see page 7868)	This is constant XSBuiltIns.SDecimal.
SHexMarker (see page 7868)	This is constant XSBuiltIns.SHexMarker.
SLocalTimeMarker (see page 7869)	This is constant XSBuiltIns.SLocalTimeMarker.
SNAN (see page 7869)	This is constant XSBuiltIns.SNAN.
SNegative (see page 7869)	This is constant XSBuiltIns.SNegative.
SoapDecimalSeparator (see page 7870)	This is constant XSBuiltIns.SoapDecimalSeparator.
SoapTimePrefix (see page 7870)	This is constant XSBuiltIns.SoapTimePrefix.
SPlus (see page 7870)	This is constant XSBuiltIns.SPlus.
SSciNotationMarker (see page 7871)	This is constant XSBuiltIns.SSciNotationMarker.
XMLDateSeparator (see page 7871)	This is constant XSBuiltIns.XMLDateSeparator.
XMLDayPos (see page 7871)	This is constant XSBuiltIns.XMLDayPos.
XMLDefaultYearDigits (see page 7872)	This is constant XSBuiltIns.XMLDefaultYearDigits.
XMLDurationDay (see page 7872)	This is constant XSBuiltIns.XMLDurationDay.
XMLDurationHour (see page 7872)	This is constant XSBuiltIns.XMLDurationHour.
XMLDurationMinute (see page 7873)	This is constant XSBuiltIns.XMLDurationMinute.
XMLDurationMonth (see page 7873)	This is constant XSBuiltIns.XMLDurationMonth.
XMLDurationSecond (see page 7873)	This is constant XSBuiltIns.XMLDurationSecond.
XMLDurationStart (see page 7874)	This is constant XSBuiltIns.XMLDurationStart.
XMLDurationYear (see page 7874)	This is constant XSBuiltIns.XMLDurationYear.
XMLHourOffsetMinusMarker (see page 7874)	This is constant XSBuiltIns.XMLHourOffsetMinusMarker.
XMLHourOffsetPlusMarker (see page 7875)	This is constant XSBuiltIns.XMLHourOffsetPlusMarker.
XMLMilSecPos (see page 7875)	This is constant XSBuiltIns.XMLMilSecPos.
XMLMonthPos (see page 7875)	This is constant XSBuiltIns.XMLMonthPos.
XMLTimeSeparator (see page 7876)	This is constant XSBuiltIns.XMLTimeSeparator.
XMLYearPos (see page 7876)	This is constant XSBuiltIns.XMLYearPos.

Functions

	Name	Description
	DateTimeToXMLTime (see page 7861)	Returns the XML string that represents a TDateTime (see page 3323) value.
	DateTimeToXSDateTime (see page 7861)	Returns a TXSDateTime (see page 7828) object that encodes a TDateTime (see page 3323) value.
	GetDataFromFile (see page 7862)	This is function XSBuiltIns.GetDataFromFile.
	InitXSTypes (see page 7862)	This is function XSBuiltIns.InitXSTypes.
	SoapFloatToStr (see page 7863)	This is function XSBuiltIns.SoapFloatToStr.
	SoapStrToFloat (see page 7863)	This is function XSBuiltIns.SoapStrToFloat.
	XMLTimeToDateTime (see page 7863)	Returns a TDateTime (see page 3323) value to represent an XML datetime value.

Types

Name	Description
TXSTimeInstant (see page 7865)	TXSTimeInstant represents the timeInstant type for Web Services applications.

86.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EXSDateTimeException (see page 7795)	EXSDateTimeException is the exception class for errors encountered by the remotable objects that represent XML schema date and time values.
	EXSDecimalException (see page 7796)	EXSDecimalException is the exception class for errors encountered by the remotable objects that represent decimal values.
	EXSHexBinaryException (see page 7796)	EXSHexBinaryException is the exception class for errors encountered by the remotable objects that represent hexadecimal values.
	TXMLData (see page 7797)	This is class XSBuiltIns.TXMLData.
	TXSBoolean (see page 7801)	This is class XSBuiltIns.TXSBoolean.
	TXSCustomDateTime (see page 7803)	TXSCustomDateTime is the base class for classes that represent both date and time values for an invokable interface.
	TXSDate (see page 7822)	TXSDate implements the XML schema date type so that it can be used on invokable interfaces.
	TXSDateTime (see page 7828)	TXSDateTime implements the XML schema datetime type so that it can be used on invokable interfaces.
	TXSDecimal (see page 7832)	TXSDecimal implements the XML schema decimal type so that it can be used on invokable interfaces.
	TXSDuration (see page 7836)	TXSDuration implements the XML schema duration type so that it can be used on invokable interfaces.
	TXSHexBinary (see page 7840)	TXSHexBinary implements the XML schema hexBinary type so that it can be used on invokable interfaces.
	TXSInteger (see page 7843)	This is class XSBuiltIns.TXSInteger.
	TXSLong (see page 7845)	This is class XSBuiltIns.TXSLong.
	TXSString (see page 7847)	This is class XSBuiltIns.TXSString.
	TXSTime (see page 7849)	TXSTime implements the XML schema time type so that it can be used on invokable interfaces.

86.1.1 EXSDateTimeException Class

EXSDateTimeException is the exception class for errors encountered by the remotable objects that represent XML schema date and time values.

Class Hierarchy

Pascal

```
EXSDateTimeException = class(Exception);
```

C++

```
class EXSDateTimeException : public Exception;
```

File

XSBuiltIns

Description

EXSDateTimeException is raised by the TXSDate (see page 7822), TXSTime (see page 7849), TXSDateTime (see page

7828), and TXSDuration (see page 7836) objects when

An application assigns a value that is out of range to one of their properties. Such values include Month values greater than 12, Hour values greater than 23, Minute values greater than 59, and so on.

The string that represents the object's value does not have the proper format and can't be parsed.

See Also

TXSTime (see page 7849)

TXSDate (see page 7822)

TXSDateTime (see page 7828)

TXSDuration (see page 7836)

86.1.2 EXSDecimalException Class

EXSDecimalException is the exception class for errors encountered by the remotable objects that represent decimal values.

Class Hierarchy

Pascal

```
EXSDecimalException = class(Exception);
```

C++

```
class EXSDecimalException : public Exception;
```

File

XSBuiltIns

Description

EXSDecimalException is raised by TXSDecimal (see page 7832) when it is unable to convert between its string value and a TBcd value.

See Also

TXSDecimal (see page 7832)

TBcd

86.1.3 EXSHexBinaryException Class

EXSHexBinaryException is the exception class for errors encountered by the remotable objects that represent hexadecimal values.

Class Hierarchy

Pascal

```
EXSHexBinaryException = class(Exception);
```

C++

```
class EXSHexBinaryException : public Exception;
```

File

XSBuiltIns

Description

EXSHexBinaryException is raised by TXSHexBinary (see page 7840) when it encounters a string that contains invalid characters for a hexadecimal value.

See Also

TXSDecimal (see page 7832)

TBcd

86.1.4 TXMLData Class

Class Hierarchy

Pascal

```
TXMLData = class(TRemotable);
```

C++

```
class TXMLData : public TRemotable;
```

File

XSBuiltIns

Description

This is class XSBuiltIns.TXMLData.

86.1.4.1 TXMLData Members

The following tables list the members exposed by TXMLData.

Public Methods

	Name	Description
	Create (see page 7798)	Creates and initializes a TRemotable object.
	Destroy (see page 7798)	Frees the memory associated with the TRemotable object.
	LoadFromXML (see page 7799)	This is the overview for the LoadFromXML method overload.
	ObjectToSOAP (see page 7799)	Converts this remotable object to its SOAP representation.
	SOAPToObject (see page 7800)	Initializes this TRemotable instance to represent the value of its SOAP representation.

Public Properties

	Name	Description
	XMLNode (see page 7801)	This is XMLNode, a member of class TXMLData.

86.1.4.2 TXMLData.Create Constructor

Creates and initializes a TRemotable object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TXMLData();
```

Description

The TRemotable constructor does nothing special. It exists primarily because

The remotable type registry knows how to call it.

It is virtual, so that the remotable type registry can also instantiate descendant classes.

See Also

RemTypeRegistry

86.1.4.3 TXMLData.Destroy Destructor

Frees the memory associated with the TRemotable object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLData();
```

Description

Use the Free method to free a TRemotable instance. Free checks that the object is not nil before calling Destroy.

On server applications, there is typically no need to explicitly free a TRemotable instance (for example, one created as a return value or output parameter). By default, when a TRemotable descendant is created in a method that was called remotely using an invokable interface, it is added to a data context (the value of the DataContext property). As long as the remotable object belongs to the data context, the data context handles freeing the object. Similarly, TRemotable instances that are passed in as a parameter belong to the data context.

On client applications, TRemotable instances created and passed to an invokable interface or returned as a parameter or result of an invokable interface must be freed by the calling application.

See Also

System::TObject::Free (see page 3372)

DataContext

86.1.4.4 TXMLData Methods

The methods of the TXMLData class are listed here.

Public Methods

	Name	Description
	LoadFromXML (see page 7799)	This is the overview for the LoadFromXML method overload.
	ObjectToSOAP (see page 7799)	Converts this remotable object to its SOAP representation.
	SOAPToObject (see page 7800)	Initializes this TRemotable instance to represent the value of its SOAP representation.

86.1.4.4.1 LoadFromXML Method

This is the overview for the LoadFromXML method overload.

Overload List

	Name	Description
	TXMLData.LoadFromXML (string) (see page 7799)	This is LoadFromXML, a member of class TXMLData.
	TXMLData.LoadFromXML (WideString) (see page 7799)	This is LoadFromXML, a member of class TXMLData.

86.1.4.4.1.1 TXMLData.LoadFromXML Method (WideString)

Pascal

```
procedure LoadFromXML(const XML: WideString); overload;
```

C++

```
__fastcall LoadFromXML(const BSTR XML);
```

Description

This is LoadFromXML, a member of class TXMLData.

86.1.4.4.1.2 TXMLData.LoadFromXML Method (string)

Pascal

```
procedure LoadFromXML(const XML: string); overload;
```

C++

```
__fastcall LoadFromXML(const UnicodeString XML);
```

Description

This is LoadFromXML, a member of class TXMLData.

86.1.4.4.2 TXMLData.ObjectToSOAP Method

Converts this remotable object to its SOAP representation.

Pascal

```
function ObjectToSOAP(RootNode: IXMLNode; ParentNode: IXMLNode; const ObjConverter:
IObjConverter; const Name: InvString; const URI: InvString; ObjConvOpts:
TObjectConvertOptions; out RefID: InvString): IXMLNode; override;
```

C++

```
virtual __fastcall IXMLNode ObjectToSOAP(IXMLNode RootNode, IXMLNode ParentNode, const
IObjConverter ObjConverter, const InvString Name, const InvString URI, TObjectConvertOptions
```

```
ObjConvOpts, InvString RefID);
```

Description

Override ObjectToSOAP to customize the way your application converts a TRemotable descendant to its SOAP representation. In TRemotable, ObjectToSOAP simply calls the ObjInstanceToSOAP method of the converter that is supplied by the ObjConverter parameter.

RootNode is an ancestor of the generated node to which information about the generated node can be added as attributes.

ParentNode is the node in the SOAP representation that should act as a parent to the node that ObjectToSOAP generates.

ObjConverter is the interface of the default converter that translates between remotable objects and their SOAP representation. This is the interface to a TOPToSoapDomConvert instance.

Name is the name of the node that is generated.

URI is the URI for the namespace in which Name is defined.

ObjConvOpts are flags that customize the way the node is serialized.

RefID returns a reference ID for the node. This is used if the node is multi-referenced.

ObjectToSOAP returns the XML for the newly generated node.

See Also

ObjInstanceToSOAP

SOAPToObject

86.1.4.4.3 TXMLData.SOAPToObject Method

Initializes this TRemotable instance to represent the value of its SOAP representation.

Pascal

```
procedure SOAPToObject(const RootNode: IXMLNode; const Node: IXMLNode; const ObjConverter:
IObjConverter); override;
```

C++

```
virtual __fastcall SOAPToObject(const IXMLNode RootNode, const IXMLNode Node, const
IObjConverter ObjConverter);
```

Description

SOAPToObject initializes the published properties of this object instance so that they reflect the header's SOAP representation. Override this method to customize the way your application creates a specific remotable type from its XML representation.

RootNode is an ancestor node of the node for this object that can contain information about the remotable type's value.

Node is the node in the SOAP envelope that represents the remotable type's value.

ObjConverter is the interface of the default converter that translates between remotable objects and their SOAP representation. This is the interface to a TOPToSoapDomConvert instance.

In TRemotable, SOAPToObject simply calls the InitObjectFromSOAP method of the converter supplied by the ObjConverter parameter.

See Also

ObjectToSOAP

InitObjectFromSOAP

86.1.4.5 TXMLData Properties

The properties of the TXMLData class are listed here.

Public Properties

	Name	Description
	XMLNode (see page 7801)	This is XMLNode, a member of class TXMLData.

86.1.4.5.1 TXMLData.XMLNode Property

Pascal

```
property XMLNode: IXMLNode;
```

C++

```
__property IXMLNode XMLNode;
```

Description

This is XMLNode, a member of class TXMLData.

86.1.5 TXSBoolean Class

Class Hierarchy

Pascal

```
TXSBoolean = class(TRemotableXS);
```

C++

```
class TXSBoolean : public TRemotableXS;
```

File

XSBuiltIns

Description

This is class XSBuiltIns.TXSBoolean.

86.1.5.1 TXSBoolean Members

The following tables list the members exposed by TXSBoolean.

Public Methods

	Name	Description
	NativeToXS (see page 7802)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7802)	Assigns the value of a string to the TRemotableXS instance.

Public Properties

	Name	Description
	AsBoolean (see page 7803)	This is AsBoolean, a member of class TXSBoolean.

86.1.5.2 TXSBoolean Methods

The methods of the TXSBoolean class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7802)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7802)	Assigns the value of a string to the TRemotableXS instance.

86.1.5.2.1 TXSBoolean.NativeToXS Method

Returns a string that represents the value of a TRemotableXS instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

Override NativeToXS when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS returns a string that represents the value of the TRemotableXS instance. This string is used when marshaling the value of the TRemotableXS descendant.

Classes that implement NativeToXS must also override the XSToNative method so that it performs the converse transformation.

See Also

XSToNative

Using Remotable Objects

86.1.5.2.2 TXSBoolean.XSToNative Method

Assigns the value of a string to the TRemotableXS instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

Override XSToNative when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS interprets a string that represents the value of the TRemotableXS instance and uses it to make any necessary changes so that the TRemotableXS object reflects that value. It reverses the transformation that the NativeToXS method performs.

Data is a string that represents the value of the TRemotableXS instance.

See Also

NativeToXS

Using Remotable Objects

86.1.5.3 TXSBoolean Properties

The properties of the TXSBoolean class are listed here.

Public Properties

	Name	Description
	AsBoolean (see page 7803)	This is AsBoolean, a member of class TXSBoolean.

86.1.5.3.1 TXSBoolean.AsBoolean Property

Pascal

```
property AsBoolean: Boolean;
```

C++

```
__property Boolean AsBoolean;
```

Description

This is AsBoolean, a member of class TXSBoolean.

86.1.6 TXSCustomDateTime Class

TXSCustomDateTime is the base class for classes that represent both date and time values for an invokable interface.

Class Hierarchy

Pascal

```
TXSCustomDateTime = class(TRemotableXS);
```

C++

```
class TXSCustomDateTime : public TRemotableXS;
```

File

XSBuiltIns

Description

Use TXSCustomDateTime as a base class when defining a class to represent a type that includes both date and time portions and that represents a scalar value in a WSDL document. When creating a TXSCustomDateTime descendant, override the XSToNative and NativeToXS methods to indicate how the value of the class can be converted to and from the string representation that is used to encode the value for transport.

On server applications, instances of TXSCustomDateTime descendants that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSCustomDateTime descendant is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSCustomDateTime instances that it passes as input parameters, and for freeing any TXSCustomDateTime instances it creates or that are returned as output parameters or method results.

See Also

IInvokable (see page 3504)

TXSDateTime (see page 7828)

TXSDuration (see page 7836)

86.1.6.1 TXSCustomDateTime Members

The following tables list the members exposed by TXSCustomDateTime.

Protected Fields

	Name	Description
	FDateTime (see page 7806)	This is FDateTime, a member of class TXSCustomDateTime.

Protected Methods

	Name	Description
	GetAsDateTime (see page 7807)	Returns the value of the AsDateTime (see page 7815) property.
	GetAsUTCDateTime (see page 7807)	This is GetAsUTCDateTime, a member of class TXSCustomDateTime.
	GetDay (see page 7807)	Returns the value of the Day (see page 7816) property.
	GetFractionalSeconds (see page 7808)	Returns the value of the FractionalSeconds (see page 7817) property.
	GetHour (see page 7808)	Returns the value of the Hour (see page 7817) property.
	GetHourOffset (see page 7808)	Returns the value of the HourOffset (see page 7818) property.
	GetMillisecond (see page 7808)	Returns the value of the Millisecond (see page 7818) property.
	GetMinute (see page 7809)	Returns the value of the Minute (see page 7819) property.
	GetMinuteOffset (see page 7809)	Returns the value of the MinuteOffset (see page 7819) property.
	GetMonth (see page 7809)	Returns the value of the Month (see page 7820) property.
	GetSecond (see page 7810)	Returns the value of the Second (see page 7820) property.
	GetUseZeroMilliseconds (see page 7810)	Returns the value of the UseZeroMilliseconds (see page 7821) property.
	GetYear (see page 7810)	Returns the value of the Year (see page 7821) property.
	SetAsDateTime (see page 7811)	Sets the value of the AsDateTime (see page 7815) property.
	SetAsUTCDateTime (see page 7811)	Sets the value of the AsUTCDateTime (see page 7816) property.
	SetDay (see page 7811)	Sets the value of the Day (see page 7816) property.
	SetFractionalSeconds (see page 7811)	Sets the value of the FractionalSeconds (see page 7817) property.
	SetHour (see page 7812)	Sets the value of the Hour (see page 7817) property.
	SetHourOffset (see page 7812)	Sets the value of the HourOffset (see page 7818) property.
	SetMillisecond (see page 7812)	Sets the value of the Millisecond (see page 7818) property.
	SetMinute (see page 7813)	Sets the value of the Minute (see page 7819) property.
	SetMinuteOffset (see page 7813)	Sets the value of the MinuteOffset (see page 7819) property.
	SetMonth (see page 7813)	Sets the value of the Month (see page 7820) property.
	SetSecond (see page 7814)	Sets the value of the Second (see page 7820) property.
	SetUseZeroMilliseconds (see page 7814)	Sets the value of the UseZeroMilliseconds (see page 7821) property.
	SetYear (see page 7814)	Sets the value of the Year (see page 7821) property.

Protected Properties

	Name	Description
	Millisecond (see page 7818)	Indicates the Millisecond of the second that the object represents.

Public Methods

	Name	Description
	Create (see page 7805)	Creates and initializes a TXSCustomDateTime (see page 7803) object.
	Destroy (see page 7805)	Frees the memory associated with the TXSCustomDateTime (see page 7803) object.

Public Properties

	Name	Description
	AsDateTime (see page 7815)	Represents the object's value as a TDateTime (see page 3323) value.
	AsUTCDateTime (see page 7816)	Represents the object's value as a TDateTime (see page 3323) value using UTC time.
	Day (see page 7816)	Indicates the Day of the month that the object represents.
	FractionalSeconds (see page 7817)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7820) property.
	Hour (see page 7817)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7818)	Indicates the difference between the Hour (see page 7817) property and the hour in the local time zone.
	Minute (see page 7819)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7819)	Indicates the difference between the Minute (see page 7819) property and the minute of the hour in local time.
	Month (see page 7820)	Indicates the month of the year that the object represents.
	Second (see page 7820)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7821)	Indicates whether the string representation of this object's value includes a portion for milliseconds when the value of Millisecond (see page 7818) is zero.
	Year (see page 7821)	Indicates the year that the object represents.

86.1.6.2 TXSCustomDateTime.Create Constructor

Creates and initializes a TXSCustomDateTime (see page 7803) object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TXSCustomDateTime();
```

Description

Call Create to create a TXSCustomDateTime (see page 7803) object at runtime.

See Also

Destroy (see page 7805)

86.1.6.3 TXSCustomDateTime.Destroy Destructor

Frees the memory associated with the TXSCustomDateTime (see page 7803) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXSCustomDateTime();
```

Description

Do not call Destroy to free a TXSCustomDateTime (see page 7803) object. Instead, use the Free method, which checks that the TXSCustomDateTime (see page 7803) reference is not nil before calling Destroy.

On server applications, there is typically no need to explicitly free a TXSCustomDateTime (see page 7803) instance (for example, one created as a return value or output parameter). By default, when a TXSCustomDateTime (see page 7803) descendant is created in a method that was called remotely using an invokable interface, it is added to a data context (the value of the DataContext property). As long as the remotable object belongs to the data context, the data context handles freeing the

object. Similarly, TCustomXSDateTime objects that are passed in as a parameter belong to the data context.

On client applications, TXSCustomDateTime (see page 7803) instances created and passed to an invokable interface or returned as a parameter or result of an invokable interface must be freed by the calling application.

See Also

DataContext

86.1.6.4 TXSCustomDateTime Fields

The fields of the TXSCustomDateTime class are listed here.

Protected Fields

	Name	Description
	FDateTime (see page 7806)	This is FDateTime, a member of class TXSCustomDateTime.

86.1.6.4.1 TXSCustomDateTime.FDateTime Field

Pascal

```
FDateTime: WideString;
```

C++

```
BSTR FDateTime;
```

Description

This is FDateTime, a member of class TXSCustomDateTime.

86.1.6.5 TXSCustomDateTime Methods

The methods of the TXSCustomDateTime class are listed here.

Protected Methods

	Name	Description
	GetAsDateTime (see page 7807)	Returns the value of the AsDateTime (see page 7815) property.
	GetAsUTCDateTime (see page 7807)	This is GetAsUTCDateTime, a member of class TXSCustomDateTime.
	GetDay (see page 7807)	Returns the value of the Day (see page 7816) property.
	GetFractionalSeconds (see page 7808)	Returns the value of the FractionalSeconds (see page 7817) property.
	GetHour (see page 7808)	Returns the value of the Hour (see page 7817) property.
	GetHourOffset (see page 7808)	Returns the value of the HourOffset (see page 7818) property.
	GetMillisecond (see page 7808)	Returns the value of the Millisecond (see page 7818) property.
	GetMinute (see page 7809)	Returns the value of the Minute (see page 7819) property.
	GetMinuteOffset (see page 7809)	Returns the value of the MinuteOffset (see page 7819) property.
	GetMonth (see page 7809)	Returns the value of the Month (see page 7820) property.
	GetSecond (see page 7810)	Returns the value of the Second (see page 7820) property.
	GetUseZeroMilliseconds (see page 7810)	Returns the value of the UseZeroMilliseconds (see page 7821) property.
	GetYear (see page 7810)	Returns the value of the Year (see page 7821) property.
	SetAsDateTime (see page 7811)	Sets the value of the AsDateTime (see page 7815) property.
	SetAsUTCDateTime (see page 7811)	Sets the value of the AsUTCDateTime (see page 7816) property.
	SetDay (see page 7811)	Sets the value of the Day (see page 7816) property.
	SetFractionalSeconds (see page 7811)	Sets the value of the FractionalSeconds (see page 7817) property.
	SetHour (see page 7812)	Sets the value of the Hour (see page 7817) property.
	SetHourOffset (see page 7812)	Sets the value of the HourOffset (see page 7818) property.

	SetMillisecond (see page 7812)	Sets the value of the Millisecond (see page 7818) property.
	SetMinute (see page 7813)	Sets the value of the Minute (see page 7819) property.
	SetMinuteOffset (see page 7813)	Sets the value of the MinuteOffset (see page 7819) property.
	SetMonth (see page 7813)	Sets the value of the Month (see page 7820) property.
	SetSecond (see page 7814)	Sets the value of the Second (see page 7820) property.
	SetUseZeroMilliseconds (see page 7814)	Sets the value of the UseZeroMilliseconds (see page 7821) property.
	SetYear (see page 7814)	Sets the value of the Year (see page 7821) property.

86.1.6.5.1 TXSCustomDateTime.GetAsDateTime Method

Returns the value of the AsDateTime (see page 7815) property.

Pascal

```
function GetAsDateTime: TDateTime;
```

C++

```
__fastcall TDateTime GetAsDateTime();
```

Description

GetAsDateTime is the protected read implementation of the AsDateTime (see page 7815) property.

See Also

AsDateTime (see page 7815)

86.1.6.5.2 TXSCustomDateTime.GetAsUTCDateTime Method

Pascal

```
function GetAsUTCDateTime: TDateTime;
```

C++

```
__fastcall TDateTime GetAsUTCDateTime();
```

Description

This is GetAsUTCDateTime, a member of class TXSCustomDateTime.

86.1.6.5.3 TXSCustomDateTime.GetDay Method

Returns the value of the Day (see page 7816) property.

Pascal

```
function GetDay: Word;
```

C++

```
__fastcall Word GetDay();
```

Description

GetDay is the protected read implementation of the Day (see page 7816) property.

See Also

Day (see page 7816)

86.1.6.5.4 TXSCustomDateTime.GetFractionalSeconds Method

Returns the value of the FractionalSeconds (see page 7817) property.

Pascal

```
function GetFractionalSeconds: Double;
```

C++

```
__fastcall Double GetFractionalSeconds();
```

Description

GetFractionalSeconds is the protected read implementation of the FractionalSeconds (see page 7817) property.

See Also

FractionalSeconds (see page 7817)

86.1.6.5.5 TXSCustomDateTime.GetHour Method

Returns the value of the Hour (see page 7817) property.

Pascal

```
function GetHour: Word;
```

C++

```
__fastcall Word GetHour();
```

Description

GetHour is the protected read implementation of the Hour (see page 7817) property.

See Also

Hour (see page 7817)

86.1.6.5.6 TXSCustomDateTime.GetHourOffset Method

Returns the value of the HourOffset (see page 7818) property.

Pascal

```
function GetHourOffset: SmallInt;
```

C++

```
__fastcall SmallInt GetHourOffset();
```

Description

GetHourOffset is the protected read implementation of the HourOffset (see page 7818) property.

See Also

HourOffset (see page 7818)

86.1.6.5.7 TXSCustomDateTime.GetMillisecond Method

Returns the value of the Millisecond (see page 7818) property.

Pascal

```
function GetMillisecond: Word;
```

C++

```
__fastcall Word GetMillisecond();
```

Description

GetMillisecond is the protected read implementation of the Millisecond (see page 7818) property.

See Also

Millisecond (see page 7818)

86.1.6.5.8 TXSCustomDateTime.GetMinute Method

Returns the value of the Minute (see page 7819) property.

Pascal

```
function GetMinute: Word;
```

C++

```
__fastcall Word GetMinute();
```

Description

GetMinute is the protected read implementation of the Minute (see page 7819) property.

See Also

Minute (see page 7819)

86.1.6.5.9 TXSCustomDateTime.GetMinuteOffset Method

Returns the value of the MinuteOffset (see page 7819) property.

Pascal

```
function GetMinuteOffset: SmallInt;
```

C++

```
__fastcall SmallInt GetMinuteOffset();
```

Description

GetMinuteOffset is the protected read implementation of the MinuteOffset (see page 7819) property.

See Also

MinuteOffset (see page 7819)

86.1.6.5.10 TXSCustomDateTime.GetMonth Method

Returns the value of the Month (see page 7820) property.

Pascal

```
function GetMonth: Word;
```

C++

```
__fastcall Word GetMonth();
```

Description

GetMonth is the protected read implementation of the Month (see page 7820) property.

See Also

Month (see page 7820)

86.1.6.5.11 TXSCustomDateTime.GetSecond Method

Returns the value of the Second (see page 7820) property.

Pascal

```
function GetSecond: Word;
```

C++

```
__fastcall Word GetSecond();
```

Description

GetSecond is the protected read implementation of the Second (see page 7820) property.

See Also

Second (see page 7820)

86.1.6.5.12 TXSCustomDateTime.GetUseZeroMilliseconds Method

Returns the value of the UseZeroMilliseconds (see page 7821) property.

Pascal

```
function GetUseZeroMilliseconds: Boolean;
```

C++

```
__fastcall Boolean GetUseZeroMilliseconds();
```

Description

GetUseZeroMilliseconds is the protected read implementation of the UseZeroMilliseconds (see page 7821) property.

See Also

UseZeroMilliseconds (see page 7821)

86.1.6.5.13 TXSCustomDateTime.GetYear Method

Returns the value of the Year (see page 7821) property.

Pascal

```
function GetYear: Integer;
```

C++

```
__fastcall int GetYear();
```

Description

GetYear is the protected read implementation of the Year (see page 7821) property.

See Also

Year (see page 7821)

86.1.6.5.14 TXSCustomDateTime.SetAsDateTime Method

Sets the value of the AsDateTime (see page 7815) property.

Pascal

```
procedure SetAsDateTime(const Value: TDateTime);
```

C++

```
__fastcall SetAsDateTime(const TDateTime Value);
```

Description

SetAsDateTime is the protected write implementation of the AsDateTime (see page 7815) property.

See Also

AsDateTime (see page 7815)

86.1.6.5.15 TXSCustomDateTime.SetAsUTCDateTime Method

Sets the value of the AsUTCDateTime (see page 7816) property.

Pascal

```
procedure SetAsUTCDateTime(const Value: TDateTime);
```

C++

```
__fastcall SetAsUTCDateTime(const TDateTime Value);
```

Description

SetAsUTCDateTime is the protected write implementation of the AsUTCDateTime (see page 7816) property.

See Also

AsUTCDateTime (see page 7816)

86.1.6.5.16 TXSCustomDateTime.SetDay Method

Sets the value of the Day (see page 7816) property.

Pascal

```
procedure SetDay(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetDay(const Word Value);
```

Description

SetDay is the protected write implementation of the Day (see page 7816) property.

See Also

Day (see page 7816)

86.1.6.5.17 TXSCustomDateTime.SetFractionalSeconds Method

Sets the value of the FractionalSeconds (see page 7817) property.

Pascal

```
procedure SetFractionalSeconds(const Value: Double);
```

C++

```
__fastcall SetFractionalSeconds(const Double Value);
```

Description

SetDay (see page 7811) is the protected write implementation of the FractionalSeconds (see page 7817) property.

Value is the fraction of a second. It is a value between 0 and 1.

See Also

FractionalSeconds (see page 7817)

86.1.6.5.18 TXSCustomDateTime.SetHour Method

Sets the value of the Hour (see page 7817) property.

Pascal

```
procedure SetHour(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetHour(const Word Value);
```

Description

SetHour is the protected write implementation of the Hour (see page 7817) property.

See Also

Hour (see page 7817)

86.1.6.5.19 TXSCustomDateTime.SetHourOffset Method

Sets the value of the HourOffset (see page 7818) property.

Pascal

```
procedure SetHourOffset(const Value: SmallInt); virtual;
```

C++

```
virtual __fastcall SetHourOffset(const SmallInt Value);
```

Description

SetHourOffset is the protected write implementation of the HourOffset (see page 7818) property.

See Also

HourOffset (see page 7818)

86.1.6.5.20 TXSCustomDateTime.SetMillisecond Method

Sets the value of the Millisecond (see page 7818) property.

Pascal

```
procedure SetMillisecond(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetMillisecond(const Word Value);
```

Description

SetMillisecond is the protected write implementation for the Millisecond (see page 7818) property.

See Also

Millisecond (see page 7818)

86.1.6.5.21 TXSCustomDateTime.SetMinute Method

Sets the value of the Minute (see page 7819) property.

Pascal

```
procedure SetMinute(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetMinute(const Word Value);
```

Description

SetMinute is the protected write implementation of the Minute (see page 7819) property.

See Also

Minute (see page 7819)

86.1.6.5.22 TXSCustomDateTime.SetMinuteOffset Method

Sets the value of the MinuteOffset (see page 7819) property.

Pascal

```
procedure SetMinuteOffset(const Value: SmallInt); virtual;
```

C++

```
virtual __fastcall SetMinuteOffset(const SmallInt Value);
```

Description

SetMinuteOffest is the protected write implementation of the MinuteOffset (see page 7819) property.

See Also

MinuteOffset (see page 7819)

86.1.6.5.23 TXSCustomDateTime.SetMonth Method

Sets the value of the Month (see page 7820) property.

Pascal

```
procedure SetMonth(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetMonth(const Word Value);
```

Description

SetMonth is the protected write implementation of the Month (see page 7820) property.

See Also

Month (see page 7820)

86.1.6.5.24 TXSCustomDateTime.SetSecond Method

Sets the value of the Second (see page 7820) property.

Pascal

```
procedure SetSecond(const Value: Word); virtual;
```

C++

```
virtual __fastcall SetSecond(const Word Value);
```

Description

SetSecond is the protected write implementation of the Second (see page 7820) property.

See Also

Second (see page 7820)

86.1.6.5.25 TXSCustomDateTime.SetUseZeroMilliseconds Method

Sets the value of the UseZeroMilliseconds (see page 7821) property.

Pascal

```
procedure SetUseZeroMilliseconds(const Value: Boolean);
```

C++

```
__fastcall SetUseZeroMilliseconds(const Boolean Value);
```

Description

SetUseZeroMilliseconds is the protected write implementation of the UseZeroMilliseconds (see page 7821) property.

See Also

UseZeroMilliseconds (see page 7821)

86.1.6.5.26 TXSCustomDateTime.SetYear Method

Sets the value of the Year (see page 7821) property.

Pascal

```
procedure SetYear(const Value: Integer); virtual;
```

C++

```
virtual __fastcall SetYear(const int Value);
```

Description

SetYear is the protected write implementation of the Year (see page 7821) property.

See Also

Year (see page 7821)

86.1.6.6 TXSCustomDateTime Properties

The properties of the TXSCustomDateTime class are listed here.

Protected Properties

	Name	Description
	Millisecond (see page 7818)	Indicates the Millisecond of the second that the object represents.

Public Properties

	Name	Description
	AsDateTime (see page 7815)	Represents the object's value as a TDateTime (see page 3323) value.
	AsUTCDateTime (see page 7816)	Represents the object's value as a TDateTime (see page 3323) value using UTC time.
	Day (see page 7816)	Indicates the Day of the month that the object represents.
	FractionalSeconds (see page 7817)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7820) property.
	Hour (see page 7817)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7818)	Indicates the difference between the Hour (see page 7817) property and the hour in the local time zone.
	Minute (see page 7819)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7819)	Indicates the difference between the Minute (see page 7819) property and the minute of the hour in local time.
	Month (see page 7820)	Indicates the month of the year that the object represents.
	Second (see page 7820)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7821)	Indicates whether the string representation of this object's value includes a portion for milliseconds when the value of Millisecond (see page 7818) is zero.
	Year (see page 7821)	Indicates the year that the object represents.

86.1.6.6.1 TXSCustomDateTime.AsDateTime Property

Represents the object's value as a TDateTime (see page 3323) value.

Pascal

```
property AsDateTime: TDateTime;
```

C++

```
__property TDateTime AsDateTime;
```

Description

Use AsDateTime to read the value of the TXSCustomDateTime (see page 7803) object into a variable of type TDateTime (see page 3323) or set its value from a TDateTime (see page 3323) value. AsDateTime handles the mapping between a TDateTime (see page 3323) value and the Year (see page 7821), Month (see page 7820), Day (see page 7816), Hour (see page 7817), Minute (see page 7819), and Second (see page 7820) values.

Note: AsDateTime represents the local date-and-time, without using Coordinated Universal Time (see page 4297) (UTC). That is, AsDateTime ignores the HourOffset (see page 7818) and MinuteOffset (see page 7819) properties. To get or set the value taking the HourOffset (see page 7818) and MinuteOffset (see page 7819) properties into account, use the AsUTCDateTime (see page 7816) property instead.

See Also

Day (see page 7816)

Hour (see page 7817)

Minute (see page 7819)

Month (see page 7820)

Second (see page 7820)

Year (see page 7821)

HourOffset (see page 7818)

MinuteOffset (see page 7819)

Millisecond (see page 7818)

AsUTCDateTime (see page 7816)

86.1.6.6.2 TXSCustomDateTime.AsUTCDateTime Property

Represents the object's value as a TDateTime (see page 3323) value using UTC time.

Pascal

```
property AsUTCDateTime: TDateTime;
```

C++

```
__property TDateTime AsUTCDateTime;
```

Description

Use AsUTCDateTime to read the value of the TXSCustomDateTime (see page 7803) object into a variable of type TDateTime (see page 3323) or set its value from a TDateTime (see page 3323) value. AsUTCDateTime handles the mapping between a TDateTime (see page 3323) value and the Year (see page 7821), Month (see page 7820), Day (see page 7816), Hour (see page 7817), Minute (see page 7819), and Second (see page 7820) values. It also makes an adjustment for the HourOffset (see page 7818) and MinuteOffset (see page 7819) properties, so that the value of AsUTCDateTime is a Coordinated Universal Time (see page 4297) (UTC) value rather than a local time value.

Note: To get or set the value as a local time value ignoring the HourOffset (see page 7818) and MinuteOffset (see page 7819) properties, use the AsDateTime (see page 7815) property instead.

See Also

Day (see page 7816)

Hour (see page 7817)

Minute (see page 7819)

Month (see page 7820)

Second (see page 7820)

Year (see page 7821)

HourOffset (see page 7818)

MinuteOffset (see page 7819)

Millisecond (see page 7818)

AsDateTime (see page 7815)

86.1.6.6.3 TXSCustomDateTime.Day Property

Indicates the Day of the month that the object represents.

Pascal

```
property Day: Word;
```

C++

```
__property Word Day;
```

Description

Use Day to get or set the day portion of the date-and-time value. Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month (see page 7820) value.

See Also

AsDateTime (see page 7815)

Hour (see page 7817)

Minute (see page 7819)

Month (see page 7820)

Second (see page 7820)

Year (see page 7821)

Millisecond (see page 7818)

86.1.6.6.4 TXSCustomDateTime.FractionalSeconds Property

Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7820) property.

Pascal

```
property FractionalSeconds: Double;
```

C++

```
__property Double FractionalSeconds;
```

Description

Use FractionalSeconds to get or set the fractional seconds of the time value. FractionalSeconds represents the same information as the Millisecond (see page 7818) property, but can provide greater precision.

See Also

AsDateTime (see page 7815)

Minute (see page 7819)

Second (see page 7820)

Millisecond (see page 7818)

UseZeroMilliseconds (see page 7821)

86.1.6.6.5 TXSCustomDateTime.Hour Property

Indicates the hour of the day that the object represents.

Pascal

```
property Hour: Word;
```

C++

```
__property Word Hour;
```

Description

Use Hour to get or set the hour portion of the date-and-time value. Valid Hour values are 0 through 23.

Note: Hour represents the hour using Coordinated Universal Time (see page 4297) (UTC). To convert the hour to local time, you must add the hour offset.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Minute (see page 7819)

Month (see page 7820)

Second (see page 7820)

Year (see page 7821)

HourOffset (see page 7818)

Millisecond (see page 7818)

86.1.6.6.6 TXSCustomDateTime.HourOffset Property

Indicates the difference between the Hour (see page 7817) property and the hour in the local time zone.

Pascal

```
property HourOffset: SmallInt;
```

C++

```
__property SmallInt HourOffset;
```

Description

The Hour (see page 7817) property represents the hour of the day using Coordinated Universal Time (see page 4297) (UTC). HourOffset is the correction factor you can add to Hour (see page 7817) to obtain the hour of the day in local time.

See Also

Hour (see page 7817)

86.1.6.6.7 TXSCustomDateTime.Millisecond Property

Indicates the Millisecond of the second that the object represents.

Pascal

```
property Millisecond: Word;
```

C++

```
__property Word Millisecond;
```

Description

Use Millisecond to get or set the millisecond portion of the date-and-time value. Valid Millisecond values are 1 through 59.

Note: Millisecond values are not used by TXSDuration (see page 7836).

Note: You can also use the FractionalSeconds (see page 7817) property to obtain fractional portions of the seconds. Unlike Millisecond, which gives the value in milliseconds, FractionalSeconds (see page 7817) returns a fraction of a second.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Hour (see page 7817)

Minute (see page 7819)

Second (see page 7820)

Year (see page 7821)

Month (see page 7820)

UseZeroMilliseconds (see page 7821)

FractionalSeconds (see page 7817)

86.1.6.6.8 TXSCustomDateTime.Minute Property

Indicates the minute of the hour that the object represents.

Pascal

```
property Minute: Word;
```

C++

```
__property Word Minute;
```

Description

Use Minute to get or set the minute portion of the date-and-time value. Valid Minute values are 0 through 59.

Note: Minute represents the minute using Coordinated Universal Time (see page 4297) (UTC). To convert the minutes to local time, you must add the minute offset.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Hour (see page 7817)

Month (see page 7820)

Second (see page 7820)

Year (see page 7821)

MinuteOffset (see page 7819)

Millisecond (see page 7818)

86.1.6.6.9 TXSCustomDateTime.MinuteOffset Property

Indicates the difference between the Minute (see page 7819) property and the minute of the hour in local time.

Pascal

```
property MinuteOffset: SmallInt;
```

C++

```
__property SmallInt MinuteOffset;
```

Description

The Minute (see page 7819) property represents the minute of the hour using Coordinated Universal Time (see page 4297) (UTC). MinuteOffset is the correction factor you can add to Minute (see page 7819) to obtain the minute of the hour in local time.

See Also

Minute (see page 7819)

86.1.6.6.10 TXSCustomDateTime.Month Property

Indicates the month of the year that the object represents.

Pascal

```
property Month: Word;
```

C++

```
__property Word Month;
```

Description

Use Month to get or set the month portion of the date-and-time value. Valid Month values are 1 through 12.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Hour (see page 7817)

Minute (see page 7819)

Second (see page 7820)

Year (see page 7821)

Millisecond (see page 7818)

86.1.6.6.11 TXSCustomDateTime.Second Property

Indicates the second of the minute that the object represents.

Pascal

```
property Second: Word;
```

C++

```
__property Word Second;
```

Description

Use Second to get or set the seconds portion of the date-and-time value. Valid Second values are 0 through 59.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Hour (see page 7817)

Minute (see page 7819)

Year (see page 7821)

Millisecond (see page 7818)

86.1.6.6.12 TXSCustomDateTime.UseZeroMilliseconds Property

Indicates whether the string representation of this object's value includes a portion for milliseconds when the value of Millisecond (see page 7818) is zero.

Pascal

```
property UseZeroMilliseconds: Boolean;
```

C++

```
__property Boolean UseZeroMilliseconds;
```

Description

By default, the NativeToXS method does not include the milliseconds in the string encoding of this object's value when the value of the Millisecond (see page 7818) property is zero. If you set UseZeroMilliseconds, NativeToXS changes its encoding to include the milliseconds even when the value is zero. This is necessary for some Web Services that do not support the full schema defined by W3C.

See Also

Millisecond (see page 7818)

NativeToXS

86.1.6.6.13 TXSCustomDateTime.Year Property

Indicates the year that the object represents.

Pascal

```
property Year: Integer;
```

C++

```
__property int Year;
```

Description

Use Year to get or set the year portion of the date-and-time value. Valid Year values are 1 through 9999.

See Also

AsDateTime (see page 7815)

Day (see page 7816)

Hour (see page 7817)

Month (see page 7820)

Millisecond (see page 7818)

86.1.7 TXSDate Class

TXSDate implements the XML schema date type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSDate = class(TRemotableXS);
```

C++

```
class TXSDate : public TRemotableXS;
```

File

XSBuiltIns

Description

TXSDate acts as a wrapper for the simple scalar type date that W3C defines for XML schemas. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSDate enables this marshaling because it is a descendant of TRemotable.

To convert a TXSDate value to a TDateTime (see page 3323) value, use the AsDate (see page 7827) property. Other properties give the Year (see page 7828), Month (see page 7827), and Day (see page 7827) that make up that value.

On server applications, instances of TXSDate that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSDate instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSDate instances that it passes as input parameters, and for freeing any TXSDate instances it creates or that are returned as output parameters or method results.

See Also

IInvokable (see page 3504)

TXSDuration (see page 7836)

TXSTime (see page 7849)

86.1.7.1 TXSDate Members

The following tables list the members exposed by TXSDate.

Protected Methods

	Name	Description
	GetAsDate (see page 7824)	This is GetAsDate, a member of class TXSDate.

	GetDay (see page 7824)	This is GetDay, a member of class TXSDate.
	GetMonth (see page 7824)	This is GetMonth, a member of class TXSDate.
	GetYear (see page 7825)	This is GetYear, a member of class TXSDate.
	SetAsDate (see page 7825)	This is SetAsDate, a member of class TXSDate.
	SetDay (see page 7825)	This is SetDay, a member of class TXSDate.
	SetMonth (see page 7826)	This is SetMonth, a member of class TXSDate.
	SetYear (see page 7826)	This is SetYear, a member of class TXSDate.

Public Methods

	Name	Description
	Clone (see page 7824)	Returns a new TXSDate (see page 7822) object that represents the same value as this one.
V	Create (see page 7823)	Creates and initializes a Create object.
V	NativeToXS (see page 7825)	Returns a string that represents the value of a TXSDate (see page 7822) instance.
V	XSToNative (see page 7826)	Assigns the properties of the TXSDate (see page 7822) instance from the string representation of its value.

Public Properties

	Name	Description
	AsDate (see page 7827)	Represents the object's value as a TDateTime (see page 3323) value.
	Day (see page 7827)	Indicates the Day of the month that the object represents.
	Month (see page 7827)	Indicates the month of the year that the object represents.
	Year (see page 7828)	Indicates the year that the object represents.

86.1.7.2 TXSDate.Create Constructor

Creates and initializes a Create object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TXSDate();
```

Description

Call Create indirectly, using the new keyword, to create a Create object at runtime.

86.1.7.3 TXSDate Methods

The methods of the TXSDate class are listed here.

Protected Methods

	Name	Description
	GetAsDate (see page 7824)	This is GetAsDate, a member of class TXSDate.
	GetDay (see page 7824)	This is GetDay, a member of class TXSDate.
	GetMonth (see page 7824)	This is GetMonth, a member of class TXSDate.
	GetYear (see page 7825)	This is GetYear, a member of class TXSDate.
	SetAsDate (see page 7825)	This is SetAsDate, a member of class TXSDate.
	SetDay (see page 7825)	This is SetDay, a member of class TXSDate.
	SetMonth (see page 7826)	This is SetMonth, a member of class TXSDate.
	SetYear (see page 7826)	This is SetYear, a member of class TXSDate.

Public Methods

	Name	Description
	Clone (see page 7824)	Returns a new TXSDate (see page 7822) object that represents the same value as this one.
V	NativeToXS (see page 7825)	Returns a string that represents the value of a TXSDate (see page 7822) instance.
V	XSToNative (see page 7826)	Assigns the properties of the TXSDate (see page 7822) instance from the string representation of its value.

86.1.7.3.1 TXSDate.Clone Method

Returns a new TXSDate (see page 7822) object that represents the same value as this one.

Pascal

```
function Clone: TXSDate;
```

C++

```
__fastcall TXSDate Clone();
```

Description

Call Clone to obtain a new TXSDate (see page 7822) instance that represents the same time as this one. Clone returns the new TXSDate (see page 7822) object.

86.1.7.3.2 TXSDate.GetAsDate Method

Pascal

```
function GetAsDate: TDateTime;
```

C++

```
__fastcall TDateTime GetAsDate();
```

Description

This is GetAsDate, a member of class TXSDate.

86.1.7.3.3 TXSDate.GetDay Method

Pascal

```
function GetDay: Word;
```

C++

```
__fastcall Word GetDay();
```

Description

This is GetDay, a member of class TXSDate.

86.1.7.3.4 TXSDate.GetMonth Method

Pascal

```
function GetMonth: Word;
```

C++

```
__fastcall Word GetMonth();
```

Description

This is GetMonth, a member of class TXSDate.

86.1.7.3.5 TXSDate.GetYear Method

Pascal

```
function GetYear: Integer;
```

C++

```
__fastcall int GetYear();
```

Description

This is GetYear, a member of class TXSDate.

86.1.7.3.6 TXSDate.NativeToXS Method

Returns a string that represents the value of a TXSDate (see page 7822) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSDate (see page 7822) in a SOAP packet.

See Also

XSToNative (see page 7826)

86.1.7.3.7 TXSDate.SetAsDate Method

Pascal

```
procedure SetAsDate(const Value: TDateTime);
```

C++

```
__fastcall SetAsDate(const TDateTime Value);
```

Description

This is SetAsDate, a member of class TXSDate.

86.1.7.3.8 TXSDate.SetDay Method

Pascal

```
procedure SetDay(const Value: Word);
```

C++

```
__fastcall SetDay(const Word Value);
```

Description

This is SetDay, a member of class TXSDate.

86.1.7.3.9 TXSDate.SetMonth Method

Pascal

```
procedure SetMonth(const Value: Word);
```

C++

```
__fastcall SetMonth(const Word Value);
```

Description

This is SetMonth, a member of class TXSDate.

86.1.7.3.10 TXSDate.SetYear Method

Pascal

```
procedure SetYear(const Value: Integer);
```

C++

```
__fastcall SetYear(const int Value);
```

Description

This is SetYear, a member of class TXSDate.

86.1.7.3.11 TXSDate.XSToNative Method

Assigns the properties of the TXSDate (see page 7822) instance from the string representation of its value.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative parses the string specified by Data, which is the SOAP encoding of a date value. It uses this information to set the properties of the TXSDate (see page 7822) object.

See Also

NativeToXS (see page 7825)

86.1.7.4 TXSDate Properties

The properties of the TXSDate class are listed here.

Public Properties

	Name	Description
	AsDate (see page 7827)	Represents the object's value as a TDateTime (see page 3323) value.
	Day (see page 7827)	Indicates the Day of the month that the object represents.
	Month (see page 7827)	Indicates the month of the year that the object represents.
	Year (see page 7828)	Indicates the year that the object represents.

86.1.7.4.1 TXSDate.AsDate Property

Represents the object's value as a TDateTime (see page 3323) value.

Pascal

```
property AsDate: TDateTime;
```

C++

```
__property TDateTime AsDate;
```

Description

Use AsDate to read the value of the TXSDate (see page 7822) object into a variable of type TDateTime (see page 3323) or set this objects value from a TDateTime (see page 3323) value. AsDate handles the mapping between a TDateTime (see page 3323) value and the Year (see page 7828), Month (see page 7827), and Day (see page 7827) properties. When reading AsDate, the resulting TDateTime (see page 3323) value has a time portion of 0. When setting AsDate, the time portion is ignored.

See Also

Day (see page 7827)

Month (see page 7827)

Year (see page 7828)

86.1.7.4.2 TXSDate.Day Property

Indicates the Day of the month that the object represents.

Pascal

```
property Day: Word;
```

C++

```
__property Word Day;
```

Description

Use Day to get or set the day portion of the date-and-time value. Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month (see page 7827) value.

See Also

AsDate (see page 7827)

Month (see page 7827)

Year (see page 7828)

86.1.7.4.3 TXSDate.Month Property

Indicates the month of the year that the object represents.

Pascal

```
property Month: Word;
```

C++

```
__property Word Month;
```

Description

Use Month to get or set the month portion of the date-and-time value. Valid Month values are 1 through 12.

See Also

AsDate (see page 7827)

Day (see page 7827)

Year (see page 7828)

86.1.7.4.4 TXSDate.Year Property

Indicates the year that the object represents.

Pascal

```
property Year: Integer;
```

C++

```
__property int Year;
```

Description

Use Year to get or set the year portion of the date-and-time value. Valid Year values are 1 through 9999.

See Also

AsDate (see page 7827)

Day (see page 7827)

Month (see page 7827)

86.1.8 TXSDateTime Class

TXSDateTime implements the XML schema datetime type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSDateTime = class(TXSCustomDateTime);
```

C++

```
class TXSDateTime : public TXSCustomDateTime;
```

File

XSBuiltIns

Description

TXSDateTime acts as a wrapper for the simple scalar type datetime that W3C defines for XML schemas. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSDateTime enables this marshaling because it is a descendant of TRemotable.

To convert a TXSDateTime value to a TDateTime (see page 3323) value, use the AsDateTime (see page 7815) property. The resulting value represents the time portion using Coordinated Universal Time (see page 4297) (UTC). To convert that to a

local time zone, adjust the hour and minute portions using the HourOffset (see page 7818) and MinuteOffset (see page 7819) properties.

On server applications, instances of TXSDateTime that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSDateTime instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSDateTime instances that it passes as input parameters, and for freeing any TXSDateTime instances it creates or that are returned as output parameters or method results.

86.1.8.1 TXSDateTime Members

The following tables list the members exposed by TXSDateTime.

Protected Fields

	Name	Description
	FDateTime (see page 7806)	This is FDateTime, a member of class TXSCustomDateTime.

Protected Methods

	Name	Description
	GetAsDateTime (see page 7807)	Returns the value of the AsDateTime (see page 7815) property.
	GetAsUTCDateTime (see page 7807)	This is GetAsUTCDateTime, a member of class TXSCustomDateTime.
	GetDay (see page 7807)	Returns the value of the Day (see page 7816) property.
	GetFractionalSeconds (see page 7808)	Returns the value of the FractionalSeconds (see page 7817) property.
	GetHour (see page 7808)	Returns the value of the Hour (see page 7817) property.
	GetHourOffset (see page 7808)	Returns the value of the HourOffset (see page 7818) property.
	GetMillisecond (see page 7808)	Returns the value of the Millisecond (see page 7818) property.
	GetMinute (see page 7809)	Returns the value of the Minute (see page 7819) property.
	GetMinuteOffset (see page 7809)	Returns the value of the MinuteOffset (see page 7819) property.
	GetMonth (see page 7809)	Returns the value of the Month (see page 7820) property.
	GetSecond (see page 7810)	Returns the value of the Second (see page 7820) property.
	GetUseZeroMilliseconds (see page 7810)	Returns the value of the UseZeroMilliseconds (see page 7821) property.
	GetYear (see page 7810)	Returns the value of the Year (see page 7821) property.
	SetAsDateTime (see page 7811)	Sets the value of the AsDateTime (see page 7815) property.
	SetAsUTCDateTime (see page 7811)	Sets the value of the AsUTCDateTime (see page 7816) property.
	SetDay (see page 7811)	Sets the value of the Day (see page 7816) property.
	SetFractionalSeconds (see page 7811)	Sets the value of the FractionalSeconds (see page 7817) property.
	SetHour (see page 7812)	Sets the value of the Hour (see page 7817) property.
	SetHourOffset (see page 7812)	Sets the value of the HourOffset (see page 7818) property.
	SetMillisecond (see page 7812)	Sets the value of the Millisecond (see page 7818) property.
	SetMinute (see page 7813)	Sets the value of the Minute (see page 7819) property.
	SetMinuteOffset (see page 7813)	Sets the value of the MinuteOffset (see page 7819) property.
	SetMonth (see page 7813)	Sets the value of the Month (see page 7820) property.
	SetSecond (see page 7814)	Sets the value of the Second (see page 7820) property.

	SetUseZeroMilliseconds (see page 7814)	Sets the value of the UseZeroMilliseconds (see page 7821) property.
	SetYear (see page 7814)	Sets the value of the Year (see page 7821) property.

Public Methods

	Name	Description
	Clone (see page 7830)	Returns a new TXSDateTime (see page 7828) object that represents the same value as this one.
	CompareDateTimeParam (see page 7831)	This is CompareDateTimeParam, a member of class TXSDateTime.
	Create (see page 7805)	Creates and initializes a TXSCustomDateTime (see page 7803) object.
	Destroy (see page 7805)	Frees the memory associated with the TXSCustomDateTime (see page 7803) object.
	NativeToXS (see page 7831)	Returns a string that represents the value of a TXSDateTime (see page 7828) instance.
	XSToNative (see page 7831)	Assigns the properties of the TXSDateTime (see page 7828) instance from the string representation of its value.

Public Properties

	Name	Description
	AsDateTime (see page 7815)	Represents the object's value as a TDateTime (see page 3323) value.
	AsUTCDateTime (see page 7816)	Represents the object's value as a TDateTime (see page 3323) value using UTC time.
	Day (see page 7816)	Indicates the Day of the month that the object represents.
	FractionalSeconds (see page 7817)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7820) property.
	Hour (see page 7817)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7818)	Indicates the difference between the Hour (see page 7817) property and the hour in the local time zone.
	Millisecond (see page 7832)	Indicates the Millisecond of the second that the object represents.
	Minute (see page 7819)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7819)	Indicates the difference between the Minute (see page 7819) property and the minute of the hour in local time.
	Month (see page 7820)	Indicates the month of the year that the object represents.
	Second (see page 7820)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7821)	Indicates whether the string representation of this object's value includes a portion for milliseconds when the value of Millisecond (see page 7818) is zero.
	Year (see page 7821)	Indicates the year that the object represents.

86.1.8.2 TXSDateTime Methods

The methods of the TXSDateTime class are listed here.

Public Methods

	Name	Description
	Clone (see page 7830)	Returns a new TXSDateTime (see page 7828) object that represents the same value as this one.
	CompareDateTimeParam (see page 7831)	This is CompareDateTimeParam, a member of class TXSDateTime.
	NativeToXS (see page 7831)	Returns a string that represents the value of a TXSDateTime (see page 7828) instance.
	XSToNative (see page 7831)	Assigns the properties of the TXSDateTime (see page 7828) instance from the string representation of its value.

86.1.8.2.1 TXSDateTime.Clone Method

Returns a new TXSDateTime (see page 7828) object that represents the same value as this one.

Pascal

```
function Clone: TXSDateTime;
```

C++

```
__fastcall TXSDateTime Clone();
```

Description

Call Clone to obtain a new TXSDateTime (see page 7828) instance that represents the same date and time as this one. Clone returns the new TXSDateTime (see page 7828) object.

86.1.8.2.2 TXSDateTime.CompareDateTimeParam Method

Pascal

```
function CompareDateTimeParam(const Value1: TXSDateTime; const Value2: TXSDateTime):
TXSDuration;
```

C++

```
__fastcall TXSDuration CompareDateTimeParam(const TXSDateTime Value1, const TXSDateTime
Value2);
```

Description

This is CompareDateTimeParam, a member of class TXSDateTime.

86.1.8.2.3 TXSDateTime.NativeToXS Method

Returns a string that represents the value of a TXSDateTime (see page 7828) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSDateTime (see page 7828) in a SOAP packet.

See Also

XSToNative (see page 7831)

UseZeroMilliseconds (see page 7821)

86.1.8.2.4 TXSDateTime.XSToNative Method

Assigns the properties of the TXSDateTime (see page 7828) instance from the string representation of its value.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative parses the string specified by Data, which is the SOAP encoding of a datetime value. It uses this information to set the properties of the TXSDateTime (see page 7828) object.

See Also

NativeToXS (see page 7831)

86.1.8.3 TXSDateTime Properties

The properties of the TXSDateTime class are listed here.

Public Properties

	Name	Description
	Millisecond (see page 7832)	Indicates the Millisecond of the second that the object represents.

86.1.8.3.1 TXSDateTime.Millisecond Property

Indicates the Millisecond of the second that the object represents.

Pascal

```
property Millisecond: Word;
```

C++

```
__property Word Millisecond;
```

Description

Use Millisecond to get or set the millisecond portion of the date-and-time value. Valid Millisecond values are 1 through 59.

Note: Millisecond values are not used by TXSDuration.

Note: You can also use the FractionalSeconds property to obtain fractional portions of the seconds. Unlike Millisecond, which gives the value in milliseconds, FractionalSeconds returns a fraction of a second.

86.1.9 TXSDecimal Class

TXSDecimal implements the XML schema decimal type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSDecimal = class(TRemotableXS);
```

C++

```
class TXSDecimal : public TRemotableXS;
```

File

XSBuiltIns

Description

TXSDecimal acts as a wrapper for the simple scalar decimal type that W3C defines for XML schemas. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSDecimal enables this marshaling because it is a descendant of TRemotable.

To convert a TXSDecimal value to a TBcd value, use the AsBcd (see page 7835) property.

On server applications, instances of TXSDecimal that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSDecimal instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSDecimal instances that it passes as input parameters, and for freeing any TXSDecimal instances it creates or that are returned as output parameters or method results.

IInvokable (see page 3504)

TXSHexBinary (see page 7840)

EXSDecimalException (see page 7796)

86.1.9.1 TXSDecimal Members

The following tables list the members exposed by TXSDecimal.

Public Methods

	Name	Description
	NativeToXS (see page 7834)	Returns a string that represents the value of a TXSDecimal (see page 7832) instance.
	XSToNative (see page 7834)	Assigns a string as the value of the TXSDecimal (see page 7832) instance.

Public Properties

	Name	Description
	AsBcd (see page 7835)	Represents the object's value as a TBcd value.
	DecimalString (see page 7835)	Represents the object's value as a string.

86.1.9.2 TXSDecimal Methods

The methods of the TXSDecimal class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7834)	Returns a string that represents the value of a TXSDecimal (see page 7832) instance.
	XSToNative (see page 7834)	Assigns a string as the value of the TXSDecimal (see page 7832) instance.

86.1.9.2.1 TXSDecimal.NativeToXS Method

Returns a string that represents the value of a TXSDecimal (see page 7832) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSDecimal (see page 7832) object in a SOAP packet. That is, NativeToXS converts the DecimalString (see page 7835) property to a WideString (see page 3467) and returns the result.

See Also

XSToNative (see page 7834)

DecimalString (see page 7835)

86.1.9.2.2 TXSDecimal.XSToNative Method

Assigns a string as the value of the TXSDecimal (see page 7832) instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative sets the value of this TXSDecimal (see page 7832) object to a string that represents a formatted decimal value.

Data is the SOAP encoding of a decimal value. It becomes the value of the DecimalString (see page 7835) property.

See Also

NativeToXS (see page 7834)

DecimalString (see page 7835)

86.1.9.3 TXSDecimal Properties

The properties of the TXSDecimal class are listed here.

Public Properties

	Name	Description
	AsBcd (see page 7835)	Represents the object's value as a TBcd value.
	DecimalString (see page 7835)	Represents the object's value as a string.

86.1.9.3.1 TXSDecimal.AsBcd Property

Represents the object's value as a TBcd value.

Pascal

```
property AsBcd: TBcd;
```

C++

```
__property TBcd AsBcd;
```

Description

Use AsBcd to get or set this object's value as a TBcd type. TXSDecimal (see page 7832) converts between the internal string representation that is the value of the DecimalString (see page 7835) property and a TBcd value when the application gets or sets this property. Thus, if the string representation is ill-formed, reading AsBcd can cause an EXSDecimalException (see page 7796) exception. Similarly, setting AsBcd can cause an EXSDecimalException (see page 7796) exception if the TBcd value has an invalid scale or precision.

See Also

BcdToStr

TryStrToBcd

DecimalString (see page 7835)

EXSDecimalException (see page 7796)

86.1.9.3.2 TXSDecimal.DecimalString Property

Represents the object's value as a string.

Pascal

```
property DecimalString: string;
```

C++

```
__property UnicodeString DecimalString;
```

Description

Use DecimalString to obtain the value of the TXSDecimal (see page 7832) object as a string. This value is the same as the string that appears in XML documents to represent the decimal value. To work with this object's value as a TBcd value, use the AsBcd (see page 7835) property instead.

Note: If you do not need the precision of binary-coded decimal values, you can use global functions such as StrToFloat (see page 4282) and FloatToStr (see page 4180) or StrToCurr (see page 4278) and CurrToStr (see page 4086) to convert this string to a floating-point representation.

See Also

StrToCurr (see page 4278)

CurrToStr (see page 4086)

StrToFloat (see page 4282)

FloatToStr (see page 4180)

AsBcd (see page 7835)

86.1.10 TXSDuration Class

TXSDuration implements the XML schema duration type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSDuration = class(TXSCustomDateTime);
```

C++

```
class TXSDuration : public TXSCustomDateTime;
```

File

XSBuiltIns

Description

TXSDuration acts as a wrapper for the simple scalar type duration that W3C defines for XML schemas. That is, TXSDuration represents the interval between two points in time. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSDuration enables this marshaling because it is a descendant of TRemotable.

To convert a TXSDuration value to a TDateTime (see page 3323) value, use the AsDateTime (see page 7815) property.

On server applications, instances of TXSDuration that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSDuration instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSDuration instances that it passes as input parameters, and for freeing any TXSDuration instances it creates or that are returned as output parameters or method results.

IInvokable (see page 3504)

TXSDate (see page 7822)

TXSTime (see page 7849)

86.1.10.1 TXSDuration Members

The following tables list the members exposed by TXSDuration.

Protected Fields

	Name	Description
	FDateTime (see page 7806)	This is FDateTime, a member of class TXSCustomDateTime.

Protected Methods

	Name	Description
	GetAsDateTime (see page 7807)	Returns the value of the AsDateTime (see page 7815) property.
	GetAsUTCDateTime (see page 7807)	This is GetAsUTCDateTime, a member of class TXSCustomDateTime.

	GetDay (see page 7807)	Returns the value of the Day (see page 7816) property.
	GetDecimalSecond (see page 7838)	This is GetDecimalSecond, a member of class TXSDuration.
	GetFractionalSeconds (see page 7808)	Returns the value of the FractionalSeconds (see page 7817) property.
	GetHour (see page 7808)	Returns the value of the Hour (see page 7817) property.
	GetHourOffset (see page 7808)	Returns the value of the HourOffset (see page 7818) property.
	GetMillisecond (see page 7808)	Returns the value of the Millisecond (see page 7818) property.
	GetMinute (see page 7809)	Returns the value of the Minute (see page 7819) property.
	GetMinuteOffset (see page 7809)	Returns the value of the MinuteOffset (see page 7819) property.
	GetMonth (see page 7809)	Returns the value of the Month (see page 7820) property.
	GetSecond (see page 7810)	Returns the value of the Second (see page 7820) property.
	GetUseZeroMilliseconds (see page 7810)	Returns the value of the UseZeroMilliseconds (see page 7821) property.
	GetYear (see page 7810)	Returns the value of the Year (see page 7821) property.
	SetAsDateTime (see page 7811)	Sets the value of the AsDateTime (see page 7815) property.
	SetAsUTCDateTime (see page 7811)	Sets the value of the AsUTCDateTime (see page 7816) property.
	SetDay (see page 7811)	Sets the value of the Day (see page 7816) property.
	SetDecimalSecond (see page 7839)	This is SetDecimalSecond, a member of class TXSDuration.
	SetFractionalSeconds (see page 7811)	Sets the value of the FractionalSeconds (see page 7817) property.
	SetHour (see page 7812)	Sets the value of the Hour (see page 7817) property.
	SetHourOffset (see page 7812)	Sets the value of the HourOffset (see page 7818) property.
	SetMillisecond (see page 7812)	Sets the value of the Millisecond (see page 7818) property.
	SetMinute (see page 7813)	Sets the value of the Minute (see page 7819) property.
	SetMinuteOffset (see page 7813)	Sets the value of the MinuteOffset (see page 7819) property.
	SetMonth (see page 7813)	Sets the value of the Month (see page 7820) property.
	SetSecond (see page 7814)	Sets the value of the Second (see page 7820) property.
	SetUseZeroMilliseconds (see page 7814)	Sets the value of the UseZeroMilliseconds (see page 7821) property.
	SetYear (see page 7814)	Sets the value of the Year (see page 7821) property.

Protected Properties

	Name	Description
	Millisecond (see page 7818)	Indicates the Millisecond of the second that the object represents.

Public Methods

	Name	Description
	Create (see page 7838)	Creates and initializes a TXSDuration (see page 7836) object.
	Destroy (see page 7805)	Frees the memory associated with the TXSCustomDateTime (see page 7803) object.
	NativeToXS (see page 7838)	Returns a string that represents the value of a TXSDuration (see page 7836) instance.
	XSToNative (see page 7839)	Assigns the properties of the TXSDuration (see page 7836) instance from the string representation of its value.

Public Properties

	Name	Description
	AsDateTime (see page 7815)	Represents the object's value as a TDateTime (see page 3323) value.
	AsUTCDateTime (see page 7816)	Represents the object's value as a TDateTime (see page 3323) value using UTC time.
	Day (see page 7816)	Indicates the Day of the month that the object represents.
	DecimalSecond (see page 7839)	Indicates the number of seconds, including fractional seconds, in the duration.
	FractionalSeconds (see page 7817)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7820) property.
	Hour (see page 7817)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7818)	Indicates the difference between the Hour (see page 7817) property and the hour in the local time zone.
	Minute (see page 7819)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7819)	Indicates the difference between the Minute (see page 7819) property and the minute of the hour in local time.
	Month (see page 7820)	Indicates the month of the year that the object represents.

	Second (see page 7820)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7821)	Indicates whether the string representation of this object's value includes a portion for milliseconds when the value of Millisecond (see page 7818) is zero.
	Year (see page 7821)	Indicates the year that the object represents.

86.1.10.2 TXSDuration.Create Constructor

Creates and initializes a TXSDuration (see page 7836) object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TXSDuration();
```

Description

Call Create to create a TXSDuration (see page 7836) object at runtime.

86.1.10.3 TXSDuration Methods

The methods of the TXSDuration class are listed here.

Protected Methods

	Name	Description
	GetDecimalSecond (see page 7838)	This is GetDecimalSecond, a member of class TXSDuration.
	SetDecimalSecond (see page 7839)	This is SetDecimalSecond, a member of class TXSDuration.

Public Methods

	Name	Description
	NativeToXS (see page 7838)	Returns a string that represents the value of a TXSDuration (see page 7836) instance.
	XSToNative (see page 7839)	Assigns the properties of the TXSDuration (see page 7836) instance from the string representation of its value.

86.1.10.3.1 TXSDuration.GetDecimalSecond Method

Pascal

```
function GetDecimalSecond: Double;
```

C++

```
__fastcall Double GetDecimalSecond();
```

Description

This is GetDecimalSecond, a member of class TXSDuration.

86.1.10.3.2 TXSDuration.NativeToXS Method

Returns a string that represents the value of a TXSDuration (see page 7836) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSDuration (see page 7836) in a SOAP packet.

See Also

XSToNative (see page 7839)

86.1.10.3.3 TXSDuration.SetDecimalSecond Method

Pascal

```
procedure SetDecimalSecond(const Value: Double);
```

C++

```
__fastcall SetDecimalSecond(const Double Value);
```

Description

This is SetDecimalSecond, a member of class TXSDuration.

86.1.10.3.4 TXSDuration.XSToNative Method

Assigns the properties of the TXSDuration (see page 7836) instance from the string representation of its value.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative parses the string specified by Data, which is the SOAP encoding of a duration value. It uses this information to set the properties of the TXSDuration (see page 7836) object.

See Also

NativeToXS (see page 7838)

86.1.10.4 TXSDuration Properties

The properties of the TXSDuration class are listed here.

Public Properties

	Name	Description
	DecimalSecond (see page 7839)	Indicates the number of seconds, including fractional seconds, in the duration.

86.1.10.4.1 TXSDuration.DecimalSecond Property

Indicates the number of seconds, including fractional seconds, in the duration.

Pascal

```
property DecimalSecond: Double;
```

C++

```
__property Double DecimalSecond;
```

Description

Use the DecimalSecond property to determine the size of the duration with a granularity finer than the Seconds property provides. DecimalSecond represents the number of seconds in the duration (above and beyond the years, months, days, hours and minutes represented by the other TXSDuration (see page 7836) properties), including any fractional seconds.

See Also

Second (see page 7820)

FractionalSeconds (see page 7817)

86.1.11 TXSHexBinary Class

TXSHexBinary implements the XML schema hexBinary type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSHexBinary = class(TRemotableXS);
```

C++

```
class TXSHexBinary : public TRemotableXS;
```

File

XSBuiltIns

Description

TXSHexBinary acts as a wrapper for the simple scalar hexBinary type that W3C defines for XML schemas. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSHexBinary enables this marshaling because it is a descendant of TRemotable.

Use the AsByteArray (see page 7842) property to get or set the value of TXSHexBinary as an array of bytes. You can also set the value of TXSHexBinary from an integer using the global IntToHex (see page 4215) function to convert an integer into a hexadecimal string and setting the HexBinaryString (see page 7843) property.

On server applications, instances of TXSHexBinary that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSHexBinary instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSHexBinary instances that it passes as input parameters, and for freeing any TXSHexBinary instances it creates or that are returned as output parameters or method results.

HexToBin

BinToHex

IntToHex (see page 4215)

EXSHexBinaryException (see page 7796)

86.1.11.1 TXSHexBinary Members

The following tables list the members exposed by TXSHexBinary.

Public Methods

	Name	Description
	NativeToXS (see page 7841)	Returns a string that represents the value of a TXSHexBinary (see page 7840) instance.
	XSToNative (see page 7842)	Assigns a string as the value of the TXSHexBinary (see page 7840) instance.

Public Properties

	Name	Description
	AsByteArray (see page 7842)	Represents the object's value as an array of bytes.
	HexBinaryString (see page 7843)	Represents the object's value as a string.

86.1.11.2 TXSHexBinary Methods

The methods of the TXSHexBinary class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7841)	Returns a string that represents the value of a TXSHexBinary (see page 7840) instance.
	XSToNative (see page 7842)	Assigns a string as the value of the TXSHexBinary (see page 7840) instance.

86.1.11.2.1 TXSHexBinary.NativeToXS Method

Returns a string that represents the value of a TXSHexBinary (see page 7840) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSHexBinary (see page 7840) object in a SOAP packet. That is, NativeToXS converts the HexBinaryString (see page 7843) property to a WideString (see page 3467) and returns the result.

See Also

XSToNative (see page 7842)

HexBinaryString (see page 7843)

86.1.11.2.2 TXSHexBinary.XSToNative Method

Assigns a string as the value of the TXSHexBinary (see page 7840) instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative sets the value of this TXSHexBinary (see page 7840) object to a string that represents a formatted hexadecimal value.

Data is the SOAP encoding of a hexadecimal value. It becomes the value of the HexBinaryString (see page 7843) property.

See Also

NativeToXS (see page 7841)

HexBinaryString (see page 7843)

86.1.11.3 TXSHexBinary Properties

The properties of the TXSHexBinary class are listed here.

Public Properties

	Name	Description
	AsByteArray (see page 7842)	Represents the object's value as an array of bytes.
	HexBinaryString (see page 7843)	Represents the object's value as a string.

86.1.11.3.1 TXSHexBinary.AsByteArray Property

Represents the object's value as an array of bytes.

Pascal

```
property AsByteArray: TByteDynArray;
```

C++

```
__property TByteDynArray AsByteArray;
```

Description

Use AsByteArray to obtain the value of the TXSHexBinary (see page 7840) object as an array of bytes. This value is obtained from the HexBinaryString (see page 7843) property using the global HexToBin function. When you set AsByteArray, TXSHexBinary (see page 7840) uses the global BinToHex function to convert the binary value to a string and sets the HexBinaryString (see page 7843) property.

See Also

BinToHex

HexToBin

HexBinaryString (see page 7843)

86.1.11.3.2 TXSHexBinary.HexBinaryString Property

Represents the object's value as a string.

Pascal

```
property HexBinaryString: string;
```

C++

```
__property UnicodeString HexBinaryString;
```

Description

Use HexBinaryString to obtain the value of the TXSHexBinary (see page 7840) object. This value is represented as the string that appears in XML documents to represent the hexadecimal value.

To work with the value as an array of bytes, use the AsByteArray (see page 7842) property instead. You can convert an integer to a string that can be assigned to this property using the global IntToHex (see page 4215) function.

See Also

IntToHex (see page 4215)

AsByteArray (see page 7842)

86.1.12 TXSInteger Class

Class Hierarchy

Pascal

```
TXSInteger = class(TRemotableXS);
```

C++

```
class TXSInteger : public TRemotableXS;
```

File

XSBuiltIns

Description

This is class XSBuiltIns.TXSInteger.

86.1.12.1 TXSInteger Members

The following tables list the members exposed by TXSInteger.

Public Methods

	Name	Description
	NativeToXS (see page 7844)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7844)	Assigns the value of a string to the TRemotableXS instance.

Public Properties

	Name	Description
	AsInteger (see page 7845)	This is AsInteger, a member of class TXSInteger.

86.1.12.2 TXSInteger Methods

The methods of the TXSInteger class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7844)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7844)	Assigns the value of a string to the TRemotableXS instance.

86.1.12.2.1 TXSInteger.NativeToXS Method

Returns a string that represents the value of a TRemotableXS instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

Override NativeToXS when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS returns a string that represents the value of the TRemotableXS instance. This string is used when marshaling the value of the TRemotableXS descendant.

Classes that implement NativeToXS must also override the XSToNative method so that it performs the converse transformation.

See Also

XSToNative

Using Remotable Objects

86.1.12.2.2 TXSInteger.XSToNative Method

Assigns the value of a string to the TRemotableXS instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

Override XSToNative when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS interprets a string that represents the value of the TRemotableXS instance and uses it to make any necessary changes so that the TRemotableXS object reflects that value. It reverses the transformation that the NativeToXS method performs.

Data is a string that represents the value of the TRemotableXS instance.

NativeToXS

Using Remotable Objects

86.1.12.3 TXSInteger Properties

The properties of the TXSInteger class are listed here.

Public Properties

	Name	Description
	AsInteger (see page 7845)	This is AsInteger, a member of class TXSInteger.

86.1.12.3.1 TXSInteger.AsInteger Property

Pascal

```
property AsInteger: Integer;
```

C++

```
__property int AsInteger;
```

Description

This is AsInteger, a member of class TXSInteger.

86.1.13 TXSLong Class

Class Hierarchy

Pascal

```
TXSLong = class(TRemotableXS);
```

C++

```
class TXSLong : public TRemotableXS;
```

File

XSBuiltIns

Description

This is class XSBuiltIns.TXSLong.

86.1.13.1 TXSLong Members

The following tables list the members exposed by TXSLong.

Public Methods

	Name	Description
	NativeToXS (see page 7846)	Returns a string that represents the value of a TRemotableXS instance.

	XSToNative (see page 7846)	Assigns the value of a string to the TRemotableXS instance.

Public Properties

	Name	Description
	AsLong (see page 7847)	This is AsLong, a member of class TXSLong.

86.1.13.2 TXSLong Methods

The methods of the TXSLong class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7846)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7846)	Assigns the value of a string to the TRemotableXS instance.

86.1.13.2.1 TXSLong.NativeToXS Method

Returns a string that represents the value of a TRemotableXS instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

Override NativeToXS when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS returns a string that represents the value of the TRemotableXS instance. This string is used when marshaling the value of the TRemotableXS descendant.

Classes that implement NativeToXS must also override the XSToNative method so that it performs the converse transformation.

XSToNative

Using Remotable Objects

86.1.13.2.2 TXSLong.XSToNative Method

Assigns the value of a string to the TRemotableXS instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

Override XSToNative when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS interprets a string that represents the value of the TRemotableXS instance and uses it to make any necessary changes so that the TRemotableXS object reflects that value. It reverses the transformation that the NativeToXS method performs.

Data is a string that represents the value of the TRemotableXS instance.

86.1.13.3 TXSLong Properties

The properties of the TXSLong class are listed here.

Public Properties

	Name	Description
	AsLong (see page 7847)	This is AsLong, a member of class TXSLong.

86.1.13.3.1 TXSLong.AsLong Property

Pascal

```
property AsLong: Int64;
```

C++

```
__property Int64 AsLong;
```

Description

This is AsLong, a member of class TXSLong.

86.1.14 TXSString Class

Class Hierarchy

Pascal

```
TXSString = class(TRemotableXS);
```

C++

```
class TXSString : public TRemotableXS;
```

File

XSBuiltIns

Description

This is class XSBuiltIns.TXSString.

86.1.14.1 TXSString Members

The following tables list the members exposed by TXSString.

Public Methods

	Name	Description
	NativeToXS (see page 7848)	Returns a string that represents the value of a TRemotableXS instance.

	XSToNative (see page 7848)	Assigns the value of a string to the TRemotableXS instance.

86.1.14.2 TXSString Methods

The methods of the TXSString class are listed here.

Public Methods

	Name	Description
	NativeToXS (see page 7848)	Returns a string that represents the value of a TRemotableXS instance.
	XSToNative (see page 7848)	Assigns the value of a string to the TRemotableXS instance.

86.1.14.2.1 TXSString.NativeToXS Method

Returns a string that represents the value of a TRemotableXS instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

Override NativeToXS when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS returns a string that represents the value of the TRemotableXS instance. This string is used when marshaling the value of the TRemotableXS descendant.

Classes that implement NativeToXS must also override the XSToNative method so that it performs the converse transformation.

See Also

XSToNative

Using Remotable Objects

86.1.14.2.2 TXSString.XSToNative Method

Assigns the value of a string to the TRemotableXS instance.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

Override XSToNative when implementing a TRemotableXS descendant that represents a non-native scalar type. NativeToXS interprets a string that represents the value of the TRemotableXS instance and uses it to make any necessary changes so that the TRemotableXS object reflects that value. It reverses the transformation that the NativeToXS method performs.

Data is a string that represents the value of the TRemotableXS instance.

86.1.15 TXSTime Class

TXSTime implements the XML schema time type so that it can be used on invokable interfaces.

Class Hierarchy

Pascal

```
TXSTime = class(TRemotableXS);
```

C++

```
class TXSTime : public TRemotableXS;
```

File

XSBuiltIns

Description

TXSTime acts as a wrapper for the simple scalar type time that W3C defines for XML schemas. Because this type does not correspond directly to a Delphi or C++ type, it requires special marshaling when used in an invokable interface. TXSTime enables this marshaling because it is a descendant of TRemotable.

To convert a TXSTime value to a TDateTime (see page 3323) value, use the AsTime (see page 7856) property. Other properties give the Hour (see page 7857), Minute (see page 7859), Second (see page 7859), and Millisecond (see page 7858) that make up that value. These properties represent the time using Coordinated Universal Time (see page 4297) (UTC). To convert that to a local time zone, adjust the hour and minute portions using the HourOffset (see page 7858) and MinuteOffset (see page 7859) properties.

On server applications, instances of TXSTime that are input parameters on an invokable interface are automatically created when the method call is unmarshaled and automatically freed after any output parameters or return value are marshaled so that they can be sent to the client. When a TXSTime instance is created in a method that was called remotely using an invokable interface, the instance is automatically freed after the value of the TRemotable descendant is marshaled for transport back to the client application.

The caller of an invokable interface (client) is responsible for creating any TXSTime instances that it passes as input parameters, and for freeing any TXSTime instances it creates or that are returned as output parameters or method results.

TXSDateTime (see page 7828)

86.1.15.1 TXSTime Members

The following tables list the members exposed by TXSTime.

Protected Methods

	Name	Description
	GetAsTime (see page 7851)	This is GetAsTime, a member of class TXSTime.

	GetFractionalSeconds (see page 7851)	This is GetFractionalSeconds, a member of class TXSTime.
	GetFractionalSecondString (see page 7852)	This is GetFractionalSecondString, a member of class TXSTime.
	GetHour (see page 7852)	This is GetHour, a member of class TXSTime.
	GetHourOffset (see page 7852)	This is GetHourOffset, a member of class TXSTime.
	GetMillisecond (see page 7852)	This is GetMillisecond, a member of class TXSTime.
	GetMinute (see page 7853)	This is GetMinute, a member of class TXSTime.
	GetMinuteOffset (see page 7853)	This is GetMinuteOffset, a member of class TXSTime.
	GetSecond (see page 7853)	This is GetSecond, a member of class TXSTime.
	SetAsTime (see page 7854)	This is SetAsTime, a member of class TXSTime.
	SetFractionalSeconds (see page 7854)	This is SetFractionalSeconds, a member of class TXSTime.
	SetHour (see page 7854)	This is SetHour, a member of class TXSTime.
	SetHourOffset (see page 7854)	This is SetHourOffset, a member of class TXSTime.
	SetMillisecond (see page 7854)	This is SetMillisecond, a member of class TXSTime.
	SetMinute (see page 7855)	This is SetMinute, a member of class TXSTime.
	SetMinuteOffset (see page 7855)	This is SetMinuteOffset, a member of class TXSTime.
	SetSecond (see page 7855)	This is SetSecond, a member of class TXSTime.

Protected Properties

	Name	Description
R	FractionalSecondString (see page 7857)	This is FractionalSecondString, a member of class TXSTime.

Public Methods

	Name	Description
	Clone (see page 7851)	Returns a new TXSTime (see page 7849) object that represents the same value as this one.
V	NativeToXS (see page 7853)	Returns a string that represents the value of a TXSTime (see page 7849) instance.
V	XSToNative (see page 7855)	Assigns the properties of the TXSTime (see page 7849) instance from the string representation of its value.

Public Properties

	Name	Description
	AsTime (see page 7856)	Represents the object's value as a TDateTime (see page 3323) value.
	FractionalSeconds (see page 7857)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7859) property.
	Hour (see page 7857)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7858)	Indicates the difference between the Hour (see page 7857) property and the hour in the local time zone.
	Millisecond (see page 7858)	Indicates the Millisecond of the second that the object represents.
	Minute (see page 7859)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7859)	Indicates the difference between the Minute (see page 7859) property and the minute of the hour in local time.
	Second (see page 7859)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7860)	Indicates whether the string representation of this object's value includes a portion for fractions of a second when the value of Millisecond (see page 7858) and FractionalSeconds (see page 7857) is zero.

86.1.15.2 TXSTime Methods

The methods of the TXSTime class are listed here.

Protected Methods

	Name	Description
	GetAsTime (see page 7851)	This is GetAsTime, a member of class TXSTime.
	GetFractionalSeconds (see page 7851)	This is GetFractionalSeconds, a member of class TXSTime.
	GetFractionalSecondString (see page 7852)	This is GetFractionalSecondString, a member of class TXSTime.

	GetHour (see page 7852)	This is GetHour, a member of class TXSTime.
	GetHourOffset (see page 7852)	This is GetHourOffset, a member of class TXSTime.
	GetMillisecond (see page 7852)	This is GetMillisecond, a member of class TXSTime.
	GetMinute (see page 7853)	This is GetMinute, a member of class TXSTime.
	GetMinuteOffset (see page 7853)	This is GetMinuteOffset, a member of class TXSTime.
	GetSecond (see page 7853)	This is GetSecond, a member of class TXSTime.
	SetAsTime (see page 7854)	This is SetAsTime, a member of class TXSTime.
	SetFractionalSeconds (see page 7854)	This is SetFractionalSeconds, a member of class TXSTime.
	SetHour (see page 7854)	This is SetHour, a member of class TXSTime.
	SetHourOffset (see page 7854)	This is SetHourOffset, a member of class TXSTime.
	SetMillisecond (see page 7854)	This is SetMillisecond, a member of class TXSTime.
	SetMinute (see page 7855)	This is SetMinute, a member of class TXSTime.
	SetMinuteOffset (see page 7855)	This is SetMinuteOffset, a member of class TXSTime.
	SetSecond (see page 7855)	This is SetSecond, a member of class TXSTime.

Public Methods

	Name	Description
	Clone (see page 7851)	Returns a new TXSTime (see page 7849) object that represents the same value as this one.
V	NativeToXS (see page 7853)	Returns a string that represents the value of a TXSTime (see page 7849) instance.
V	XSToNative (see page 7855)	Assigns the properties of the TXSTime (see page 7849) instance from the string representation of its value.

86.1.15.2.1 TXSTime.Clone Method

Returns a new TXSTime (see page 7849) object that represents the same value as this one.

Pascal

```
function Clone: TXSTime;
```

C++

```
__fastcall TXSTime Clone();
```

Description

Call Clone to obtain a new TXSTime (see page 7849) instance that represents the same time as this one. Clone returns the new TXSTime (see page 7849) object.

86.1.15.2.2 TXSTime.GetAsTime Method

Pascal

```
function GetAsTime: TDateTime;
```

C++

```
__fastcall TDateTime GetAsTime();
```

Description

This is GetAsTime, a member of class TXSTime.

86.1.15.2.3 TXSTime.GetFractionalSeconds Method

Pascal

```
function GetFractionalSeconds: Double;
```

C++

```
__fastcall Double GetFractionalSeconds();
```

Description

This is GetFractionalSeconds, a member of class TXSTime.

86.1.15.2.4 TXSTime.GetFractionalSecondString Method

Pascal

```
function GetFractionalSecondString: string;
```

C++

```
__fastcall UnicodeString GetFractionalSecondString();
```

Description

This is GetFractionalSecondString, a member of class TXSTime.

86.1.15.2.5 TXSTime.GetHour Method

Pascal

```
function GetHour: Word;
```

C++

```
__fastcall Word GetHour();
```

Description

This is GetHour, a member of class TXSTime.

86.1.15.2.6 TXSTime.GetHourOffset Method

Pascal

```
function GetHourOffset: SmallInt;
```

C++

```
__fastcall SmallInt GetHourOffset();
```

Description

This is GetHourOffset, a member of class TXSTime.

86.1.15.2.7 TXSTime.GetMillisecond Method

Pascal

```
function GetMillisecond: Word;
```

C++

```
__fastcall Word GetMillisecond();
```

Description

This is GetMillisecond, a member of class TXSTime.

86.1.15.2.8 TXSTime.GetMinute Method

Pascal

```
function GetMinute: Word;
```

C++

```
__fastcall Word GetMinute();
```

Description

This is GetMinute, a member of class TXSTime.

86.1.15.2.9 TXSTime.GetMinuteOffset Method

Pascal

```
function GetMinuteOffset: SmallInt;
```

C++

```
__fastcall SmallInt GetMinuteOffset();
```

Description

This is GetMinuteOffset, a member of class TXSTime.

86.1.15.2.10 TXSTime.GetSecond Method

Pascal

```
function GetSecond: Word;
```

C++

```
__fastcall Word GetSecond();
```

Description

This is GetSecond, a member of class TXSTime.

86.1.15.2.11 TXSTime.NativeToXS Method

Returns a string that represents the value of a TXSTime (see page 7849) instance.

Pascal

```
function NativeToXS: InvString; override;
```

C++

```
virtual __fastcall InvString NativeToXS();
```

Description

NativeToXS returns the string that represents the value of this TXSTime (see page 7849) object in a SOAP packet.

See Also

XSToNative (see page 7855)

UseZeroMilliseconds (see page 7860)

86.1.15.2.12 TXSTime.SetAsTime Method

Pascal

```
procedure SetAsTime(const Value: TDateTime);
```

C++

```
__fastcall SetAsTime(const TDateTime Value);
```

Description

This is SetAsTime, a member of class TXSTime.

86.1.15.2.13 TXSTime.SetFractionalSeconds Method

Pascal

```
procedure SetFractionalSeconds(const Value: Double);
```

C++

```
__fastcall SetFractionalSeconds(const Double Value);
```

Description

This is SetFractionalSeconds, a member of class TXSTime.

86.1.15.2.14 TXSTime.SetHour Method

Pascal

```
procedure SetHour(const Value: Word);
```

C++

```
__fastcall SetHour(const Word Value);
```

Description

This is SetHour, a member of class TXSTime.

86.1.15.2.15 TXSTime.SetHourOffset Method

Pascal

```
procedure SetHourOffset(const Value: SmallInt);
```

C++

```
__fastcall SetHourOffset(const SmallInt Value);
```

Description

This is SetHourOffset, a member of class TXSTime.

86.1.15.2.16 TXSTime.SetMillisecond Method

Pascal

```
procedure SetMillisecond(const Value: Word);
```

C++

```
__fastcall SetMillisecond(const Word Value);
```

Description

This is SetMillisecond, a member of class TXSTime.

86.1.15.2.17 TXSTime.SetMinute Method

Pascal

```
procedure SetMinute(const Value: Word);
```

C++

```
__fastcall SetMinute(const Word Value);
```

Description

This is SetMinute, a member of class TXSTime.

86.1.15.2.18 TXSTime.SetMinuteOffset Method

Pascal

```
procedure SetMinuteOffset(const Value: SmallInt);
```

C++

```
__fastcall SetMinuteOffset(const SmallInt Value);
```

Description

This is SetMinuteOffset, a member of class TXSTime.

86.1.15.2.19 TXSTime.SetSecond Method

Pascal

```
procedure SetSecond(const Value: Word);
```

C++

```
__fastcall SetSecond(const Word Value);
```

Description

This is SetSecond, a member of class TXSTime.

86.1.15.2.20 TXSTime.XSToNative Method

Assigns the properties of the TXSTime (see page 7849) instance from the string representation of its value.

Pascal

```
procedure XSToNative(Value: InvString); override;
```

C++

```
virtual __fastcall XSToNative(InvString Value);
```

Description

XSToNative parses the string specified by Data, which is the SOAP encoding of a time value. It uses this information to set the properties of the TXSTime (see page 7849) object.

See Also

NativeToXS (see page 7853)

86.1.15.3 TXSTime Properties

The properties of the TXSTime class are listed here.

Protected Properties

	Name	Description
	FractionalSecondString (see page 7857)	This is FractionalSecondString, a member of class TXSTime.

Public Properties

	Name	Description
	AsTime (see page 7856)	Represents the object's value as a TDateTime (see page 3323) value.
	FractionalSeconds (see page 7857)	Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7859) property.
	Hour (see page 7857)	Indicates the hour of the day that the object represents.
	HourOffset (see page 7858)	Indicates the difference between the Hour (see page 7857) property and the hour in the local time zone.
	Millisecond (see page 7858)	Indicates the Millisecond of the second that the object represents.
	Minute (see page 7859)	Indicates the minute of the hour that the object represents.
	MinuteOffset (see page 7859)	Indicates the difference between the Minute (see page 7859) property and the minute of the hour in local time.
	Second (see page 7859)	Indicates the second of the minute that the object represents.
	UseZeroMilliseconds (see page 7860)	Indicates whether the string representation of this object's value includes a portion for fractions of a second when the value of Millisecond (see page 7858) and FractionalSeconds (see page 7857) is zero.

86.1.15.3.1 TXSTime.AsTime Property

Represents the object's value as a TDateTime (see page 3323) value.

Pascal

```
property AsTime: TDateTime;
```

C++

```
__property TDateTime AsTime;
```

Description

Use AsTime to read the value of the TXSTime (see page 7849) object into a variable of type TDateTime (see page 3323) or set its value from a TDateTime (see page 3323) value. AsTime handles the mapping between a TDateTime (see page 3323) value and the Hour (see page 7857), Minute (see page 7859), and Second (see page 7859) properties. When reading AsTime, the resulting TDateTime (see page 3323) value is given a data portion of 0. When setting AsTime, the data portion is ignored.

Note: AsTime represents the time using Coordinated Universal Time (see page 4297) (UTC). To convert this to a local time, add the offsets specified by HourOffset (see page 7858) and MinuteOffset (see page 7859) to the hours and minutes.

See Also

Hour (see page 7857)

Minute (see page 7859)

Second (see page 7859)

HourOffset (see page 7858)

MinuteOffset (see page 7859)

86.1.15.3.2 TXSTime.FractionalSeconds Property

Indicates any factional portion of a second beyond the seconds specified in the Second (see page 7859) property.

Pascal

```
property FractionalSeconds: Double;
```

C++

```
__property Double FractionalSeconds;
```

Description

Use FractionalSeconds to get or set the fractional seconds of the time value. FractionalSeconds represents the same information as the Millisecond (see page 7858) property, but can provide greater precision.

See Also

AsTime (see page 7856)

Minute (see page 7859)

Second (see page 7859)

Millisecond (see page 7858)

UseZeroMilliseconds (see page 7860)

86.1.15.3.3 TXSTime.FractionalSecondString Property

Pascal

```
property FractionalSecondString: string;
```

C++

```
__property UnicodeString FractionalSecondString;
```

Description

This is FractionalSecondString, a member of class TXSTime.

86.1.15.3.4 TXSTime.Hour Property

Indicates the hour of the day that the object represents.

Pascal

```
property Hour: Word;
```

C++

```
__property Word Hour;
```

Description

Use Hour to get or set the hour portion of the time value. Valid Hour values are 0 through 23.

Note: Hour represents the hour using Coordinated Universal Time (see page 4297) (UTC). To convert the hour to local time, you must add the value of the HourOffset (see page 7858) property.

See Also

AsTime (see page 7856)

Minute (see page 7859)

Second (see page 7859)

Millisecond (see page 7858)

HourOffset (see page 7858)

86.1.15.3.5 TXSTime.HourOffset Property

Indicates the difference between the Hour (see page 7857) property and the hour in the local time zone.

Pascal

```
property HourOffset: SmallInt;
```

C++

```
__property SmallInt HourOffset;
```

Description

The Hour (see page 7857) property represents the hour of the day using Coordinated Universal Time (see page 4297) (UTC). HourOffset is the correction factor you can add to Hour (see page 7857) to obtain the hour of the day in local time.

See Also

Hour (see page 7857)

86.1.15.3.6 TXSTime.Millisecond Property

Indicates the Millisecond of the second that the object represents.

Pascal

```
property Millisecond: Word;
```

C++

```
__property Word Millisecond;
```

Description

Use Millisecond to get or set the millisecond portion of the time value. Valid Millisecond values are 1 through 59.

Note: You can also use the FractionalSeconds (see page 7857) property to obtain fractional portions of the seconds. Unlike Millisecond, which gives the value in milliseconds, FractionalSeconds (see page 7857) returns a fraction of a second.

See Also

AsTime (see page 7856)

Hour (see page 7857)

Minute (see page 7859)

Second (see page 7859)

UseZeroMilliseconds (see page 7860)

FractionalSeconds (see page 7857)

86.1.15.3.7 TXSTime.Minute Property

Indicates the minute of the hour that the object represents.

Pascal

```
property Minute: Word;
```

C++

```
__property Word Minute;
```

Description

Use Minute to get or set the minute portion of the time value. Valid Minute values are 0 through 59.

Note: Minute represents the minute using Coordinated Universal Time (see page 4297) (UTC). To convert the minutes to local time, you must add the value of the MinuteOffset (see page 7859) property.

See Also

AsTime (see page 7856)

Hour (see page 7857)

Second (see page 7859)

Millisecond (see page 7858)

MinuteOffset (see page 7859)

86.1.15.3.8 TXSTime.MinuteOffset Property

Indicates the difference between the Minute (see page 7859) property and the minute of the hour in local time.

Pascal

```
property MinuteOffset: SmallInt;
```

C++

```
__property SmallInt MinuteOffset;
```

Description

The Minute (see page 7859) property represents the minute of the hour using Coordinated Universal Time (see page 4297) (UTC). MinuteOffset is the correction factor you can add to Minute (see page 7859) to obtain the minute of the hour in local time.

See Also

Minute (see page 7859)

86.1.15.3.9 TXSTime.Second Property

Indicates the second of the minute that the object represents.

Pascal

```
property Second: Word;
```

C++

```
__property Word Second;
```

Description

Use Second to get or set the seconds portion of the time value. Valid Second values are 0 through 59.

See Also

AsTime (see page 7856)

Millisecond (see page 7858)

Hour (see page 7857)

Minute (see page 7859)

86.1.15.3.10 TXSTime.UseZeroMilliseconds Property

Indicates whether the string representation of this object's value includes a portion for fractions of a second when the value of Millisecond (see page 7858) and FractionalSeconds (see page 7857) is zero.

Pascal

```
property UseZeroMilliseconds: Boolean;
```

C++

```
__property Boolean UseZeroMilliseconds;
```

Description

By default, the NativeToXS (see page 7853) method does not include the fractional portion of a second in the string encoding of this object's value when the value represents an exact number of seconds. If you set UseZeroMilliseconds, NativeToXS (see page 7853) changes its encoding to include milliseconds even when the value is zero. This is necessary for some Web Services that do not support the full time schema defined by W3C.

See Also

Millisecond (see page 7858)

NativeToXS (see page 7853)

FractionalSeconds (see page 7857)

86.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DateTimeToXMLTime (see page 7861)	Returns the XML string that represents a TDateTime (see page 3323) value.
	DateTimeToXSDateTime (see page 7861)	Returns a TXSDateTime (see page 7828) object that encodes a TDateTime (see page 3323) value.
	GetDataFromFile (see page 7862)	This is function XSBuiltIns.GetDataFromFile.
	InitXSTypes (see page 7862)	This is function XSBuiltIns.InitXSTypes.
	SoapFloatToStr (see page 7863)	This is function XSBuiltIns.SoapFloatToStr.
	SoapStrToFloat (see page 7863)	This is function XSBuiltIns.SoapStrToFloat.
	XMLTimeToDateTime (see page 7863)	Returns a TDateTime (see page 3323) value to represent an XML datetime value.

86.2.1 XSBuiltIns.DateTimeToXMLTime Function

Returns the XML string that represents a TDateTime (see page 3323) value.

Pascal

```
function DateTimeToXMLTime(Value: TDateTime; ApplyLocalBias: Boolean = True): WideString;
```

C++

```
BSTR DateTimeToXMLTime(TDateTime Value, Boolean ApplyLocalBias = True);
```

File

XSBuiltIns

Description

DateTimeToXMLTime returns the XML representation of a specified TDateTime (see page 3323) value.

Value is the TDateTime (see page 3323) value to convert. If the time zone information is important, this value is assumed to be given in Coordinated Universal Time (see page 4297) (UTC).

CalcLocalBias indicates whether the XML string should include offsets for converting Value to the local time.

See Also

DateTimeToXSDateTime (see page 7861)

XMLTimeToDateTime (see page 7863)

86.2.2 XSBuiltIns.DateTimeToXSDateTime Function

Returns a TXSDateTime (see page 7828) object that encodes a TDateTime (see page 3323) value.

Pascal

```
function DateTimeToXSDateTime(const Value: TDateTime; ApplyLocalBias: Boolean = False):
TXSDateTime;
```

C++

```
TXSDateTime DateTimeToXSDateTime(const TDateTime Value, Boolean ApplyLocalBias = False);
```

File

XSBuiltIns

Description

DateTimeToXSDateTime returns a TXSDateTime (see page 7828) object that corresponds to a specified TDateTime (see page 3323) value. The TXSDateTime (see page 7828) object can be used to represent a date-and-time value on an invokable interface. As a remotable object, it can encoded in SOAP packets.

Value is the TDateTime (see page 3323) value to convert. If the time zone information is important, this value is assumed to be given in Coordinated Universal Time (see page 4297) (UTC).

CalcLocalBias indicates whether the TXSDateTime (see page 7828) object should include offsets for converting Value to the local time zone. If CalcLocalBias is true, DateTimeToXSDateTime looks up the local time zone and uses it to set the HourOffset and MinuteOffset properties of the return value.

IInvokable (see page 3504)

TXSCustomDateTime (see page 7803)

86.2.3 XSBuiltIns.GetDataFromFile Function

Pascal

```
function GetDataFromFile(AFileName: string): string;
```

C++

```
UnicodeString GetDataFromFile(UnicodeString AFileName);
```

File

XSBuiltIns

Description

This is function XSBuiltIns.GetDataFromFile.

86.2.4 XSBuiltIns.InitXSTypes Function

Pascal

```
procedure InitXSTypes;
```

C++

```
InitXSTypes();
```

File

XSBuiltIns

Description

This is function XSBuiltIns.InitXSTypes.

86.2.5 XSBuiltIns.SoapFloatToStr Function

Pascal

```
function SoapFloatToStr(Value: double): string;
```

C++

```
UnicodeString SoapFloatToStr(double Value);
```

File

XSBuiltIns

Description

This is function XSBuiltIns.SoapFloatToStr.

86.2.6 XSBuiltIns.SoapStrToFloat Function

Pascal

```
function SoapStrToFloat(Value: string): double;
```

C++

```
double SoapStrToFloat(UnicodeString Value);
```

File

XSBuiltIns

Description

This is function XSBuiltIns.SoapStrToFloat.

86.2.7 XSBuiltIns.XMLTimeToDateTime Function

Returns a TDateTime (see page 3323) value to represent an XML datetime value.

Pascal

```
function XMLTimeToDateTime(const XMLDateTime: WideString; AsUTCTime: Boolean = False):
TDateTime;
```

C++

```
TDateTime XMLTimeToDateTime(const BSTR XMLDateTime, Boolean AsUTCTime = False);
```

File

XSBuiltIns

Description

XMLTimeToDateTime returns a TDateTime (see page 3323) value for an XML date-and time value. This function is the inverse to the DateTimeToXMLTime (see page 7861) function.

Value is the XML string to convert.

See Also

DateTimeToXSDateTime (see page 7861)

DateTimeToXMLTime (see page 7861)

86.3 Types

The following table lists types in this documentation.

Types

Name	Description
TXSTimeInstant (see page 7865)	TXSTimeInstant represents the timeInstant type for Web Services applications.

86.3.1 XSBuiltIns.TXSTimeInstant Type

TXSTimeInstant represents the timeInstant type for Web Services applications.

Pascal

```
TXSTimeInstant = TXSDateTime;
```

C++

```
TXSDateTime TXSTimeInstant;
```

File

XSBuiltIns

Description

TXSTimeInstant is a remotable class for representing the timeInstant type that W3C defines for XML schemas. It maps to the TXSDateTime (see page 7828) class, which represents W3C's datetime type. The timeInstant type is replaced by the datetime type but some Web Service applications still use the older type definition.

86.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
IncrementAmount (see page 7866)	This is constant XSBuiltIns.IncrementAmount.
MaxDay (see page 7867)	This is constant XSBuiltIns.MaxDay.
MaxMonth (see page 7867)	This is constant XSBuiltIns.MaxMonth.
MinDay (see page 7867)	This is constant XSBuiltIns.MinDay.
MinMonth (see page 7868)	This is constant XSBuiltIns.MinMonth.
SDecimal (see page 7868)	This is constant XSBuiltIns.SDecimal.
SHexMarker (see page 7868)	This is constant XSBuiltIns.SHexMarker.
SLocalTimeMarker (see page 7869)	This is constant XSBuiltIns.SLocalTimeMarker.
SNAN (see page 7869)	This is constant XSBuiltIns.SNAN.
SNegative (see page 7869)	This is constant XSBuiltIns.SNegative.
SoapDecimalSeparator (see page 7870)	This is constant XSBuiltIns.SoapDecimalSeparator.
SoapTimePrefix (see page 7870)	This is constant XSBuiltIns.SoapTimePrefix.
SPlus (see page 7870)	This is constant XSBuiltIns.SPlus.
SSciNotationMarker (see page 7871)	This is constant XSBuiltIns.SSciNotationMarker.
XMLDateSeparator (see page 7871)	This is constant XSBuiltIns.XMLDateSeparator.
XMLDayPos (see page 7871)	This is constant XSBuiltIns.XMLDayPos.
XMLDefaultYearDigits (see page 7872)	This is constant XSBuiltIns.XMLDefaultYearDigits.
XMLDurationDay (see page 7872)	This is constant XSBuiltIns.XMLDurationDay.
XMLDurationHour (see page 7872)	This is constant XSBuiltIns.XMLDurationHour.
XMLDurationMinute (see page 7873)	This is constant XSBuiltIns.XMLDurationMinute.
XMLDurationMonth (see page 7873)	This is constant XSBuiltIns.XMLDurationMonth.
XMLDurationSecond (see page 7873)	This is constant XSBuiltIns.XMLDurationSecond.
XMLDurationStart (see page 7874)	This is constant XSBuiltIns.XMLDurationStart.
XMLDurationYear (see page 7874)	This is constant XSBuiltIns.XMLDurationYear.
XMLHourOffsetMinusMarker (see page 7874)	This is constant XSBuiltIns.XMLHourOffsetMinusMarker.
XMLHourOffsetPlusMarker (see page 7875)	This is constant XSBuiltIns.XMLHourOffsetPlusMarker.
XMLMilSecPos (see page 7875)	This is constant XSBuiltIns.XMLMilSecPos.
XMLMonthPos (see page 7875)	This is constant XSBuiltIns.XMLMonthPos.
XMLTimeSeparator (see page 7876)	This is constant XSBuiltIns.XMLTimeSeparator.
XMLYearPos (see page 7876)	This is constant XSBuiltIns.XMLYearPos.

86.4.1 XSBuiltIns.IncrementAmount Constant

Pascal

```
IncrementAmount: array[Boolean] of Integer = (1, -1);
```

C++

```
array[Boolean] of Integer IncrementAmount = (1, -1);
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.IncrementAmount.

86.4.2 XSBuiltIns.MaxDay Constant

Pascal

```
MaxDay = 31;
```

C++

```
MaxDay = 31;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.MaxDay.

86.4.3 XSBuiltIns.MaxMonth Constant

Pascal

```
MaxMonth = 12;
```

C++

```
MaxMonth = 12;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.MaxMonth.

86.4.4 XSBuiltIns.MinDay Constant

Pascal

```
MinDay = 1;
```

C++

```
MinDay = 1;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.MinDay.

86.4.5 XSBuiltIns.MinMonth Constant

Pascal

```
MinMonth = 1;
```

C++

```
MinMonth = 1;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.MinMonth.

86.4.6 XSBuiltIns.SDecimal Constant

Pascal

```
SDecimal: Char = '.';
```

C++

```
Char SDecimal = '.';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SDecimal.

86.4.7 XSBuiltIns.SHexMarker Constant

Pascal

```
SHexMarker = '$';
```

C++

```
SHexMarker = '$';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SHexMarker.

86.4.8 XSBuiltIns.SLocalTimeMarker Constant

Pascal

```
SLocalTimeMarker = 'Z';
```

C++

```
SLocalTimeMarker = 'Z';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SLocalTimeMarker.

86.4.9 XSBuiltIns.SNAN Constant

Pascal

```
SNAN = 'NAN';
```

C++

```
SNAN = 'NAN';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SNAN.

86.4.10 XSBuiltIns.SNegative Constant

Pascal

```
SNegative: Char = '-';
```

C++

```
Char SNegative = '-';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SNegative.

86.4.11 XSBuiltIns.SoapDecimalSeparator Constant

Pascal

```
SoapDecimalSeparator = '.';
```

C++

```
SoapDecimalSeparator = '.';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SoapDecimalSeparator.

86.4.12 XSBuiltIns.SoapTimePrefix Constant

Pascal

```
SoapTimePrefix: InvString = 'T';
```

C++

```
InvString SoapTimePrefix = 'T';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SoapTimePrefix.

86.4.13 XSBuiltIns.SPlus Constant

Pascal

```
SPlus: Char = '+';
```

C++

```
Char SPlus = '+';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SPlus.

86.4.14 XSBuiltIns.SSciNotationMarker Constant

Pascal

```
SSciNotationMarker: Char = 'E';
```

C++

```
Char SSciNotationMarker = 'E';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.SSciNotationMarker.

86.4.15 XSBuiltIns.XMLDateSeparator Constant

Pascal

```
XMLDateSeparator = '-';
```

C++

```
XMLDateSeparator = '-';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDateSeparator.

86.4.16 XSBuiltIns.XMLDayPos Constant

Pascal

```
XMLDayPos = 9;
```

C++

```
XMLDayPos = 9;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDayPos.

86.4.17 XSBuiltIns.XMLDefaultYearDigits Constant

Pascal

```
XMLDefaultYearDigits = 4;
```

C++

```
XMLDefaultYearDigits = 4;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDefaultYearDigits.

86.4.18 XSBuiltIns.XMLDurationDay Constant

Pascal

```
XMLDurationDay = 'D';
```

C++

```
XMLDurationDay = 'D';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationDay.

86.4.19 XSBuiltIns.XMLDurationHour Constant

Pascal

```
XMLDurationHour = 'H';
```

C++

```
XMLDurationHour = 'H';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationHour.

86.4.20 XSBuiltIns.XMLDurationMinute Constant

Pascal

```
XMLDurationMinute = 'M';
```

C++

```
XMLDurationMinute = 'M';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationMinute.

86.4.21 XSBuiltIns.XMLDurationMonth Constant

Pascal

```
XMLDurationMonth = 'M';
```

C++

```
XMLDurationMonth = 'M';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationMonth.

86.4.22 XSBuiltIns.XMLDurationSecond Constant

Pascal

```
XMLDurationSecond = 'S';
```

C++

```
XMLDurationSecond = 'S';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationSecond.

86.4.23 XSBuiltIns.XMLDurationStart Constant

Pascal

```
XMLDurationStart = 'P';
```

C++

```
XMLDurationStart = 'P';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationStart.

86.4.24 XSBuiltIns.XMLDurationYear Constant

Pascal

```
XMLDurationYear = 'Y';
```

C++

```
XMLDurationYear = 'Y';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLDurationYear.

86.4.25 XSBuiltIns.XMLHourOffsetMinusMarker Constant

Pascal

```
XMLHourOffsetMinusMarker = '-';
```

C++

```
XMLHourOffsetMinusMarker = '-';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLHourOffsetMinusMarker.

86.4.26 XSBuiltIns.XMLHourOffsetPlusMarker Constant

Pascal

```
XMLHourOffsetPlusMarker = '+';
```

C++

```
XMLHourOffsetPlusMarker = '+';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLHourOffsetPlusMarker.

86.4.27 XSBuiltIns.XMLMilSecPos Constant

Pascal

```
XMLMilSecPos = 10;
```

C++

```
XMLMilSecPos = 10;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLMilSecPos.

86.4.28 XSBuiltIns.XMLMonthPos Constant

Pascal

```
XMLMonthPos = 6;
```

C++

```
XMLMonthPos = 6;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLMonthPos.

86.4.29 XSBuiltIns.XMLTimeSeparator Constant

Pascal

```
XMLTimeSeparator = ':';
```

C++

```
XMLTimeSeparator = ':';
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLTimeSeparator.

86.4.30 XSBuiltIns.XMLYearPos Constant

Pascal

```
XMLYearPos = 1;
```

C++

```
XMLYearPos = 1;
```

File

XSBuiltIns

Description

This is constant XSBuiltIns.XMLYearPos.

87 XSLProd Namespace

This is namespace XSLProd.

Topics

Name	Description
Classes (see page 7878)	The following table lists classes in this documentation.

Classes

	Name	Description
	EXSLPageProducerError (see page 7878)	EXSLPageProducerError is the exception that is raised when TXSLPageProducer (see page 7893) encounters a problem.
	TCustomXSLPageProducer (see page 7878)	TCustomXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.
	TXSLPageProducer (see page 7893)	TXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.

87.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EXSLPageProducerError (see page 7878)	EXSLPageProducerError is the exception that is raised when TXSLPageProducer (see page 7893) encounters a problem.
	TCustomXSLPageProducer (see page 7878)	TCustomXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.
	TXSLPageProducer (see page 7893)	TXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.

87.1.1 EXSLPageProducerError Class

EXSLPageProducerError is the exception that is raised when TXSLPageProducer (see page 7893) encounters a problem.

Class Hierarchy

Pascal

```
EXSLPageProducerError = class(EWebBrokerException);
```

C++

```
class EXSLPageProducerError : public EWebBrokerException;
```

File

XSLProd

Description

TXSLPageProducer (see page 7893) raises an EXSLPageProducerError exception when it tries to produce content and the WebSnap application has not yet specified the source XML document or the XSL template that transforms that source into the final content.

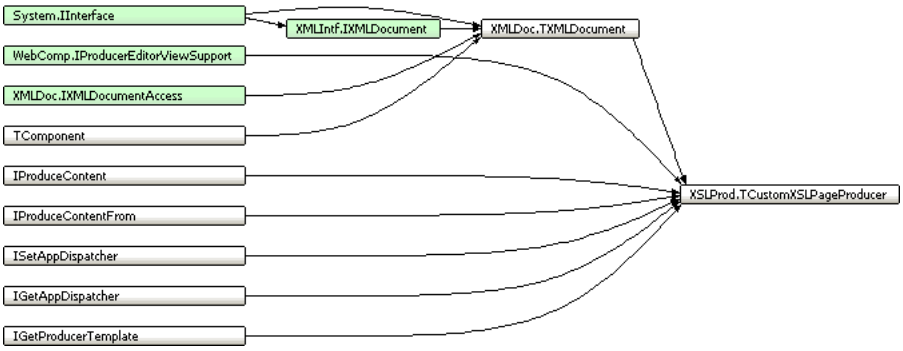
See Also

TXSLPageProducer (see page 7893)

87.1.2 TCustomXSLPageProducer Class

TCustomXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.

Class Hierarchy



Pascal

```
TCustomXSLPageProducer = class(TXMLDocument, IProduceContent, IProduceContentFrom,
ISetAppDispatcher, IGetAppDispatcher, IProducerEditorViewSupport, IGetProducerTemplate);
```

C++

```
class TCustomXSLPageProducer : public TXMLDocument, public IProduceContent, public
IProduceContentFrom, public ISetAppDispatcher, public IGetAppDispatcher, public
IProducerEditorViewSupport, public IGetProducerTemplate;
```

File

XSLProd

Description

TCustomXSLPageProducer is the base class for components that transform the data in an XML document using an XSL template. This class introduces all the properties and methods necessary for specifying the XML document to transform, the XSL template that describes the transformation, and for performing the transformation.

The XMLData (see page 7892) property identifies the XML data that this component transforms. XMLData (see page 7892) must be set to a component that supports either the IXMLDocument (see page 7640) interface (for example, TXMLDocument (see page 7347) or one of its descendants) or the IGetXMLStream (see page 6083) interface (for example, TXMLBroker).

To obtain the results of the transformation, you can use any of the following methods:

The Content (see page 7885) method performs the transformation using the XSL template that is specified by the FileName or XML property. When using the Content (see page 7885) method, you can also read an XSL document by calling the LoadFromFile, LoadFromStream, or LoadFromXML method first.

The ContentFromString (see page 7886) and ContentFromWideString (see page 7886) methods perform the transformation using an XSL template that is supplied as a parameter.

The ContentFromStream (see page 7885) method performs the transformation using an XSL template that it reads from a specified stream.

87.1.2.1 TCustomXSLPageProducer Members

The following tables list the members exposed by TCustomXSLPageProducer.

Protected Methods

	Name	Description
	_AddRef (see page 7354)	Called when an application uses a component interface.

	_Release (see page 7354)	Called when an application releases a component interface.
	AssignParseOptions (see page 7356)	This is AssignParseOptions, a member of class TXMLDocument.
	CheckActive (see page 7356)	This is CheckActive, a member of class TXMLDocument.
	CheckAutoSave (see page 7356)	This is CheckAutoSave, a member of class TXMLDocument.
	CheckDOM (see page 7356)	This is CheckDOM, a member of class TXMLDocument.
V	DefineProperties (see page 7358)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoAfterClose (see page 7359)	This is DoAfterClose, a member of class TXMLDocument.
	DoAfterOpen (see page 7359)	This is DoAfterOpen, a member of class TXMLDocument.
	DoBeforeClose (see page 7359)	This is DoBeforeClose, a member of class TXMLDocument.
	DoBeforeOpen (see page 7360)	This is DoBeforeOpen, a member of class TXMLDocument.
	DoNodeChange (see page 7360)	This is DoNodeChange, a member of class TXMLDocument.
V	GetActive (see page 7360)	Returns the value of the Active property.
	GetAppDispatcher (see page 7887)	This is GetAppDispatcher, a member of class TCustomXSLPageProducer.
	GetAsyncLoadState (see page 7361)	Returns the value of the AsyncLoadState property.
V	GetChildNodeClass (see page 7361)	This is GetChildNodeClass, a member of class TXMLDocument.
	GetChildNodes (see page 7361)	Returns the value of the ChildNodes property.
	GetDocumentElement (see page 7362)	Returns the value of the DocumentElement property.
	GetDocumentNode (see page 7362)	Returns the value of the Node property.
	GetDocumentObject (see page 7363)	This is GetDocumentObject, a member of class TXMLDocument.
	GetDOMDocument (see page 7363)	Returns the value of the DOMDocument property.
	GetDOMPersist (see page 7363)	This is GetDOMPersist, a member of class TXMLDocument.
	GetEncoding (see page 7363)	Returns the value of the Encoding property.
	GetFileName (see page 7364)	Returns the value of the FileName property.
	GetModified (see page 7364)	Returns the value of the Modified property.
	GetNodeIndentStr (see page 7364)	Returns the value of the NodeIndentStr property.
	GetOptions (see page 7365)	Returns the value of the Options property.
	GetParseOptions (see page 7365)	Returns the value of the ParseOptions property.
	GetProducerTemplateFileName (see page 7887)	This is GetProducerTemplateFileName, a member of class TCustomXSLPageProducer.
	GetProducerTemplateStream (see page 7887)	This is GetProducerTemplateStream, a member of class TCustomXSLPageProducer.
	GetPrologNode (see page 7365)	This is GetPrologNode, a member of class TXMLDocument.
	GetPrologValue (see page 7366)	This is GetPrologValue, a member of class TXMLDocument.
	GetSchemaRef (see page 7366)	Returns the value of the SchemaRef property.
	GetStandAlone (see page 7366)	Returns the value of the StandAlone property.
	GetTemplateFileType (see page 7887)	This is GetTemplateFileType, a member of class TCustomXSLPageProducer.
	GetTemplateStream (see page 7888)	This is GetTemplateStream, a member of class TCustomXSLPageProducer.
	GetVersion (see page 7366)	Returns the value of the Version property.
	GetXML (see page 7367)	Returns the value of the XML property.
	GetXMLData (see page 7888)	This is GetXMLData, a member of class TCustomXSLPageProducer.
	GetXMLDocument (see page 7888)	This is GetXMLDocument, a member of class TCustomXSLPageProducer.
	GetXSLData (see page 7888)	This is GetXSLData, a member of class TCustomXSLPageProducer.
	HasHTMLBrowserView (see page 7888)	This is HasHTMLBrowserView, a member of class TCustomXSLPageProducer.
	HasScriptView (see page 7889)	This is HasScriptView, a member of class TCustomXSLPageProducer.
	HasXMLBrowserView (see page 7889)	This is HasXMLBrowserView, a member of class TCustomXSLPageProducer.
	HasXSLBrowserView (see page 7889)	This is HasXSLBrowserView, a member of class TCustomXSLPageProducer.
	InternalSetPrologValue (see page 7367)	This is InternalSetPrologValue, a member of class TXMLDocument.
	LoadData (see page 7368)	This is LoadData, a member of class TXMLDocument.
V	Loaded (see page 7368)	Initializes the component after the form file has been read into memory.
V	Notification (see page 7889)	Forwards notification messages to all owned components.
	ProduceContent (see page 7890)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 7890)	This is ProduceContentFromStream, a member of class TCustomXSLPageProducer.
	ProduceContentFromString (see page 7890)	This is ProduceContentFromString, a member of class TCustomXSLPageProducer.

	ReadDOMVendor (see page 7371)	This is ReadDOMVendor, a member of class TXMLDocument.
	ReleaseDoc (see page 7372)	This is ReleaseDoc, a member of class TXMLDocument.
	SaveToUTF8String (see page 7374)	This is SaveToUTF8String, a member of class TXMLDocument.
	SaveToXMLStrings (see page 7375)	Saves the XML (see page 7392) document to an internal string list.
V	SetActive (see page 7375)	Sets the value of the Active property.
	SetAppDispatcher (see page 7891)	This is SetAppDispatcher, a member of class TCustomXSLPageProducer.
	SetDocumentElement (see page 7375)	Sets the value of the DocumentElement property.
	SetDOMDocument (see page 7376)	Sets the value of the DOMDocument property.
	SetEncoding (see page 7376)	Sets the value of the Encoding property.
	SetFileName (see page 7376)	Sets the value of the FileName property.
	SetModified (see page 7377)	This is SetModified, a member of class TXMLDocument.
	SetNodeIndentStr (see page 7377)	Sets the value of the NodeIndentStr property.
	SetOnAsyncLoad (see page 7377)	Supplies an event handler that responds when the AsyncLoadState property changes.
	SetOptions (see page 7378)	Sets the value of the Options property.
	SetParseOptions (see page 7378)	Sets the value of the ParseOptions property.
	SetPrologValue (see page 7378)	This is SetPrologValue, a member of class TXMLDocument.
	SetStandAlone (see page 7378)	Sets the value of the StandAlone property.
	SetVersion (see page 7379)	Sets the value of the Version property.
	SetXML (see page 7379)	Sets the value of the XML property.
	SetXMLStrings (see page 7379)	This is SetXMLStrings, a member of class TXMLDocument.
	WriteDOMVendor (see page 7380)	This is WriteDOMVendor, a member of class TXMLDocument.
	XMLStringsChanging (see page 7380)	This is XMLStringsChanging, a member of class TXMLDocument.

Protected Properties

	Name	Description
R	DocBindingInfo (see page 7383)	This is DocBindingInfo, a member of class TXMLDocument.
	DocSource (see page 7383)	This is DocSource, a member of class TXMLDocument.
R	DOMParseOptions (see page 7385)	This is DOMParseOptions, a member of class TXMLDocument.
R	DOMPersist (see page 7386)	This is DOMPersist, a member of class TXMLDocument.
	PrefixID (see page 7391)	This is PrefixID, a member of class TXMLDocument.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AddChild (see page 7354)	This is the overview for the AddChild method overload.
	AddChild (see page 7643)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 7355)	Responds after the last constructor has executed.
V	Content (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property.
V	ContentFromStream (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using an XSL template that can be read from a specified stream.
	ContentFromString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.
V	ContentFromWideString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.
	Create (see page 7351)	This is the overview for the Create constructor overload.
	CreateElement (see page 7357)	Creates a new element node that is associated with this document.
	CreateElement (see page 7644)	Creates a new element node that is associated with this document.
	CreateNode (see page 7357)	Creates a new node that is associated with this document.
	CreateNode (see page 7645)	Creates a new node that is associated with this document.
V	Destroy (see page 7352)	Disposes of a TXMLDocument (see page 7347) object.
	GeneratePrefix (see page 7360)	Generates a unique namespace prefix that can be used for a node in the document.
	GeneratePrefix (see page 7646)	Generates a unique namespace prefix that can be used for a node in the document.

	GetActive (see page 7646)	Returns the value of the Active (see page 7661) property.
	GetAsyncLoadState (see page 7647)	Returns the value of the AsyncLoadState (see page 7662) property.
	GetChildNodes (see page 7647)	Returns the value of the ChildNodes (see page 7663) property.
	GetDocBinding (see page 7362)	Replaces the document element with an instance of a specified implementation class.
	GetDocBinding (see page 7647)	Replaces a specified child node with an instance of a specified implementation class.
	GetDocumentElement (see page 7648)	Returns the value of the DocumentElement (see page 7663) property.
	GetDocumentNode (see page 7648)	Returns the value of the Node (see page 7665) property.
	GetDocumentObject (see page 7479)	This is GetDocumentObject, a member of class IXMLDocumentAccess.
	GetDOMDocument (see page 7648)	Returns the value of the DOMDocument (see page 7663) property.
	GetDOMPersist (see page 7479)	This is GetDOMPersist, a member of class IXMLDocumentAccess.
	GetEncoding (see page 7649)	Returns the value of the Encoding (see page 7664) property.
	GetFileName (see page 7649)	Returns the value of the FileName (see page 7664) property.
	GetModified (see page 7649)	Returns the value of the Modified (see page 7665) property.
	GetNodeIndentStr (see page 7650)	Returns the value of the NodeIndentStr (see page 7666) property.
	GetOptions (see page 7650)	Returns the value of the Options (see page 7666) property.
	GetParseOptions (see page 7650)	Returns the value of the ParseOptions (see page 7667) property.
	GetSchemaRef (see page 7650)	Returns the value of the SchemaRef (see page 7667) property.
	GetStandAlone (see page 7651)	Returns the value of the StandAlone (see page 7668) property.
	GetVersion (see page 7651)	Returns the value of the Version (see page 7668) property.
	GetXML (see page 7651)	Returns the value of the XML (see page 7668) property.
	IsEmptyDoc (see page 7367)	Indicates whether the TXMLDocument (see page 7347) instance represents an empty document.
	IsEmptyDoc (see page 7652)	Indicates whether the IXMLDocument (see page 7640) instance represents an empty document.
	LoadFromFile (see page 7368)	Loads an XML (see page 7392) document and activates it.
	LoadFromFile (see page 7652)	Loads an XML (see page 7668) document from disk.
	LoadFromStream (see page 7369)	Loads an XML (see page 7392) document from a stream and activates it.
	LoadFromStream (see page 7653)	Loads an XML (see page 7668) document from a stream and activates it.
	LoadFromXML (see page 7370)	This is the overview for the LoadFromXML method overload.
	LoadFromXML (see page 7653)	This is the overview for the LoadFromXML method overload.
	NewInstance (see page 7370)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	Refresh (see page 7371)	Updates the parsed XML (see page 7392) document to reflect external changes.
	Refresh (see page 7654)	Updates the parsed XML (see page 7668) document to reflect external changes.
	RegisterDocBinding (see page 7372)	Registers an implementation class for child nodes with a specified tag name.
	RegisterDocBinding (see page 7654)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7372)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	Resync (see page 7655)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7373)	Saves the XML (see page 7392) document to disk.
	SaveToFile (see page 7655)	Saves the XML (see page 7668) document to disk.
	SaveToStream (see page 7373)	Saves the XML (see page 7392) document to a stream.
	SaveToStream (see page 7656)	Saves the XML (see page 7668) document to a stream.
	SaveToXML (see page 7374)	This is the overview for the SaveToXML method overload.
	SaveToXML (see page 7656)	This is the overview for the SaveToXML method overload.
	SetActive (see page 7657)	Sets the value of the Active (see page 7661) property.
	SetDocumentElement (see page 7657)	Sets the value of the DocumentElement (see page 7663) property.
	SetDOMDocument (see page 7658)	Sets the value of the DOMDocument (see page 7663) property.
	SetEncoding (see page 7658)	Sets the value of the Encoding (see page 7664) property.
	SetFileName (see page 7658)	Sets the value of the FileName (see page 7664) property.
	SetNodeIndentStr (see page 7659)	Sets the value of the NodeIndentStr (see page 7666) property.

	SetOnAsyncLoad (see page 7659)	Supplies an event handler that responds when the AsyncLoadState (see page 7662) property changes.
	SetOptions (see page 7659)	Sets the value of the Options (see page 7666) property.
	SetParseOptions (see page 7660)	Sets the value of the ParseOptions (see page 7667) property.
	SetStandAlone (see page 7660)	Sets the value of the StandAlone (see page 7668) property.
	SetVersion (see page 7660)	Sets the value of the Version (see page 7668) property.
	SetXML (see page 7661)	Sets the value of the XML (see page 7668) property.

Public Properties

	Name	Description
	Active (see page 7661)	Specifies whether the XML (see page 7668) document has been parsed so that the DOM interfaces are available to examine or change its contents.
R	AsyncLoadState (see page 7382)	Indicates the state of the DOM parser when it parses the XML (see page 7392) document asynchronously.
R	AsyncLoadState (see page 7662)	Indicates the state of the DOM parser when it parses the XML (see page 7668) document asynchronously.
R	ChildNodes (see page 7383)	Lists all of the child nodes of the document.
R	ChildNodes (see page 7663)	Lists all of the child nodes of the document.
R	Dispatcher (see page 7891)	Specifies the interface of a component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
R	DispatcherComponent (see page 7892)	Specifies the component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
	DocumentElement (see page 7383)	Provides access to the root node of the XML (see page 7392) document.
	DocumentElement (see page 7663)	Provides access to the root node of the XML (see page 7668) document.
R	DocumentObject (see page 7479)	This is DocumentObject, a member of class IXMLDocumentAccess.
	DOMDocument (see page 7384)	Provides access to the DOM interface for the parsed XML (see page 7392) document.
	DOMDocument (see page 7663)	Provides access to the DOM interface for the parsed XML (see page 7668) document.
	DOMImplementation (see page 7385)	Provides access to the DOM interface for document-independent functions.
R	DOMPersist (see page 7480)	This is DOMPersist, a member of class IXMLDocumentAccess.
	Encoding (see page 7386)	Indicates the character set that the XML (see page 7392) document uses to encode characters.
	Encoding (see page 7664)	Indicates the character set that the XML (see page 7668) document uses to encode characters.
	FileName (see page 7664)	Indicates the XML (see page 7668) document file, if any, that this interface represents.
R	Modified (see page 7387)	Indicates whether the XML (see page 7392) document has been modified.
R	Modified (see page 7665)	Indicates whether the XML (see page 7668) document has been modified.
R	Node (see page 7388)	Provides access to the document node for the XML (see page 7392) document.
R	Node (see page 7665)	Provides access to the document node for the XML (see page 7668) document.
	NodeIndentStr (see page 7666)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7668) text.
	NSPrefixBase (see page 7389)	Specifies the base string for automatically-generated namespace prefixes.
	Options (see page 7666)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7667)	Specifies implementation-specific options that are followed when parsing the XML (see page 7668) document.
R	SchemaRef (see page 7391)	Returns the name of the schema associated with this XML (see page 7392) document.
R	SchemaRef (see page 7667)	Returns the name of the schema associated with this XML (see page 7668) document.
	StandAlone (see page 7391)	Indicates whether the XML (see page 7392) document includes any external markup declarations.
	StandAlone (see page 7668)	Indicates whether the XML (see page 7668) document includes any external markup declarations.
	Version (see page 7391)	Indicates the XML (see page 7392) version that the document uses.
	Version (see page 7668)	Indicates the XML (see page 7668) version that the document uses.

	XML (see page 7668)	Specifies the content of the XML document associated with this IXMLDocument (see page 7640) interface.
	XMLData (see page 7892)	Specifies the component that supplies the XML data that this component transforms.

Published Events

	Name	Description
	AfterClose (see page 7393)	Occurs after the XML (see page 7392) document is closed.
	AfterNodeChange (see page 7393)	Occurs after a change is made to one of the nodes in the document.
	AfterOpen (see page 7394)	Occurs immediately after the XML (see page 7392) document is opened.
	BeforeClose (see page 7394)	Occurs immediately before the XML (see page 7392) document is closed.
	BeforeNodeChange (see page 7394)	Occurs before a change is made to one of the nodes in the document.
	BeforeOpen (see page 7395)	Occurs immediately before the XML (see page 7392) document is opened.
	OnAsyncLoad (see page 7395)	Occurs at various stages during the asynchronous parsing of an XML (see page 7392) document.

Published Properties

	Name	Description
	Active (see page 7381)	Specifies whether the XML (see page 7392) document has been parsed so that the DOM interfaces are available to examine or change its contents.
	DOMVendor (see page 7386)	Specifies the DOM implementation to use for parsing and manipulating the XML (see page 7392) document.
	FileName (see page 7387)	Specifies the file name for the XML (see page 7392) document associated with this TXMLDocument (see page 7347) object.
	NodeIndentStr (see page 7388)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7392) text.
	Options (see page 7389)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7390)	Specifies implementation-specific options that are followed when parsing the XML (see page 7392) document.
	XML (see page 7392)	Specifies the content of the XML document associated with this TXMLDocument (see page 7347) object.

87.1.2.2 TCustomXSLPageProducer Methods

The methods of the TCustomXSLPageProducer class are listed here.

Protected Methods

	Name	Description
	GetAppDispatcher (see page 7887)	This is GetAppDispatcher, a member of class TCustomXSLPageProducer.
	GetProducerTemplateFileName (see page 7887)	This is GetProducerTemplateFileName, a member of class TCustomXSLPageProducer.
	GetProducerTemplateStream (see page 7887)	This is GetProducerTemplateStream, a member of class TCustomXSLPageProducer.
	GetTemplateFileType (see page 7887)	This is GetTemplateFileType, a member of class TCustomXSLPageProducer.
	GetTemplateStream (see page 7888)	This is GetTemplateStream, a member of class TCustomXSLPageProducer.
	GetXMLData (see page 7888)	This is GetXMLData, a member of class TCustomXSLPageProducer.
	GetXMLDocument (see page 7888)	This is GetXMLDocument, a member of class TCustomXSLPageProducer.
	GetXSLData (see page 7888)	This is GetXSLData, a member of class TCustomXSLPageProducer.
	HasHTMLBrowserView (see page 7888)	This is HasHTMLBrowserView, a member of class TCustomXSLPageProducer.
	HasScriptView (see page 7889)	This is HasScriptView, a member of class TCustomXSLPageProducer.
	HasXMLBrowserView (see page 7889)	This is HasXMLBrowserView, a member of class TCustomXSLPageProducer.
	HasXSLBrowserView (see page 7889)	This is HasXSLBrowserView, a member of class TCustomXSLPageProducer.
	Notification (see page 7889)	Forwards notification messages to all owned components.
	ProduceContent (see page 7890)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 7890)	This is ProduceContentFromStream, a member of class TCustomXSLPageProducer.

	ProduceContentFromString (see page 7890)	This is ProduceContentFromString, a member of class TCustomXSLPageProducer.
	SetAppDispatcher (see page 7891)	This is SetAppDispatcher, a member of class TCustomXSLPageProducer.

Public Methods

	Name	Description
	Content (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property.
	ContentFromStream (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using an XSL template that can be read from a specified stream.
	ContentFromString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.
	ContentFromWideString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.

87.1.2.2.1 TCustomXSLPageProducer.Content Method

Returns the transformed value of the XML supplied by the XMLData (see page 7892) property.

Pascal

```
function Content: string; virtual;
```

C++

```
virtual __fastcall UnicodeString Content();
```

Description

Call Content to retrieve the content for using in an HTTP response message. Content transforms the XML data that is supplied by the XMLData (see page 7892) property using the XSL template associated with this component. The XSL template can be specified in several ways:

If the FileName property is set, it specifies a file that contains the XSL template.

If FileName is not set, you can assign an XSL template using the XML property.

At runtime, you can supply an XSL template by calling the LoadFromFile, LoadFromStream, or LoadFromXML method first.

See Also

ContentFromStream (see page 7885)

ContentFromString (see page 7886)

ContentFromWideString (see page 7886)

XMLData (see page 7892)

FileName (see page 7387)

XML (see page 7392)

LoadFromFile (see page 7368)

LoadFromStream (see page 7369)

LoadFromXML (see page 7370)

87.1.2.2.2 TCustomXSLPageProducer.ContentFromStream Method

Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using an XSL template that can be read from a specified stream.

Pascal

```
function ContentFromStream(InStream: TStream): string; virtual;
```

C++

```
virtual __fastcall UnicodeString ContentFromStream(TStream InStream);
```

Description

Call Content (see page 7885) to retrieve the content for using in an HTTP response message. Content (see page 7885) transforms the XML data that is supplied by the XMLData (see page 7892) property using the XSL template that is reads from InStream.

See Also

Content (see page 7885)

ContentFromString (see page 7886)

ContentFromWideString (see page 7886)

XMLData (see page 7892)

87.1.2.2.3 TCustomXSLPageProducer.ContentFromString Method

Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.

Pascal

```
function ContentFromString(const S: string): string;
```

C++

```
__fastcall UnicodeString ContentFromString(const UnicodeString S);
```

Description

Call Content (see page 7885) to retrieve the content for using in an HTTP response message. Content (see page 7885) transforms the XML data that is supplied by the XMLData (see page 7892) property using the XSL template specified by S.

See Also

Content (see page 7885)

ContentFromStream (see page 7885)

ContentFromWideString (see page 7886)

XMLData (see page 7892)

87.1.2.2.4 TCustomXSLPageProducer.ContentFromWideString Method

Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.

Pascal

```
function ContentFromWideString(const S: WideString): string; virtual;
```

C++

```
virtual __fastcall UnicodeString ContentFromWideString(const BSTR S);
```

Description

Call Content (see page 7885) to retrieve the content for using in an HTTP response message. Content (see page 7885) transforms the XML data that is supplied by the XMLData (see page 7892) property using the XSL template specified by S.

See Also

Content (see page 7885)

ContentFromStream (see page 7885)

ContentFromString (see page 7886)

XMLData (see page 7892)

87.1.2.2.5 TCustomXSLPageProducer.GetAppDispatcher Method

Pascal

```
function GetAppDispatcher: TComponent;
```

C++

```
__fastcall TComponent * GetAppDispatcher();
```

Description

This is GetAppDispatcher, a member of class TCustomXSLPageProducer.

87.1.2.2.6 TCustomXSLPageProducer.GetProducerTemplateFileName Method

Pascal

```
function GetProducerTemplateFileName: string;
```

C++

```
__fastcall UnicodeString GetProducerTemplateFileName();
```

Description

This is GetProducerTemplateFileName, a member of class TCustomXSLPageProducer.

87.1.2.2.7 TCustomXSLPageProducer.GetProducerTemplateStream Method

Pascal

```
function GetProducerTemplateStream(out AOwned: Boolean): TStream;
```

C++

```
__fastcall TStream GetProducerTemplateStream(Boolean AOwned);
```

Description

This is GetProducerTemplateStream, a member of class TCustomXSLPageProducer.

87.1.2.2.8 TCustomXSLPageProducer.GetTemplateFileType Method

Pascal

```
function GetTemplateFileType: string;
```

C++

```
__fastcall UnicodeString GetTemplateFileType();
```

Description

This is GetTemplateFileType, a member of class TCustomXSLPageProducer.

87.1.2.2.9 TCustomXSLPageProducer.GetTemplateStream Method

Pascal

```
function GetTemplateStream(out AOwned: Boolean): TStream;
```

C++

```
__fastcall TStream GetTemplateStream(Boolean AOwned);
```

Description

This is GetTemplateStream, a member of class TCustomXSLPageProducer.

87.1.2.2.10 TCustomXSLPageProducer.GetXMLData Method

Pascal

```
function GetXMLData(var Owned: Boolean): TStream;
```

C++

```
__fastcall TStream GetXMLData(Boolean Owned);
```

Description

This is GetXMLData, a member of class TCustomXSLPageProducer.

87.1.2.2.11 TCustomXSLPageProducer.GetXMLDocument Method

Pascal

```
function GetXMLDocument(out AXMLDocument: IXMLDocument): Boolean;
```

C++

```
__fastcall Boolean GetXMLDocument(IXMLDocument AXMLDocument);
```

Description

This is GetXMLDocument, a member of class TCustomXSLPageProducer.

87.1.2.2.12 TCustomXSLPageProducer.GetXSLData Method

Pascal

```
function GetXSLData(var Owned: Boolean): TStream;
```

C++

```
__fastcall TStream GetXSLData(Boolean Owned);
```

Description

This is GetXSLData, a member of class TCustomXSLPageProducer.

87.1.2.2.13 TCustomXSLPageProducer.HasHTMLBrowserView Method

Pascal

```
function HasHTMLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasHTMLBrowserView();
```

Description

This is HasHTMLBrowserView, a member of class TCustomXSLPageProducer.

87.1.2.2.14 TCustomXSLPageProducer.HasScriptView Method

Pascal

```
function HasScriptView: Boolean;
```

C++

```
__fastcall Boolean HasScriptView();
```

Description

This is HasScriptView, a member of class TCustomXSLPageProducer.

87.1.2.2.15 TCustomXSLPageProducer.HasXMLBrowserView Method

Pascal

```
function HasXMLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasXMLBrowserView();
```

Description

This is HasXMLBrowserView, a member of class TCustomXSLPageProducer.

87.1.2.2.16 TCustomXSLPageProducer.HasXSLBrowserView Method

Pascal

```
function HasXSLBrowserView: Boolean;
```

C++

```
__fastcall Boolean HasXSLBrowserView();
```

Description

This is HasXSLBrowserView, a member of class TCustomXSLPageProducer.

87.1.2.2.17 TCustomXSLPageProducer.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component

has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

87.1.2.2.18 TCustomXSLPageProducer.ProduceContent Method

Returns the content that the producer creates.

Pascal

```
function ProduceContent: string;
```

C++

```
__fastcall UnicodeString ProduceContent();
```

Description

Call ProduceContent to retrieve the content for using in an HTTP response message. In most cases, this content is a string of HTML commands defining a Web page, although it can be any valid MIME type.

See Also

Content

87.1.2.2.19 TCustomXSLPageProducer.ProduceContentFromStream Method

Pascal

```
function ProduceContentFromStream(Stream: TStream): string;
```

C++

```
__fastcall UnicodeString ProduceContentFromStream(TStream Stream);
```

Description

This is ProduceContentFromStream, a member of class TCustomXSLPageProducer.

87.1.2.2.20 TCustomXSLPageProducer.ProduceContentFromString Method

Pascal

```
function ProduceContentFromString(const S: string): string;
```

C++

```
__fastcall UnicodeString ProduceContentFromString(const UnicodeString S);
```

Description

This is ProduceContentFromString, a member of class TCustomXSLPageProducer.

87.1.2.2.21 TCustomXSLPageProducer.SetAppDispatcher Method

Pascal

```
procedure SetAppDispatcher(const ADispatcher: TComponent);
```

C++

```
__fastcall SetAppDispatcher(const TComponent * ADispatcher);
```

Description

This is SetAppDispatcher, a member of class TCustomXSLPageProducer.

87.1.2.3 TCustomXSLPageProducer Properties

The properties of the TCustomXSLPageProducer class are listed here.

Public Properties

	Name	Description
	Dispatcher (see page 7891)	Specifies the interface of a component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
	DispatcherComponent (see page 7892)	Specifies the component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
	XMLData (see page 7892)	Specifies the component that supplies the XML data that this component transforms.

87.1.2.3.1 TCustomXSLPageProducer.Dispatcher Property

Specifies the interface of a component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.

Pascal

```
property Dispatcher: IWebDispatcherAccess;
```

C++

```
__property IWebDispatcherAccess Dispatcher;
```

Description

Read (see page 3634) Dispatcher to access the interface of the dispatcher. In Web Broker applications, this is the interface of a TWebDispatcher or TWebModule component. In WebSnap applications, this is the interface of a TWebAppComponents component.

The IWebDispatcherAccess interface has two methods:

Request, which returns the HTTP request message to which this page producer responds.

Response, which returns the HTTP response message for which this page producer generates content.

See Also

TWebModule

TWebDispatcher

TWebAppComponents (see page 6243)

TWebRequest

TWebResponse

DispatcherComponent (see page 7892)

87.1.2.3.2 TCustomXSLPageProducer.DispatcherComponent Property

Specifies the component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.

Pascal

```
property DispatcherComponent: TComponent;
```

C++

```
__property TComponent * DispatcherComponent;
```

Description

Read (see page 3634) DispatcherComponent to access the dispatcher that handles the HTTP request and response messages for this Web Server application. In Web Broker applications, this is the interface of a TWebDispatcherComponent or TWebModule component. In WebSnap applications, this is the interface of a TWebAppComponents component.

Dispatcher (see page 7891) implements the interface that is the value of the Dispatcher (see page 7891) property. The XSL page producer uses this property so that it can respond to notifications when the component is freed. To use the dispatcher, use the Dispatcher (see page 7891) property instead.

87.1.2.3.3 TCustomXSLPageProducer.XMLData Property

Specifies the component that supplies the XML data that this component transforms.

Pascal

```
property XMLData: TComponent;
```

C++

```
__property TComponent * XMLData;
```

Description

Use the XMLData property to specify the XML data that this component transforms. XMLData must be set to a component that supports either the IXMLDocument (see page 7640) interface (for example, TXMLDocument (see page 7347) or one of its descendants) or the IGetXMLStream (see page 6083) interface (for example, TXMLBroker).

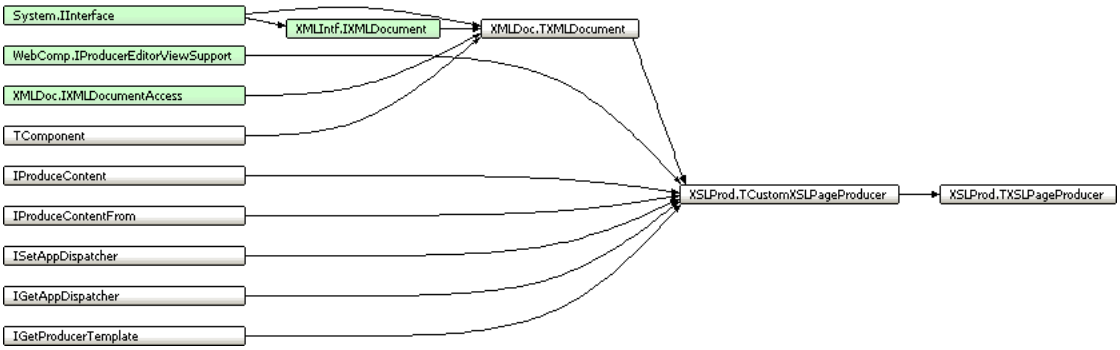
TXMLDocument (see page 7347)

TXMLBroker (see page 7303)

87.1.3 TXSLPageProducer Class

TXSLPageProducer generates web page content by transforming data described with XML (Extensible Markup Language) using an XSL (Extensible Stylesheet Language) template.

Class Hierarchy



Pascal

```
TXSLPageProducer = class(TCustomXSLPageProducer);
```

C++

```
class TXSLPageProducer : public TCustomXSLPageProducer;
```

File

XSLProd

Description

Use the Web Page Module wizard to create a web page that uses TXSLPageProducer. To produce content, TXSLPageProducer uses an XSL template to transform the data in an XML document. Typically, the XSL transforms the XML document into another XML document that is HTML compliant (that is, into a document whose tags are actually HTML tags). However, as specified by the XSL template, TXSLPageProducer can return any arbitrary output as a result of the transformation.

Use the XMLData (see page 7899) property to specify the XML data that this component transforms. XMLData (see page 7899) must be set to a component that supports either the IXMLDocument (see page 7640) interface (for example, TXMLDocument (see page 7347) or one of its descendants) or the IGetXMLStream (see page 6083) interface (for example, TXMLBroker).

To obtain the results of the transformation, you can use any of the following methods:

The Content (see page 7885) method performs the transformation using the XSL template that is specified by the FileName or XML property. When using the Content (see page 7885) method, you can also read an XSL document by calling the LoadFromFile, LoadFromStream, or LoadFromXML method first.

The ContentFromString (see page 7886) and ContentFromWideString (see page 7886) methods perform the transformation using an XSL template that is supplied as a parameter.

The ContentFromStream (see page 7885) method performs the transformation using an XSL template that it reads from a specified stream.

At design time, Web page modules that use the TXMLPageProducer have editor views called XML Tree and XSL Tree. These views provide a read only tree of the XML and XSL respectively.

TXMLDocument (see page 7347)

TXMLBroker (see page 7303)

87.1.3.1 TXSLPageProducer Members

The following tables list the members exposed by TXSLPageProducer.

Protected Methods

	Name	Description
	_AddRef (see page 7354)	Called when an application uses a component interface.
	_Release (see page 7354)	Called when an application releases a component interface.
	AssignParseOptions (see page 7356)	This is AssignParseOptions, a member of class TXMLDocument.
	CheckActive (see page 7356)	This is CheckActive, a member of class TXMLDocument.
	CheckAutoSave (see page 7356)	This is CheckAutoSave, a member of class TXMLDocument.
	CheckDOM (see page 7356)	This is CheckDOM, a member of class TXMLDocument.
V	DefineProperties (see page 7358)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoAfterClose (see page 7359)	This is DoAfterClose, a member of class TXMLDocument.
	DoAfterOpen (see page 7359)	This is DoAfterOpen, a member of class TXMLDocument.
	DoBeforeClose (see page 7359)	This is DoBeforeClose, a member of class TXMLDocument.
	DoBeforeOpen (see page 7360)	This is DoBeforeOpen, a member of class TXMLDocument.
	DoNodeChange (see page 7360)	This is DoNodeChange, a member of class TXMLDocument.
V	GetActive (see page 7360)	Returns the value of the Active property.
	GetAppDispatcher (see page 7887)	This is GetAppDispatcher, a member of class TCustomXSLPageProducer.
	GetAsyncLoadState (see page 7361)	Returns the value of the AsyncLoadState property.
V	GetChildNodeClass (see page 7361)	This is GetChildNodeClass, a member of class TXMLDocument.
	GetChildNodes (see page 7361)	Returns the value of the ChildNodes property.
	GetDocumentElement (see page 7362)	Returns the value of the DocumentElement property.
	GetDocumentNode (see page 7362)	Returns the value of the Node property.
	GetDocumentObject (see page 7363)	This is GetDocumentObject, a member of class TXMLDocument.
	GetDOMDocument (see page 7363)	Returns the value of the DOMDocument property.
	GetDOMPersist (see page 7363)	This is GetDOMPersist, a member of class TXMLDocument.
	GetEncoding (see page 7363)	Returns the value of the Encoding property.
	GetFileName (see page 7364)	Returns the value of the FileName property.
	GetModified (see page 7364)	Returns the value of the Modified property.
	GetNodeIndentStr (see page 7364)	Returns the value of the NodeIndentStr property.
	GetOptions (see page 7365)	Returns the value of the Options property.
	GetParseOptions (see page 7365)	Returns the value of the ParseOptions property.
	GetProducerTemplateFileName (see page 7887)	This is GetProducerTemplateFileName, a member of class TCustomXSLPageProducer.
	GetProducerTemplateStream (see page 7887)	This is GetProducerTemplateStream, a member of class TCustomXSLPageProducer.
	GetPrologNode (see page 7365)	This is GetPrologNode, a member of class TXMLDocument.
	GetPrologValue (see page 7366)	This is GetPrologValue, a member of class TXMLDocument.
	GetSchemaRef (see page 7366)	Returns the value of the SchemaRef property.
	GetStandAlone (see page 7366)	Returns the value of the StandAlone property.
	GetTemplateFileType (see page 7887)	This is GetTemplateFileType, a member of class TCustomXSLPageProducer.
	GetTemplateStream (see page 7888)	This is GetTemplateStream, a member of class TCustomXSLPageProducer.
	GetVersion (see page 7366)	Returns the value of the Version property.
	GetXML (see page 7367)	Returns the value of the XML property.
	GetXMLData (see page 7888)	This is GetXMLData, a member of class TCustomXSLPageProducer.
	GetXMLDocument (see page 7888)	This is GetXMLDocument, a member of class TCustomXSLPageProducer.

	GetXSLData (see page 7888)	This is GetXSLData, a member of class TCustomXSLPageProducer.
	HasHTMLBrowserView (see page 7888)	This is HasHTMLBrowserView, a member of class TCustomXSLPageProducer.
	HasScriptView (see page 7889)	This is HasScriptView, a member of class TCustomXSLPageProducer.
	HasXMLBrowserView (see page 7889)	This is HasXMLBrowserView, a member of class TCustomXSLPageProducer.
	HasXSLBrowserView (see page 7889)	This is HasXSLBrowserView, a member of class TCustomXSLPageProducer.
	InternalSetPrologValue (see page 7367)	This is InternalSetPrologValue, a member of class TXMLDocument.
	LoadData (see page 7368)	This is LoadData, a member of class TXMLDocument.
V	Loaded (see page 7368)	Initializes the component after the form file has been read into memory.
V	Notification (see page 7889)	Forwards notification messages to all owned components.
	ProduceContent (see page 7890)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 7890)	This is ProduceContentFromStream, a member of class TCustomXSLPageProducer.
	ProduceContentFromString (see page 7890)	This is ProduceContentFromString, a member of class TCustomXSLPageProducer.
	ReadDOMVendor (see page 7371)	This is ReadDOMVendor, a member of class TXMLDocument.
	ReleaseDoc (see page 7372)	This is ReleaseDoc, a member of class TXMLDocument.
	SaveToUTF8String (see page 7374)	This is SaveToUTF8String, a member of class TXMLDocument.
	SaveToXMLStrings (see page 7375)	Saves the XML (see page 7392) document to an internal string list.
V	SetActive (see page 7375)	Sets the value of the Active property.
	SetAppDispatcher (see page 7891)	This is SetAppDispatcher, a member of class TCustomXSLPageProducer.
	SetDocumentElement (see page 7375)	Sets the value of the DocumentElement property.
	SetDOMDocument (see page 7376)	Sets the value of the DOMDocument property.
	SetEncoding (see page 7376)	Sets the value of the Encoding property.
	SetFileName (see page 7376)	Sets the value of the FileName property.
	SetModified (see page 7377)	This is SetModified, a member of class TXMLDocument.
	SetNodeIndentStr (see page 7377)	Sets the value of the NodeIndentStr property.
	SetOnAsyncLoad (see page 7377)	Supplies an event handler that responds when the AsyncLoadState property changes.
	SetOptions (see page 7378)	Sets the value of the Options property.
	SetParseOptions (see page 7378)	Sets the value of the ParseOptions property.
	SetPrologValue (see page 7378)	This is SetPrologValue, a member of class TXMLDocument.
	SetStandAlone (see page 7378)	Sets the value of the StandAlone property.
	SetVersion (see page 7379)	Sets the value of the Version property.
	SetXML (see page 7379)	Sets the value of the XML property.
	SetXMLStrings (see page 7379)	This is SetXMLStrings, a member of class TXMLDocument.
	WriteDOMVendor (see page 7380)	This is WriteDOMVendor, a member of class TXMLDocument.
	XMLStringsChanging (see page 7380)	This is XMLStringsChanging, a member of class TXMLDocument.

Protected Properties

	Name	Description
R	DocBindingInfo (see page 7383)	This is DocBindingInfo, a member of class TXMLDocument.
	DocSource (see page 7383)	This is DocSource, a member of class TXMLDocument.
R	DOMParseOptions (see page 7385)	This is DOMParseOptions, a member of class TXMLDocument.
R	DOMPersist (see page 7386)	This is DOMPersist, a member of class TXMLDocument.
	PrefixID (see page 7391)	This is PrefixID, a member of class TXMLDocument.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AddChild (see page 7354)	This is the overview for the AddChild method overload.
	AddChild (see page 7643)	This is the overview for the AddChild method overload.
V	AfterConstruction (see page 7355)	Responds after the last constructor has executed.
V	Content (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property.

	ContentFromStream (see page 7885)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using an XSL template that can be read from a specified stream.
	ContentFromString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.
	ContentFromWideString (see page 7886)	Returns the transformed value of the XML supplied by the XMLData (see page 7892) property using a specified XSL template.
	Create (see page 7351)	This is the overview for the Create constructor overload.
	CreateElement (see page 7357)	Creates a new element node that is associated with this document.
	CreateElement (see page 7644)	Creates a new element node that is associated with this document.
	CreateNode (see page 7357)	Creates a new node that is associated with this document.
	CreateNode (see page 7645)	Creates a new node that is associated with this document.
	Destroy (see page 7352)	Disposes of a TXMLDocument (see page 7347) object.
	GeneratePrefix (see page 7360)	Generates a unique namespace prefix that can be used for a node in the document.
	GeneratePrefix (see page 7646)	Generates a unique namespace prefix that can be used for a node in the document.
	GetActive (see page 7646)	Returns the value of the Active (see page 7661) property.
	GetAsyncLoadState (see page 7647)	Returns the value of the AsyncLoadState (see page 7662) property.
	GetChildNodes (see page 7647)	Returns the value of the ChildNodes (see page 7663) property.
	GetDocBinding (see page 7362)	Replaces the document element with an instance of a specified implementation class.
	GetDocBinding (see page 7647)	Replaces a specified child node with an instance of a specified implementation class.
	GetDocumentElement (see page 7648)	Returns the value of the DocumentElement (see page 7663) property.
	GetDocumentNode (see page 7648)	Returns the value of the Node (see page 7665) property.
	GetDocumentObject (see page 7479)	This is GetDocumentObject, a member of class IXMLDocumentAccess.
	GetDOMDocument (see page 7648)	Returns the value of the DOMDocument (see page 7663) property.
	GetDOMPersist (see page 7479)	This is GetDOMPersist, a member of class IXMLDocumentAccess.
	GetEncoding (see page 7649)	Returns the value of the Encoding (see page 7664) property.
	GetFileName (see page 7649)	Returns the value of the FileName (see page 7664) property.
	GetModified (see page 7649)	Returns the value of the Modified (see page 7665) property.
	GetNodeIndentStr (see page 7650)	Returns the value of the NodeIndentStr (see page 7666) property.
	GetOptions (see page 7650)	Returns the value of the Options (see page 7666) property.
	GetParseOptions (see page 7650)	Returns the value of the ParseOptions (see page 7667) property.
	GetSchemaRef (see page 7650)	Returns the value of the SchemaRef (see page 7667) property.
	GetStandAlone (see page 7651)	Returns the value of the StandAlone (see page 7668) property.
	GetTemplateFileType (see page 6090)	This is GetTemplateFileType, a member of class IProducerEditorViewSupport.
	GetVersion (see page 7651)	Returns the value of the Version (see page 7668) property.
	GetXML (see page 7651)	Returns the value of the XML (see page 7668) property.
	GetXMLData (see page 6090)	This is GetXMLData, a member of class IProducerEditorViewSupport.
	GetXSLData (see page 6090)	This is GetXSLData, a member of class IProducerEditorViewSupport.
	HasHTMLBrowserView (see page 6091)	This is HasHTMLBrowserView, a member of class IProducerEditorViewSupport.
	HasScriptView (see page 6091)	This is HasScriptView, a member of class IProducerEditorViewSupport.
	HasXMLBrowserView (see page 6091)	This is HasXMLBrowserView, a member of class IProducerEditorViewSupport.
	HasXSLBrowserView (see page 6091)	This is HasXSLBrowserView, a member of class IProducerEditorViewSupport.
	IsEmptyDoc (see page 7367)	Indicates whether the TXMLDocument (see page 7347) instance represents an empty document.
	IsEmptyDoc (see page 7652)	Indicates whether the IXMLDocument (see page 7640) instance represents an empty document.
	LoadFromFile (see page 7368)	Loads an XML (see page 7392) document and activates it.
	LoadFromFile (see page 7652)	Loads an XML (see page 7668) document from disk.
	LoadFromStream (see page 7369)	Loads an XML (see page 7392) document from a stream and activates it.
	LoadFromStream (see page 7653)	Loads an XML (see page 7668) document from a stream and activates it.
	LoadFromXML (see page 7370)	This is the overview for the LoadFromXML method overload.
	LoadFromXML (see page 7653)	This is the overview for the LoadFromXML method overload.
	NewInstance (see page 7370)	Allocates memory for an instance of an object type and returns a pointer to that new instance.

	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	Refresh (see page 7371)	Updates the parsed XML (see page 7392) document to reflect external changes.
	Refresh (see page 7654)	Updates the parsed XML (see page 7668) document to reflect external changes.
	RegisterDocBinding (see page 7372)	Registers an implementation class for child nodes with a specified tag name.
	RegisterDocBinding (see page 7654)	Registers an implementation class for child nodes with a specified tag name.
	Resync (see page 7372)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	Resync (see page 7655)	Forces all child nodes and attribute nodes to be reread from the underlying DOM implementation.
	SaveToFile (see page 7373)	Saves the XML (see page 7392) document to disk.
	SaveToFile (see page 7655)	Saves the XML (see page 7668) document to disk.
	SaveToStream (see page 7373)	Saves the XML (see page 7392) document to a stream.
	SaveToStream (see page 7656)	Saves the XML (see page 7668) document to a stream.
	SaveToXML (see page 7374)	This is the overview for the SaveToXML method overload.
	SaveToXML (see page 7656)	This is the overview for the SaveToXML method overload.
	SetActive (see page 7657)	Sets the value of the Active (see page 7661) property.
	SetDocumentElement (see page 7657)	Sets the value of the DocumentElement (see page 7663) property.
	SetDOMDocument (see page 7658)	Sets the value of the DOMDocument (see page 7663) property.
	SetEncoding (see page 7658)	Sets the value of the Encoding (see page 7664) property.
	SetFileName (see page 7658)	Sets the value of the FileName (see page 7664) property.
	SetNodeIndentStr (see page 7659)	Sets the value of the NodeIndentStr (see page 7666) property.
	SetOnAsyncLoad (see page 7659)	Supplies an event handler that responds when the AsyncLoadState (see page 7662) property changes.
	SetOptions (see page 7659)	Sets the value of the Options (see page 7666) property.
	SetParseOptions (see page 7660)	Sets the value of the ParseOptions (see page 7667) property.
	SetStandAlone (see page 7660)	Sets the value of the StandAlone (see page 7668) property.
	SetVersion (see page 7660)	Sets the value of the Version (see page 7668) property.
	SetXML (see page 7661)	Sets the value of the XML (see page 7668) property.

Public Properties

	Name	Description
	Active (see page 7661)	Specifies whether the XML (see page 7668) document has been parsed so that the DOM interfaces are available to examine or change its contents.
R	AsyncLoadState (see page 7382)	Indicates the state of the DOM parser when it parses the XML (see page 7392) document asynchronously.
R	AsyncLoadState (see page 7662)	Indicates the state of the DOM parser when it parses the XML (see page 7668) document asynchronously.
R	ChildNodes (see page 7383)	Lists all of the child nodes of the document.
R	ChildNodes (see page 7663)	Lists all of the child nodes of the document.
R	Dispatcher (see page 7891)	Specifies the interface of a component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
R	DispatcherComponent (see page 7892)	Specifies the component that manages the HTTP request messages to which this page producer responds and that receives the response content that this page producer creates.
	DocumentElement (see page 7383)	Provides access to the root node of the XML (see page 7392) document.
	DocumentElement (see page 7663)	Provides access to the root node of the XML (see page 7668) document.
R	DocumentObject (see page 7479)	This is DocumentObject, a member of class IXMLDocumentAccess.
	DOMDocument (see page 7384)	Provides access to the DOM interface for the parsed XML (see page 7392) document.
	DOMDocument (see page 7663)	Provides access to the DOM interface for the parsed XML (see page 7668) document.
	DOMImplementation (see page 7385)	Provides access to the DOM interface for document-independent functions.
R	DOMPersist (see page 7480)	This is DOMPersist, a member of class IXMLDocumentAccess.
	Encoding (see page 7386)	Indicates the character set that the XML (see page 7392) document uses to encode characters.

	Encoding (see page 7664)	Indicates the character set that the XML (see page 7668) document uses to encode characters.
	FileName (see page 7664)	Indicates the XML (see page 7668) document file, if any, that this interface represents.
R	Modified (see page 7387)	Indicates whether the XML (see page 7392) document has been modified.
R	Modified (see page 7665)	Indicates whether the XML (see page 7668) document has been modified.
R	Node (see page 7388)	Provides access to the document node for the XML (see page 7392) document.
R	Node (see page 7665)	Provides access to the document node for the XML (see page 7668) document.
	NodeIndentStr (see page 7666)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7668) text.
	NSPrefixBase (see page 7389)	Specifies the base string for automatically-generated namespace prefixes.
	Options (see page 7666)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7667)	Specifies implementation-specific options that are followed when parsing the XML (see page 7668) document.
R	SchemaRef (see page 7391)	Returns the name of the schema associated with this XML (see page 7392) document.
R	SchemaRef (see page 7667)	Returns the name of the schema associated with this XML (see page 7668) document.
	StandAlone (see page 7391)	Indicates whether the XML (see page 7392) document includes any external markup declarations.
	StandAlone (see page 7668)	Indicates whether the XML (see page 7668) document includes any external markup declarations.
	Version (see page 7391)	Indicates the XML (see page 7392) version that the document uses.
	Version (see page 7668)	Indicates the XML (see page 7668) version that the document uses.
	XML (see page 7668)	Specifies the content of the XML document associated with this IXMLDocument (see page 7640) interface.

Published Events

	Name	Description
	AfterClose (see page 7393)	Occurs after the XML (see page 7392) document is closed.
	AfterNodeChange (see page 7393)	Occurs after a change is made to one of the nodes in the document.
	AfterOpen (see page 7394)	Occurs immediately after the XML (see page 7392) document is opened.
	BeforeClose (see page 7394)	Occurs immediately before the XML (see page 7392) document is closed.
	BeforeNodeChange (see page 7394)	Occurs before a change is made to one of the nodes in the document.
	BeforeOpen (see page 7395)	Occurs immediately before the XML (see page 7392) document is opened.
	OnAsyncLoad (see page 7395)	Occurs at various stages during the asynchronous parsing of an XML (see page 7392) document.

Published Properties

	Name	Description
	Active (see page 7381)	Specifies whether the XML (see page 7392) document has been parsed so that the DOM interfaces are available to examine or change its contents.
	DOMVendor (see page 7386)	Specifies the DOM implementation to use for parsing and manipulating the XML (see page 7392) document.
	FileName (see page 7387)	Specifies the file name for the XML (see page 7392) document associated with this TXMLDocument (see page 7347) object.
	NodeIndentStr (see page 7388)	Indicates the string that is inserted before nested nodes in the formatted XML (see page 7392) text.
	Options (see page 7389)	Influences various aspects of the document's behavior.
	ParseOptions (see page 7390)	Specifies implementation-specific options that are followed when parsing the XML (see page 7392) document.
	XML (see page 7392)	Specifies the content of the XML document associated with this TXMLDocument (see page 7347) object.
	XMLData (see page 7899)	Specifies the component that supplies the XML data that this component transforms.

87.1.3.2 TXSLPageProducer Properties

The properties of the TXSLPageProducer class are listed here.

Published Properties

	Name	Description
	XMLData (see page 7899)	Specifies the component that supplies the XML data that this component transforms.

87.1.3.2.1 TXSLPageProducer.XMLData Property

Specifies the component that supplies the XML data that this component transforms.

Pascal

```
property XMLData: TComponent;
```

C++

```
__property TComponent * XMLData;
```

Description

Use the XMLData property to specify the XML data that this component transforms. XMLData must be set to a component that supports either the IXMLDocument interface (for example, TXMLDocument or one of its descendants) or the IGetXMLStream interface (for example, TXMLBroker).

Classes

	Name	Description
	EZCompressionError (see page 7904)	This is class ZLib.EZCompressionError.
	EZDecompressionError (see page 7904)	This is class ZLib.EZDecompressionError.
	EZLibError (see page 7905)	This is class ZLib.EZLibError.
	TCustomZStream (see page 7905)	Abstract ancestor class for compression streams.
	TZCompressionStream (see page 7907)	Compresses data as it is written to the stream.
	TZDecompressionStream (see page 7912)	Decompresses data that was written to a TZCompressionStream (see page 7907) object.

Constants

Name	Description
_z_errmsg (see page 7932)	This is constant ZLib._z_errmsg.
SZInvalid (see page 7933)	This is constant ZLib.SZInvalid.
Z_ASCII (see page 7933)	This is constant ZLib.Z_ASCII.
Z_BEST_COMPRESSION (see page 7933)	This is constant ZLib.Z_BEST_COMPRESSION.
Z_BEST_SPEED (see page 7934)	This is constant ZLib.Z_BEST_SPEED.
Z_BINARY (see page 7934)	This is constant ZLib.Z_BINARY.
Z_BUF_ERROR (see page 7934)	This is constant ZLib.Z_BUF_ERROR.
Z_DATA_ERROR (see page 7935)	This is constant ZLib.Z_DATA_ERROR.
Z_DEFAULT_COMPRESSION (see page 7935)	This is constant ZLib.Z_DEFAULT_COMPRESSION.
Z_DEFAULT_STRATEGY (see page 7935)	This is constant ZLib.Z_DEFAULT_STRATEGY.
Z_DEFLATED (see page 7936)	This is constant ZLib.Z_DEFLATED.
Z_ERRNO (see page 7936)	This is constant ZLib.Z_ERRNO.
Z_FILTERED (see page 7936)	This is constant ZLib.Z_FILTERED.

Z_FINISH (see page 7937)	This is constant ZLib.Z_FINISH.
Z_FULL_FLUSH (see page 7937)	This is constant ZLib.Z_FULL_FLUSH.
Z_HUFFMAN_ONLY (see page 7937)	This is constant ZLib.Z_HUFFMAN_ONLY.
Z_MEM_ERROR (see page 7938)	This is constant ZLib.Z_MEM_ERROR.
Z_NEED_DICT (see page 7938)	This is constant ZLib.Z_NEED_DICT.
Z_NO_COMPRESSION (see page 7938)	This is constant ZLib.Z_NO_COMPRESSION.
Z_NO_FLUSH (see page 7939)	This is constant ZLib.Z_NO_FLUSH.
Z_OK (see page 7939)	This is constant ZLib.Z_OK.
Z_PARTIAL_FLUSH (see page 7939)	This is constant ZLib.Z_PARTIAL_FLUSH.
Z_STREAM_END (see page 7940)	This is constant ZLib.Z_STREAM_END.
Z_STREAM_ERROR (see page 7940)	This is constant ZLib.Z_STREAM_ERROR.
Z_SYNC_FLUSH (see page 7940)	This is constant ZLib.Z_SYNC_FLUSH.
Z_UNKNOWN (see page 7941)	This is constant ZLib.Z_UNKNOWN.
Z_VERSION_ERROR (see page 7941)	This is constant ZLib.Z_VERSION_ERROR.
ZLevels (see page 7941)	This is constant ZLib.ZLevels.
ZLIB_VERSION (see page 7942)	This is constant ZLib.ZLIB_VERSION.

Functions

	Name	Description
	adler32 (see page 7917)	This is function ZLib.adler32.
	deflate (see page 7918)	This is function ZLib.deflate.
	deflateEnd (see page 7918)	This is function ZLib.deflateEnd.
	deflateInit_ (see page 7918)	This is function ZLib.deflateInit_.
	DeflateInit2_ (see page 7919)	This is function ZLib.DeflateInit2_.
	inflate (see page 7919)	This is function ZLib.inflate.
	inflateEnd (see page 7919)	This is function ZLib.inflateEnd.
	inflateInit_ (see page 7920)	This is function ZLib.inflateInit_.
	inflateInit2_ (see page 7920)	This is function ZLib.inflateInit2_.
	inflateReset (see page 7920)	This is function ZLib.inflateReset.
	MoveI32 (see page 7921)	This is function ZLib.MoveI32.
	ZCompress (see page 7921)	This is function ZLib.ZCompress.
	ZCompress (see page 7921)	This is function ZLib.ZCompress.
	ZCompressStr (see page 7922)	This is function ZLib.ZCompressStr.
	ZCompressStr (see page 7922)	This is function ZLib.ZCompressStr.
	ZCompressStream (see page 7922)	This is function ZLib.ZCompressStream.
	ZCompressStream (see page 7923)	This is function ZLib.ZCompressStream.
	ZDecompress (see page 7923)	This is function ZLib.ZDecompress.
	ZDecompressStr (see page 7923)	This is function ZLib.ZDecompressStr.
	ZDecompressStream (see page 7924)	This is function ZLib.ZDecompressStream.
	zlibAllocMem (see page 7924)	This is function ZLib.zlibAllocMem.
	zlibFreeMem (see page 7924)	This is function ZLib.zlibFreeMem.
	ZSendToBrowser (see page 7925)	This is function ZLib.ZSendToBrowser.

Structs, Records, Enums

	Name	Description
	TCompressionLevel (see page 7926)	TCompressionLevel indicates the type of compression algorithm to be used when creating a compressed data stream.
	TZCompressionLevel (see page 7927)	This is record ZLib.TZCompressionLevel.
	TZStreamRec (see page 7927)	This is record ZLib.TZStreamRec.

Types

Name	Description
TCompressionStream (see page 7929)	Compresses data as it is written to the stream.
TCustomZLibStream (see page 7929)	This is type ZLib.TCustomZLibStream.

TDecompressionStream (see page 7930)	Decompresses data that was written to a TZCompressionStream (see page 7907) object.
TZAlloc (see page 7930)	This is type ZLib.TZAlloc.
TZFree (see page 7930)	This is type ZLib.TZFree.

88.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EZCompressionError (see page 7904)	This is class ZLib.EZCompressionError.
	EZDecompressionError (see page 7904)	This is class ZLib.EZDecompressionError.
	EZLibError (see page 7905)	This is class ZLib.EZLibError.
	TCustomZStream (see page 7905)	Abstract ancestor class for compression streams.
	TZCompressionStream (see page 7907)	Compresses data as it is written to the stream.
	TZDecompressionStream (see page 7912)	Decompresses data that was written to a TZCompressionStream (see page 7907) object.

88.1.1 EZCompressionError Class

Class Hierarchy

Pascal

```
EZCompressionError = class(EZLibError);
```

C++

```
class EZCompressionError : public EZLibError;
```

File

ZLib

Description

This is class ZLib.EZCompressionError.

88.1.2 EZDecompressionError Class

Class Hierarchy

Pascal

```
EZDecompressionError = class(EZLibError);
```

C++

```
class EZDecompressionError : public EZLibError;
```

File

ZLib

Description

This is class ZLib.EZDecompressionError.

88.1.3 EZLibError Class

Class Hierarchy

Pascal

```
EZLibError = class(Exception);
```

C++

```
class EZLibError : public Exception;
```

File

ZLib

Description

This is class ZLib.EZLibError.

88.1.4 TCustomZStream Class

Abstract ancestor class for compression streams.

Class Hierarchy

Pascal

```
TCustomZStream = class(TStream);
```

C++

```
class TCustomZStream : public TStream;
```

File

ZLib

Description

TCustomZStream is an abstract class, which forms the base for TCompressionStream (see page 7929) and TDecompressionStream (see page 7930). Since it is an abstract class, instances of TCustomZStream cannot be directly instantiated. TCustomZStream serves as the starting point for your own custom data compression streams.

See Also

TCompressionStream (see page 7929)

TDecompressionStream (see page 7930)

TStream

88.1.4.1 TCustomZStream Members

The following tables list the members exposed by TCustomZStream.

Protected Events

	Name	Description
	OnProgress (see page 7907)	Occurs when reading or writing a large block of data in a single call.

Protected Methods

	Name	Description
	Create (see page 7906)	Initializes an instance of a TCustomZStream (see page 7905)-derived object.
	DoProgress (see page 7906)	Calls the OnDoProgress method, if assigned.

88.1.4.2 TCustomZStream.Create Constructor

Initializes an instance of a TCustomZStream (see page 7905)-derived object.

Pascal

```
constructor Create(stream: TStream);
```

C++

```
__fastcall TCustomZStream(TStream stream);
```

Description

TCustomZStream (see page 7905) is intended to be an abstract base class for your own custom data compression streams. Its constructor is protected; therefore you cannot directly instantiate an instance of this class.

A concrete class derived from TCustomZStream (see page 7905) should, in its own public constructor, call the constructor inherited from TCustomZStream (see page 7905).

88.1.4.3 TCustomZStream Methods

The methods of the TCustomZStream class are listed here.

Protected Methods

	Name	Description
	DoProgress (see page 7906)	Calls the OnDoProgress method, if assigned.

88.1.4.3.1 TCustomZStream.DoProgress Method

Calls the OnDoProgress method, if assigned.

Pascal

```
procedure DoProgress; dynamic;
```

C++

```
__fastcall DoProgress();
```

Description

Derived compression stream classes should call the DoProgress method when reading or writing a large block of data in a single call. This gives the derived class an opportunity to update a user interface control such as a progress indicator.

See Also

OnProgress (see page 7907)

88.1.4.4 TCustomZStream Events

The events of the TCustomZStream class are listed here.

Protected Events

	Name	Description
	OnProgress (see page 7907)	Occurs when reading or writing a large block of data in a single call.

88.1.4.4.1 TCustomZStream.OnProgress Event

Occurs when reading or writing a large block of data in a single call.

Pascal

```
property OnProgress: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnProgress;
```

Description

Classes derived from TCustomZStream (see page 7905) can use the OnProgress event to perform some action during a long read or write operation.

For example, the TCompressionStream (see page 7929) class calls the OnProgress event handler, after the stream's output buffer has been filled and subsequently written. Similarly, the TDecompressionStream (see page 7930) class calls the OnProgress event handler when its input buffer has been filled and is ready to be decompressed.

See Also

DoProgress (see page 7906)

88.1.5 TZCompressionStream Class

Compresses data as it is written to the stream.

Class Hierarchy

Pascal

```
TZCompressionStream = class(TCustomZStream);
```

C++

```
class TZCompressionStream : public TCustomZStream;
```

File

ZLib

Description

TZCompressionStream is a write-only, sequential access stream that compresses data as it is written. The compressed data is

written to a separate stream, which is passed to the TZCompressionStream constructor. TZCompressionStream does not take ownership of the output stream; you are responsible for creating, initializing, and destroying the stream when it is no longer needed.

Reading from a TZCompressionStream object will raise an exception of type ECompressionError, with the message string set to "Invalid Stream Operation." Similarly, a Seek (see page 7910) operation causes an ECompressionError exception, however, you can perform a Seek (see page 7910) operation with a zero offset from the current position. This will return the number of raw, uncompressed bytes that have been written to the stream.

You set the compression level to be used when you create the stream object. The possible compression levels are: clNone, clFastest, clDefault, and clMax.

When the stream's output buffer is filled, a Write (see page 7910) operation on TZCompressionStream will write the contents of the buffer to the output stream, and then call the OnProgress (see page 7912) event. You can use the OnProgress (see page 7912) event to update a user interface control such as a progress indicator.

See Also

TCustomZStream (see page 7905)

TZDecompressionStream (see page 7912)

TStream

88.1.5.1 TZCompressionStream Members

The following tables list the members exposed by TZCompressionStream.

Protected Methods

	Name	Description
	DoProgress (see page 7906)	Calls the OnDoProgress method, if assigned.

Public Events

	Name	Description
	OnProgress (see page 7912)	Occurs after the stream's output buffer has been written.

Public Methods

	Name	Description
	Create (see page 7908)	This is the overview for the Create constructor overload.
V	Destroy (see page 7909)	Destroys the TZCompressionStream (see page 7907) object.
V	Read (see page 7910)	Raises an exception of type ECompressionError.
V	Seek (see page 7910)	Raises an exception of type ECompressionErrror.
V	Write (see page 7910)	Writes compressed data to the destination output stream.

Public Properties

	Name	Description
R	CompressionRate (see page 7911)	Returns the percentage by which the data has been compressed.

88.1.5.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TZCompressionStream.Create (TCompressionLevel, TStream) (see page 7909)	Creates and initializes an instance of a TZCompressionStream (see page 7907) object.
	TZCompressionStream.Create (TStream, TZCompressionLevel) (see page 7909)	Creates and initializes an instance of a TZCompressionStream (see page 7907) object.

88.1.5.2.1 TZCompressionStream.Create Constructor (TCompressionLevel, TStream)

Creates and initializes an instance of a TZCompressionStream (see page 7907) object.

Pascal

```
constructor Create(dest: TStream; compressionLevel: TZCompressionLevel = zcDefault); overload;
constructor Create(compressionLevel: TCompressionLevel; dest: TStream); overload;
```

C++

```
__fastcall TZCompressionStream(TStream dest, TZCompressionLevel compressionLevel = zcDefault);
__fastcall TZCompressionStream(TCompressionLevel compressionLevel, TStream dest);
```

Description

Call Create to instantiate a TZCompressionStream (see page 7907) object.

The CompressionLevel parameter determines the type of compression algorithm to be used, and must be one of the following: clNone, clFastest, clDefault, or clMax.

The Dest parameter is a TStream object; compressed data will be written to this stream.

88.1.5.3 TZCompressionStream.Destroy Destructor

Destroys the TZCompressionStream (see page 7907) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TZCompressionStream();
```

Description

Do not call the Destroy method directly. Instead, use the Free method, as this will check the validity of the object before calling Destroy.

All data in the TZCompressionStream (see page 7907)'s cache is flushed to the output stream when the object is destroyed.

88.1.5.4 TZCompressionStream Methods

The methods of the TZCompressionStream class are listed here.

Public Methods

	Name	Description
	Read (see page 7910)	Raises an exception of type ECompressionError.
	Seek (see page 7910)	Raises an exception of type ECompressionErrror.
	Write (see page 7910)	Writes compressed data to the destination output stream.

88.1.5.4.1 TZCompressionStream.Read Method

Raises an exception of type ECompressionError.

Pascal

```
function Read(var buffer; count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( buffer, Longint count);
```

Description

Read operations are not permitted on a TZCompressionStream (see page 7907) object. If a Read is attempted, an exception of type ECompressionError will be raised, with the message string "Invalid Stream Operation."

See Also

Write (see page 7910)

Seek (see page 7910)

Read

88.1.5.4.2 TZCompressionStream.Seek Method

Raises an exception of type ECompressionErrror.

Pascal

```
function Seek(offset: Longint; origin: Word): Longint; override;
```

C++

```
virtual __fastcall Longint Seek(Longint offset, Word origin);
```

Description

A TZCompressionStream (see page 7907) is a write-only, sequential access data stream. Read (see page 7910) operations are not permitted, and will raise an exception of type ECompressionError. Similarly, Seek operations will also raise an ECompressionError, with the message string "Invalid Stream Operation."

However, you can call the Seek method with an offset of zero, and the Origin set to soFromCurrent. In this special case, the Seek method will return the number of raw (uncompressed) bytes that have been written to the stream so far.

See Also

Read (see page 7910)

Write (see page 7910)

Seek

88.1.5.4.3 TZCompressionStream.Write Method

Writes compressed data to the destination output stream.

Pascal

```
function Write(const buffer; count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  buffer, Longint count);
```

Description

The Write method causes the data in the supplied buffer to be written the output stream. Buffer contains the raw (uncompressed) data to be written, and Count contains the number of bytes to write.

The TZCompressionStream (see page 7907) object caches data internally; data is flushed to the output stream when the cache becomes full, and when the object is destroyed (if pending data remains in the cache).

After data is written to the output stream, the OnProgress (see page 7912) event is called. This gives you an opportunity to update a user interface control such as a progress indicator.

The result of the Write method is the number of bytes transferred from the buffer

See Also

Read (see page 7910)

Seek (see page 7910)

Write

88.1.5.5 TZCompressionStream Properties

The properties of the TZCompressionStream class are listed here.

Public Properties

	Name	Description
	CompressionRate (see page 7911)	Returns the percentage by which the data has been compressed.

88.1.5.5.1 TZCompressionStream.CompressionRate Property

Returns the percentage by which the data has been compressed.

Pascal

```
property CompressionRate: Single;
```

C++

```
__property Single CompressionRate;
```

Description

The compression rate is a read-only property. Its value is calculated and updated as data is written to the stream. For example, if a total of 100 raw (uncompressed) bytes have been written to the stream, and only 25 compressed bytes have been written out, then reading the CompressionRate property will return a value of 75.

88.1.5.6 TZCompressionStream Events

The events of the TZCompressionStream class are listed here.

Public Events

	Name	Description
	OnProgress (see page 7912)	Occurs after the stream's output buffer has been written.

88.1.5.6.1 TZCompressionStream.OnProgress Event

Occurs after the stream's output buffer has been written.

Pascal

```
property OnProgress: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnProgress;
```

Description

The OnProgress event is automatically called from a Write (see page 7910) operation, after the object's internal buffer has been filled and written to the output stream.

The OnProgress event is of type TNotifyEvent. When your procedure is called, the Sender parameter will be set to the object itself. You can use the OnProgress event to update a user interface control, such as a progress indicator. You can use the Position property, inherited from TStream, to determine the number of raw (uncompressed) bytes written to the output stream so far.

88.1.6 TZDecompressionStream Class

Decompresses data that was written to a TZCompressionStream (see page 7907) object.

Class Hierarchy

Pascal

```
TZDecompressionStream = class(TCustomZStream);
```

C++

```
class TZDecompressionStream : public TCustomZStream;
```

File

ZLib

Description

TZDecompressionStream is the analog of the TCompressionStream (see page 7929) class. It is a read-only, unidirectional stream; you can seek forward in the stream, but not backwards. A separate input stream provides the source data. The input stream will be a stream that was previously written to using a TCompressionStream (see page 7929) object. The input stream is passed to the constructor, however, TZDecompressionStream does not take ownership of this object. You are responsible for creating, initializing, and destroying the input stream when it is no longer needed.

Writing to the stream will raise an exception, as will requesting the size of the stream, and attempting to perform a Seek (see page 7914) operation backwards or relative to the current position.

The TZDecompressionStream object's OnProgress (see page 7915) event is called when a block of data is read from the input stream. You can read the TZDecompressionStream object's Position property to determine the number of raw, uncompressed

bytes that have been read from the input stream so far.

88.1.6.1 TZDecompressionStream Members

The following tables list the members exposed by TZDecompressionStream.

Protected Methods

	Name	Description
	DoProgress (see page 7906)	Calls the OnDoProgress method, if assigned.

Public Events

	Name	Description
	OnProgress (see page 7915)	Occurs after a block of data has been read from the input stream.

Public Methods

	Name	Description
	Create (see page 7913)	Creates and initializes an instance of a TZDecompressionStream (see page 7912) object.
	Destroy (see page 7913)	Destroys the TZDecompressionStream (see page 7912) object.
	Read (see page 7914)	Reads a block of data from the input stream, and decompresses it.
	Seek (see page 7914)	Resets the input stream, or moves the position forward.
	Write (see page 7915)	Raises an exception of type ECompressionError.

88.1.6.2 TZDecompressionStream.Create Constructor

Creates and initializes an instance of a TZDecompressionStream (see page 7912) object.

Pascal

```
constructor Create(source: TStream);
```

C++

```
__fastcall TZDecompressionStream(TStream source);
```

Description

Call Create to instantiate a TZDecompressionStream (see page 7912) object.

The Source parameter is the source input stream, which was previously created with a TZCompressionStream (see page 7907) object. Subsequent Read (see page 7914) operations will read data from the Source stream, and decompress the data on the fly.

88.1.6.3 TZDecompressionStream.Destroy Destructor

Destroys the TZDecompressionStream (see page 7912) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TZDecompressionStream();
```

Description

Do not call the Destroy method directly. Instead, use the Free method, as this will check the validity of the object before calling

Destroy.

If there is data remaining in the object's internal buffer, the input stream position is moved backwards by the number of bytes remaining.

88.1.6.4 TZDecompressionStream Methods

The methods of the TZDecompressionStream class are listed here.

Public Methods

	Name	Description
	Read (see page 7914)	Reads a block of data from the input stream, and decompresses it.
	Seek (see page 7914)	Resets the input stream, or moves the position forward.
	Write (see page 7915)	Raises an exception of type ECompressionError.

88.1.6.4.1 TZDecompressionStream.Read Method

Reads a block of data from the input stream, and decompresses it.

Pascal

```
function Read(var buffer; count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( buffer, Longint count);
```

Description

The Read method reads a block of data from the input stream, decompresses it, and stores it in the supplied buffer.

The Buffer parameter is the destination for the decompressed data.

Count is size of the destination buffer. The Read operation will end when the destination buffer is full, or when there are no more bytes available to be read from the input stream.

After reading a block of data, the OnProgress (see page 7915) event is fired by the object. This gives you a chance to update a user interface control such as a progress indicator during a long Read operation.

The result of the Read operation is the number of decompressed bytes placed into the destination buffer.

See Also

Write (see page 7915)

Seek (see page 7914)

Read

88.1.6.4.2 TZDecompressionStream.Seek Method

Resets the input stream, or moves the position forward.

Pascal

```
function Seek(offset: Longint; origin: Word): Longint; override;
```

C++

```
virtual __fastcall Longint Seek(Longint offset, Word origin);
```

Description

A TZDecompressionStream (see page 7912) is a read-only, unidirectional input stream. Write (see page 7915) operations are not permitted, and will raise an exception of type ECompressionError. Seek operations can be used to move the stream position forward, but a Seek operation that attempts to move the position backwards will raise an ECompressionError exception, with the message string set to "Invalid Stream Operation."

You can call the Seek method with an Offset of zero, and the Origin set to soFromBeginning. This has the effect of resetting the input stream, effectively rewinding the stream back to the beginning.

Otherwise, the Offset parameter must be a positive Longint, and the Origin parameter must be either soFromCurrent, or soFromBeginning. This has the effect of moving the input stream position forward, decompressing data as it goes.

See Also

Read (see page 7914)

Write (see page 7915)

Seek

88.1.6.4.3 TZDecompressionStream.Write Method

Raises an exception of type ECompressionError.

Pascal

```
function Write(const buffer; count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  buffer, Longint count);
```

Description

Write operations are not permitted on a TZDecompressionStream (see page 7912) object. If a Write operation is attempted, an exception of type ECompressionError will be raised, with the message string set to "Invalid Stream Operation."

See Also

Read (see page 7914)

Seek (see page 7914)

Write

88.1.6.5 TZDecompressionStream Events

The events of the TZDecompressionStream class are listed here.

Public Events

	Name	Description
	OnProgress (see page 7915)	Occurs after a block of data has been read from the input stream.

88.1.6.5.1 TZDecompressionStream.OnProgress Event

Occurs after a block of data has been read from the input stream.

Pascal

```
property OnProgress: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnProgress;
```

Description

The OnProgress event is automatically called from a Read (see page 7914) operation. The event occurs after a block of data has been read from the input stream, and before the data has been decompressed.

The OnProgress event is of type TNotifyEvent. When your procedure is called, the Sender parameter will be set to the object itself. You can use the OnProgress event to update a user interface control, such as a progress indicator. You can use the Position property, inherited from TStream, to determine the number of raw (uncompressed) bytes read from the input stream so far.

88.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	adler32 (see page 7917)	This is function ZLib.adler32.
	deflate (see page 7918)	This is function ZLib.deflate.
	deflateEnd (see page 7918)	This is function ZLib.deflateEnd.
	deflateInit_ (see page 7918)	This is function ZLib.deflateInit_.
	DeflateInit2_ (see page 7919)	This is function ZLib.DeflateInit2_.
	inflate (see page 7919)	This is function ZLib.inflate.
	inflateEnd (see page 7919)	This is function ZLib.inflateEnd.
	inflateInit_ (see page 7920)	This is function ZLib.inflateInit_.
	inflateInit2_ (see page 7920)	This is function ZLib.inflateInit2_.
	inflateReset (see page 7920)	This is function ZLib.inflateReset.
	MoveI32 (see page 7921)	This is function ZLib.MoveI32.
	ZCompress (see page 7921)	This is function ZLib.ZCompress.
	ZCompress (see page 7921)	This is function ZLib.ZCompress.
	ZCompressStr (see page 7922)	This is function ZLib.ZCompressStr.
	ZCompressStr (see page 7922)	This is function ZLib.ZCompressStr.
	ZCompressStream (see page 7922)	This is function ZLib.ZCompressStream.
	ZCompressStream (see page 7923)	This is function ZLib.ZCompressStream.
	ZDecompress (see page 7923)	This is function ZLib.ZDecompress.
	ZDecompressStr (see page 7923)	This is function ZLib.ZDecompressStr.
	ZDecompressStream (see page 7924)	This is function ZLib.ZDecompressStream.
	zlibAllocMem (see page 7924)	This is function ZLib.zlibAllocMem.
	zlibFreeMem (see page 7924)	This is function ZLib.zlibFreeMem.
	ZSendToBrowser (see page 7925)	This is function ZLib.ZSendToBrowser.

88.2.1 ZLib.adler32 Function

Pascal

```
function adler32(adler: LongInt; const buf: PChar; len: Integer): LongInt;
```

C++

```
LongInt adler32(LongInt adler, const const char * buf, int len);
```

File

ZLib

Description

This is function ZLib.adler32.

88.2.2 ZLib.deflate Function

Pascal

```
function deflate(var strm: TZStreamRec; flush: Integer): Integer;
```

C++

```
int deflate(TZStreamRec strm, int flush);
```

File

ZLib

Description

This is function ZLib.deflate.

88.2.3 ZLib.deflateEnd Function

Pascal

```
function deflateEnd(var strm: TZStreamRec): Integer;
```

C++

```
int deflateEnd(TZStreamRec strm);
```

File

ZLib

Description

This is function ZLib.deflateEnd.

88.2.4 ZLib.deflateInit_ Function

Pascal

```
function deflateInit_(var strm: TZStreamRec; level: Integer; version: PChar; recsize:
Integer): Integer;
```

C++

```
int deflateInit_(TZStreamRec strm, int level, const char * version, int recsize);
```

File

ZLib

Description

This is function ZLib.deflateInit_.

88.2.5 ZLib.DeflateInit2_ Function

Pascal

```
function DeflateInit2_(var strm: TZStreamRec; level: integer; method: integer; windowBits:
integer; memLevel: integer; strategy: integer; version: PChar; recsize: integer): integer;
```

C++

```
int DeflateInit2_(TZStreamRec strm, int level, int method, int windowBits, int memLevel, int
strategy, const char * version, int recsize);
```

File

ZLib

Description

This is function ZLib.DeflateInit2_.

88.2.6 ZLib.inflate Function

Pascal

```
function inflate(var strm: TZStreamRec; flush: Integer): Integer;
```

C++

```
int inflate(TZStreamRec strm, int flush);
```

File

ZLib

Description

This is function ZLib.inflate.

88.2.7 ZLib.inflateEnd Function

Pascal

```
function inflateEnd(var strm: TZStreamRec): Integer;
```

C++

```
int inflateEnd(TZStreamRec strm);
```

File

ZLib

Description

This is function ZLib.inflateEnd.

88.2.8 ZLib.inflateInit_ Function

Pascal

```
function inflateInit_(var strm: TZStreamRec; version: PChar; recsize: Integer): Integer;
```

C++

```
int inflateInit_(TZStreamRec strm, const char * version, int recsize);
```

File

ZLib

Description

This is function ZLib.inflateInit_.

88.2.9 ZLib.inflateInit2_ Function

Pascal

```
function inflateInit2_(var strm: TZStreamRec; windowBits: integer; version: PChar; recsize:
integer): integer;
```

C++

```
int inflateInit2_(TZStreamRec strm, int windowBits, const char * version, int recsize);
```

File

ZLib

Description

This is function ZLib.inflateInit2_.

88.2.10 ZLib.inflateReset Function

Pascal

```
function inflateReset(var strm: TZStreamRec): Integer;
```

C++

```
int inflateReset(TZStreamRec strm);
```

File

ZLib

Description

This is function ZLib.inflateReset.

88.2.11 ZLib.MoveI32 Function

Pascal

```
procedure MoveI32(const Source; var Dest; Count: Integer);
```

C++

```
MoveI32(const  Source,  Dest, int Count);
```

File

ZLib

Description

This is function ZLib.MoveI32.

88.2.12 ZLib.ZCompress Function

Pascal

```
procedure ZCompress(const inBuffer: Pointer; inSize: Integer; out outBuffer: Pointer; out
outSize: Integer; level: TCompressionLevel); overload;
```

C++

```
ZCompress(const void * inBuffer, int inSize, void * outBuffer, int outSize, TCompressionLevel
level);
```

File

ZLib

Description

This is function ZLib.ZCompress.

88.2.13 ZLib.ZCompress Function

Pascal

```
procedure ZCompress(const inBuffer: Pointer; inSize: Integer; out outBuffer: Pointer; out
outSize: Integer; level: TZCompressionLevel = zcDefault); overload;
```

C++

```
ZCompress(const void * inBuffer, int inSize, void * outBuffer, int outSize, TZCompressionLevel
level = zcDefault);
```

File

ZLib

Description

This is function ZLib.ZCompress.

88.2.14 ZLib.ZCompressStr Function

Pascal

```
function ZCompressStr(const s: string; level: TCompressionLevel): TBytes; overload;
```

C++

```
TBytes ZCompressStr(const UnicodeString s, TCompressionLevel level);
```

File

ZLib

Description

This is function ZLib.ZCompressStr.

88.2.15 ZLib.ZCompressStr Function

Pascal

```
function ZCompressStr(const s: string; level: TZCompressionLevel = zcDefault): TBytes;
overload;
```

C++

```
TBytes ZCompressStr(const UnicodeString s, TZCompressionLevel level = zcDefault);
```

File

ZLib

Description

This is function ZLib.ZCompressStr.

88.2.16 ZLib.ZCompressStream Function

Pascal

```
procedure ZCompressStream(inStream: TStream; outStream: TStream; level: TCompressionLevel);
overload;
```

C++

```
ZCompressStream(TStream inStream, TStream outStream, TCompressionLevel level);
```

File

ZLib

Description

This is function ZLib.ZCompressStream.

88.2.17 ZLib.ZCompressStream Function

Pascal

```
procedure ZCompressStream(inStream: TStream; outStream: TStream; level: TZCompressionLevel =
zcDefault); overload;
```

C++

```
ZCompressStream(TStream inStream, TStream outStream, TZCompressionLevel level = zcDefault);
```

File

ZLib

Description

This is function ZLib.ZCompressStream.

88.2.18 ZLib.ZDecompress Function

Pascal

```
procedure ZDecompress(const inBuffer: Pointer; inSize: Integer; out outBuffer: Pointer; out
outSize: Integer; outEstimate: Integer = 0);
```

C++

```
ZDecompress(const void * inBuffer, int inSize, void * outBuffer, int outSize, int outEstimate
= 0);
```

File

ZLib

Description

This is function ZLib.ZDecompress.

88.2.19 ZLib.ZDecompressStr Function

Pascal

```
function ZDecompressStr(const s: TBytes): string;
```

C++

```
UnicodeString ZDecompressStr(const TBytes s);
```

File

ZLib

Description

This is function ZLib.ZDecompressStr.

88.2.20 ZLib.ZDecompressStream Function

Pascal

```
procedure ZDecompressStream(inStream: TStream; outStream: TStream);
```

C++

```
ZDecompressStream(TStream inStream, TStream outStream);
```

File

ZLib

Description

This is function ZLib.ZDecompressStream.

88.2.21 ZLib.zlibAllocMem Function

Pascal

```
function zlibAllocMem(AppData: Pointer; Items: Integer; Size: Integer): Pointer;
```

C++

```
void * zlibAllocMem(void * AppData, int Items, int Size);
```

File

ZLib

Description

This is function ZLib.zlibAllocMem.

88.2.22 ZLib.zlibFreeMem Function

Pascal

```
procedure zlibFreeMem(AppData: Pointer; Block: Pointer);
```

C++

```
zlibFreeMem(void * AppData, void * Block);
```

File

ZLib

Description

This is function ZLib.zlibFreeMem.

88.2.23 ZLib.ZSendToBrowser Function

Pascal

```
procedure ZSendToBrowser(var s: string);
```

C++

```
ZSendToBrowser(UnicodeString s);
```

File

ZLib

Description

This is function ZLib.ZSendToBrowser.

88.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCompressionLevel (see page 7926)	TCompressionLevel indicates the type of compression algorithm to be used when creating a compressed data stream.
	TZCompressionLevel (see page 7927)	This is record ZLib.TZCompressionLevel.

Records

	Name	Description
	TZStreamRec (see page 7927)	This is record ZLib.TZStreamRec.

88.3.1 ZLib.TCompressionLevel Enumeration

TCompressionLevel indicates the type of compression algorithm to be used when creating a compressed data stream.

Pascal

```
TCompressionLevel = (
  clNone = Integer(zcNone
);
```

C++

```
enum TCompressionLevel {
  clNone = Integer(zcNone
};
```

File

ZLib

Description

The following table lists the possible values:

Value	Meaning
clNone	Specifies no compression; data is merely copied to the output stream.
clFastest	Specifies fastest compression, resulting in a larger archive.
clDefault	Compromise between speed and amount of compression.
clMax	Specifies maximum compression, resulting in a longer time to perform the operation.

See Also

TCustomZStream (see page 7905)

TZDecompressionStream (see page 7912)

TZCompressionStream (see page 7907)

88.3.2 ZLib.TZCompressionLevel Enumeration

Pascal

```
TZCompressionLevel = (
  zcNone,
  zcFastest,
  zcDefault,
  zcMax
);
```

C++

```
enum TZCompressionLevel {
  zcNone,
  zcFastest,
  zcDefault,
  zcMax
};
```

File

ZLib

Description

This is record ZLib.TZCompressionLevel.

88.3.3 ZLib.TZStreamRec Record

Pascal

```
TZStreamRec = packed record
  next_in: PAnsiChar;
  avail_in: Longint;
  total_in: Longint;
  next_out: PAnsiChar;
  avail_out: Longint;
  total_out: Longint;
  msg: PAnsiChar;
  state: Pointer;
  zalloc: TZAlloc;
  zfree: TZFree;
  opaque: Pointer;
  data_type: Integer;
  adler: Longint;
  reserved: Longint;
end;
```

C++

```
struct TZStreamRec {
  PAnsiChar next_in;
  Longint avail_in;
  Longint total_in;
  PAnsiChar next_out;
  Longint avail_out;
  Longint total_out;
  PAnsiChar msg;
  void * state;
```

```
    TZAlloc zalloc;
    TZFree zfree;
    void * opaque;
    int data_type;
    Longint adler;
    Longint reserved;
  };
```

File

ZLib

Description

This is record ZLib.TZStreamRec.

88.4 Types

The following table lists types in this documentation.

Types

Name	Description
TCompressionStream (see page 7929)	Compresses data as it is written to the stream.
TCustomZLibStream (see page 7929)	This is type ZLib.TCustomZLibStream.
TDecompressionStream (see page 7930)	Decompresses data that was written to a TZCompressionStream (see page 7907) object.
TZAlloc (see page 7930)	This is type ZLib.TZAlloc.
TZFree (see page 7930)	This is type ZLib.TZFree.

88.4.1 ZLib.TCompressionStream Type

Compresses data as it is written to the stream.

Pascal

```
TCompressionStream = TZCompressionStream;
```

C++

```
TZCompressionStream TCompressionStream;
```

File

ZLib

Description

TCompressionStream type is just an alias for TZCompressionStream (see page 7907) class.

See Also

TZCompressionStream (see page 7907)

TZDecompressionStream (see page 7912)

88.4.2 ZLib.TCustomZLibStream Type

Pascal

```
TCustomZLibStream = TCustomZStream;
```

C++

```
TCustomZStream TCustomZLibStream;
```

File

ZLib

Description

This is type ZLib.TCustomZLibStream.

88.4.3 ZLib.TDecompressionStream Type

Decompresses data that was written to a TZCompressionStream (see page 7907) object.

Pascal

```
TDecompressionStream = TZDecompressionStream;
```

C++

```
TZDecompressionStream TDecompressionStream;
```

File

ZLib

Description

TCompressionStream (see page 7929) type is just an alias for TZDecompressionStream (see page 7912) class.

See Also

TZDecompressionStream (see page 7912)

TZCompressionStream (see page 7907)

88.4.4 ZLib.TZAlloc Type

Pascal

```
TZAlloc = function (opaque: Pointer; items, size: Integer): Pointer;
```

C++

```
(opaque: Pointer; items, size: Integer): Pointer ( TZAlloc)();
```

File

ZLib

Description

This is type ZLib.TZAlloc.

88.4.5 ZLib.TZFree Type

Pascal

```
TZFree = procedure (opaque, block: Pointer);
```

C++

```
(opaque, block: Pointer) ( TZFree)();
```

File

ZLib

Description

This is type ZLib.TZFree.

88.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
_z_errmsg (see page 7932)	This is constant ZLib._z_errmsg.
SZInvalid (see page 7933)	This is constant ZLib.SZInvalid.
Z_ASCII (see page 7933)	This is constant ZLib.Z_ASCII.
Z_BEST_COMPRESSION (see page 7933)	This is constant ZLib.Z_BEST_COMPRESSION.
Z_BEST_SPEED (see page 7934)	This is constant ZLib.Z_BEST_SPEED.
Z_BINARY (see page 7934)	This is constant ZLib.Z_BINARY.
Z_BUF_ERROR (see page 7934)	This is constant ZLib.Z_BUF_ERROR.
Z_DATA_ERROR (see page 7935)	This is constant ZLib.Z_DATA_ERROR.
Z_DEFAULT_COMPRESSION (see page 7935)	This is constant ZLib.Z_DEFAULT_COMPRESSION.
Z_DEFAULT_STRATEGY (see page 7935)	This is constant ZLib.Z_DEFAULT_STRATEGY.
Z_DEFLATED (see page 7936)	This is constant ZLib.Z_DEFLATED.
Z_ERRNO (see page 7936)	This is constant ZLib.Z_ERRNO.
Z_FILTERED (see page 7936)	This is constant ZLib.Z_FILTERED.
Z_FINISH (see page 7937)	This is constant ZLib.Z_FINISH.
Z_FULL_FLUSH (see page 7937)	This is constant ZLib.Z_FULL_FLUSH.
Z_HUFFMAN_ONLY (see page 7937)	This is constant ZLib.Z_HUFFMAN_ONLY.
Z_MEM_ERROR (see page 7938)	This is constant ZLib.Z_MEM_ERROR.
Z_NEED_DICT (see page 7938)	This is constant ZLib.Z_NEED_DICT.
Z_NO_COMPRESSION (see page 7938)	This is constant ZLib.Z_NO_COMPRESSION.
Z_NO_FLUSH (see page 7939)	This is constant ZLib.Z_NO_FLUSH.
Z_OK (see page 7939)	This is constant ZLib.Z_OK.
Z_PARTIAL_FLUSH (see page 7939)	This is constant ZLib.Z_PARTIAL_FLUSH.
Z_STREAM_END (see page 7940)	This is constant ZLib.Z_STREAM_END.
Z_STREAM_ERROR (see page 7940)	This is constant ZLib.Z_STREAM_ERROR.
Z_SYNC_FLUSH (see page 7940)	This is constant ZLib.Z_SYNC_FLUSH.
Z_UNKNOWN (see page 7941)	This is constant ZLib.Z_UNKNOWN.
Z_VERSION_ERROR (see page 7941)	This is constant ZLib.Z_VERSION_ERROR.
ZLevels (see page 7941)	This is constant ZLib.ZLevels.
ZLIB_VERSION (see page 7942)	This is constant ZLib.ZLIB_VERSION.

88.5.1 ZLib._z_errmsg Constant

Pascal

```
_z_errmsg: array[0..9] of PChar = ( 'need dictionary', 'stream end', '', 'file error', 'stream
error', 'data error', 'insufficient memory', 'buffer error', 'incompatible version', '' );
```

C++

```
array[0..9] of PChar _z_errmsg = ( 'need dictionary', 'stream end', '', 'file error', 'stream
error', 'data error', 'insufficient memory', 'buffer error', 'incompatible version', '' );
```

File

ZLib

Description

This is constant ZLib._z_errmsg.

88.5.2 ZLib.SZInvalid Constant

Pascal

```
SZInvalid = 'Invalid ZStream operation!';
```

C++

```
SZInvalid = 'Invalid ZStream operation!';
```

File

ZLib

Description

This is constant ZLib.SZInvalid.

88.5.3 ZLib.Z_ASCII Constant

Pascal

```
Z_ASCII = 1;
```

C++

```
Z_ASCII = 1;
```

File

ZLib

Description

This is constant ZLib.Z_ASCII.

88.5.4 ZLib.Z_BEST_COMPRESSION Constant

Pascal

```
Z_BEST_COMPRESSION = 9;
```

C++

```
Z_BEST_COMPRESSION = 9;
```

File

ZLib

Description

This is constant ZLib.Z_BEST_COMPRESSION.

88.5.5 ZLib.Z_BEST_SPEED Constant

Pascal

```
Z_BEST_SPEED = 1;
```

C++

```
Z_BEST_SPEED = 1;
```

File

ZLib

Description

This is constant ZLib.Z_BEST_SPEED.

88.5.6 ZLib.Z_BINARY Constant

Pascal

```
Z_BINARY = 0;
```

C++

```
Z_BINARY = 0;
```

File

ZLib

Description

This is constant ZLib.Z_BINARY.

88.5.7 ZLib.Z_BUF_ERROR Constant

Pascal

```
Z_BUF_ERROR = (-5);
```

C++

```
Z_BUF_ERROR = (-5);
```

File

ZLib

Description

This is constant ZLib.Z_BUF_ERROR.

88.5.8 ZLib.Z_DATA_ERROR Constant

Pascal

```
Z_DATA_ERROR = (-3);
```

C++

```
Z_DATA_ERROR = (-3);
```

File

ZLib

Description

This is constant ZLib.Z_DATA_ERROR.

88.5.9 ZLib.Z_DEFAULT_COMPRESSION Constant

Pascal

```
Z_DEFAULT_COMPRESSION = (-1);
```

C++

```
Z_DEFAULT_COMPRESSION = (-1);
```

File

ZLib

Description

This is constant ZLib.Z_DEFAULT_COMPRESSION.

88.5.10 ZLib.Z_DEFAULT_STRATEGY Constant

Pascal

```
Z_DEFAULT_STRATEGY = 0;
```

C++

```
Z_DEFAULT_STRATEGY = 0;
```

File

ZLib

Description

This is constant ZLib.Z_DEFAULT_STRATEGY.

88.5.11 ZLib.Z_DEFLATED Constant

Pascal

```
Z_DEFLATED = 8;
```

C++

```
Z_DEFLATED = 8;
```

File

ZLib

Description

This is constant ZLib.Z_DEFLATED.

88.5.12 ZLib.Z_ERRNO Constant

Pascal

```
Z_ERRNO = (-1);
```

C++

```
Z_ERRNO = (-1);
```

File

ZLib

Description

This is constant ZLib.Z_ERRNO.

88.5.13 ZLib.Z_FILTERED Constant

Pascal

```
Z_FILTERED = 1;
```

C++

```
Z_FILTERED = 1;
```

File

ZLib

Description

This is constant ZLib.Z_FILTERED.

88.5.14 ZLib.Z_FINISH Constant

Pascal

```
Z_FINISH = 4;
```

C++

```
Z_FINISH = 4;
```

File

ZLib

Description

This is constant ZLib.Z_FINISH.

88.5.15 ZLib.Z_FULL_FLUSH Constant

Pascal

```
Z_FULL_FLUSH = 3;
```

C++

```
Z_FULL_FLUSH = 3;
```

File

ZLib

Description

This is constant ZLib.Z_FULL_FLUSH.

88.5.16 ZLib.Z_HUFFMAN_ONLY Constant

Pascal

```
Z_HUFFMAN_ONLY = 2;
```

C++

```
Z_HUFFMAN_ONLY = 2;
```

File

ZLib

Description

This is constant ZLib.Z_HUFFMAN_ONLY.

88.5.17 ZLib.Z_MEM_ERROR Constant

Pascal

```
Z_MEM_ERROR = (-4);
```

C++

```
Z_MEM_ERROR = (-4);
```

File

ZLib

Description

This is constant ZLib.Z_MEM_ERROR.

88.5.18 ZLib.Z_NEED_DICT Constant

Pascal

```
Z_NEED_DICT = 2;
```

C++

```
Z_NEED_DICT = 2;
```

File

ZLib

Description

This is constant ZLib.Z_NEED_DICT.

88.5.19 ZLib.Z_NO_COMPRESSION Constant

Pascal

```
Z_NO_COMPRESSION = 0;
```

C++

```
Z_NO_COMPRESSION = 0;
```

File

ZLib

Description

This is constant ZLib.Z_NO_COMPRESSION.

88.5.20 ZLib.Z_NO_FLUSH Constant

Pascal

```
Z_NO_FLUSH = 0;
```

C++

```
Z_NO_FLUSH = 0;
```

File

ZLib

Description

This is constant ZLib.Z_NO_FLUSH.

88.5.21 ZLib.Z_OK Constant

Pascal

```
Z_OK = 0;
```

C++

```
Z_OK = 0;
```

File

ZLib

Description

This is constant ZLib.Z_OK.

88.5.22 ZLib.Z_PARTIAL_FLUSH Constant

Pascal

```
Z_PARTIAL_FLUSH = 1;
```

C++

```
Z_PARTIAL_FLUSH = 1;
```

File

ZLib

Description

This is constant ZLib.Z_PARTIAL_FLUSH.

88.5.23 ZLib.Z_STREAM_END Constant

Pascal

```
Z_STREAM_END = 1;
```

C++

```
Z_STREAM_END = 1;
```

File

ZLib

Description

This is constant ZLib.Z_STREAM_END.

88.5.24 ZLib.Z_STREAM_ERROR Constant

Pascal

```
Z_STREAM_ERROR = (-2);
```

C++

```
Z_STREAM_ERROR = (-2);
```

File

ZLib

Description

This is constant ZLib.Z_STREAM_ERROR.

88.5.25 ZLib.Z_SYNC_FLUSH Constant

Pascal

```
Z_SYNC_FLUSH = 2;
```

C++

```
Z_SYNC_FLUSH = 2;
```

File

ZLib

Description

This is constant ZLib.Z_SYNC_FLUSH.

88.5.26 ZLib.Z_UNKNOWN Constant

Pascal

```
Z_UNKNOWN = 2;
```

C++

```
Z_UNKNOWN = 2;
```

File

ZLib

Description

This is constant ZLib.Z_UNKNOWN.

88.5.27 ZLib.Z_VERSION_ERROR Constant

Pascal

```
Z_VERSION_ERROR = (-6);
```

C++

```
Z_VERSION_ERROR = (-6);
```

File

ZLib

Description

This is constant ZLib.Z_VERSION_ERROR.

88.5.28 ZLib.ZLevels Constant

Pascal

```
ZLevels: array[TZCompressionLevel] of Shortint = ( Z_NO_COMPRESSION, Z_BEST_SPEED,
Z_DEFAULT_COMPRESSION, Z_BEST_COMPRESSION );
```

C++

```
array[TZCompressionLevel] of Shortint ZLevels = ( Z_NO_COMPRESSION, Z_BEST_SPEED,
Z_DEFAULT_COMPRESSION, Z_BEST_COMPRESSION );
```

File

ZLib

Description

This is constant ZLib.ZLevels.

88.5.29 ZLib.ZLIB_VERSION Constant

Pascal

```
ZLIB_VERSION = '1.2.3';
```

C++

```
ZLIB_VERSION = '1.2.3';
```

File

ZLib

Description

This is constant ZLib.ZLIB_VERSION.

SysUtils.FormatBuf function 4193
SysUtils.FormatCurr 4194
SysUtils.FormatCurr function 4194
SysUtils.FormatDateTime 4195
SysUtils.FormatDateTime function 4195
SysUtils.FormatFloat 4197
SysUtils.FormatFloat function 4197
SysUtils.FreeAndNil 4201
SysUtils.FreeAndNil function 4201
SysUtils.GDAL 4202
SysUtils.GDAL function 4202
SysUtils.GetCurrentDir 4202
SysUtils.GetCurrentDir function 4202
SysUtils.GetDiskFreeSpaceEx 4353
SysUtils.GetDiskFreeSpaceEx variable 4353
SysUtils.GetEnvironmentVariable 4204
SysUtils.GetEnvironmentVariable function 4204
SysUtils.GetFileVersion 4205
SysUtils.GetFileVersion function 4205
SysUtils.GetFormatSettings 4206
SysUtils.GetFormatSettings function 4206
SysUtils.GetLocaleChar 4206
SysUtils.GetLocaleChar function 4206
SysUtils.GetLocaleFormatSettings 4206

SysUtils.GetLocaleFormatSettings function 4206
SysUtils.GetLocaleStr 4207
SysUtils.GetLocaleStr function 4207
SysUtils.GetModuleName 4207
SysUtils.GetModuleName function 4207
SysUtils.GetPackageDescription 4208
SysUtils.GetPackageDescription function 4208
SysUtils.GetPackageInfo 4209
SysUtils.GetPackageInfo function 4209
SysUtils.GetTime 4209
SysUtils.GetTime function 4209
SysUtils.GUIDToString 4210
SysUtils.GUIDToString function 4210
SysUtils.HashName 4212
SysUtils.HashName function 4212
SysUtils.HexDisplayPrefix 4353
SysUtils.HexDisplayPrefix variable 4353
SysUtils.HoursPerDay 4382
SysUtils.HoursPerDay constant 4382
SysUtils.IncAMonth 4212
SysUtils.IncAMonth function 4212
SysUtils.IncludeTrailingBackslash 4213
SysUtils.IncludeTrailingBackslash function 4213
SysUtils.IncludeTrailingPathDelimiter 4213
SysUtils.IncludeTrailingPathDelimiter function 4213
SysUtils.IncMonth 4214
SysUtils.IncMonth function 4214
SysUtils.InitializePackage 4215
SysUtils.InitializePackage function 4215
SysUtils.Int64Rec 4320
SysUtils.Int64Rec record 4320
SysUtils.IntToHex 4215
SysUtils.IntToHex function 4215
SysUtils.IntToStr 4216
SysUtils.IntToStr function 4216
SysUtils.IReadWriteSync 4037
SysUtils.IReadWriteSync.BeginRead 4038
SysUtils.IReadWriteSync.BeginWrite 4038
SysUtils.IReadWriteSync.EndRead 4038
SysUtils.IReadWriteSync.EndWrite 4038
SysUtils.IsAssembly 4217
SysUtils.IsAssembly function 4217
SysUtils.IsDelimiter 4218
SysUtils.IsDelimiter function 4218
SysUtils.IsEqualGUID 4218
SysUtils.IsEqualGUID function 4218
SysUtils.IsLeadChar 4220
SysUtils.IsLeadChar function 4220
SysUtils.IsLeapYear 4220
SysUtils.IsLeapYear function 4220
SysUtils.IsPathDelimiter 4222
SysUtils.IsPathDelimiter function 4222
SysUtils.IsValidIdent 4222
SysUtils.IsValidIdent function 4222
SysUtils.Languages 4223
SysUtils.Languages function 4223
SysUtils.LastDelimiter 4223
SysUtils.LastDelimiter function 4223
SysUtils.LeadBytes 4354
SysUtils.LeadBytes variable 4354
SysUtils.ListSeparator 4354
SysUtils.ListSeparator variable 4354
SysUtils.LoadPackage 4224
SysUtils.LoadPackage function 4224
SysUtils.LoadStr 4224
SysUtils.LoadStr function 4224
SysUtils.LongDateFormat 4354
SysUtils.LongDateFormat variable 4354
SysUtils.LongDayNames 4355
SysUtils.LongDayNames variable 4355
SysUtils.LongMonthNames 4355
SysUtils.LongMonthNames variable 4355
SysUtils.LongRec 4321
SysUtils.LongRec record 4321
SysUtils.LongTimeFormat 4356
SysUtils.LongTimeFormat variable 4356
SysUtils.LowerCase 4225
SysUtils.LowerCase function 4225

SysUtils.MaxCurrency 4383
SysUtils.MaxCurrency constant 4383
SysUtils.MaxDateTime 4383
SysUtils.MaxDateTime constant 4383
SysUtils.MaxEraCount 4384
SysUtils.MaxEraCount constant 4384
SysUtils.MinCurrency 4384
SysUtils.MinCurrency constant 4384
SysUtils.MinDateTime 4384
SysUtils.MinDateTime constant 4384
SysUtils.MinsPerDay 4385
SysUtils.MinsPerDay constant 4385
SysUtils.MinsPerHour 4386
SysUtils.MinsPerHour constant 4386
SysUtils.MonthDays 4386
SysUtils.MonthDays constant 4386
SysUtils.MSecsPerDay 4387
SysUtils.MSecsPerDay constant 4387
SysUtils.MSecsPerSec 4387
SysUtils.MSecsPerSec constant 4387
SysUtils.MSecsToTimeStamp 4226
SysUtils.MSecsToTimeStamp function 4226
SysUtils.NegCurrFormat 4356
SysUtils.NegCurrFormat variable 4356
SysUtils.NewStr 4227
SysUtils.NewStr function 4227
SysUtils.NextCharIndex 4227
SysUtils.NextCharIndex function 4227
SysUtils.Now 4227
SysUtils.Now function 4227
SysUtils.NullAnsiStr 4357
SysUtils.NullAnsiStr variable 4357
SysUtils.NullStr 4357
SysUtils.NullStr variable 4357
SysUtils.NullWideStr 4358
SysUtils.NullWideStr variable 4358
SysUtils.OutOfMemoryError 4228
SysUtils.OutOfMemoryError function 4228
SysUtils.PathDelim 4388
SysUtils.PathDelim constant 4388
SysUtils.PathSep 4388
SysUtils.PathSep constant 4388
SysUtils.PByteArray 4337
SysUtils.PByteArray type 4337
SysUtils.PDayTable 4337
SysUtils.PDayTable type 4337
SysUtils.PExceptionRecord 4338
SysUtils.PExceptionRecord type 4338
SysUtils.pfBCB4Produced 4389
SysUtils.pfBCB4Produced constant 4389
SysUtils.pfConsumerBCB 4389
SysUtils.pfConsumerBCB constant 4389
SysUtils.pfConsumerCompat 4390
SysUtils.pfConsumerCompat constant 4390
SysUtils.pfConsumerDelphi 4390
SysUtils.pfConsumerDelphi constant 4390
SysUtils.pfConsumerMask 4391
SysUtils.pfConsumerMask constant 4391
SysUtils.pfDelphi4Produced 4391
SysUtils.pfDelphi4Produced constant 4391
SysUtils.pfDesignOnly 4392
SysUtils.pfDesignOnly constant 4392
SysUtils.pfExeModule 4392
SysUtils.pfExeModule constant 4392
SysUtils.pfIgnoreDupUnits 4392
SysUtils.pfIgnoreDupUnits constant 4392
SysUtils.pfLibraryModule 4393
SysUtils.pfLibraryModule constant 4393
SysUtils.pfModuleTypeMask 4393
SysUtils.pfModuleTypeMask constant 4393
SysUtils.pfNeverBuild 4394
SysUtils.pfNeverBuild constant 4394
SysUtils.pfPackageModule 4394
SysUtils.pfPackageModule constant 4394
SysUtils.pfProducerMask 4395
SysUtils.pfProducerMask constant 4395

SysUtils.pfRunOnly constant 4396
SysUtils.pfV3Produced 4396
SysUtils.pfV3Produced constant 4396
SysUtils.PlatformBytesOf 4229
SysUtils.PlatformBytesOf function 4229
SysUtils.PlatformStringOf 4229
SysUtils.PlatformStringOf function 4229
SysUtils.PThreadInfo 4338
SysUtils.PThreadInfo type 4338
SysUtils.PWordArray 4338
SysUtils.PWordArray type 4338
SysUtils.QuotedStr 4229
SysUtils.QuotedStr function 4229
SysUtils.RaiseLastOSError 4230
SysUtils.RaiseLastOSError function 4230
SysUtils.RaiseLastWin32Error 4231
SysUtils.RaiseLastWin32Error function 4231
SysUtils.RCS 4232
SysUtils.RCS function 4232
SysUtils.RemoveDir 4232
SysUtils.RemoveDir function 4232
SysUtils.RenameFile 4233
SysUtils.RenameFile function 4233
SysUtils.ReplaceDate 4236
SysUtils.ReplaceDate function 4236
SysUtils.ReplaceTime 4236
SysUtils.ReplaceTime function 4236
SysUtils.RPR 4237
SysUtils.RPR function 4237
SysUtils.SafeLoadLibrary 4238
SysUtils.SafeLoadLibrary function 4238
SysUtils.SameFileName 4238
SysUtils.SameFileName function 4238
SysUtils.SameStr 4239
SysUtils.SameStr function 4239
SysUtils.SameText 4239
SysUtils.SameText function 4239
SysUtils.SecsPerDay 4397
SysUtils.SecsPerDay constant 4397
SysUtils.SecsPerHour 4397
SysUtils.SecsPerHour constant 4397
SysUtils.SecsPerMin 4398
SysUtils.SecsPerMin constant 4398
SysUtils.SetCurrentDir 4240
SysUtils.SetCurrentDir function 4240
SysUtils.ShortDateFormat 4358
SysUtils.ShortDateFormat variable 4358
SysUtils.ShortDayNames 4359
SysUtils.ShortDayNames variable 4359
SysUtils.ShortMonthNames 4359
SysUtils.ShortMonthNames variable 4359
SysUtils.ShortTimeFormat 4360
SysUtils.ShortTimeFormat variable 4360
SysUtils.ShowException 4240
SysUtils.ShowException function 4240
SysUtils.Sleep 4241
SysUtils.Sleep function 4241
SysUtils.StrAlloc 4241
SysUtils.StrAlloc function 4241
SysUtils.StrBufSize 4242
SysUtils.StrBufSize function 4242
SysUtils.StrByteType 4242
SysUtils.StrByteType function 4242
SysUtils.StrCat 4243
SysUtils.StrCat function 4243
SysUtils.StrCharLength 4244
SysUtils.StrCharLength function 4244
SysUtils.StrComp 4244
SysUtils.StrComp function 4244
SysUtils.StrCopy 4246
SysUtils.StrCopy function 4246
SysUtils.StrDispose 4247
SysUtils.StrDispose function 4247
SysUtils.StrECopy 4248
SysUtils.StrECopy function 4248
SysUtils.StrEnd 4249
SysUtils.StrEnd function 4249

SysUtils.StrFmt 4250
SysUtils.StrFmt function 4250
SysUtils.StrIComp 4251
SysUtils.StrIComp function 4251
SysUtils.StringOf 4253
SysUtils.StringOf function 4253
SysUtils.StringReplace 4253
SysUtils.StringReplace function 4253
SysUtils.StringToGUID 4254
SysUtils.StringToGUID function 4254
SysUtils.StrLCat 4255
SysUtils.StrLCat function 4255
SysUtils.StrLComp 4257
SysUtils.StrLComp function 4257
SysUtils.StrLCopy 4258
SysUtils.StrLCopy function 4258
SysUtils.StrLen 4260
SysUtils.StrLen function 4260
SysUtils.StrLFmt 4261
SysUtils.StrLFmt function 4261
SysUtils.StrLIComp 4262
SysUtils.StrLIComp function 4262
SysUtils.StrLower 4264
SysUtils.StrLower function 4264
SysUtils.StrMove 4265
SysUtils.StrMove function 4265
SysUtils.StrNew 4266
SysUtils.StrNew function 4266
SysUtils.StrNextChar 4268
SysUtils.StrNextChar function 4268
SysUtils.StrPas 4268, 4269
SysUtils.StrPas function 4268, 4269
SysUtils.StrPCopy 4271
SysUtils.StrPCopy function 4271
SysUtils.StrPLCopy 4272
SysUtils.StrPLCopy function 4272
SysUtils.StrPos 4272, 4273
SysUtils.StrPos function 4272, 4273
SysUtils.StrRScan 4274
SysUtils.StrRScan function 4274
SysUtils.StrScan 4275
SysUtils.StrScan function 4275
SysUtils.StrToBool 4276
SysUtils.StrToBool function 4276
SysUtils.StrToBoolDef 4277
SysUtils.StrToBoolDef function 4277
SysUtils.StrToCurr 4278
SysUtils.StrToCurr function 4278
SysUtils.StrToCurrDef 4278
SysUtils.StrToCurrDef function 4278
SysUtils.StrToDate 4279
SysUtils.StrToDate function 4279
SysUtils.StrToDateDef 4280
SysUtils.StrToDateDef function 4280
SysUtils.StrToDateTime 4281
SysUtils.StrToDateTime function 4281
SysUtils.StrToDateTimeDef 4282
SysUtils.StrToDateTimeDef function 4282
SysUtils.StrToFloat 4282
SysUtils.StrToFloat function 4282
SysUtils.StrToFloatDef 4286
SysUtils.StrToFloatDef function 4286
SysUtils.StrToInt 4286
SysUtils.StrToInt function 4286
SysUtils.StrToInt64 4287
SysUtils.StrToInt64 function 4287
SysUtils.StrToInt64Def 4288
SysUtils.StrToInt64Def function 4288
SysUtils.StrToIntDef 4288
SysUtils.StrToIntDef function 4288
SysUtils.StrToTime 4291
SysUtils.StrToTime function 4291
SysUtils.StrToTimeDef 4292
SysUtils.StrToTimeDef function 4292
SysUtils.StrUpper 4292
SysUtils.StrUpper function 4292
SysUtils.Supports 4294
SysUtils.Supports function 4294

SysUtils.SwitchChars 4398
SysUtils.SwitchChars constant 4398
SysUtils.SysErrorMessage 4294
SysUtils.SysErrorMessage function 4294
SysUtils.SysLocale 4360
SysUtils.SysLocale variable 4360
SysUtils.SystemTimeToDateTime 4295
SysUtils.SystemTimeToDateTime function 4295
SysUtils.TBigEndianUnicodeEncoding 3967
SysUtils.TBigEndianUnicodeEncoding.GetBytes 3968
SysUtils.TBigEndianUnicodeEncoding.GetChars 3969
