
File

SysUtils

Description

The TWordArray type declares a static array of Words. The array size is 16,384 (2**14) elements.

Note: Static arrays are declared with an immutable size.

37.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CurrencyDecimals (see page 4348)	CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.
CurrencyFormat (see page 4348)	CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 \| 1 = 1$ | 2 = $ 1 | 3 = 1 $
CurrencyString (see page 4349)	CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.
DateSeparator (see page 4349)	DateSeparator is the character used to separate the year, month, and day parts of a date value.
DecimalSeparator (see page 4350)	DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.
EmptyAnsiStr (see page 4351)	This is variable SysUtils.EmptyAnsiStr.
EmptyStr (see page 4351)	An empty string constant.
EmptyWideStr (see page 4351)	An empty string version of the WideString (see page 3467) constant.
EraNames (see page 4352)	Defines the names of calendar eras for East Asian locales.
EraYearOffsets (see page 4352)	Controls the DateTimeToStr (see page 4089) function (for East Asian locales).
FalseBoolStrs (see page 4352)	Lists strings that can represent the boolean value false.
GetDiskFreeSpaceEx (see page 4353)	This is variable SysUtils.GetDiskFreeSpaceEx.
HexDisplayPrefix (see page 4353)	HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.
LeadBytes (see page 4354)	Lists all values that can be the first byte of a double byte character on the local system.
ListSeparator (see page 4354)	The character used to separate items in a list.
LongDateFormat (see page 4354)	LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.
LongDayNames (see page 4355)	LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a long day name to be substituted.
LongMonthNames (see page 4355)	LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a long month name to be substituted.
LongTimeFormat (see page 4356)	LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.
NegCurrFormat (see page 4356)	NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.
NullAnsiStr (see page 4357)	This is variable SysUtils.NullAnsiStr.
NullStr (see page 4357)	A pointer to an empty string.
NullWideStr (see page 4358)	A pointer to an empty wide string.
ShortDateFormat (see page 4358)	ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.
ShortDayNames (see page 4359)	ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a short day name to be substituted.
ShortMonthNames (see page 4359)	ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a short month name to be substituted.
ShortTimeFormat (see page 4360)	ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.
SysLocale (see page 4360)	SysLocale holds locale information.
ThousandSeparator (see page 4362)	ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.

TimeAMString (see page 4362)	TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.
TimePMString (see page 4362)	TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.
TimeSeparator (see page 4363)	TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.
TrueBoolStrs (see page 4363)	Lists strings that can represent the boolean value false.
TwoDigitYearCenturyWindow (see page 4364)	Determines what century is added to two-digit years when string dates are converted to numeric dates.
Win32BuildNumber (see page 4364)	Specifies which the build level of the Windows Operating System (see page 3159) operating.
Win32CSDVersion (see page 4365)	Specifies the Win32 latest installed service pack.
Win32MajorVersion (see page 4365)	Specifies which major Windows Operating System (see page 3159) version is operating.
Win32MinorVersion (see page 4366)	Specifies which minor Windows Operating System (see page 3159) version is operating.
Win32Platform (see page 4366)	Specifies the Windows Operating System (see page 3159) platform identifier.

37.6.1 SysUtils.CurrencyDecimals Variable

CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.

Pascal

```
CurrencyDecimals: Byte;
```

C++

```
Byte CurrencyDecimals;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_ICURRDIGITS.

37.6.2 SysUtils.CurrencyFormat Variable

CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 | 1 = 1$ | 2 = $ 1 | 3 = 1 $

Pascal

```
CurrencyFormat: Byte;
```

C++

```
Byte CurrencyFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_ICURRENCY.

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DateSeparator = '-';
  ShortDateFormat = "m/d/yyyy";
  Label1->Caption = DateToStr(Date());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DateSeparator := '-';
  ShortDateFormat := 'm/d/yyyy';
  Label1.Caption := DateToStr(Date);
end;
```

37.6.3 SysUtils.CurrencyString Variable

CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.

Pascal

```
CurrencyString: string;
```

C++

```
UnicodeString CurrencyString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SCURRENCY.

37.6.4 SysUtils.DateSeparator Variable

DateSeparator is the character used to separate the year, month, and day parts of a date value.

Pascal

```
DateSeparator: Char;
```

C++

```
Char DateSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SDATE.

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DateSeparator = '-';
  ShortDateFormat = "m/d/yyyy";
  Label1->Caption = DateToStr(Date());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DateSeparator := '-';
  ShortDateFormat := 'm/d/yyyy';
  Label1.Caption := DateToStr(Date);
end;
```

37.6.5 SysUtils.DecimalSeparator Variable

DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.

Pascal

```
DecimalSeparator: Char;
```

C++

```
Char DecimalSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SDECIMAL.

37.6.6 SysUtils.EmptyAnsiStr Variable

Pascal

```
EmptyAnsiStr: AnsiString = '';
```

C++

```
AnsiString EmptyAnsiStr = '';
```

File

SysUtils

Description

This is variable SysUtils.EmptyAnsiStr.

37.6.7 SysUtils.EmptyStr Variable

An empty string constant.

Pascal

```
EmptyStr: string = '';
```

C++

```
UnicodeString EmptyStr = '';
```

File

SysUtils

Description

Included for backward compatibility only.

37.6.8 SysUtils.EmptyWideStr Variable

An empty string version of the WideString (see page 3467) constant.

Pascal

```
EmptyWideStr: WideString = '';
```

C++

```
BSTR EmptyWideStr = '';
```

File

SysUtils

Description

Included for backward compatibility only.

37.6.9 SysUtils.EraNames Variable

Defines the names of calendar eras for East Asian locales.

Pascal

```
EraNames: array [1..MaxEraCount] of string;
```

C++

```
array [1..MaxEraCount] of string EraNames;
```

File

SysUtils

Description

EraNames defines an array of 7 era names for Japanese and Taiwanese locales. It is principally used for date formatting.

See Also

FormatDateTime (see page 4195)

DateTimeToString (see page 4089)

37.6.10 SysUtils.EraYearOffsets Variable

Controls the DateTimeToStr (see page 4089) function (for East Asian locales).

Pascal

```
EraYearOffsets: array [1..MaxEraCount] of Integer;
```

C++

```
array [1..MaxEraCount] of Integer EraYearOffsets;
```

File

SysUtils

37.6.11 SysUtils.FalseBoolStrs Variable

Lists strings that can represent the boolean value false.

Pascal

```
FalseBoolStrs: array of String;
```

C++

```
array of String FalseBoolStrs;
```

File

SysUtils

Description

FalseBoolStrs is an array of strings that are used in conversions between Boolean values and strings.

When using the BoolToStr (see page 4066) function, false values are converted to the first string in the list.

When using the StrToBool (see page 4276) function, any string found in the list, regardless of case, is converted to false. If no string match is found, TrueBoolStrs (see page 4363) is checked, true being returned if a match is found. No matches result in the EConvertError (see page 3919) exception being thrown.

See Also

StrToBool (see page 4276)

TryStrToBool (see page 4305)

TrueBoolStrs (see page 4363)

BoolToStr (see page 4066)

37.6.12 SysUtils.GetDiskFreeSpaceEx Variable

Pascal

```
GetDiskFreeSpaceEx: function (Directory: PChar; var FreeAvailable, TotalSpace: TLargeInteger;
TotalFree: PLargeInteger): Bool stdcall = nil;
```

C++

```
function (Directory: PChar; var FreeAvailable, TotalSpace: TLargeInteger; TotalFree:
PLargeInteger): Bool stdcall GetDiskFreeSpaceEx = nil;
```

File

SysUtils

Description

This is variable SysUtils.GetDiskFreeSpaceEx.

37.6.13 SysUtils.HexDisplayPrefix Variable

HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.

Pascal

```
HexDisplayPrefix: string = '$';
```

C++

```
UnicodeString HexDisplayPrefix = '$';
```

File

SysUtils

Description

This is for display only - this does not affect the string-to-integer conversion routines.

37.6.14 SysUtils.LeadBytes Variable

Lists all values that can be the first byte of a double byte character on the local system.

Pascal

```
LeadBytes: set of AnsiChar = [];
```

C++

```
set of AnsiChar LeadBytes = [];
```

File

SysUtils

Description

Use LeadBytes to test whether a value can represent the lead byte in a double byte character. If an individual value is in the LeadBytes set, it is not necessarily used as the lead byte of a double byte character. It may also appear as the second byte of a double byte character. To determine whether the character is used as a lead byte, use the global ByteType (see page 4070) or StrByteType (see page 4242) function.

Note: LeadBytes is always empty when running on a system with a locale that does not use a multi byte character system (MBCS).

See Also

ByteType (see page 4070)

StrByteType (see page 4242)

37.6.15 SysUtils.ListSeparator Variable

The character used to separate items in a list.

Pascal

```
ListSeparator: Char;
```

C++

```
Char ListSeparator;
```

File

SysUtils

Description

On Windows, the default value is fetched from LOCALE_SLIST.

37.6.16 SysUtils.LongDateFormat Variable

LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.

Pascal

```
LongDateFormat: string;
```

C++

```
UnicodeString LongDateFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SLONGDATE.

37.6.17 SysUtils.LongDayNames Variable

LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a long day name to be substituted.

Pascal

```
LongDayNames: array[1..7] of string;
```

C++

```
array[1..7] of string LongDayNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SDAYNAME system locale entries.

37.6.18 SysUtils.LongMonthNames Variable

LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a long month name to be substituted.

Pascal

```
LongMonthNames: array[1..12] of string;
```

C++

```
array[1..12] of string LongMonthNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SMONTHNAME system locale entries.

37.6.19 SysUtils.LongTimeFormat Variable

LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.

Pascal

```
LongTimeFormat: string;
```

C++

```
UnicodeString LongTimeFormat;
```

File

SysUtils

Description

On Windows, the default value is computed from LOCALE_ITIME and LOCALE_ITLZERO.

37.6.20 SysUtils.NegCurrFormat Variable

NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.

Pascal

```
NegCurrFormat: Byte;
```

C++

```
Byte NegCurrFormat;
```

File

SysUtils

Description

Possible values are:

Value	Format (see page 4188)
0	($1)
1	-$1
2	$-1
3	$1-
4	(1$)
5	-1$
6	1-$
7	1$-
8	-1 $
9	-$ 1
10	1 $-
11	$ 1-

12	$ -1
13	1- $
14	($ 1)
15	(1 $)

On Windows, the initial value is fetched from LOCALE_INEGCURR.

37.6.21 SysUtils.NullAnsiStr Variable

Pascal

```
NullAnsiStr: PAnsiString = @EmptyAnsiStr;
```

C++

```
PAnsiString NullAnsiStr = @EmptyAnsiStr;
```

File

SysUtils

Description

This is variable SysUtils.NullAnsiStr.

37.6.22 SysUtils.NullStr Variable

A pointer to an empty string.

Pascal

```
NullStr: PString = @EmptyStr;
```

C++

```
PString NullStr = @EmptyStr;
```

File

SysUtils

Description

NullStr defines a pointer to the empty string EmptyStr (see page 4351).

See Also

EmptyStr (see page 4351)

NullWideStr (see page 4358)

PString (see page 3776)

37.6.23 SysUtils.NullWideStr Variable

A pointer to an empty wide string.

Pascal

```
NullWideStr: PWideString = @EmptyWideStr;
```

C++

```
PWideString NullWideStr = @EmptyWideStr;
```

File

SysUtils

Description

NullWideStr defines a pointer to the empty wide string EmptyWideStr (see page 4351).

See Also

EmptyWideStr (see page 4351)

NullStr (see page 4357)

PWideString (see page 3782)

37.6.24 SysUtils.ShortDateFormat Variable

ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.

Pascal

```
ShortDateFormat: string;
```

C++

```
UnicodeString ShortDateFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SSHORTDATE.

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DateSeparator = '-';
  ShortDateFormat = "m/d/yyyy";
```

```
  Label1->Caption = DateToStr(Date());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date displays in the
caption of the label. Because some of the date variables are
assigned new values, the format of the date in the label
changes. For example, if the date is 9/15/94, the date
displays as 9-15-1994.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DateSeparator := '-';
  ShortDateFormat := 'm/d/yyyy';
  Label1.Caption := DateToStr(Date);
end;
```

37.6.25 SysUtils.ShortDayNames Variable

ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 4195) causes a short day name to be substituted.

Pascal

```
ShortDayNames: array[1..7] of string;
```

C++

```
array[1..7] of string ShortDayNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SABBREVDAYNAME system locale entries.

37.6.26 SysUtils.ShortMonthNames Variable

ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 4195) causes a short month name to be substituted.

Pascal

```
ShortMonthNames: array[1..12] of string;
```

C++

```
array[1..12] of string ShortMonthNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SABBREVMONTHNAME system locale entries.

37.6.27 SysUtils.ShortTimeFormat Variable

ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.

Pascal

```
ShortTimeFormat: string;
```

C++

```
UnicodeString ShortTimeFormat;
```

File

SysUtils

Description

On Windows, the default value is computed from LOCALE_ITIME and LOCALE_ITLZERO.

37.6.28 SysUtils.SysLocale Variable

SysLocale holds locale information.

Pascal

```
SysLocale: TSysLocale;
```

C++

```
TSysLocale SysLocale;
```

File

SysUtils

Description

The SysLocale holds the attributes of the current locale. The locale determines how dates and times are formatted, how items are alphabetically sorted, and how strings are compared.

The **DefaultLCID** field represents the locale identifier. This is a 32-bit value that specifies a default sort order and a default language identifier.

The **PirLangID** field specifies the primary type of the language identifier. This is one of the constants that identify a language group, such as **LANG_ENGLISH** or **LANG_FRENCH**.

The **SubLangID** field specifies the subtype of the language identifier. This is one of the constants that identify a language subgroup, such as **SUBLANG_ENGLISH_US** or **SUBLANG_FRENCH_CANADIAN**.

FarEast is true or nonzero if User32.dll supports DBCS; false or zero otherwise. In other words, **FarEast** is true or nonzero if the double-byte character-set (DBCS) version of User.exe is installed; false or zero otherwise.

MiddleEast is true if the system is enabled for Hebrew and Arabic languages; false otherwise.

C++ Examples:

```
/*
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
```

```
Regional and Language Options in the Windows Control Panel.
*/
void __fastcall TForm1::ApplicationEvents1SettingChange(TObject *Sender, int Flag, const
AnsiString Section, int &Result)
{
  Memo1->Lines->BeginUpdate();
  try
  {
//    char buffer[64];
    AnsiString buffer;
    buffer.sprintf("Section = %s", Section.c_str());
    Memo1->Lines->Add(buffer);
    buffer.sprintf("Flag = %8x", Flag);
    Memo1->Lines->Add(buffer);
    if (strcmp(Section.c_str(), "intl") == 0)
    {
      buffer.sprintf("DefaultLCID = %8x", SysLocale.DefaultLCID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("PriLangID = %8x", SysLocale.PriLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("SubLangID = %8x", SysLocale.SubLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("FarEast = %s", BoolToStr(SysLocale.FarEast, true));
      Memo1->Lines->Add(buffer);
      buffer.sprintf("MiddleEast = %s", BoolToStr(SysLocale.MiddleEast, true));
      Memo1->Lines->Add(buffer);
      Memo1->Lines->Add("");
    }
  }
  __finally
  {
    Memo1->Lines->EndUpdate();
  }
}
```

Delphi Examples:

```
{
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
Regional and Language Options in the Windows Control Panel.
}
procedure TForm1.ApplicationEvents1SettingChange(Sender: TObject; Flag: Integer; const
Section: string; var Result: Integer);
begin
  Memo1.Lines.BeginUpdate;
  try
    Memo1.Lines.Add(Format('Section  = %s', [Section]));
    Memo1.Lines.Add(Format('Flags  = %.8x', [Flag]));
    if AnsiSameStr(Section, 'intl') then
    with SysLocale do
    begin
      Memo1.Lines.Add(Format('DefaultLCID  = %.8x', [DefaultLCID]));
      Memo1.Lines.Add(Format('PriLangID  = %.8x', [PriLangID]));
      Memo1.Lines.Add(Format('SubLangID  = %.8x', [SubLangID]));
      Memo1.Lines.Add(Format('FarEast  = %s', [BoolToStr(FarEast, True)]));
      Memo1.Lines.Add(Format('MiddleEast  = %s', [BoolToStr(MiddleEast, True)]));
    end;
    Memo1.Lines.Add('');
  finally
    Memo1.Lines.EndUpdate;
  end;
//  Result:= 0;
end;
```

See Also

TSysLocale (see page 4333)

Languages (see page 4223)

37.6.29 SysUtils.ThousandSeparator Variable

ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.

Pascal

```
ThousandSeparator: Char;
```

C++

```
Char ThousandSeparator;
```

File

SysUtils

Description

A value of #0 indicates that no thousand separator character should be output, even if the format string specifies it.

On Windows, the initial value is fetched from LOCALE_STHOUSAND.

37.6.30 SysUtils.TimeAMString Variable

TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.

Pascal

```
TimeAMString: string;
```

C++

```
UnicodeString TimeAMString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_S1159.

37.6.31 SysUtils.TimePMString Variable

TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.

Pascal

```
TimePMString: string;
```

C++

```
UnicodeString TimePMString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_S2359.

37.6.32 SysUtils.TimeSeparator Variable

TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.

Pascal

```
TimeSeparator: Char;
```

C++

```
Char TimeSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_STIME.

37.6.33 SysUtils.TrueBoolStrs Variable

Lists strings that can represent the boolean value false.

Pascal

```
TrueBoolStrs: array of String;
```

C++

```
array of String TrueBoolStrs;
```

File

SysUtils

Description

TrueBoolStrs is an array of strings that are used in conversions between Boolean values and strings.

When using the BoolToStr (see page 4066) function, false values are converted to the first string in the list.

When using the StrToBool (see page 4276) function, any string found in the list, regardless of case, is converted to true. If no string match is found, FalseBoolStrs (see page 4352) is checked, false being returned if a match is found. No matches result in the EConvertError (see page 3919) exception being thrown.

See Also

StrToBool (see page 4276)

TryStrToBool (see page 4305)

FalseBoolStrs (see page 4352)

BoolToStr (see page 4066)

37.6.34 SysUtils.TwoDigitYearCenturyWindow Variable

Determines what century is added to two-digit years when string dates are converted to numeric dates.

Pascal

```
TwoDigitYearCenturyWindow: Word = 50;
```

C++

```
Word TwoDigitYearCenturyWindow = 50;
```

File

SysUtils

Description

The value of TwoDigitYearCenturyWindow, if it is nonzero, is subtracted from the current year to calculate the floating "pivot" prior to which two-digit years are interpreted as falling in the next century. The default value is 50. The table below shows some examples.

37.6.35 SysUtils.Win32BuildNumber Variable

Specifies which the build level of the Windows Operating System (see page 3159) operating.

Pascal

```
Win32BuildNumber: Integer = 0;
```

C++

```
int Win32BuildNumber = 0;
```

File

SysUtils

Description

Win32BuildNumber specifies the build number of the Operating System (see page 3159). The unique identifier for a Windows Operating System (see page 3159) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber

Note: Win32BuildNumber is available on Windows only.

See Also

Win32CSDVersion (see page 4365)

Win32MinorVersion (see page 4366)

Win32MajorVersion (see page 4365)

Win32Platform (see page 4366)

37.6.36 SysUtils.Win32CSDVersion Variable

Specifies the Win32 latest installed service pack.

Pascal

```
Win32CSDVersion: string = '';
```

C++

```
UnicodeString Win32CSDVersion = '';
```

File

SysUtils

Description

Win32CSDVersion specifies the name of the most recent service pack.

Note: Win32CSDVersion is available on Windows only.

See Also

Win32BuildNumber (see page 4364)

Win32MajorVersion (see page 4365)

Win32MinorVersion (see page 4366)

Win32Platform (see page 4366)

37.6.37 SysUtils.Win32MajorVersion Variable

Specifies which major Windows Operating System (see page 3159) version is operating.

Pascal

```
Win32MajorVersion: Integer = 0;
```

C++

```
int Win32MajorVersion = 0;
```

File

SysUtils

Description

Win32MajorVersion specifies the Major version of the Operating System (see page 3159). The unique identifier for a Windows Operating System (see page 3159) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber (see page 4364)

Note: Win32MajorVersion is available on Windows only.

See Also

Win32BuildNumber (see page 4364)

Win32CSDVersion (see page 4365)

Win32MinorVersion (see page 4366)

Win32Platform (see page 4366)

37.6.38 SysUtils.Win32MinorVersion Variable

Specifies which minor Windows Operating System (see page 3159) version is operating.

Pascal

```
Win32MinorVersion: Integer = 0;
```

C++

```
int Win32MinorVersion = 0;
```

File

SysUtils

Description

Win32MinorVersion specifies the Minor version of the Operating System (see page 3159). The unique identifier for a Windows Operating System (see page 3159) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber (see page 4364)

Note: Win32MinorVersion is available on Windows only.

See Also

Win32BuildNumber (see page 4364)

Win32CSDVersion (see page 4365)

Win32MajorVersion (see page 4365)

Win32Platform (see page 4366)

37.6.39 SysUtils.Win32Platform Variable

Specifies the Windows Operating System (see page 3159) platform identifier.

Pascal

```
Win32Platform: Integer = 0;
```

C++

```
int Win32Platform = 0;
```

File

SysUtils

Description

Win32Platform is used to identify the type of Win32 platform the system is running. This will be one of the following values:

Value	Meaning
VER_PLATFORM_WIN32s = 0	System (see page 3159) is Win32s.
VER_PLATFORM_WIN32_WINDOWS = 1	System (see page 3159) is Windows 95.

VER_PLATFORM_WIN32_NT = 2	System (see page 3159) is Windows NT. This includes Windows XP and Vista.

Note: Win32Platform is available on Windows only.

See Also

Win32BuildNumber (see page 4364)

Win32CSDVersion (see page 4365)

Win32MajorVersion (see page 4365)

Win32MinorVersion (see page 4366)

37.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DateDelta (see page 4369)	Specifies the difference between TDateTime (see page 3323) and TTimeStamp (see page 4334) starting values.
DefaultFalseBoolStr (see page 4370)	Specifies the default string representation of the boolean false value.
DefaultTrueBoolStr (see page 4370)	Specifies the default string representation of the boolean true value.
DriveDelim (see page 4371)	Specifies the character used to separate the Windows drive from the path in a file name.
faAnyFile (see page 4371)	Specifies any file type.
faArchive (see page 4372)	Specifies only Windows archived file types.
faDirectory (see page 4372)	Specifies only directory 'file' types.
faHidden (see page 4373)	Specifies only hidden file types.
faNormal (see page 4374)	This is constant SysUtils.faNormal.
faReadOnly (see page 4374)	Specifies only read only file types.
faSymLink (see page 4375)	Specifies only symbolic link file types.
faSysFile (see page 4375)	Specifies only system file types.
faTemporary (see page 4376)	This is constant SysUtils.faTemporary.
faVolumeID (see page 4376)	Specifies Volume ID file types.
fmOpenRead (see page 4377)	Specifies a file should be opened for reading only.
fmOpenReadWrite (see page 4378)	Specifies a file should be opened for reading and writing.
fmOpenWrite (see page 4378)	Specifies a file should be opened for writing only.
fmShareCompat (see page 4379)	Specifies file sharing that is FCB compatible.
fmShareDenyNone (see page 4380)	Specifies file sharing that does not prevent file access by other applications.
fmShareDenyRead (see page 4380)	Specifies file sharing that prevents read file access by other applications.
fmShareDenyWrite (see page 4381)	Specifies file sharing that prevents write file access by other applications.
fmShareExclusive (see page 4382)	Specifies file sharing that prevents any file access by other applications.
HoursPerDay (see page 4382)	Specifies the number of hours in a day.
MaxCurrency (see page 4383)	Defines the largest value supported for Currency (see page 3235) data types.
MaxDateTime (see page 4383)	Specifies the highest supported TDateTime (see page 3323) value.
MaxEraCount (see page 4384)	This is constant SysUtils.MaxEraCount.
MinCurrency (see page 4384)	Defines the largest negative value supported for Currency (see page 3235) data types.
MinDateTime (see page 4384)	Specifies the earliest supported TDateTime (see page 3323) value.
MinsPerDay (see page 4385)	Specifies the number of minutes in a day.
MinsPerHour (see page 4386)	Specifies the number of minutes in an hour.
MonthDays (see page 4386)	Defines the number of days in each month for normal and leap years.
MSecsPerDay (see page 4387)	Specifies the number of milliseconds in a day.
MSecsPerSec (see page 4387)	Specifies the number of milliseconds in a second.
PathDelim (see page 4388)	Specifies the character used to separate each directory name in a file path.
PathSep (see page 4388)	Specifies the character used to separate a sequence of file or directory names.
pfBCB4Produced (see page 4389)	Indicates that a package was produced by via C++.
pfConsumerBCB (see page 4389)	Indicates that C++ can be a consumer of a package.
pfConsumerCompat (see page 4390)	This is constant SysUtils.pfConsumerCompat.
pfConsumerDelphi (see page 4390)	Indicates that Delphi can be a consumer of a package.
pfConsumerMask (see page 4391)	Indicates the comsumer of a package.
pfDelphi4Produced (see page 4391)	Indicates that a package was produced by Delphi 4 or later.
pfDesignOnly (see page 4392)	Indicates that a package was compiled with {$DESIGNONLY ON}.

pfExeModule (see page 4392)	Indicates that a module is an executable.
pfIgnoreDupUnits (see page 4392)	Indicates that a package was compiled with {$DUPLICATEENABLE ON}.
pfLibraryModule (see page 4393)	Indicates that a module is a library.
pfModuleTypeMask (see page 4393)	Indicates that a package is a module.
pfNeverBuild (see page 4394)	Indicates that a package was compiled with the -z flag.
pfPackageModule (see page 4394)	Indicates that a module is a package.
pfProducerMask (see page 4395)	Indicates the producer of a package.
pfProducerUndefined (see page 4395)	Indicates that a package was produced by an unknown developmemt environment.
pfRunOnly (see page 4396)	Indicates that a package was compiled with {$RUNONLY ON}.
pfV3Produced (see page 4396)	Indicates that a package was produced by Delphi 3 or later.
SecsPerDay (see page 4397)	Specifies the number of seconds in a day.
SecsPerHour (see page 4397)	This is constant SysUtils.SecsPerHour.
SecsPerMin (see page 4398)	Specifies the number of seconds in a minute.
SwitchChars (see page 4398)	Specifies the prefix character(s) for program command line arguments.
ufImplicitUnit (see page 4399)	Indicates that a unit was implicitly imported into a package.
ufMainUnit (see page 4399)	Indicates that a unit is the main one in a project.
ufOrgWeakUnit (see page 4400)	This is constant SysUtils.ufOrgWeakUnit.
ufPackageUnit (see page 4400)	Indicates that a unit is a package.
ufWeakPackageUnit (see page 4400)	Indicates that a unit is a either a weak unit or a package unit.
ufWeakUnit (see page 4401)	Indicates that a unit is a weak unit.
UnixDateDelta (see page 4401)	Specifies the difference between TDateTime (see page 3323) and Lunix date/time origins.

37.7.1 SysUtils.DateDelta Constant

Specifies the difference between TDateTime (see page 3323) and TTimeStamp (see page 4334) starting values.

Pascal

```
DateDelta = 693594;
```

C++

```
DateDelta = 693594;
```

File

SysUtils

Description

DateDelta is the number of days (693594) between January 1, 0001 (starting TTimeStamp (see page 4334) value), and December 31, 1899 (starting TDateTime (see page 3323) value). This value is useful for converting date-time values between TTimeStamp (see page 4334) and TDateTime (see page 3323).

See Also

TDateTime (see page 3787)

TTimeStamp (see page 4334)

UnixDateDelta (see page 4401)

37.7.2 SysUtils.DefaultFalseBoolStr Constant

Specifies the default string representation of the boolean false value.

Pascal

```
DefaultFalseBoolStr = 'False';
```

C++

```
DefaultFalseBoolStr = 'False';
```

File

SysUtils

Description

DefaultFalseBoolStr is 'False'. It is used internally by the StrToBool (see page 4276) and BoolToStr (see page 4066) routines. They assign DefaultFalseBoolStr to the 1st element of the FalseBoolStrs (see page 4352) array, used by these routines as a default string representation of the boolean false value.

See Also

DefaultTrueBoolStr (see page 4370)

StrToBool (see page 4276)

FalseBoolStrs (see page 4352)

TrueBoolStrs (see page 4363)

BoolToStr (see page 4066)

37.7.3 SysUtils.DefaultTrueBoolStr Constant

Specifies the default string representation of the boolean true value.

Pascal

```
DefaultTrueBoolStr = 'True';
```

C++

```
DefaultTrueBoolStr = 'True';
```

File

SysUtils

Description

DefaultTrueBoolStr is 'True'. It is used internally by the StrToBool (see page 4276) and BoolToStr (see page 4066) routines. They assign DefaultTrueBoolStr to the 1st element of the TrueBoolStrs (see page 4363) array, used by these routines as a default string representation of the boolean true value.

See Also

DefaultFalseBoolStr (see page 4370)

StrToBool (see page 4276)

FalseBoolStrs (see page 4352)

TrueBoolStrs (see page 4363)

BoolToStr (see page 4066)

37.7.4 SysUtils.DriveDelim Constant

Specifies the character used to separate the Windows drive from the path in a file name.

Pascal

```
DriveDelim = ':';
```

C++

```
DriveDelim = ':';
```

File

SysUtils

Description

DriveDelim is the ':' character that follows the drive character ('A', 'B' and so on) in a full filename on a Windows Operating System (see page 3159). The value is a null character for Linux Operating Systems since they do not support drive designations.

See Also

PathDelim (see page 4388)

PathSep (see page 4388)

37.7.5 SysUtils.faAnyFile Constant

Specifies any file type.

Pascal

```
faAnyFile = $000001FF;
```

C++

```
faAnyFile = 0x000001FF;
```

File

SysUtils

Description

faAnyFile is principally used by FindFirst (see page 4175) to indicate that files of any type encountered sould be returned. Namely, all files.

See Also

faArchive (see page 4372)

faDirectory (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.6 SysUtils.faArchive Constant

Specifies only Windows archived file types.

Pascal

```
faArchive = $00000020 platform;
```

C++

```
faArchive = 0x00000020 platform;
```

File

SysUtils

Description

faArchive is principally used by FindFirst (see page 4175) to indicate that only archived files sould be returned. It is Windows specific : Linux does not support archiving.

See Also

faAnyFile (see page 4371)

faDirectory (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.7 SysUtils.faDirectory Constant

Specifies only directory 'file' types.

Pascal

```
faDirectory = $00000010;
```

C++

```
faDirectory = 0x00000010;
```

File

SysUtils

Description

faDirectory is principally used by FindFirst (see page 4175) to indicate that only directories sould be returned. Whilst FindFirst (see page 4175) is generally used to search for files, it can also return directories within the search directory.

See Also

faAnyFile (see page 4371)

faArchive (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.8 SysUtils.faHidden Constant

Specifies only hidden file types.

Pascal

```
faHidden = $00000002 platform;
```

C++

```
faHidden = 0x00000002 platform;
```

File

SysUtils

Description

faHidden is principally used by FindFirst (see page 4175) to indicate that only hidden files sould be returned. On Linux systems, hidden files are those that start with a "." character.

See Also

faAnyFile (see page 4371)

faArchive (see page 4372)

faDirectory (see page 4372)

faReadOnly (see page 4374)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.9 SysUtils.faNormal Constant

Pascal

```
faNormal = $00000080 platform;
```

C++

```
faNormal = 0x00000080 platform;
```

File

SysUtils

Description

This is constant SysUtils.faNormal.

37.7.10 SysUtils.faReadOnly Constant

Specifies only read only file types.

Pascal

```
faReadOnly = $00000001 platform;
```

C++

```
faReadOnly = 0x00000001 platform;
```

File

SysUtils

Description

faReadOnly is principally used by FindFirst (see page 4175) to indicate that only read only files sould be returned. On Linux systems, read only is not necessarily a system wide attribute - access rights are user and group dependent. Read (see page 3634) only here means that the current application does read but not write to a file.

See Also

faAnyFile (see page 4371)

faArchive (see page 4372)

faDirectory (see page 4372)

faHidden (see page 4373)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.11 SysUtils.faSymLink Constant

Specifies only symbolic link file types.

Pascal

```
faSymLink = $00000040 platform;
```

C++

```
faSymLink = 0x00000040 platform;
```

File

SysUtils

Description

faSymLink is principally used by FindFirst (see page 4175) to indicate that only symbolic link files sould be returned. Symbolic links are a feature of Linux systems, with no Windows counterpart.

See Also

faAnyFile (see page 4371)

faArchive (see page 4372)

faDirectory (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSysFile (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.12 SysUtils.faSysFile Constant

Specifies only system file types.

Pascal

```
faSysFile = $00000004 platform;
```

C++

```
faSysFile = 0x00000004 platform;
```

File

SysUtils

Description

faSysFile is principally used by FindFirst (see page 4175) to indicate that only system files sould be returned. On Linux systems, a system file is one that is treated as a socket, symbolic link, device file, or FIFO.

See Also

faAnyFile (see page 4371)

faArchive (see page 4372)

faDirectory (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSymLink (see page 4375)

FindFirst (see page 4175)

TSearchRec (see page 4330)

37.7.13 SysUtils.faTemporary Constant

Pascal

```
faTemporary = $00000100 platform;
```

C++

```
faTemporary = 0x00000100 platform;
```

File

SysUtils

Description

This is constant SysUtils.faTemporary.

37.7.14 SysUtils.faVolumeID Constant

Specifies Volume ID file types.

Pascal

```
faVolumeID = $00000008 platform deprecated;
```

C++

```
faVolumeID = 0x00000008 platform deprecated;
```

File

SysUtils

Description

faVolumeID is deprecated. Use your operating system functions to obtain this information.

Note: faVolumeID was used only for DOS/9x compatibility.

See Also

faArchive (see page 4372)

faDirectory (see page 4372)

faHidden (see page 4373)

faReadOnly (see page 4374)

faSymLink (see page 4375)

faSysFile (see page 4375)

FindFirst (see page 4175)

37.7.15 SysUtils.fmOpenRead Constant

Specifies a file should be opened for reading only.

Pascal

```
fmOpenRead = $0000;
```

C++

```
fmOpenRead = 0x0000;
```

File

SysUtils

Description

fmOpenRead is one of the values you can assign to FileMode (see page 3824). It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenRead, subsequent calls to Reset (see page 3643) open files for reading only.

Note: You must use this value when you plan to read a read only file - using fmOpenReadWrite (see page 4378) will cause the open to fail because it will attempt and fail to get write access.

See Also

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Reset (see page 3643)

FileMode (see page 3824)

Create

37.7.16 SysUtils.fmOpenReadWrite Constant

Specifies a file should be opened for reading and writing.

Pascal

```
fmOpenReadWrite = $0002;
```

C++

```
fmOpenReadWrite = 0x0002;
```

File

SysUtils

Description

fmOpenReadWrite is one of the values you can assign to FileMode (see page 3824). It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenReadWrite, subsequent calls to Reset (see page 3643) open files for reading and writing.

Note: Do not assign this value when you plan to read a read only file - the open will fail because write access will be attempted but be denied.

See Also

fmOpenRead (see page 4377)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Reset (see page 3643)

FileMode (see page 3824)

Create

37.7.17 SysUtils.fmOpenWrite Constant

Specifies a file should be opened for writing only.

Pascal

```
fmOpenWrite = $0001;
```

C++

```
fmOpenWrite = 0x0001;
```

File

SysUtils

Description

fmOpenWrite is one of the values you can assign to FileMode (see page 3824). It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenWrite, subsequent calls to Reset (see page 3643) open files for writing only.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Reset (see page 3643)

FileMode (see page 3824)

Create

37.7.18 SysUtils.fmShareCompat Constant

Specifies file sharing that is FCB compatible.

Pascal

```
fmShareCompat = $0000 platform;
```

C++

```
fmShareCompat = 0x0000 platform;
```

File

SysUtils

Description

fmShareCompat is one of the attributes assignable in the Create. The TFileStream is used to read and write files. It specifies file sharing that is compatible with the way that FCB's (File Control Blocks) are opened.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Create

37.7.19 SysUtils.fmShareDenyNone Constant

Specifies file sharing that does not prevent file access by other applications.

Pascal

```
fmShareDenyNone = $0040;
```

C++

```
fmShareDenyNone = 0x0040;
```

File

SysUtils

Description

fmShareDenyNone is one of the attributes assignable in the Create. The TFileStream is used to read and write files. It specifies file sharing that does not prevent any other applications from reading from or writing to the file.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Create

37.7.20 SysUtils.fmShareDenyRead Constant

Specifies file sharing that prevents read file access by other applications.

Pascal

```
fmShareDenyRead = $0030 platform;
```

C++

```
fmShareDenyRead = 0x0030 platform;
```

File

SysUtils

Description

fmShareDenyRead is one of the attributes assignable in the Create. The TFileStream is used to read and write files. It specifies file sharing that prevents other applications from reading the file. Other applications may open the file for writing only.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyWrite (see page 4381)

fmShareExclusive (see page 4382)

Create

37.7.21 SysUtils.fmShareDenyWrite Constant

Specifies file sharing that prevents write file access by other applications.

Pascal

```
fmShareDenyWrite = $0020;
```

C++

```
fmShareDenyWrite = 0x0020;
```

File

SysUtils

Description

fmShareDenyWrite is one of the attributes assignable in the Create. The TFileStream is used to read and write files. It specifies file sharing that prevents other applications from writing to the file. Other applications may open the file for reading only.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareExclusive (see page 4382)

Create

37.7.22 SysUtils.fmShareExclusive Constant

Specifies file sharing that prevents any file access by other applications.

Pascal

```
fmShareExclusive = $0010;
```

C++

```
fmShareExclusive = 0x0010;
```

File

SysUtils

Description

fmShareExclusive is one of the attributes assignable in the Create. The TFileStream is used to read and write files. It specifies file sharing that prevents other applications from opening the file at all.

See Also

fmOpenRead (see page 4377)

fmOpenReadWrite (see page 4378)

fmOpenWrite (see page 4378)

fmShareCompat (see page 4379)

fmShareDenyNone (see page 4380)

fmShareDenyRead (see page 4380)

fmShareDenyWrite (see page 4381)

Create

37.7.23 SysUtils.HoursPerDay Constant

Specifies the number of hours in a day.

Pascal

```
HoursPerDay = 24;
```

C++

```
HoursPerDay = 24;
```

File

SysUtils

Description

HoursPerDay is the number of hours (24) in a day. Using this constant rather than hard coding 24 makes for more readable code.

See Also

DateDelta (see page 4369)

MinsPerDay (see page 4385)

MinsPerHour (see page 4386)

MSecsPerDay (see page 4387)

MSecsPerSec (see page 4387)

SecsPerDay (see page 4397)

SecsPerMin (see page 4398)

37.7.24 SysUtils.MaxCurrency Constant

Defines the largest value supported for Currency (see page 3235) data types.

Pascal

```
MaxCurrency: Currency = 922337203685477.5807;
```

C++

```
Currency MaxCurrency = 922337203685477.5807;
```

File

SysUtils

Description

MaxCurrency is the largest value that can be held by a Currency (see page 3235) data variable on the Windows Opersting System (see page 3159).

Note: Linux supports a value 1.0 less than this maximum (922337203685476.5807).

See Also

MinCurrency (see page 4384)

37.7.25 SysUtils.MaxDateTime Constant

Specifies the highest supported TDateTime (see page 3323) value.

Pascal

```
MaxDateTime: TDateTime = 2958465.99999;
```

C++

```
TDateTime MaxDateTime = 2958465.99999;
```

File

SysUtils

Description

MaxDateTime is the most future date : 12/31/9999 23:59:59.999 that the TDateTime (see page 3323) type supports. The actual shown value of 2958465.99999 reflects the fact that TDateTime (see page 3323) is actually a floating point number, rather than a structured type. The mantissa holds the number of days relative to 12/30/1899 00:00:00.000, the exponent holds a fraction of a day.

See Also

TDateTime (see page 3787)

MinDateTime (see page 4384)

37.7.26 SysUtils.MaxEraCount Constant

Pascal

```
MaxEraCount = 7;
```

C++

```
MaxEraCount = 7;
```

File

SysUtils

Description

This is constant SysUtils.MaxEraCount.

37.7.27 SysUtils.MinCurrency Constant

Defines the largest negative value supported for Currency (see page 3235) data types.

Pascal

```
MinCurrency: Currency = -922337203685477.5807;
```

C++

```
Currency MinCurrency = -922337203685477.5807;
```

File

SysUtils

Description

MinCurrency is the largest negative value that can be held by a Currency (see page 3235) data variable on the Windows Opersting System (see page 3159).

Note: Linux supports a value 1.0 less negative than this minimum (-922337203685476.5807).

See Also

MaxCurrency (see page 4383)

37.7.28 SysUtils.MinDateTime Constant

Specifies the earliest supported TDateTime (see page 3323) value.

Pascal

```
MinDateTime: TDateTime = -657434.0;
```

C++

```
TDateTime MinDateTime = -657434.0;
```

File

SysUtils

Description

MinDateTime is the most historic date : 01/01/0100 00:00:00.000 that the TDateTime (see page 3323) type supports. The actual shown value of -657434.0 reflects the fact that TDateTime (see page 3323) is actually a floating point number, rather than a structured type. The mantissa holds the number of days relative to 12/30/1899 00:00:00.000, the exponent holds a fraction of a day.

Note: The fractional part of a TDateTime (see page 3323) is always treated in a positive sense. It always means the elapsed part of a day - if the TDateTime (see page 3323) value is negative, this refers only to a negative offset of the integral day value from 12/30/1899.

See Also

TDateTime (see page 3787)

MaxDateTime (see page 4383)

37.7.29 SysUtils.MinsPerDay Constant

Specifies the number of minutes in a day.

Pascal

```
MinsPerDay = HoursPerDay * MinsPerHour;
```

C++

```
MinsPerDay = HoursPerDay * MinsPerHour;
```

File

SysUtils

Description

MinsPerDay is the number of minutes (1440) in a day. It is the product of HoursPerDay (see page 4382) and MinsPerHour (see page 4386).

Using this constant rather than hard coding 1440 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MinsPerHour (see page 4386)

MSecsPerDay (see page 4387)

MSecsPerSec (see page 4387)

SecsPerDay (see page 4397)

SecsPerMin (see page 4398)

37.7.30 SysUtils.MinsPerHour Constant

Specifies the number of minutes in an hour.

Pascal

```
MinsPerHour = 60;
```

C++

```
MinsPerHour = 60;
```

File

SysUtils

Description

MinsPerHour is the number of minutes (60) in an hour. Using this constant rather than hard coding 60 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MSecsPerDay (see page 4387)

MSecsPerSec (see page 4387)

SecsPerDay (see page 4397)

SecsPerMin (see page 4398)

37.7.31 SysUtils.MonthDays Constant

Defines the number of days in each month for normal and leap years.

Pascal

```
MonthDays: array [Boolean] of TDayTable = ((31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31),
(31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31));
```

C++

```
array [Boolean] of TDayTable MonthDays = ((31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31),
(31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31));
```

File

SysUtils

Description

MonthDays defines a 2 dimensional array of TDayTable (see page 4340) values. Namely, an array of two sets of 12 words. The first set holds the number of days in each month in a normal year, the second set the number in a leap year.

Use MonthDays[IsLeapYear (see page 4220)(Y), M] to find the number of days in Year 'Y', month 'M'.

See Also

DaysInMonth

IsLeapYear (see page 4220)

TDayTable (see page 4340)

37.7.32 SysUtils.MSecsPerDay Constant

Specifies the number of milliseconds in a day.

Pascal

```
MSecsPerDay = SecsPerDay * MSecsPerSec;
```

C++

```
MSecsPerDay = SecsPerDay * MSecsPerSec;
```

File

SysUtils

Description

MSecsPerDay is the number of milliseconds (86,400,000) in a day. It is the product of SecsPerDay (see page 4397) and MSecsPerSec (see page 4387).

Using this constant rather than hard coding 86400000 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MinsPerDay (see page 4385)

MinsPerHour (see page 4386)

MSecsPerSec (see page 4387)

SecsPerDay (see page 4397)

SecsPerMin (see page 4398)

37.7.33 SysUtils.MSecsPerSec Constant

Specifies the number of milliseconds in a second.

Pascal

```
MSecsPerSec = 1000;
```

C++

```
MSecsPerSec = 1000;
```

File

SysUtils

Description

MSecsPerSec is the number of milliseconds (1000) in a second.

Using this constant rather than hard coding 1000 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MinsPerDay (see page 4385)

MinsPerHour (see page 4386)

MSecsPerDay (see page 4387)

SecsPerMin (see page 4398)

SecsPerDay (see page 4397)

37.7.34 SysUtils.PathDelim Constant

Specifies the character used to separate each directory name in a file path.

Pascal

```
PathDelim = '\';
```

C++

```
PathDelim = '\';
```

File

SysUtils

Description

PathDelim is the '\' character for Windows, or '/' for Linux that is used to separate each directory in the hierarchy of directories in a path. A path is used to navigate to a specific directory or file(s).

See Also

DriveDelim (see page 4371)

PathSep (see page 4388)

37.7.35 SysUtils.PathSep Constant

Specifies the character used to separate a sequence of file or directory names.

Pascal

```
PathSep = ';';
```

C++

```
PathSep = ';';
```

File

SysUtils

Description

PathSep is the ';' character for Windows, or ':' for Linux that is used to separate filenames in a sequence of file or directory names. FileSearch (see page 4156), for example, expects PathSep to be used to separate the values in the string of directory names.

See Also

DriveDelim (see page 4371)

FileSearch (see page 4156)

37.7.36 SysUtils.pfBCB4Produced Constant

Indicates that a package was produced by via C++.

Pascal

```
pfBCB4Produced = $08000000;
```

C++

```
pfBCB4Produced = 0x08000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfBCB4Produced is one of these flag values, indicating that a package was produced by C++. BCB stands for Borland C++ Builder.

See Also

GetPackageInfo (see page 4209)

37.7.37 SysUtils.pfConsumerBCB Constant

Indicates that C++ can be a consumer of a package.

Pascal

```
pfConsumerBCB = $00200000;
```

C++

```
pfConsumerBCB = 0x00200000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfConsumerBCB is one of these flag values, indicating that C++ is a legitimate consumer, or user, of a package. The C++ consumer is the Borland C++ Builder compiler, linking in the package.

A package will be marked with the pfConsumerBCB when the -JL flag has been set during compilation. This ensures that the extra support files (.lib, .bpi, .hpp)required by a C++ consumer are generated and included in the package.

See Also

GetPackageInfo (see page 4209)

37.7.38 SysUtils.pfConsumerCompat Constant

Pascal

```
pfConsumerCompat = $00000000;
```

C++

```
pfConsumerCompat = 0x00000000;
```

File

SysUtils

Description

This is constant SysUtils.pfConsumerCompat.

37.7.39 SysUtils.pfConsumerDelphi Constant

Indicates that Delphi can be a consumer of a package.

Pascal

```
pfConsumerDelphi = $00100000;
```

C++

```
pfConsumerDelphi = 0x00100000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfConsumerDelphi is one of these flag values, indicating that Delphi is a legitimate consumer, or user, of a package. The Delphi consumer is the Delphi compiler, linking in the package.

See Also

GetPackageInfo (see page 4209)

37.7.40 SysUtils.pfConsumerMask Constant

Indicates the comsumer of a package.

Pascal

```
pfConsumerMask = $00F00000;
```

C++

```
pfConsumerMask = 0x00F00000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfConsumerMask is a mask that you can use to detect the consumers can use a package. This mask covers these flags : pfConsumerBCB (see page 4389), pfConsumerCompat (see page 4390) and pfConsumerDelphi (see page 4390) flags.

Note: pfConsumerMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 4209)

pfConsumerBCB (see page 4389)

pfConsumerCompat (see page 4390)

pfConsumerDelphi (see page 4390)

37.7.41 SysUtils.pfDelphi4Produced Constant

Indicates that a package was produced by Delphi 4 or later.

Pascal

```
pfDelphi4Produced = $0C000000;
```

C++

```
pfDelphi4Produced = 0x0C000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfDelphi4Produced is one of these flag values, indicating that the a package was produced by Delphi 4 or later. Packages were introduced in Delphi 3.

See Also

GetPackageInfo (see page 4209)

37.7.42 SysUtils.pfDesignOnly Constant

Indicates that a package was compiled with {$DESIGNONLY ON}.

Pascal

```
pfDesignOnly = $00000002;
```

C++

```
pfDesignOnly = 0x00000002;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfDesignOnly is one of these flag values, indicating that the package was compiled with the $DESIGNONLY compiler directive set ON. This means that the for package is intended for installation in the IDE.

See Also

GetPackageInfo (see page 4209)

37.7.43 SysUtils.pfExeModule Constant

Indicates that a module is an executable.

Pascal

```
pfExeModule = $00000000;
```

C++

```
pfExeModule = 0x00000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfExeModule is one of these flag values, indicating that the module is an executable.

See Also

GetPackageInfo (see page 4209)

37.7.44 SysUtils.pfIgnoreDupUnits Constant

Indicates that a package was compiled with {$DUPLICATEENABLE ON}.

Pascal

```
pfIgnoreDupUnits = $00000008;
```

C++

```
pfIgnoreDupUnits = 0x00000008;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfIgnoreDupUnits is one of these flag values, indicating that the package was compiled with the $DUPLICATEENABLE compiler directive set ON.

See Also

GetPackageInfo (see page 4209)

37.7.45 SysUtils.pfLibraryModule Constant

Indicates that a module is a library.

Pascal

```
pfLibraryModule = $80000000;
```

C++

```
pfLibraryModule = 0x80000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfLibraryModule is one of these flag values, indicating that the module is a library (.dll file extension).

See Also

GetPackageInfo (see page 4209)

37.7.46 SysUtils.pfModuleTypeMask Constant

Indicates that a package is a module.

Pascal

```
pfModuleTypeMask = $C0000000;
```

C++

```
pfModuleTypeMask = 0xC0000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfModuleTypeMask is a mask that you can use to detect whether the package is a module. This mask is the binary AND of the pfExeModule (see page 4392), pfPackageModule (see page 4394) and pfLibraryModule (see page 4393) flags.

Note: pfModuleTypeMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 4209)

37.7.47 SysUtils.pfNeverBuild Constant

Indicates that a package was compiled with the -z flag.

Pascal

```
pfNeverBuild = $00000001;
```

C++

```
pfNeverBuild = 0x00000001;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfNeverBuild is one of these flag values, indicating that the package was compiled with the -z flag.

See Also

GetPackageInfo (see page 4209)

37.7.48 SysUtils.pfPackageModule Constant

Indicates that a module is a package.

Pascal

```
pfPackageModule = $40000000;
```

C++

```
pfPackageModule = 0x40000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfPackageModule is one of these flag values, indicating that the module is a package (.bpl file extension).

See Also

GetPackageInfo (see page 4209)

37.7.49 SysUtils.pfProducerMask Constant

Indicates the producer of a package.

Pascal

```
pfProducerMask = $0C000000;
```

C++

```
pfProducerMask = 0x0C000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfProducerMask is a mask that you can use to detect the producer of a package. This mask is the binary AND of the pfBCB4Produced (see page 4389), pfDelphi4Produced (see page 4391), pfProducerUndefined (see page 4395) and pfV3Produced (see page 4396) flags.

Note: pfProducerMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 4209)

pfBCB4Produced (see page 4389)

pfDelphi4Produced (see page 4391)

pfProducerUndefined (see page 4395)

pfV3Produced (see page 4396)

37.7.50 SysUtils.pfProducerUndefined Constant

Indicates that a package was produced by an unknown developmemt environment.

Pascal

```
pfProducerUndefined = $04000000;
```

C++

```
pfProducerUndefined = 0x04000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfProducerUndefined is one of these flag values, indicating that the producer of a package was undefined.

See Also

GetPackageInfo (see page 4209)

37.7.51 SysUtils.pfRunOnly Constant

Indicates that a package was compiled with {$RUNONLY ON}.

Pascal

```
pfRunOnly = $00000004;
```

C++

```
pfRunOnly = 0x00000004;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfRunOnly is one of these flag values, indicating that the package was compiled with the $RUNONLY compiler directive set ON. The {$RUNONLY ON} directive causes the package where it occurs to be compiled as runtime only. Packages compiled with {$RUNONLY ON} cannot be installed as design-time packages in the IDE.

See Also

GetPackageInfo (see page 4209)

37.7.52 SysUtils.pfV3Produced Constant

Indicates that a package was produced by Delphi 3 or later.

Pascal

```
pfV3Produced = $00000000;
```

C++

```
pfV3Produced = 0x00000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about a package. It returns a set of flags.

pfV3Produced is one of these flag values, indicating that the a package was produced by Delphi 3 or later. Packages were introduced in Delphi 3.

See Also

GetPackageInfo (see page 4209)

37.7.53 SysUtils.SecsPerDay Constant

Specifies the number of seconds in a day.

Pascal

```
SecsPerDay = MinsPerDay * SecsPerMin;
```

C++

```
SecsPerDay = MinsPerDay * SecsPerMin;
```

File

SysUtils

Description

SecsPerDay is the number of seconds (86,400) in a day. It is the product of MinsPerDay (see page 4385) and SecsPerMin (see page 4398).

Using this constant rather than hard coding 86400 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MinsPerDay (see page 4385)

MinsPerHour (see page 4386)

MSecsPerDay (see page 4387)

MSecsPerSec (see page 4387)

SecsPerMin (see page 4398)

37.7.54 SysUtils.SecsPerHour Constant

Pascal

```
SecsPerHour = SecsPerMin * MinsPerHour;
```

C++

```
SecsPerHour = SecsPerMin * MinsPerHour;
```

File

SysUtils

Description

This is constant SysUtils.SecsPerHour.

37.7.55 SysUtils.SecsPerMin Constant

Specifies the number of seconds in a minute.

Pascal

```
SecsPerMin = 60;
```

C++

```
SecsPerMin = 60;
```

File

SysUtils

Description

SecsPerMin is the number of seconds (60) in a minute.

Using this constant rather than hard coding 60 makes for more readable code.

See Also

DateDelta (see page 4369)

HoursPerDay (see page 4382)

MinsPerDay (see page 4385)

MinsPerHour (see page 4386)

MSecsPerDay (see page 4387)

MSecsPerSec (see page 4387)

SecsPerDay (see page 4397)

37.7.56 SysUtils.SwitchChars Constant

Specifies the prefix character(s) for program command line arguments.

Pascal

```
SwitchChars = ['/','-'];
```

C++

```
SwitchChars = ['/','-'];
```

File

SysUtils

Description

When a program is started, an optional 'command line' string may be supplied. Such a string may specify program operational arguments, or 'switches', prefixed by a separator character. SwitchChars defines these separator characters as either '-' or '/' on a Windows system, and as '-' on Linux systems.

See Also

FindCmdLineSwitch (see page 4174)

37.7.57 SysUtils.ufImplicitUnit Constant

Indicates that a unit was implicitly imported into a package.

Pascal

```
ufImplicitUnit = $10;
```

C++

```
ufImplicitUnit = 0x10;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about the units within a package. TPackageInfoProc (see page 4342) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufImplicitUnit is set, then the unit was implicitly imported into a package. This means that the unit is not used in another package required by this package, but is used by one of the units this package contains.

See Also

GetPackageInfo (see page 4209)

TPackageInfoProc (see page 4342)

37.7.58 SysUtils.ufMainUnit Constant

Indicates that a unit is the main one in a project.

Pascal

```
ufMainUnit = $01;
```

C++

```
ufMainUnit = 0x01;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about the units within a package. TPackageInfoProc (see page 4342) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufMainUnit is set, then the unit is a Main unit.

See Also

GetPackageInfo (see page 4209)

TPackageInfoProc (see page 4342)

37.7.59 SysUtils.ufOrgWeakUnit Constant

Pascal

```
ufOrgWeakUnit = $08;
```

C++

```
ufOrgWeakUnit = 0x08;
```

File

SysUtils

Description

This is constant SysUtils.ufOrgWeakUnit.

37.7.60 SysUtils.ufPackageUnit Constant

Indicates that a unit is a package.

Pascal

```
ufPackageUnit = $02;
```

C++

```
ufPackageUnit = 0x02;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about the units within a package. TPackageInfoProc (see page 4342) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufPackageUnit is set, then the unit is a package unit.

See Also

GetPackageInfo (see page 4209)

TPackageInfoProc (see page 4342)

37.7.61 SysUtils.ufWeakPackageUnit Constant

Indicates that a unit is a either a weak unit or a package unit.

Pascal

```
ufWeakPackageUnit = ufPackageUnit or ufWeakUnit;
```

C++

```
ufWeakPackageUnit = ufPackageUnit or ufWeakUnit;
```

File

SysUtils

Description

ufWeakPackageUnit is used internally in Delphi. It is equal to the logical or of ufWeakUnit (see page 4401) and ufPackageUnit (see page 4400)

37.7.62 SysUtils.ufWeakUnit Constant

Indicates that a unit is a weak unit.

Pascal

```
ufWeakUnit = $04;
```

C++

```
ufWeakUnit = 0x04;
```

File

SysUtils

Description

The GetPackageInfo (see page 4209) function returns information about the units within a package. TPackageInfoProc (see page 4342) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufWeakUnit is set, then the unit was compiled with the $WEAKPACKAGEUNIT compiler directive set.

See Also

GetPackageInfo (see page 4209)

TPackageInfoProc (see page 4342)

37.7.63 SysUtils.UnixDateDelta Constant

Specifies the difference between TDateTime (see page 3323) and Lunix date/time origins.

Pascal

```
UnixDateDelta = 25569;
```

C++

```
UnixDateDelta = 25569;
```

File

SysUtils

Description

UnixDateDelta is the number of days (25569) between December 30, 1899 (starting TDateTime (see page 3323) value), and Jamuary 1, 1970 (starting value for Linux date time values). This value is useful for converting date-time values between TDateTime (see page 3323) and Linux file date time values.

See Also

TDateTime (see page 3787)

TTimeStamp (see page 4334)

DateDelta (see page 4369)

38 TabNotBk Namespace

This is namespace TabNotBk.

Topics

Name	Description
Classes (see page 4404)	The following table lists classes in this documentation.
Types (see page 4454)	The following table lists types in this documentation.
Constants (see page 4455)	The following table lists constants in this documentation.

Classes

	Name	Description
	TTabbedNotebook (see page 4404)	TTabbedNotebook contains multiple pages, each with its own set of controls.
	TTabPage (see page 4443)	TTabPage implements an individual tab page of a tabbed notebook control.

Constants

Name	Description
CM_TABFONTCHANGED (see page 4455)	This is constant TabNotBk.CM_TABFONTCHANGED.

Types

Name	Description
TPageChangeEvent (see page 4454)	TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 4404) control.

38.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TTabbedNotebook (see page 4404)	TTabbedNotebook contains multiple pages, each with its own set of controls.
	TTabPage (see page 4443)	TTabPage implements an individual tab page of a tabbed notebook control.

38.1.1 TTabbedNotebook Class

TTabbedNotebook contains multiple pages, each with its own set of controls.

Class Hierarchy

Pascal

```
TTabbedNotebook = class(TCustomTabControl);
```

C++

```
class TTabbedNotebook : public TCustomTabControl;
```

File

TabNotBk

Description

TTabbedNotebook is provided for backwards compatibility. New (see page 3619) applications should use TPageControl instead.

38.1.1.1 TTabbedNotebook Members

The following tables list the members exposed by TTabbedNotebook.

Protected Methods

	Name	Description
	AlignControls (see page 4407)	Aligns any controls for which the control is the parent within a specified area of the control.
	Change (see page 4407)	Pending tab change event dispatcher.
	Click (see page 4407)	Respond to user click.
	CreateHandle (see page 4408)	Creates underlying screen object.
	CreateParams (see page 4409)	Sets up the window-creation parameters for the tab control.
	GetChildOwner (see page 4409)	Returns the owner of a child component being read from a stream.
	KeyDown (see page 4410)	Respond to key press events.
	Loaded (see page 4411)	Form load event dispatcher.
	ReadState (see page 4411)	Prepares the control for having its properties assigned values from a stream.
	SetPageIndex (see page 4412)	This is SetPageIndex, a member of class TTabbedNotebook.
	ShowControl (see page 4412)	Ensures that a specified child control is visible.

Protected Properties

	Name	Description
	Tabs (see page 4431)	Contains the list of text strings that label the tabs of the tab control.

Public Methods

	Name	Description
	CMTabFontChanged (see page 4408)	This is CMTabFontChanged, a member of class TTabbedNotebook.
V	Create (see page 4405)	Constructs a tabbed notebook component.
V	Destroy (see page 4406)	Destroys a tabbed notebook component.
V	GetChildren (see page 4409)	Calls a specified method for each child of the control.
	GetIndexForPage (see page 4410)	Returns the PageIndex (see page 4421) value of the specified page.
	TabFontChanged (see page 4412)	Invalidates the tabs when the TabFont (see page 4430) property changes.

Public Properties

	Name	Description
R	TopFont (see page 4433)	Returns the current value of font used on the tabs of the tabbed notebook.

Published Events

	Name	Description
	OnChange (see page 4435)	Occurs when the page of a tabbed notebook changes.
	OnClick (see page 4436)	Occurs when a tab of a tabbed notebook is selected.
	OnContextPopup (see page 4436)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 4437)	Occurs when a control receives the input focus.
	OnExit (see page 4439)	Occurs when the input focus shifts away from one control to another.

Published Properties

	Name	Description
	ActivePage (see page 4413)	Determines which page displays in the tabbed notebook control.
	Align (see page 4414)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4417)	Specifies how the control is anchored to its parent.
	Constraints (see page 4418)	Specifies the size constraints for the control.
	DoubleBuffered (see page 4418)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 4420)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 4420)	Controls the attributes of text written on or in the control.
	PageIndex (see page 4421)	Determines which page displays in the tabbed notebook component.
	Pages (see page 4422)	Contains the strings that identify the individual pages of the tabbed notebook control.
	ParentDoubleBuffered (see page 4422)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 4423)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4423)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 4428)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabFont (see page 4430)	Determines the font used on the tabs of the tabbed notebook control.
	TabOrder (see page 4430)	Indicates the position of the control in its parent's tab order.
	TabsPerRow (see page 4432)	TabsPerRow is obsolete and retained only for backwards compatibility.
	TabStop (see page 4433)	Determines if the user can tab to a control.
	Visible (see page 4433)	Determines whether the component appears onscreen.

38.1.1.2 TTabbedNotebook.Create Constructor

Constructs a tabbed notebook component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabbedNotebook(TComponent * AOwner);
```

Description

Call Create TTabbedNotebook (see page 4404) indirectly, using the new keyword, to instantiate a tabbed notebook at runtime. Tabbed notebooks added to forms at design time are created automatically.

The AOwner parameter assigns a value to the notebook's Owner property.

See Also

Owner

38.1.1.3 TTabbedNotebook.Destroy Destructor

Destroys a tabbed notebook component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTabbedNotebook();
```

Description

Do not call Destroy directly in an application, Instead, use Free method, which checks that the notebook is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

38.1.1.4 TTabbedNotebook Methods

The methods of the TTabbedNotebook class are listed here.

Protected Methods

	Name	Description
	AlignControls (see page 4407)	Aligns any controls for which the control is the parent within a specified area of the control.
	Change (see page 4407)	Pending tab change event dispatcher.
	Click (see page 4407)	Respond to user click.
	CreateHandle (see page 4408)	Creates underlying screen object.
	CreateParams (see page 4409)	Sets up the window-creation parameters for the tab control.
	GetChildOwner (see page 4409)	Returns the owner of a child component being read from a stream.
	KeyDown (see page 4410)	Respond to key press events.
	Loaded (see page 4411)	Form load event dispatcher.
	ReadState (see page 4411)	Prepares the control for having its properties assigned values from a stream.
	SetPageIndex (see page 4412)	This is SetPageIndex, a member of class TTabbedNotebook.
	ShowControl (see page 4412)	Ensures that a specified child control is visible.

Public Methods

	Name	Description
	CMTabFontChanged (see page 4408)	This is CMTabFontChanged, a member of class TTabbedNotebook.
V	GetChildren (see page 4409)	Calls a specified method for each child of the control.
	GetIndexForPage (see page 4410)	Returns the PageIndex (see page 4421) value of the specified page.
	TabFontChanged (see page 4412)	Invalidates the tabs when the TabFont (see page 4430) property changes.

38.1.1.4.1 TTabbedNotebook.AlignControls Method

Aligns any controls for which the control is the parent within a specified area of the control.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of a form, panel, group box, scroll box, or any container control. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly-aligned controls.

See Also

Align

38.1.1.4.2 TTabbedNotebook.Change Method

Pending tab change event dispatcher.

Pascal

```
procedure Change; override;
```

C++

```
virtual __fastcall Change();
```

Description

Change is called automatically when the selected tab changes. Override Change to specify additional processing before the OnChange event handler executes, or to block the OnChange event.

See Also

OnChange

38.1.1.4.3 TTabbedNotebook.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action

OnExecute

Execute

DblClick

OnClick

38.1.1.4.4 TTabbedNotebook.CMTabFontChanged Method

Pascal

```
procedure CMTabFontChanged(var Message: TMessage); message CM_TABFONTCHANGED;
```

C++

```
__fastcall CMTabFontChanged(TMessage Message);
```

Description

This is CMTabFontChanged, a member of class TTabbedNotebook.

38.1.1.4.5 TTabbedNotebook.CreateHandle Method

Creates underlying screen object.

Pascal

```
procedure CreateHandle; override;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

CreateHandle creates the Microsoft Windows screen object that underlies the control. if it does not already exist. The new window handle becomes the value of the Handle property.

CreateHandle creates or locates the parent control's window before it creates a window for the control itself.

Note: If the Parent property is nil (Delphi) or NULL (C++), CreateHandle raises an exception.

See Also

CreateWindowHandle

CreateWnd

Handle

Parent

38.1.1.4.6 TTabbedNotebook.CreateParams Method

Sets up the window-creation parameters for the tab control.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

Tab controls call CreateParams internally when the window for the tab control must be generated. CreateParams overrides the inherited method to specify a tab control window with the current property settings.

See Also

CreateWnd

38.1.1.4.7 TTabbedNotebook.GetChildOwner Method

Returns the owner of a child component being read from a stream.

Pascal

```
function GetChildOwner: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetChildOwner();
```

Description

GetChildOwner is used internally by the component streaming system. It is rarely necessary to call it directly.

In TComponent, GetChildOwner always returns nil (Delphi) or NULL (C++), indicating that the owner is the root component currently being read (usually a form or data module). The Owner of a component is responsible for destroying it.

See Also

Create

Owner

38.1.1.4.8 TTabbedNotebook.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls

Owner

38.1.1.4.9 TTabbedNotebook.GetIndexForPage Method

Returns the PageIndex (see page 4421) value of the specified page.

Pascal

```
function GetIndexForPage(const PageName: string): Integer;
```

C++

```
__fastcall int GetIndexForPage(const UnicodeString PageName);
```

Description

The PageIndex (see page 4421) property value is determined by the page's position in the Pages (see page 4422) property array. Specify the name of the page as the value of the PageName parameter. The name you specify must be one of the strings in the Pages (see page 4422) property.

See Also

PageIndex (see page 4421)

Pages (see page 4422)

38.1.1.4.10 TTabbedNotebook.KeyDown Method

Respond to key press events.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-down message (WM_KEYDOWN) from Windows, its message handler calls the DoKeyDown method. If DoKeyDown determines that the control should, in fact, process the character, it calls KeyDown, passing the key code and shift-key state in the Key and Shift parameters, respectively.

KeyDown calls any event handler attached to the OnKeyDown event. Override KeyDown to provide other responses in addition to the event-handler call.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use WinAPI virtual key codes to determine the key pressed. For more information, search for virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

Either KeyDown or the OnKeyDown event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

See Also

KeyUp

OnKeyDown

DoKeyDown

DoKeyPress

DoKeyUp

38.1.1.4.11 TTabbedNotebook.Loaded Method

Form load event dispatcher.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The protected Loaded method is called automatically when the form that contains the tab control is loaded into memory. It provides an opportunity for the tab control to perform any initializations after the control and all other components in the form are loaded into memory, but before the first paint operation.

In TCustomTabControl, Loaded ensures that the layout of the tabs accommodate the images specified by the Images property.

See Also

Images

38.1.1.4.12 TTabbedNotebook.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

See Also

Parent

ReadState

38.1.1.4.13 TTabbedNotebook.SetPageIndex Method

Pascal

```
procedure SetPageIndex(Value: Integer);
```

C++

```
__fastcall SetPageIndex(int Value);
```

Description

This is SetPageIndex, a member of class TTabbedNotebook.

38.1.1.4.14 TTabbedNotebook.ShowControl Method

Ensures that a specified child control is visible.

Pascal

```
procedure ShowControl(AControl: TControl); override;
```

C++

```
virtual __fastcall ShowControl(TControl * AControl);
```

Description

Call ShowControl to display a child control. Specify the control you want to ensure will be visible as the value of the AControl parameter.

As implemented in TWinControl, ShowControl simply calls the ShowControl method of the control's parent. Derived objects override ShowControl to perform whatever actions are necessary to allow the indicated child object to be visible. Possible actions include scrolling the particular child object into view, or changing to the appropriate notebook page.

See Also

Show

Parent

38.1.1.4.15 TTabbedNotebook.TabFontChanged Method

Invalidates the tabs when the TabFont (see page 4430) property changes.

Pascal

```
procedure TabFontChanged(Sender: TObject);
```

C++

```
__fastcall TabFontChanged(TObject * Sender);
```

Description

TabFontChanged is called automatically when the TabFont (see page 4430) property changes. It invalidates the notebook so that the tabs are repainted in the new font.

See Also

TabFont (see page 4430)

Invalidate

38.1.1.5 TTabbedNotebook Properties

The properties of the TTabbedNotebook class are listed here.

Protected Properties

	Name	Description
	Tabs (see page 4431)	Contains the list of text strings that label the tabs of the tab control.

Public Properties

	Name	Description
R	TopFont (see page 4433)	Returns the current value of font used on the tabs of the tabbed notebook.

Published Properties

	Name	Description
	ActivePage (see page 4413)	Determines which page displays in the tabbed notebook control.
	Align (see page 4414)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4417)	Specifies how the control is anchored to its parent.
	Constraints (see page 4418)	Specifies the size constraints for the control.
	DoubleBuffered (see page 4418)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 4420)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 4420)	Controls the attributes of text written on or in the control.
	PageIndex (see page 4421)	Determines which page displays in the tabbed notebook component.
	Pages (see page 4422)	Contains the strings that identify the individual pages of the tabbed notebook control.
	ParentDoubleBuffered (see page 4422)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 4423)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4423)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 4428)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabFont (see page 4430)	Determines the font used on the tabs of the tabbed notebook control.
	TabOrder (see page 4430)	Indicates the position of the control in its parent's tab order.
	TabsPerRow (see page 4432)	TabsPerRow is obsolete and retained only for backwards compatibility.
	TabStop (see page 4433)	Determines if the user can tab to a control.
	Visible (see page 4433)	Determines whether the component appears onscreen.

38.1.1.5.1 TTabbedNotebook.ActivePage Property

Determines which page displays in the tabbed notebook control.

Pascal

```
property ActivePage: string;
```

C++

```
__property UnicodeString ActivePage;
```

Description

The value of ActivePage must be one of the strings contained in the Pages (see page 4422) property.

Note: To indicate the page that appears in the tabbed notebook by index rather than text, use the PageIndex (see page 4421) property instead.

See Also

PageIndex (see page 4421)

Pages (see page 4422)

38.1.1.5.2 TTabbedNotebook.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;
```

```
  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
```

```
  it is important to set its position to the appropriate side
  of the control it will resize.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    Split: TSplitter;
    Files: TFileListBox;
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane - a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

Parent

Anchors

38.1.1.5.3 TTabbedNotebook.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

38.1.1.5.4 TTabbedNotebook.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

38.1.1.5.5 TTabbedNotebook.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
```

```
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;

38.1.1.5.6 TTabbedNotebook.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

38.1.1.5.7 TTabbedNotebook.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

38.1.1.5.8 TTabbedNotebook.PageIndex Property

Determines which page displays in the tabbed notebook component.

Pascal

```
property PageIndex: Integer;
```

C++

```
__property int PageIndex;
```

Description

Changing the PageIndex value changes the page in the control.

Each string in the Pages (see page 4422) property is automatically assigned a PageIndex value when the page is created. The first page receives a value of 0, the second has a value of 1, and so on. If you delete a string from the Pages (see page 4422) property, the PageIndex values are reassigned so that the values always begin with 0 and continue to increase without any gaps between values.

See Also

ActivePage (see page 4413)

Pages (see page 4422)

38.1.1.5.9 TTabbedNotebook.Pages Property

Contains the strings that identify the individual pages of the tabbed notebook control.

Pascal

```
property Pages: TStrings;
```

C++

```
__property TStrings Pages;
```

Description

Tabbed notebook controls create a separate page for each string in the Pages property. For example, if Pages contains three strings, First, Second, and Third, the control has three separate pages. Each string in Pages corresponds to a TTabPage (see page 4443) object whose Caption property is the same as the string.

You can change the active page in a tabbed notebook control with either the ActivePage (see page 4413) or PageIndex (see page 4421) property.

See Also

ActivePage (see page 4413)

PageIndex (see page 4421)

38.1.1.5.10 TTabbedNotebook.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of

the parent's DoubleBuffered property.

38.1.1.5.11 TTabbedNotebook.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

ShowHint

38.1.1.5.12 TTabbedNotebook.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
```

```
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)

    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
```

```
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

38.1.1.5.13 TTabbedNotebook.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{

38.1.1.5.14 TTabbedNotebook.TabFont Property

Determines the font used on the tabs of the tabbed notebook control.

Pascal

```
property TabFont: TFont;
```

C++

```
__property TFont TabFont;
```

Description

Use TabFont to specify the font characteristics used to display the label on the tabs of the notebook.

Note: The text on the selected tab is boldfaced if the selected font for the TabFont property is not also boldfaced.

See Also

TopFont (see page 4433)

38.1.1.5.15 TTabbedNotebook.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

TabStop

38.1.1.5.16 TTabbedNotebook.Tabs Property

Contains the list of text strings that label the tabs of the tab control.

Pascal

```
property Tabs;
```

C++

```
__property Tabs;
```

Description

Tabs contains a list of strings that label the tabs in the tab control. Tabs can also contain objects associated with the labels, using the TStrings Objects property. Add new strings to the Tabs property to add new tabs to the tab control. Rearrange the list to rearrange the tabs.

C++ Examples:

```
/*
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
*/
void __fastcall TForm1::Add_a_fileClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    int index = TabControl1->Tabs->Add(OpenDialog1->FileName);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[index]);
    TabControl1Change(Sender);
  }
}

void __fastcall TForm1::Assign_filesClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TabControl1->Tabs->Assign(OpenDialog1->Files);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[TabControl1->TabIndex]);
  }
}
/*
Place the following code in the tab control's OnChange event
handler:
*/
void __fastcall TForm1::TabControl1Change(TObject *Sender)
{
    Memo1->Lines->LoadFromFile(
      TabControl1->Tabs->Strings[TabControl1->TabIndex]);
}
```

Delphi Examples:

```
{
This example uses a tab control to display the contents of
```

```
  several files. To run the example, place a tab control on a
  form and add a memo control that fits into its client area.
  Be sure to leave enough room for the tabs when they appear.
  Then add an OpenDialog and a button to the form.  The
  "Add a file" button adds a single file to the tabcontrol.
  The "Assign files" button removes previous files and can be
  used to assign multiple files.  To assign multiple files,
  use CNTL Select or SHIFT Select to select files in the
  OpenDialog.
  }
  procedure TForm1.Add_a_fileClick(Sender: TObject);
  var index : integer;
  begin
    OpenDialog1.Options :=
      [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
    if OpenDialog1.Execute then
    begin
      index:= TabControl1.Tabs.Add(OpenDialog1.FileName);
      Memo1.Lines.LoadFromFile(TabControl1.Tabs[index]);
      TabControl1Change(Sender);
    end;
  end;

  procedure TForm1.Assign_filesClick(Sender: TObject);
  var index : integer;
  begin
    OpenDialog1.Options :=
      [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
    if OpenDialog1.Execute then
    begin
      TabControl1.Tabs.Assign(OpenDialog1.Files);
      Memo1.Lines.LoadFromFile(
        TabControl1.Tabs[TabControl1.TabIndex]);
    end;
  end;

  {
  Place the following code in the tab control's OnChange event
  handler:
  }
  procedure TForm1.TabControl1Change(Sender: TObject);
  begin
    with TabControl1 do
      Memo1.Lines.LoadFromFile(Tabs[TabIndex]);
  end;

TTabControl

38.1.1.5.17 TTabbedNotebook.TabsPerRow Property

TabsPerRow is obsolete and retained only for backwards compatibility.

Pascal

```
property TabsPerRow: Integer;
```

C++

```
__property int TabsPerRow;
```

Description

The TabsPerRow property determines the number of tabs that can appear in a row at the top of the tabbed notebook control. If there are more tabbed pages in the control than can fit in one row, multiple rows are displayed. The number of tabs you specify affects the size of the tabs--the more tabs per row--the smaller the tabs.

TabsPerRow can't be set to a value smaller than 3.

See Also

TabFont (see page 4430)

RowCount

38.1.1.5.18 TTabbedNotebook.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

38.1.1.5.19 TTabbedNotebook.TopFont Property

Returns the current value of font used on the tabs of the tabbed notebook.

Pascal

```
property TopFont: TFont;
```

C++

```
__property TFont TopFont;
```

Description

TopFont is a read-only property that reports the TabFont (see page 4430) value.

See Also

TabFont (see page 4430)

38.1.1.5.20 TTabbedNotebook.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);

38.1.1.6 TTabbedNotebook Events

The events of the TTabbedNotebook class are listed here.

Published Events

	Name	Description
	OnChange (see page 4435)	Occurs when the page of a tabbed notebook changes.
	OnClick (see page 4436)	Occurs when a tab of a tabbed notebook is selected.
	OnContextPopup (see page 4436)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 4437)	Occurs when a control receives the input focus.
	OnExit (see page 4439)	Occurs when the input focus shifts away from one control to another.

38.1.1.6.1 TTabbedNotebook.OnChange Event

Occurs when the page of a tabbed notebook changes.

Pascal

```
property OnChange: TPageChangeEvent;
```

C++

```
__property TPageChangeEvent OnChange;
```

Description

Write (see page 3707) an OnPage event handler to respond to a page change in a tabbed notebook.

See Also

OnClick (see page 4436)

38.1.1.6.2 TTabbedNotebook.OnClick Event

Occurs when a tab of a tabbed notebook is selected.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Write (see page 3707) an OnClick event handler to respond when the user selects a tab in the tabbed notebook. Immediately after the OnClick event occurs, the OnChange (see page 4435) event occurs.

See Also

OnChange (see page 4435)

38.1.1.6.3 TTabbedNotebook.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu

PopupMenu

AutoPopup

38.1.1.6.4 TTabbedNotebook.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
```

```
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
```

```
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;
```

38.1.1.6.5 TTabbedNotebook.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // initialize the maskedit boxes to contain the empty string
  MaskEdit1->Text = "";

    // extract the net and host mask from the subnet mask
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
```

```
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;

38.1.2 TTabPage Class

TTabPage implements an individual tab page of a tabbed notebook control.

Class Hierarchy

Pascal

```
TTabPage = class(TWinControl);
```

C++

```
class TTabPage : public TWinControl;
```

File

TabNotBk

Description

Each instance of this class holds the controls to be displayed when it is the active page of a tabbed notebook. TTabPage objects are associated with the strings in the corresponding tabbed notebook's Pages property by setting their Caption (see page 4445) property.

See Also

TTabbedNotebook (see page 4404)

38.1.2.1 TTabPage Members

The following tables list the members exposed by TTabPage.

Protected Methods

	Name	Description
	ReadState (see page 4445)	Prepares the control for having its properties assigned values from a stream.

Public Methods

	Name	Description
	Create (see page 4444)	Creates an instance of TWinControl.

Published Properties

	Name	Description
	Caption (see page 4445)	Specifies a text string that identifies the control to the user.
	Enabled (see page 4448)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 4449)	Specifies the vertical size of the control in pixels.
	TabOrder (see page 4450)	Indicates the position of the control in its parent's tab order.
	Visible (see page 4450)	Determines whether the component appears onscreen.
	Width (see page 4452)	Specifies the horizontal size of the control or form in pixels.

38.1.2.2 TTabPage.Create Constructor

Creates an instance of TWinControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabPage(TComponent * AOwner);
```

Description

Call Create to construct and initialize a new control and insert the newly-constructed control into its owner, as specified by the AOwner parameter. Create inserts the control in the owner by calling the owner's InsertComponent method.

Most controls override Create to initialize their unique properties. Objects that override the Create method must always call the inherited Create method first, and then proceed with the component-specific initialization. Specify the override directive when overriding the Create method.

If a component's Create method allocates resources or memory, override the Destroy method to free those resources.

38.1.2.3 TTabPage Methods

The methods of the TTabPage class are listed here.

Protected Methods

	Name	Description
	ReadState (see page 4445)	Prepares the control for having its properties assigned values from a stream.

38.1.2.3.1 TTabPage.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

ReadState

38.1.2.4 TTabPage Properties

The properties of the TTabPage class are listed here.

Published Properties

	Name	Description
	Caption (see page 4445)	Specifies a text string that identifies the control to the user.
	Enabled (see page 4448)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 4449)	Specifies the vertical size of the control in pixels.
	TabOrder (see page 4450)	Indicates the position of the control in its parent's tab order.
	Visible (see page 4450)	Determines whether the component appears onscreen.
	Width (see page 4452)	Specifies the horizontal size of the control or form in pixels.

38.1.2.4.1 TTabPage.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

Note: The Caption property inheritted from TControl is a protected property. Access to the Caption requires casting the class to an inheritted one where Caption is a published or public property.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
```

```
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
```

```
    for I := 0 to High(ButtonCaptions) do
      begin
        with TToolButton.Create(ToolBar) do
        begin
          Parent := ToolBar;
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
    ToolBar1.Free;
  end;
```

38.1.2.4.2 TTabPage.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

38.1.2.4.3 TTabPage.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height;
```

C++

```
__property Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
```

```
    end;
end;
```

38.1.2.4.4 TTabPage.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

38.1.2.4.5 TTabPage.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false,

the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
```

```
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

38.1.2.4.6 TTabPage.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width;
```

C++

```
__property Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
    ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
    ps->Align = pdlb->Align; // Give same alignment as directory list.

    // Each pane must be at least one quarter of the form's width.
    ps->MinSize = Form1->ClientWidth/4;

    // Finally, create the last pane - a file list box.
    pflb->Parent = Form1;
    pflb->Align = alClient;
    pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);

38.2 Types

The following table lists types in this documentation.

Types

Name	Description
TPageChangeEvent (see page 4454)	TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 4404) control.

38.2.1 TabNotBk.TPageChangeEvent Type

TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 4404) control.

Pascal

```
TPageChangeEvent = procedure (Sender: TObject; NewTab: Integer; var AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; NewTab: Integer; var AllowChange: Boolean) ( TPageChangeEvent)();
```

File

TabNotBk

Description

Sender is the TTabbedNotebook (see page 4404) control.

NewTab is the tab that is about to become the selected or current tab.

AllowChange specifies whether the change to a new page is allowed. If the event handler sets AllowChange to false, a new page change doesn't occur.

38.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CM_TABFONTCHANGED (see page 4455)	This is constant TabNotBk.CM_TABFONTCHANGED.

38.3.1 TabNotBk.CM_TABFONTCHANGED Constant

Pascal

```
CM_TABFONTCHANGED = CM_BASE + 100;
```

C++

```
CM_TABFONTCHANGED = CM_BASE + 100;
```

File

TabNotBk

Description

This is constant TabNotBk.CM_TABFONTCHANGED.

39 Tabs Namespace

This is namespace Tabs.

Topics

Name	Description
Classes (see page 4458)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 4538)	The following table lists structs, records, enums in this documentation.
Types (see page 4541)	The following table lists types in this documentation.

Classes

	Name	Description
	TScroller (see page 4458)	TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.
	TTabList (see page 4463)	This is class Tabs.TTabList.
	TTabSet (see page 4470)	The TTabSet component presents horizontal tabs users can click to initiate actions.

Structs, Records, Enums

	Name	Description
	TEdgePart (see page 4538)	This is record Tabs.TEdgePart.
	TEdgeType (see page 4538)	This is record Tabs.TEdgeType.
	TScrollBtn (see page 4539)	This is record Tabs.TScrollBtn.
	TScrollOrientation (see page 4539)	This is record Tabs.TScrollOrientation.
	TTabSetTabStyle (see page 4540)	This is record Tabs.TTabSetTabStyle.

Types

Name	Description
TDrawTabEvent (see page 4541)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.
TMeasureTabEvent (see page 4541)	TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 4470) control.
TTabChangeEvent (see page 4542)	TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 4470) control changes.
TTabSetDrawTabEvent (see page 4542)	TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.
TTabStyle (see page 4543)	TTabStyle indicates whether a TTabSet (see page 4470) control is owner-drawn.

39.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TScroller (see page 4458)	TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.
	TTabList (see page 4463)	This is class Tabs.TTabList.
	TTabSet (see page 4470)	The TTabSet component presents horizontal tabs users can click to initiate actions.

39.1.1 TScroller Class

TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.

Class Hierarchy

Pascal

```
TScroller = class(TCustomControl);
```

C++

```
class TScroller : public TCustomControl;
```

File

Tabs

Description

The TTabSet (see page 4470) object uses TScroller to scroll its visible tabs. TScroller is provided for backward compatibility only. TScroller is similar to an up-down control (TUpDown) with a horizontal orientation, except that it does not work with a companion control.

TTabSet (see page 4470)

TUpDown

39.1.1.1 TScroller Members

The following tables list the members exposed by TScroller.

Protected Methods

	Name	Description
	Paint (see page 4460)	Paints the image of the TScroller (see page 4458) object into its canvas.

Public Methods

	Name	Description
	Create (see page 4459)	Creates an instance of TScroller (see page 4458).
	Destroy (see page 4460)	Frees the memory associated with the TScroller (see page 4458) object.

Published Events

	Name	Description
	OnClick (see page 4463)	OnClick occurs after the Position (see page 4462) property has been updated in response to the user clicking one of the arrow buttons.

Published Properties

	Name	Description
	Change (see page 4461)	Specifies the number of units to scroll when the user clicks the arrow buttons.
	Max (see page 4461)	Specifies the maximum value the Position (see page 4462) property can take.
	Min (see page 4462)	Specifies the minimum value the Position (see page 4462) property can take.
	Position (see page 4462)	Position is the current position in the scroll range.
	ScrollOrientation (see page 4462)	This is ScrollOrientation, a member of class TScroller.

39.1.1.2 TScroller.Create Constructor

Creates an instance of TScroller (see page 4458).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScroller(TComponent * AOwner);
```

Description

Call TScroller (see page 4458) to create an instance of TScroller (see page 4458) at runtime. TScroller (see page 4458) allocates the memory for the TScroller (see page 4458) object and initializes

Width to 24 and Height to 13

Min (see page 4462) and Max (see page 4461) to 0

Position (see page 4462) to 0

Change (see page 4461) to 1

The AOwner parameter specifies the component (usually the form) that is responsible for freeing the scroller.

See Also

Change (see page 4461)

Height

Max (see page 4461)

Min (see page 4462)

Position (see page 4462)

Width

39.1.1.3 TScroller.Destroy Destructor

Frees the memory associated with the TScroller (see page 4458) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TScroller();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks whether the TScroller (see page 4458) reference is nil before calling Destroy.

See Also

Create (see page 4459)

System::TObject::Free (see page 3372)

39.1.1.4 TScroller Methods

The methods of the TScroller class are listed here.

Protected Methods

	Name	Description
	Paint (see page 4460)	Paints the image of the TScroller (see page 4458) object into its canvas.

39.1.1.4.1 TScroller.Paint Method

Paints the image of the TScroller (see page 4458) object into its canvas.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called automatically in response to WM_PAINT messages. Paint paints the arrow buttons, graying them out when Position (see page 4462) cannot be moved in the associated direction.

See Also

Position (see page 4462)

Canvas

39.1.1.5 TScroller Properties

The properties of the TScroller class are listed here.

Published Properties

	Name	Description
	Change (see page 4461)	Specifies the number of units to scroll when the user clicks the arrow buttons.
	Max (see page 4461)	Specifies the maximum value the Position (see page 4462) property can take.
	Min (see page 4462)	Specifies the minimum value the Position (see page 4462) property can take.
	Position (see page 4462)	Position is the current position in the scroll range.
	ScrollOrientation (see page 4462)	This is ScrollOrientation, a member of class TScroller.

39.1.1.5.1 TScroller.Change Property

Specifies the number of units to scroll when the user clicks the arrow buttons.

Pascal

```
property Change: Integer;
```

C++

```
__property int Change;
```

Description

Set Change to indicate the number of units between Min (see page 4462) and Max (see page 4461) the Position (see page 4462) moves whenever the user clicks on one of the arrow buttons. Change represents the mapping between the units used to specify Min (see page 4462), Max (see page 4461), and Position (see page 4462), and the logical units represented by the scroller.

For example, if the values of Min (see page 4462), Max (see page 4461), and Position (see page 4462) are given in screen pixels, Change would be the number of pixels to scroll whenever the user clicks the scroll arrow.

See Also

Max (see page 4461)

Min (see page 4462)

Position (see page 4462)

39.1.1.5.2 TScroller.Max Property

Specifies the maximum value the Position (see page 4462) property can take.

Pascal

```
property Max: Longint;
```

C++

```
__property Longint Max;
```

Description

Use Max to set the upper limit of the scrolling range. The Max and Min (see page 4462) properties define the range of values over which the scroller can scroll.

See Also

Change (see page 4461)

Min (see page 4462)

Position (see page 4462)

39.1.1.5.3 TScroller.Min Property

Specifies the minimum value the Position (see page 4462) property can take.

Pascal

```
property Min: Longint;
```

C++

```
__property Longint Min;
```

Description

Use Min to set the lower limit of the scrolling range. The Min and Max (see page 4461) properties define the range of values over which the scroller can scroll.

See Also

Change (see page 4461)

Max (see page 4461)

Position (see page 4462)

39.1.1.5.4 TScroller.Position Property

Position is the current position in the scroll range.

Pascal

```
property Position: Longint;
```

C++

```
__property Longint Position;
```

Description

Read (see page 3634) Position to determine the current position the scroller represents. Position is a value between Min (see page 4462) and Max (see page 4461). Use an OnClick (see page 4463) event handler to notify the object being scrolled when the Position changes.

See Also

Max (see page 4461)

Min (see page 4462)

OnClick (see page 4463)

39.1.1.5.5 TScroller.ScrollOrientation Property

Pascal

```
property ScrollOrientation: TScrollOrientation;
```

C++

```
__property TScrollOrientation ScrollOrientation;
```

Description

This is ScrollOrientation, a member of class TScroller.

39.1.1.6 TScroller Events

The events of the TScroller class are listed here.

Published Events

	Name	Description
	OnClick (see page 4463)	OnClick occurs after the Position (see page 4462) property has been updated in response to the user clicking one of the arrow buttons.

39.1.1.6.1 TScroller.OnClick Event

OnClick occurs after the Position (see page 4462) property has been updated in response to the user clicking one of the arrow buttons.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Write (see page 3707) an OnClick event handler to implement the scrolling action of the object that uses the TScroller (see page 4458) to control scrolling. When the user clicks one of the arrow buttons, the Position (see page 4462) gets updated by Change (see page 4461) (unless the Max (see page 4461) or Min (see page 4462) value is hit), and then an OnClick event occurs.

See Also

Change (see page 4461)

Max (see page 4461)

Min (see page 4462)

Position (see page 4462)

39.1.2 TTabList Class

Class Hierarchy

Pascal

```
TTabList = class(TStringList);
```

C++

```
class TTabList : public TStringList;
```

File

Tabs

Description

This is class Tabs.TTabList.

39.1.2.1 TTabList Members

The following tables list the members exposed by TTabList.

Protected Methods

	Name	Description
	Put (see page 4470)	Changes the value of the string with a specified index.

Public Methods

	Name	Description
	Add (see page 4464)	Adds a new string to the list.
	AddStrings (see page 4467)	Adds a group of strings to the list.
	Clear (see page 4468)	Deletes all the strings from the list.
	Create (see page 4464)	This is Create, a member of class TTabList.
	Delete (see page 4469)	Removes the string specified by the `Index` parameter.
	Insert (see page 4469)	Inserts a string to the list at the position specified by `Index`.

39.1.2.2 TTabList.Create Constructor

Pascal

```
constructor Create(const ATabSet: TTabSet);
```

C++

```
__fastcall TTabList(const TTabSet ATabSet);
```

Description

This is Create, a member of class TTabList.

39.1.2.3 TTabList Methods

The methods of the TTabList class are listed here.

Protected Methods

	Name	Description
	Put (see page 4470)	Changes the value of the string with a specified index.

Public Methods

	Name	Description
	Add (see page 4464)	Adds a new string to the list.
	AddStrings (see page 4467)	Adds a group of strings to the list.
	Clear (see page 4468)	Deletes all the strings from the list.
	Delete (see page 4469)	Removes the string specified by the `Index` parameter.
	Insert (see page 4469)	Inserts a string to the list at the position specified by `Index`.

39.1.2.3.1 TTabList.Add Method

Adds a new string to the list.

Pascal

```
function Add(const S: string): Integer; override;
```

C++

```
virtual __fastcall int Add(const UnicodeString S);
```

Description

Call Add to add the string S to the list. If the list is sorted, S is added to the appropriate position in the sort order. If the list is not sorted, S is added to the end of the list. Add returns the position of the item in the list, where the first item in the list has a value of 0.

Note: For sorted lists, Add will raise an EListError exception if the string S already appears in the list and Duplicates is set to dupError. If Duplicates is set to dupIgnore, trying to add a duplicate string causes Add to return the index of the existing entry.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  std::auto_ptr<TStringList> MyList(new TStringList());
  MyList->Add("Animals");
  MyList->Add("Flowers");
  MyList->Add("Ocean");
  MyList->Sort(); // Find will only work on sorted lists
  if (MyList->Find("Flowers", Index))
  {
    ListBox1->Items->AddStrings(MyList.get());
    Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
  }
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<TStrings> StringList(new TStringList());
  StringList->Add("This example uses A string List. ");
  StringList->Add("It is the easiest way to add strings");
  StringList->Add("to a combobox's list of strings. ");
  StringList->Add("Always remember TStrings is abstract,");
  StringList->Add("So create a TStringList instead.");
  ComboBox1->Width = 210;
  ComboBox1->Items->Assign(StringList.get());
  ComboBox1->ItemIndex = 0;
}
```

Delphi Examples:

```
{
```

```
  This example uses a list box and a label on a form. When the
  application runs, a string list object is created and three
  strings are added to it. The Find method searches the
  strings to look for a match with the string 'Flowers'. If
  the string is found, all the strings in the string list are
  added to the list box, and the index value of the 'Flowers'
  string appears in the caption of the label control.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    MyList: TStringList;
    Index: Integer;
  begin
    MyList := TStringList.Create;
    try
      MyList.Add('Animals');
      MyList.Add('Flowers');
      MyList.Add('Cars');
      MyList.Sort;   { Find will only work on sorted lists! }
      if MyList.Find('Flowers', Index) then
      begin
        ListBox1.Items.AddStrings(MyList);
        Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
      end;
    finally
      MyList.Free;
    end;
  end;
  {
  This example creates a stringlist, adds elements to it and
  assigns the strings to items of a combo box.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    StringList: TStringList;
  begin
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('This example uses A string List.');
        Add('It is the easiest way to add strings');
        Add('to a combobox''s list of strings.');
        Add('Always remember TStrings.Create method');
        Add('is abstract; So use TStringList.Create');
        Add('method instead.');
      end;
      with ComboBox1 do begin
        Width := 210;
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

39.1.2.3.2 TTabList.AddStrings Method

Adds a group of strings to the list.

Pascal

```
procedure AddStrings(Strings: TStrings); override;
```

C++

```
virtual __fastcall AddStrings(TStrings Strings);
```

Description

Call AddStrings to add the strings from another TStrings object to the list. If both the source and destination TStrings objects support objects associated with their strings, references to the associated objects will be added as well.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  std::auto_ptr<TStringList> MyList(new TStringList());
  MyList->Add("Animals");
  MyList->Add("Flowers");
  MyList->Add("Ocean");
  MyList->Sort(); // Find will only work on sorted lists
  if (MyList->Find("Flowers", Index))
  {
    ListBox1->Items->AddStrings(MyList.get());
    Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
  }
}
/*
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  std::auto_ptr<TStringList> list(new TStringList());
  list->Add("Plants");
  list->Add("Animals");
  list->Add("Minerals");
  list->Sorted = true;
  ListBox1->Items->AddStrings(list.get());
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
  finally
    MyList.Free;
  end;
end;
{
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
begin
  MyList := TStringList.Create;
  MyList.Add('Plants');
  MyList.Add('Animals');
  MyList.Add('Minerals');
  MyList.Sorted := True;
  ListBox1.Items.AddStrings(MyList);
  MyList.Free;
end;
```

39.1.2.3.3 TTabList.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete

Objects

Strings

39.1.2.3.4 TTabList.Delete Method

Removes the string specified by the `Index` parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add

AddObject

Clear

IndexOf

InsertObject

Objects

Strings

39.1.2.3.5 TTabList.Insert Method

Inserts a string to the list at the position specified by `Index`.

Pascal

```
procedure Insert(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Insert(int Index, const UnicodeString S);
```

Description

Call Insert to add the string S to the list at the position specified by `Index`. If `Index` is 0, the string is inserted at the beginning of the list. If `Index` is 1, the string is put in the second position of the list, and so on.

If the string has an associated object, use the InsertObject method instead.

Note: If the list is sorted, calling Insert or InsertObject will raise an EListError exception. Use Add or AddObject with sorted lists.

Strings

39.1.2.3.6 TTabList.Put Method

Changes the value of the string with a specified index.

Pascal

```
procedure Put(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Put(int Index, const UnicodeString S);
```

Description

Put is the protected write implementation of the Strings property.

Put changes the value of the string with the index specified by `Index` to S. Put does not change the object at the specified position. That is, any object associated with the previous string becomes associated with the new string.

39.1.3 TTabSet Class

The TTabSet component presents horizontal tabs users can click to initiate actions.

Class Hierarchy

Pascal

```
TTabSet = class(TCustomControl);
```

C++

```
class TTabSet : public TCustomControl;
```

File

Tabs

Description

Tab set controls are commonly used to display tabbed pages within a dialog box. TTabSet is provided for backward compatibility. Use TTabControl component in 32-bit Windows applications.

You create a set of tabs for the tab set control when you specify a list of strings as the value of the Tabs (see page 4506) property. One tab is created for each string.

To determine which tab is currently selected or to use code to select a tab, use the TabIndex (see page 4506) property. To find out which tab is the first visible tab in the tab set control or to make a tab the first visible tab, use the FirstIndex (see page 4494) property.

39.1.3.1 TTabSet Members

The following tables list the members exposed by TTabSet.

Protected Methods

	Name	Description
	CanChange (see page 4474)	This is CanChange, a member of class TTabSet.
	CMHintShow (see page 4474)	This is CMHintShow, a member of class TTabSet.
V	CreateParams (see page 4475)	Initializes a window-creation parameter data structure.
V	DrawTab (see page 4475)	This is DrawTab, a member of class TTabSet.
V	GetImageIndex (see page 4476)	This is GetImageIndex, a member of class TTabSet.
V	MeasureTab (see page 4477)	This is MeasureTab, a member of class TTabSet.
V	MouseDown (see page 4478)	OnMouseDown event dispatcher.
V	Notification (see page 4479)	Responds to notifications that components are being created or destroyed.
V	Paint (see page 4479)	Renders the image of a custom control.
V	SetTabIndex (see page 4480)	This is SetTabIndex, a member of class TTabSet.

Protected Properties

	Name	Description
R	Scroller (see page 4502)	This is Scroller, a member of class TTabSet.

Public Methods

	Name	Description
V	Create (see page 4473)	Constructs a tab set control.
V	Destroy (see page 4473)	Frees the memory associated with the TTabSet (see page 4470) object.
V	GetChildren (see page 4475)	Calls a specified method for each child of the control.
	ItemAtPos (see page 4476)	Returns the index of the tab indicated by the coordinates of a point on the control.
	ItemRect (see page 4476)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ItemWidth (see page 4477)	Returns the width, in pixels, of a specified tab in the set.
	MinClientRect (see page 4477)	This is the overview for the MinClientRect method overload.
	SelectNext (see page 4480)	Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.

Public Properties

	Name	Description
	Canvas (see page 4486)	Specifies the TCanvas object that presents a drawing surface for the control.
	FirstIndex (see page 4494)	Specifies the tab that appears in the leftmost visible position in the tab set control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 4509)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 4510)	Occurs when an object with custom alignment is aligned.
	OnChange (see page 4511)	Occurs just before a new tab is selected.
	OnClick (see page 4511)	Occurs when the user clicks the control.
	OnDragDrop (see page 4513)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 4516)	Occurs when the user drags an object over a control.
	OnDrawTab (see page 4519)	Occurs when a tab in an owner-drawn tab set control needs to redisplay.
	OnEndDock (see page 4519)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 4520)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 4521)	Occurs when a control receives the input focus.
	OnExit (see page 4523)	Occurs when the input focus shifts away from one control to another.
	OnGetImageIndex (see page 4527)	This is OnGetImageIndex, a member of class TTabSet.
	OnMeasureTab (see page 4527)	Occurs when an application needs to redisplay a tab in an owner-draw tab set.
	OnMouseActivate (see page 4528)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 4529)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 4531)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 4531)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 4532)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 4534)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 4536)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 4537)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 4481)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4485)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 4485)	Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.
	BackgroundColor (see page 4486)	Determines the background color of the tab set control.
	Constraints (see page 4488)	Specifies the size constraints for the control.
	DitherBackground (see page 4489)	Determines whether the background color set with the BackgroundColor (see page 4486) property is dithered.
	DoubleBuffered (see page 4489)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 4491)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 4491)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 4492)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 4493)	Controls whether the control responds to mouse, keyboard, and timer events.
	EndMargin (see page 4494)	Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.
	Font (see page 4494)	Controls the attributes of text written on or in the control.
	Images (see page 4496)	This is Images, a member of class TTabSet.
	ParentBackground (see page 4496)	Determines whether control uses parent's theme background.
	ParentDoubleBuffered (see page 4496)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 4496)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4497)	Identifies the pop-up menu associated with the control.
	SelectedColor (see page 4502)	Determines the color of the selected tab in the tab set control.

	ShowHint (see page 4502)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShrinkToFit (see page 4504)	This is ShrinkToFit, a member of class TTabSet.
	SoftTop (see page 4504)	Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.
	StartMargin (see page 4504)	Determines how far, in pixels, the first tab appears from the left edge of the tab set control.
	Style (see page 4505)	Determines whether the tab set is owner-drawn.
	TabHeight (see page 4505)	Determines the height of the tabs in an owner-drawn tab set control.
	TabIndex (see page 4506)	Determines which tab of a tab set control is currently selected.
	TabPosition (see page 4506)	This is TabPosition, a member of class TTabSet.
	Tabs (see page 4506)	Contains the list of text strings that appear on the tabs.
	UnselectedColor (see page 4507)	Determines the color of the tabs that aren't currently selected in the tab set control.
	Visible (see page 4507)	Determines whether the component appears onscreen.
R	VisibleTabs (see page 4508)	Contains the number of tabs currently visible in the tab set control.

39.1.3.2 TTabSet.Create Constructor

Constructs a tab set control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabSet(TComponent * AOwner);
```

Description

Create sets the initial values of the control, including creating a TTabList (see page 4463) object that holds the list of tabs for the control. The AOwner parameter specifies the component (usually a form) that is responsible for freeing the tab set.

See Also

Destroy (see page 4473)

39.1.3.3 TTabSet.Destroy Destructor

Frees the memory associated with the TTabSet (see page 4470) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTabSet();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks that the tab set is not nil before calling Destroy. Destroy frees the TTabList (see page 4463) object that holds the list of tabs.

See Also

Create (see page 4473)

System::TObject::Free (see page 3372)

39.1.3.4 TTabSet Methods

The methods of the TTabSet class are listed here.

Protected Methods

	Name	Description
	CanChange (see page 4474)	This is CanChange, a member of class TTabSet.
	CMHintShow (see page 4474)	This is CMHintShow, a member of class TTabSet.
V	CreateParams (see page 4475)	Initializes a window-creation parameter data structure.
V	DrawTab (see page 4475)	This is DrawTab, a member of class TTabSet.
V	GetImageIndex (see page 4476)	This is GetImageIndex, a member of class TTabSet.
V	MeasureTab (see page 4477)	This is MeasureTab, a member of class TTabSet.
V	MouseDown (see page 4478)	OnMouseDown event dispatcher.
V	Notification (see page 4479)	Responds to notifications that components are being created or destroyed.
V	Paint (see page 4479)	Renders the image of a custom control.
V	SetTabIndex (see page 4480)	This is SetTabIndex, a member of class TTabSet.

Public Methods

	Name	Description
V	GetChildren (see page 4475)	Calls a specified method for each child of the control.
	ItemAtPos (see page 4476)	Returns the index of the tab indicated by the coordinates of a point on the control.
	ItemRect (see page 4476)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ItemWidth (see page 4477)	Returns the width, in pixels, of a specified tab in the set.
	MinClientRect (see page 4477)	This is the overview for the MinClientRect method overload.
	SelectNext (see page 4480)	Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.

39.1.3.4.1 TTabSet.CanChange Method

Pascal

```
function CanChange(NewIndex: Integer): Boolean;
```

C++

```
__fastcall Boolean CanChange(int NewIndex);
```

Description

This is CanChange, a member of class TTabSet.

39.1.3.4.2 TTabSet.CMHintShow Method

Pascal

```
procedure CMHintShow(var Message: TCMHintShow); message CM_HINTSHOW;
```

C++

```
__fastcall CMHintShow(TCMHintShow Message);
```

Description

This is CMHintShow, a member of class TTabSet.

39.1.3.4.3 TTabSet.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

39.1.3.4.4 TTabSet.DrawTab Method

Pascal

```
procedure DrawTab(TabCanvas: TCanvas; R: TRect; Index: Integer; Selected: Boolean); virtual;
```

C++

```
virtual __fastcall DrawTab(TCanvas TabCanvas, TRect R, int Index, Boolean Selected);
```

Description

This is DrawTab, a member of class TTabSet.

39.1.3.4.5 TTabSet.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls

Owner

39.1.3.4.6 TTabSet.GetImageIndex Method

Pascal

```
function GetImageIndex(TabIndex: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int GetImageIndex(int TabIndex);
```

Description

This is GetImageIndex, a member of class TTabSet.

39.1.3.4.7 TTabSet.ItemAtPos Method

Returns the index of the tab indicated by the coordinates of a point on the control.

Pascal

```
function ItemAtPos(Pos: TPoint; IgnoreTabHeight: Boolean = False): Integer;
```

C++

```
__fastcall int ItemAtPos(TPoint Pos, Boolean IgnoreTabHeight = False);
```

Description

Call ItemAtPos to identify the tab under the point specified by the Pos (see page 3627) parameter. Pos (see page 3627) is the point in the control in client coordinates. If the returned index is 0, the tab is the first tab in the tab set, if the index is 1, the tab is the second tab, and so on. ItemAtPos returns –1 if there is no tab at the specified point.

See Also

ItemRect (see page 4476)

39.1.3.4.8 TTabSet.ItemRect Method

Returns the rectangle that surrounds the item specified in the Item parameter.

Pascal

```
function ItemRect(Index: Integer): TRect;
```

C++

```
__fastcall TRect ItemRect(int Index);
```

Description

Use ItemRect to obtain the rectangle that surrounds the tab when you are drawing on an owner-draw tab set.

See Also

ItemAtPos (see page 4476)

Style (see page 4505)

OnDrawTab (see page 4519)

OnMeasureTab (see page 4527)

39.1.3.4.9 TTabSet.ItemWidth Method

Returns the width, in pixels, of a specified tab in the set.

Pascal

```
function ItemWidth(Index: Integer): Integer;
```

C++

```
__fastcall int ItemWidth(int Index);
```

Description

Use ItemWidth to obtain the width, in pixels of a specified tab.

Index is the index of the tab, where 0 indicates the first tab, 1 indicates the second tab, and so on.

See Also

ItemAtPos (see page 4476)

ItemRect (see page 4476)

39.1.3.4.10 TTabSet.MeasureTab Method

Pascal

```
procedure MeasureTab(Index: Integer; var TabWidth: Integer); virtual;
```

C++

```
virtual __fastcall MeasureTab(int Index, int TabWidth);
```

Description

This is MeasureTab, a member of class TTabSet.

39.1.3.4.11 MinClientRect Method

This is the overview for the MinClientRect method overload.

Overload List

	Name	Description
	TTabSet.MinClientRect () (see page 4477)	Returns the boundaries that are required to display the tabs in the tab set.
	TTabSet.MinClientRect (Boolean) (see page 4477)	Returns the boundaries that are required to display the tabs in the tab set.
	TTabSet.MinClientRect (Integer, Boolean) (see page 4477)	Returns the boundaries that are required to display the tabs in the tab set.

39.1.3.4.11.1 TTabSet.MinClientRect Method ()

Returns the boundaries that are required to display the tabs in the tab set.

Pascal

```
function MinClientRect: TRect; overload;
function MinClientRect(IncludeScroller: Boolean): TRect; overload;
function MinClientRect(TabCount: Integer; IncludeScroller: Boolean = False): TRect; overload;
```

C++

```
__fastcall TRect MinClientRect();
__fastcall TRect MinClientRect(Boolean IncludeScroller);
__fastcall TRect MinClientRect(int TabCount, Boolean IncludeScroller = False);
```

Description

Use MinClientRect to obtain the minimum size that the tab set's client area must be to display its tabs and (if specified) a scroller for scrolling hidden tabs. MinClientRect calculates the width based on the widths of all the tabs up to a specified count, adding in the values of StartMargin (see page 4504) and EndMargin (see page 4494) and the space that appears between tabs. If requested, it also adds the width of a scroller for the tabs. It calculates the height based on the value of the TabHeight (see page 4505) property.

TabCount specifies the number of tabs to display. MinClientRect uses the widths of these tabs to calculate the width of the client rectangle. If you use a syntax that does not include a TabCount parameter, MinClientRect assumes that all tabs must be visible.

IncludeScroller indicates whether the client rectangle must include space for the scroller control that allows users to scroll the tabs, displaying any tabs that are not included in TabCount. If IncludeScroller is false, or if this parameter is omitted, MinClientRect does not include the width for the scroller in the resulting rectange.

MinClientRect returns the dimensions, in pixels, needed to display the specified number of tabs and, if specified, the scroller. The returned rectangle has an origin of 0,0.

See Also

TabHeight (see page 4505)

ItemWidth (see page 4477)

StartMargin (see page 4504)

EndMargin (see page 4494)

39.1.3.4.12 TTabSet.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which

it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

MouseMove

MouseUp

OnMouseDown

39.1.3.4.13 TTabSet.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

Notification

39.1.3.4.14 TTabSet.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

Canvas

PaintWindow

GetDeviceContext

ClipRect

39.1.3.4.15 TTabSet.SelectNext Method

Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.

Pascal

```
procedure SelectNext(Direction: Boolean);
```

C++

```
__fastcall SelectNext(Boolean Direction);
```

Description

The value of the Direction parameters determines if the tab to the left or right is selected. If Direction is true, the tab to the right is selected. If Direction is false, the tab to the left is selected. When the last tab in either direction is selected, calling SelectNext using the same direction wraps around to the beginning of the tab order. For example, if your application has three tabs, First, Second, and Third, and Third is the current tab, calling SelectNext(true) selects First. Likewise, if First is the current tab, SelectNext(false) selects Third.

When SelectNext is called, the OnClick (see page 4511) event of the tab set occurs, followed by the OnChange (see page 4511) event, just as if the user had clicked on a new tab.

See Also

Tabs (see page 4506)

OnChange (see page 4511)

39.1.3.4.16 TTabSet.SetTabIndex Method

Pascal

```
procedure SetTabIndex(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetTabIndex(int Value);
```

Description

This is SetTabIndex, a member of class TTabSet.

39.1.3.5 TTabSet Properties

The properties of the TTabSet class are listed here.

Protected Properties

	Name	Description
	Scroller (see page 4502)	This is Scroller, a member of class TTabSet.

Public Properties

	Name	Description
	Canvas (see page 4486)	Specifies the TCanvas object that presents a drawing surface for the control.
	FirstIndex (see page 4494)	Specifies the tab that appears in the leftmost visible position in the tab set control.

Published Properties

	Name	Description
	Align (see page 4481)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4485)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 4485)	Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.
	BackgroundColor (see page 4486)	Determines the background color of the tab set control.
	Constraints (see page 4488)	Specifies the size constraints for the control.
	DitherBackground (see page 4489)	Determines whether the background color set with the BackgroundColor (see page 4486) property is dithered.
	DoubleBuffered (see page 4489)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 4491)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 4491)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 4492)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 4493)	Controls whether the control responds to mouse, keyboard, and timer events.
	EndMargin (see page 4494)	Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.
	Font (see page 4494)	Controls the attributes of text written on or in the control.
	Images (see page 4496)	This is Images, a member of class TTabSet.
	ParentBackground (see page 4496)	Determines whether control uses parent's theme background.
	ParentDoubleBuffered (see page 4496)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 4496)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4497)	Identifies the pop-up menu associated with the control.
	SelectedColor (see page 4502)	Determines the color of the selected tab in the tab set control.
	ShowHint (see page 4502)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShrinkToFit (see page 4504)	This is ShrinkToFit, a member of class TTabSet.
	SoftTop (see page 4504)	Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.
	StartMargin (see page 4504)	Determines how far, in pixels, the first tab appears from the left edge of the tab set control.
	Style (see page 4505)	Determines whether the tab set is owner-drawn.
	TabHeight (see page 4505)	Determines the height of the tabs in an owner-drawn tab set control.
	TabIndex (see page 4506)	Determines which tab of a tab set control is currently selected.
	TabPosition (see page 4506)	This is TabPosition, a member of class TTabSet.
	Tabs (see page 4506)	Contains the list of text strings that appear on the tabs.
	UnselectedColor (see page 4507)	Determines the color of the tabs that aren't currently selected in the tab set control.
	Visible (see page 4507)	Determines whether the component appears onscreen.
R	VisibleTabs (see page 4508)	Contains the number of tabs currently visible in the tab set control.

39.1.3.5.1 TTabSet.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
```

```
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
```

```
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    ProgressBar: TProgressBar;
  begin
    ProgressBar := TProgressBar.Create(Self);
    with ProgressBar do
    begin
      Parent := Self;
      Align := alBottom;
    end;
  end;
  {
  This example dynamically creates a Page Control, then a
  series of Tab Sheets on the Page Control.
  }
  var
    PageControl1: TPageControl;
    pts: array[0..3] of TTabSheet;
  const
    TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

  procedure TForm1.FormCreate(Sender: TObject);
  const

Anchors

39.1.3.5.2 TTabSet.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

39.1.3.5.3 TTabSet.AutoScroll Property

Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is false, the application can still access tabs that aren't visible by using the FirstIndex (see page 4494) or TabIndex (see page 4506) properties at design time or runtime, but the user can't click on the tabs with the mouse at runtime.

See Also

FirstIndex (see page 4494)

TabIndex (see page 4506)

39.1.3.5.4 TTabSet.BackgroundColor Property

Determines the background color of the tab set control.

Pascal

```
property BackgroundColor: TColor;
```

C++

```
__property TColor BackgroundColor;
```

Description

Use BackgroundColor to indicate the color that the tab set control uses to paint the area between the tabs and the border of the control.

See Also

DitherBackground (see page 4489)

SelectedColor (see page 4502)

Color

39.1.3.5.5 TTabSet.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
```

```
  be called after DrawFocusRect. The OnSelectCell event handler
  must implemented to return true.
  */
  void __fastcall TForm1::DrawGrid1DrawCell(
    TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
  {
    long index = ARow * DrawGrid1->ColCount + ACol;
    DrawGrid1->Canvas->Brush->Color = clBackground;
    DrawGrid1->Canvas->FillRect(Rect);
    if (State.Contains(gdFocused))
    {
      DrawGrid1->Canvas->DrawFocusRect(Rect);
      Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
    }
    ImageList1->Draw(
      DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
  }

  void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
        bool &CanSelect)
  {
    CanSelect= True;
  }
  /*
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  */
  {
    TPoint APoint = Point(X, Y);
    int Index = ListBox1->ItemAtPos(APoint, True);
    TStringGrid *myStringGrid;
    TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
    if (String(ClassRef->ClassName()) == "TStringGrid")
    {
      myStringGrid = dynamic_cast<TStringGrid *>(ListBox1->Items->Objects[Index]);
      // make sure we are using the TControls canvas and not the from's!
      myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
      myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
  myStringGrid->ClientRect.Bottom);
      myStringGrid = NULL;
    }
  }
```

Delphi Examples:

```
  {
  The following code uses the bitmaps in an image list
  component to draw the contents of each cell in a draw grid.
  It draws a focus rectangle around the cell that has focus.
  goDrawFocusSelect in the DrawGrid Options parameter must be
  True to set focus on a cell.  The ImageList Draw method must
  be called after DrawFocusRect. The OnSelectCell event handler
  must implemented to return true.
  }
  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clWhite;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
```

```
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TStringGrid) then
  begin
    myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
    with myStringGrid.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myStringGrid.Canvas.MoveTo(Left, Top);
      myStringGrid.Canvas.LineTo(Right, Bottom);
    end;
  myStringGrid:= nil;
  end;
```

Paint

39.1.3.5.6 TTabSet.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

39.1.3.5.7 TTabSet.DitherBackground Property

Determines whether the background color set with the BackgroundColor (see page 4486) property is dithered.

Pascal

```
property DitherBackground: Boolean;
```

C++

```
__property Boolean DitherBackground;
```

Description

Dithering means the background is lightened by 50%, which is intended to make the tabs easier to see. If DitherBackground is true, the tab set control background is dithered. If it is false, there is no dithering.

See Also

BackgroundColor (see page 4486)

SelectedColor (see page 4502)

39.1.3.5.8 TTabSet.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
```

```
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
```

```
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

39.1.3.5.9 TTabSet.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

39.1.3.5.10 TTabSet.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

39.1.3.5.11 TTabSet.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
```

```
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

39.1.3.5.12 TTabSet.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

DisableControls

EnableControls

Enabling Mouse

39.1.3.5.13 TTabSet.EndMargin Property

Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.

Pascal

```
property EndMargin: Integer;
```

C++

```
__property int EndMargin;
```

Description

EndMargin determines how far in pixels the rightmost tab appears from the right edge of the tab set control. Together with the StartMargin (see page 4504) property, EndMargin can play a role in determining how many tabs can fit within the tab set control.

If AutoScroll (see page 4485) is true and scroll buttons appear in the tab set control, EndMargin determines how far in pixels the rightmost tab appears from the left edge of the scroll buttons, rather than the edge of the tab set control.

See Also

AutoScroll (see page 4485)

StartMargin (see page 4504)

39.1.3.5.14 TTabSet.FirstIndex Property

Specifies the tab that appears in the leftmost visible position in the tab set control.

Pascal

```
property FirstIndex: Integer;
```

C++

```
__property int FirstIndex;
```

Description

Any tabs with a lower value in the FirstIndex property scroll to the left in the tab set control and don't appear until the user scrolls the tabs.

The default value of FirstIndex is 0 indicating that the tab with an index of 0 is in the leftmost position. For example, if you have three tabs labeled First, Second, and Third with TabIndex (see page 4506) values of 0, 1, and 2, respectively, First appears first, by default, because it has an index value of 0. If you want to shift the tabs so the Second or Third tab appears leftmost in the tab set control, change the FirstIndex value to 1 or 2.

Tabs (see page 4506)

39.1.3.5.15 TTabSet.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

39.1.3.5.16 TTabSet.Images Property

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

This is Images, a member of class TTabSet.

39.1.3.5.17 TTabSet.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

39.1.3.5.18 TTabSet.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

39.1.3.5.19 TTabSet.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

39.1.3.5.20 TTabSet.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Paste1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }
  /*
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  */
  void __fastcall TForm1::AddButtonClick(TObject *Sender)
  {
      // The owner (PopupMenu1) will cleanup this menu item.
      TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
      int index = PopupMenu1->Items->Count;
      PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
      NewItem->Caption = "Menu Item " + IntToStr(index);
      NewItem->Tag = index;
      NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
      TNotifyEvent();
  }

  void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
  {
      TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
      if (ClickedItem)
      {
          switch (ClickedItem->Tag)
```

```
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    PopupMenu1.AutoPopup := True;
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

  type
    TForm1 = class(TForm)
      AddButton: TButton;
      EditButton: TButton;
      DestroyButton: TButton;
      PopupMenu1: TPopupMenu;
      procedure AddButtonClick(Sender: TObject);
      procedure EditButtonClick(Sender: TObject);
      procedure DestroyButtonClick(Sender: TObject);
      procedure FormCreate(Sender: TObject);
```

```
    private
      { Private declarations }

39.1.3.5.21 TTabSet.Scroller Property

Pascal

```
property Scroller: TScroller;
```

C++

```
__property TScroller Scroller;
```

Description

This is Scroller, a member of class TTabSet.

39.1.3.5.22 TTabSet.SelectedColor Property

Determines the color of the selected tab in the tab set control.

Pascal

```
property SelectedColor: TColor;
```

C++

```
__property TColor SelectedColor;
```

Description

SelectedColor determines the color of the selected tab in the tab set control.

See Also

BackgroundColor (see page 4486)

DitherBackground (see page 4489)

Color

39.1.3.5.23 TTabSet.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
```

```
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }

39.1.3.5.24 TTabSet.ShrinkToFit Property

Pascal

```
property ShrinkToFit: Boolean;
```

C++

```
__property Boolean ShrinkToFit;
```

Description

This is ShrinkToFit, a member of class TTabSet.

39.1.3.5.25 TTabSet.SoftTop Property

Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.

Pascal

```
property SoftTop: Boolean;
```

C++

```
__property Boolean SoftTop;
```

Description

When SoftTop is false (the default), a line appears at the edge of the non-current tabs. When SoftTop is true, this line is not drawn, softening the border of the tab set.

39.1.3.5.26 TTabSet.StartMargin Property

Determines how far, in pixels, the first tab appears from the left edge of the tab set control.

Pascal

```
property StartMargin: Integer;
```

C++

```
__property int StartMargin;
```

Description

Together with the EndMargin (see page 4494) property, StartMargin determines how many tabs fit in the tab set control.

See Also

EndMargin (see page 4494)

39.1.3.5.27 TTabSet.Style Property

Determines whether the tab set is owner-drawn.

Pascal

```
property Style: TTabStyle;
```

C++

```
__property TTabStyle Style;
```

Description

Owner-draw tabs can display objects other than strings, such as graphical images. Owner-draw tabs require more programming, however, because the application needs information on how to render the image for each tab in the tab set control.

Each time an item is displayed in an owner-drawn tab, two events occur. The first is the OnMeasureTab (see page 4527) event. In the OnMeasureTab (see page 4527) event handler, you write the code that calculates the width of the tab needed to hold the text or graphical image. After the OnMeasureTab (see page 4527) event, the OnDrawTab (see page 4519) event occurs. The code you write for the OnDrawTab (see page 4519) event draws the tab and its contents using the width found with the OnMeasureTab (see page 4527) event and the height specified as the value of the TabHeight (see page 4505) property.

Note: The TTabStyle (see page 4543) type defined in the tabs unit for the Style property differs from the TTabStyle (see page 4543) type defined in the comctrls unit. Do not to use or include the comctrls unit in source files where you are working with the tab control. Doing so can lead to compiler errors because of type mismatches.

See Also

TabHeight (see page 4505)

OnDrawTab (see page 4519)

OnMeasureTab (see page 4527)

39.1.3.5.28 TTabSet.TabHeight Property

Determines the height of the tabs in an owner-drawn tab set control.

Pascal

```
property TabHeight: Integer;
```

C++

```
__property int TabHeight;
```

Description

If the Style (see page 4505) property value is tsStandard, the TabHeight property value is ignored. If the Style (see page 4505) property value is tsOwnerDraw, TabHeight is the height of the tabs.

See Also

Style (see page 4505)

39.1.3.5.29 TTabSet.TabIndex Property

Determines which tab of a tab set control is currently selected.

Pascal

```
property TabIndex: Integer;
```

C++

```
__property int TabIndex;
```

Description

The value of TabIndex can be from –1 to one less than the number of strings in the Tabs (see page 4506) property array (Count – 1). TabIndex is an index to the Tabs (see page 4506) array property: A value of 0 indicates the first tab in the tab set control, 1 is the second tab, and so on. If no tabs are selected, TabIndex has a value of –1.

When a value is assigned to TabIndex, the OnClick (see page 4511) event for the tab set occurs, followed by the OnChange (see page 4511) event, just as if the user had clicked on a new tab.

Tabs (see page 4506)

OnChange (see page 4511)

OnClick

39.1.3.5.30 TTabSet.TabPosition Property

Pascal

```
property TabPosition: TTabPosition;
```

C++

```
__property TTabPosition TabPosition;
```

Description

This is TabPosition, a member of class TTabSet.

39.1.3.5.31 TTabSet.Tabs Property

Contains the list of text strings that appear on the tabs.

Pascal

```
property Tabs: TStrings;
```

C++

```
__property TStrings Tabs;
```

Description

For each string in the Tabs property, a new tab is created to display the text string. At design time, you enter the text strings you want to appear on the tabs using the String List editor. Double-click the value column of the Tabs property to display the String List editor. You can also change strings in the Tabs property at runtime.

See Also

VisibleTabs (see page 4508)

39.1.3.5.32 TTabSet.UnselectedColor Property

Determines the color of the tabs that aren't currently selected in the tab set control.

Pascal

```
property UnselectedColor: TColor;
```

C++

```
__property TColor UnselectedColor;
```

Description

UnselectedColor determines the color of the tabs that aren't currently selected in the tab set control.

See Also

BackgroundColor (see page 4486)

SelectedColor (see page 4502)

39.1.3.5.33 TTabSet.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
```

```
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

39.1.3.5.34 TTabSet.VisibleTabs Property

Contains the number of tabs currently visible in the tab set control.

Pascal

```
property VisibleTabs: Integer;
```

C++

```
__property int VisibleTabs;
```

Description

Use VisibleTabs to determine how many tabs are visible in the tab set.

39.1.3.6 TTabSet Events

The events of the TTabSet class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 4509)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 4510)	Occurs when an object with custom alignment is aligned.
	OnChange (see page 4511)	Occurs just before a new tab is selected.
	OnClick (see page 4511)	Occurs when the user clicks the control.
	OnDragDrop (see page 4513)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 4516)	Occurs when the user drags an object over a control.
	OnDrawTab (see page 4519)	Occurs when a tab in an owner-drawn tab set control needs to redisplay.
	OnEndDock (see page 4519)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 4520)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 4521)	Occurs when a control receives the input focus.
	OnExit (see page 4523)	Occurs when the input focus shifts away from one control to another.
	OnGetImageIndex (see page 4527)	This is OnGetImageIndex, a member of class TTabSet.
	OnMeasureTab (see page 4527)	Occurs when an application needs to redisplay a tab in an owner-draw tab set.
	OnMouseActivate (see page 4528)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 4529)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 4531)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 4531)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 4532)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 4534)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 4536)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 4537)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

39.1.3.6.1 TTabSet.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore

Align

TAlignInsertBeforeEvent

39.1.3.6.2 TTabSet.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

CustomAlignPosition

Align

Anchors

TAlignInfo

TAlignPositionEvent

39.1.3.6.3 TTabSet.OnChange Event

Occurs just before a new tab is selected.

Pascal

```
property OnChange: TTabChangeEvent;
```

C++

```
__property TTabChangeEvent OnChange;
```

Description

OnChange occurs just as the TabIndex (see page 4506) value is about to change. To prevent the TabIndex (see page 4506) value from changing, set AllowChange to false in the OnChange event handler.

39.1.3.6.4 TTabSet.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
```

```
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

39.1.3.6.5 TTabSet.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
```

```
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*

39.1.3.6.6 TTabSet.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

39.1.3.6.7 TTabSet.OnDrawTab Event

Occurs when a tab in an owner-drawn tab set control needs to redisplay.

Pascal

```
property OnDrawTab: TDrawTabEvent;
```

C++

```
__property TDrawTabEvent OnDrawTab;
```

Description

OnDrawTab occurs when a tab redisplays if the Style (see page 4505) property value is tsOwnerDraw. For example, it happens when the user selects a tab or scrolls the tabs.

You must write the code in the OnDrawTab event handler to draw the tab.

OnDrawTab occurs just after the OnMeasureTab (see page 4527) event, which contains the code to calculate the width of the tab needed. The height of the tab is determined by the value of the TabHeight (see page 4505) property of the tab set control. The code you write in the OnDrawTab event handler, therefore, must use the width determined with the OnMeasureTab (see page 4527) event to draw the tab.

Style (see page 4505)

39.1.3.6.8 TTabSet.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock;
```

C++

```
__property OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

39.1.3.6.9 TTabSet.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
```

```
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;

39.1.3.6.10 TTabSet.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}
```

```
void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
```

```
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}

39.1.3.6.11 TTabSet.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit

event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
```

```
  subnet mask edit box, the subnet address is automatically calculated
  using bit-wise AND operations and displayed in the third mask edit box.
  An additional test is made to assure that the values in the IP address
  and in the subnet mask are in the interval from 0 to 255,
  as this validation test cannot be accomplished
  using the edit mask property alone.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    { initialize the maskedit boxes to contain the empty string }
    MaskEdit1.Text := '';
    MaskEdit2.Text := '';
    MaskEdit3.Text := '';

    { use the Courier font in the maskedit boxes }
    MaskEdit1.Font.Name := 'Courier';
    MaskEdit2.Font.Name := 'Courier';
    MaskEdit3.Font.Name := 'Courier';

    {
    initialize the mask of each maskedit box
    according to IP address coding conventions
    }
    MaskEdit1.EditMask := '!099.099.099.099;1; ';
    MaskEdit2.EditMask := '!099.099.099.099;1; ';
    MaskEdit3.EditMask := '!099.099.099.099;1; ';

    MaskEdit2.OnExit := MaskEdit2Exit;
  end;

  procedure TForm1.MaskEdit2Exit(Sender: TObject);

39.1.3.6.12 TTabSet.OnGetImageIndex Event

Pascal

```
property OnGetImageIndex: TTabGetImageEvent;
```

C++

```
__property TTabGetImageEvent OnGetImageIndex;
```

Description

This is OnGetImageIndex, a member of class TTabSet.

39.1.3.6.13 TTabSet.OnMeasureTab Event

Occurs when an application needs to redisplay a tab in an owner-draw tab set.

Pascal

```
property OnMeasureTab: TMeasureTabEvent;
```

C++

```
__property TMeasureTabEvent OnMeasureTab;
```

Description

OnMeasureTab occurs only if the Style (see page 4505) property is tsOwnerDraw. In the OnMeasureTab event handler, write the code to calculate the width needed to draw the tab. Your code is responsible for calculating and returning the tab width, depending on what you have drawn in the tab (if the tab is of Style (see page 4505) tsOwnerDraw). After the OnMeasureTab event occurs, the OnDrawTab (see page 4519) event occurs, when the OnDrawTab (see page 4519) event handler draws the tab using the width calculated in OnMeasureTab.

OnDrawTab (see page 4519)

39.1.3.6.14 TTabSet.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

39.1.3.6.15 TTabSet.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
```

```
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else

MouseCapture

39.1.3.6.16 TTabSet.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

39.1.3.6.17 TTabSet.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

39.1.3.6.18 TTabSet.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
```

```
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

39.1.3.6.20 TTabSet.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

39.1.3.6.21 TTabSet.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

39.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TEdgePart (see page 4538)	This is record Tabs.TEdgePart.
	TEdgeType (see page 4538)	This is record Tabs.TEdgeType.
	TScrollBtn (see page 4539)	This is record Tabs.TScrollBtn.
	TScrollOrientation (see page 4539)	This is record Tabs.TScrollOrientation.
	TTabSetTabStyle (see page 4540)	This is record Tabs.TTabSetTabStyle.

39.2.1 Tabs.TEdgePart Enumeration

Pascal

```
TEdgePart = (
  epSelectedLeft,
  epUnselectedLeft,
  epSelectedRight,
  epUnselectedRight
);
```

C++

```
enum TEdgePart {
  epSelectedLeft,
  epUnselectedLeft,
  epSelectedRight,
  epUnselectedRight
};
```

File

Tabs

Description

This is record Tabs.TEdgePart.

39.2.2 Tabs.TEdgeType Enumeration

Pascal

```
TEdgeType = (
  etNone,
  etFirstIsSel,
  etFirstNotSel,
  etLastIsSel,
  etLastNotSel,
  etNotSelToSel,
  etSelToNotSel,
  etNotSelToNotSel
```

```
);
```

C++

```
enum TEdgeType {
  etNone,
  etFirstIsSel,
  etFirstNotSel,
  etLastIsSel,
  etLastNotSel,
  etNotSelToSel,
  etSelToNotSel,
  etNotSelToNotSel
};
```

File

Tabs

Description

This is record Tabs.TEdgeType.

39.2.3 Tabs.TScrollBtn Enumeration

Pascal

```
TScrollBtn = (
  sbLeft,
  sbRight
);
```

C++

```
enum TScrollBtn {
  sbLeft,
  sbRight
};
```

File

Tabs

Description

This is record Tabs.TScrollBtn.

39.2.4 Tabs.TScrollOrientation Enumeration

Pascal

```
TScrollOrientation = (
  soLeftRight,
  soUpDown
);
```

C++

```
enum TScrollOrientation {
  soLeftRight,
  soUpDown
};
```

File

Tabs

Description

This is record Tabs.TScrollOrientation.

39.2.5 Tabs.TTabSetTabStyle Enumeration

Pascal

```
TTabSetTabStyle = (
  tsStandard,
  tsOwnerDraw,
  tsSoftTabs,
  tsModernTabs,
  tsModernPopout
);
```

C++

```
enum TTabSetTabStyle {
  tsStandard,
  tsOwnerDraw,
  tsSoftTabs,
  tsModernTabs,
  tsModernPopout
};
```

File

Tabs

Description

This is record Tabs.TTabSetTabStyle.

39.3 Types

The following table lists types in this documentation.

Types

Name	Description
TDrawTabEvent (see page 4541)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.
TMeasureTabEvent (see page 4541)	TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 4470) control.
TTabChangeEvent (see page 4542)	TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 4470) control changes.
TTabSetDrawTabEvent (see page 4542)	TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.
TTabStyle (see page 4543)	TTabStyle indicates whether a TTabSet (see page 4470) control is owner-drawn.

39.3.1 Tabs.TDrawTabEvent Type

TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.

Pascal

```
TDrawTabEvent = TTabSetDrawTabEvent;
```

C++

```
TTabSetDrawTabEvent TDrawTabEvent;
```

File

Tabs

Description

TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.

Note: The TDrawTabEvent type defined in the tabs unit for the OnDrawTab event handler differs from the TDrawTabEvent type defined in the comctrls unit. Do not use the comctrls unit in source files where you are working with the tab control.

See Also

Procedural types

Creating events

39.3.2 Tabs.TMeasureTabEvent Type

TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 4470) control.

Pascal

```
TMeasureTabEvent = procedure (Sender: TObject; Index: Integer; var TabWidth: Integer) of
```

```
object;
```

C++

```
(Sender: TObject; Index: Integer; var TabWidth: Integer) ( TMeasureTabEvent)();
```

File

Tabs

Description

Sender is the TTabSet (see page 4470) control whose tab is about to be drawn.

Index identifies the position of the tab in the tab set control.

TabWidth is the width of the tab.

See Also

Procedural types

Creating events

39.3.3 Tabs.TTabChangeEvent Type

TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 4470) control changes.

Pascal

```
TTabChangeEvent = procedure (Sender: TObject; NewTab: Integer; var AllowChange: Boolean) of
object;
```

C++

```
(Sender: TObject; NewTab: Integer; var AllowChange: Boolean) ( TTabChangeEvent)();
```

File

Tabs

Description

Sender is the TTabSet (see page 4470) control whose tab is about to change.

NewTab is the tab that is about to become the selected tab.

AllowChange determines whether the change is permitted. If the event handler sets AllowChange to false, the user won't be able to select the new tab, in effect disabling it.

See Also

Procedural types

Creating events

39.3.4 Tabs.TTabSetDrawTabEvent Type

TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 4470) control.

Pascal

```
TTabSetDrawTabEvent = procedure (Sender: TObject; TabCanvas: TCanvas; R: TRect; Index:
Integer; Selected: Boolean) of object;
```

C++

```
(Sender: TObject; TabCanvas: TCanvas; R: TRect; Index: Integer; Selected: Boolean) (
TTabSetDrawTabEvent)();
```

File

Tabs

Description

TabCanvas is the canvas on which the item is drawn.

Index is the position of the tab in the tab set control.

R is the area in the tab where the item is to be drawn.

Selected indicates whether the tab is currently selected.

See Also

Procedural types

Creating events

39.3.5 Tabs.TTabStyle Type

TTabStyle indicates whether a TTabSet (see page 4470) control is owner-drawn.

Pascal

```
TTabStyle = TTabSetTabStyle;
```

C++

```
TTabSetTabStyle TTabStyle;
```

File

Tabs

Description

These are the possible values:

Value	Meaning
tsStandard	Each tab has the standard size and look.

tsOwnerDrawEach tab has the height specified with the TabHeight property and width needed to hold the text or glyph.

40 TConnect Namespace

This is namespace TConnect.

Topics

Name	Description
Classes (see page 4546)	The following table lists classes in this documentation.

Classes

	Name	Description
	TLocalConnection (see page 4546)	TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

40.1 Classes

The following table lists classes in this documentation.

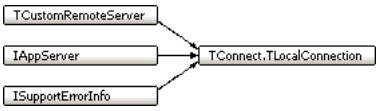
Classes

	Name	Description
	TLocalConnection (see page 4546)	TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

40.1.1 TLocalConnection Class

TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

Class Hierarchy



Pascal

```
TLocalConnection = class(TCustomRemoteServer, IAppServer, ISupportErrorInfo);
```

C++

```
class TLocalConnection : public TCustomRemoteServer, public IAppServer, public
ISupportErrorInfo;
```

File

TConnect

Description

Use TLocalConnection to manage the connection between one or more client datasets or XML brokers and the providers that reside in the same application. When working with local providers, it is not necessary to set the RemoteServer property of a client dataset or XML broker to a TLocalConnection component. However, using TLocalConnection lets your application communicate directly with local providers through the AppServer (see page 4553) property. This provides access to methods that would otherwise be unavailable, and makes it easier to scale up to a multi-tiered application at a later time.

TLocalConnection implements the IAppServer interface.

Warning: TLocalConnection only links clients to providers that are instances of TDataSetProvider.

40.1.1.1 TLocalConnection Members

The following tables list the members exposed by TLocalConnection.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 4549)	This is AS_ApplyUpdates, a member of class TLocalConnection.
	AS_DataRequest (see page 4549)	This is AS_DataRequest, a member of class TLocalConnection.
	AS_Execute (see page 4549)	This is AS_Execute, a member of class TLocalConnection.
	AS_GetParams (see page 4549)	This is AS_GetParams, a member of class TLocalConnection.
	AS_GetProviderNames (see page 4550)	This is AS_GetProviderNames, a member of class TLocalConnection.
	AS_GetRecords (see page 4550)	This is AS_GetRecords, a member of class TLocalConnection.
	AS_RowRequest (see page 4550)	This is AS_RowRequest, a member of class TLocalConnection.
V	GetConnected (see page 4550)	Returns the value of the Connected property.
V	GetProvider (see page 4551)	This is GetProvider, a member of class TLocalConnection.
	InterfaceSupportsErrorInfo (see page 4552)	This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.
V	Notification (see page 4552)	Forwards notification messages to all owned components.
	RegisterProvider (see page 4552)	This is RegisterProvider, a member of class TLocalConnection.
	UnRegisterProvider (see page 4553)	This is UnRegisterProvider, a member of class TLocalConnection.

Public Methods

	Name	Description
V	Create (see page 4547)	Creates and initializes a local connection component.
V	Destroy (see page 4548)	Frees an instance of TLocalConnection (see page 4546).
V	GetProviderNames (see page 4551)	Executes a callback for all provider objects on the application server.
V	GetServer (see page 4551)	Returns the IAppServer interface for communicating with local providers.
V	SafeCallException (see page 4553)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	AppServer (see page 4553)	Provides access to the IAppServer interface that handles communication with providers.
R	ProviderCount (see page 4554)	Indicates the number of providers in the Providers (see page 4554) property list.
R	Providers (see page 4554)	Lists the local providers with which this local connection component can communicate.

40.1.1.2 TLocalConnection.Create Constructor

Creates and initializes a local connection component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TLocalConnection(TComponent * AOwner);
```

Description

Call Create to instantiate TLocalConnection (see page 4546) at runtime. TLocalConnection (see page 4546) components placed in forms or data modules at design time are created automatically.

The AOwner parameter specifies the component (usually the form or data module) that is responsible for freeing the TLocalConnection (see page 4546) instance.

See Also

Owner

40.1.1.3 TLocalConnection.Destroy Destructor

Frees an instance of TLocalConnection (see page 4546).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLocalConnection();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the TLocalConnection (see page 4546) reference is not nil before calling the destructor.

See Also

System::TObject::Free (see page 3372)

40.1.1.4 TLocalConnection Methods

The methods of the TLocalConnection class are listed here.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 4549)	This is AS_ApplyUpdates, a member of class TLocalConnection.
	AS_DataRequest (see page 4549)	This is AS_DataRequest, a member of class TLocalConnection.
	AS_Execute (see page 4549)	This is AS_Execute, a member of class TLocalConnection.
	AS_GetParams (see page 4549)	This is AS_GetParams, a member of class TLocalConnection.
	AS_GetProviderNames (see page 4550)	This is AS_GetProviderNames, a member of class TLocalConnection.
	AS_GetRecords (see page 4550)	This is AS_GetRecords, a member of class TLocalConnection.
	AS_RowRequest (see page 4550)	This is AS_RowRequest, a member of class TLocalConnection.
V	GetConnected (see page 4550)	Returns the value of the Connected property.
V	GetProvider (see page 4551)	This is GetProvider, a member of class TLocalConnection.
	InterfaceSupportsErrorInfo (see page 4552)	This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.
V	Notification (see page 4552)	Forwards notification messages to all owned components.
	RegisterProvider (see page 4552)	This is RegisterProvider, a member of class TLocalConnection.
	UnRegisterProvider (see page 4553)	This is UnRegisterProvider, a member of class TLocalConnection.

Public Methods

	Name	Description
	GetProviderNames (see page 4551)	Executes a callback for all provider objects on the application server.
	GetServer (see page 4551)	Returns the IAppServer interface for communicating with local providers.
	SafeCallException (see page 4553)	Handles exceptions in methods declared using the safecall calling convention.

40.1.1.4.1 TLocalConnection.AS_ApplyUpdates Method

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

This is AS_ApplyUpdates, a member of class TLocalConnection.

40.1.1.4.2 TLocalConnection.AS_DataRequest Method

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

This is AS_DataRequest, a member of class TLocalConnection.

40.1.1.4.3 TLocalConnection.AS_Execute Method

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

This is AS_Execute, a member of class TLocalConnection.

40.1.1.4.4 TLocalConnection.AS_GetParams Method

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

This is AS_GetParams, a member of class TLocalConnection.

40.1.1.4.5 TLocalConnection.AS_GetProviderNames Method

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

This is AS_GetProviderNames, a member of class TLocalConnection.

40.1.1.4.6 TLocalConnection.AS_GetRecords Method

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

This is AS_GetRecords, a member of class TLocalConnection.

40.1.1.4.7 TLocalConnection.AS_RowRequest Method

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

This is AS_RowRequest, a member of class TLocalConnection.

40.1.1.4.8 TLocalConnection.GetConnected Method

Returns the value of the Connected property.

Pascal

```
function GetConnected: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection, GetConnected always returns false.

See Also

Connected

SetConnected

40.1.1.4.9 TLocalConnection.GetProvider Method

Pascal

```
function GetProvider(const ProviderName: string): TCustomProvider; virtual;
```

C++

```
virtual __fastcall TCustomProvider GetProvider(const UnicodeString ProviderName);
```

Description

This is GetProvider, a member of class TLocalConnection.

40.1.1.4.10 TLocalConnection.GetProviderNames Method

Executes a callback for all provider objects on the application server.

Pascal

```
procedure GetProviderNames(Proc: TGetStrProc); override;
```

C++

```
virtual __fastcall GetProviderNames(TGetStrProc Proc);
```

Description

Call GetProviderNames to execute the procedure specified by the Proc parameter for every provider exposed by the application server. For every provider listed by the remote data module's AS_GetProviderNames method, Proc is called with the name of the provider.

See Also

AS_GetProviderNames

AppServer

ProviderName

40.1.1.4.11 TLocalConnection.GetServer Method

Returns the IAppServer interface for communicating with local providers.

Pascal

```
function GetServer: IAppServer; override;
```

C++

```
virtual __fastcall IAppServer GetServer();
```

Description

GetServer returns the value of the AppServer (see page 4553) property.

See Also

AppServer (see page 4553)

40.1.1.4.12 TLocalConnection.InterfaceSupportsErrorInfo Method

Pascal

```
function InterfaceSupportsErrorInfo(const iid: TIID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT InterfaceSupportsErrorInfo(const TIID iid);
```

Description

This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.

40.1.1.4.13 TLocalConnection.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

RemoveComponent

Owner

40.1.1.4.14 TLocalConnection.RegisterProvider Method

Pascal

```
procedure RegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall RegisterProvider(TCustomProvider Prov);
```

Description

This is RegisterProvider, a member of class TLocalConnection.

40.1.1.4.15 TLocalConnection.SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur. TComponent calls the implementation of this method for the interface supported by the component, if it exists. If the component does not support interfaces, this method calls the SafeCallException method inherited from TObject, which returns E_UNEXPECTED. This is a default return value that is appropriate for classes that do not support any interfaces.

See Also

System::TObject::SafeCallException (see page 3380)

40.1.1.4.16 TLocalConnection.UnRegisterProvider Method

Pascal

```
procedure UnRegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall UnRegisterProvider(TCustomProvider Prov);
```

Description

This is UnRegisterProvider, a member of class TLocalConnection.

40.1.1.5 TLocalConnection Properties

The properties of the TLocalConnection class are listed here.

Public Properties

	Name	Description
	AppServer (see page 4553)	Provides access to the IAppServer interface that handles communication with providers.
	ProviderCount (see page 4554)	Indicates the number of providers in the Providers (see page 4554) property list.
	Providers (see page 4554)	Lists the local providers with which this local connection component can communicate.

40.1.1.5.1 TLocalConnection.AppServer Property

Provides access to the IAppServer interface that handles communication with providers.

Pascal

```
property AppServer: IAppServer;
```

C++

```
__property IAppServer AppServer;
```

Description

Use AppServer to make explicit IAppServer calls to communicate with the local providers. The IAppServer interface lets you call provider methods that are otherwise unavailable because they are protected.

See Also

Providers (see page 4554)

AppServer

40.1.1.5.2 TLocalConnection.ProviderCount Property

Indicates the number of providers in the Providers (see page 4554) property list.

Pascal

```
property ProviderCount: integer;
```

C++

```
__property int ProviderCount;
```

Description

Read (see page 3634) ProviderCount to determine the number of local providers. This is the number of entries in the Providers (see page 4554) property list.

See Also

Providers (see page 4554)

40.1.1.5.3 TLocalConnection.Providers Property

Lists the local providers with which this local connection component can communicate.

Pascal

```
property Providers [const ProviderName: string]: TCustomProvider;
```

C++

```
__property TCustomProvider Providers[UnicodeString const ProviderName];
```

Description

Providers provides access to the local providers that are available through the IAppServer interface. Providers only lists the providers whose Exported property is set to true.

ProviderName is the name of a provider. If you specify a name of a provider that is not listed, TLocalConnection (see page 4546) raises an exception.

See Also

ProviderCount (see page 4554)

AppServer (see page 4553)

Exported

41 ThemedActnCtrls Namespace

This is namespace ThemedActnCtrls.

Topics

Name	Description
Classes (see page 4556)	The following table lists classes in this documentation.

Classes

	Name	Description
	TThemedAddRemoveItem (see page 4556)	This is class ThemedActnCtrls.TThemedAddRemoveItem.
	TThemedButtonControl (see page 4559)	This is class ThemedActnCtrls.TThemedButtonControl.
	TThemedCustomizePopup (see page 4561)	This is class ThemedActnCtrls.TThemedCustomizePopup.
	TThemedDropDownButton (see page 4563)	This is class ThemedActnCtrls.TThemedDropDownButton.
	TThemedExpandBtn (see page 4566)	This is class ThemedActnCtrls.TThemedExpandBtn.
	TThemedMenuButton (see page 4567)	This is class ThemedActnCtrls.TThemedMenuButton.
	TThemedMenuItem (see page 4569)	This is class ThemedActnCtrls.TThemedMenuItem.
	TThemedPopupMenu (see page 4573)	This is class ThemedActnCtrls.TThemedPopupMenu.
	TThemedToolScrollBtn (see page 4575)	This is class ThemedActnCtrls.TThemedToolScrollBtn.

41.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TThemedAddRemoveItem (see page 4556)	This is class ThemedActnCtrls.TThemedAddRemoveItem.
	TThemedButtonControl (see page 4559)	This is class ThemedActnCtrls.TThemedButtonControl.
	TThemedCustomizePopup (see page 4561)	This is class ThemedActnCtrls.TThemedCustomizePopup.
	TThemedDropDownButton (see page 4563)	This is class ThemedActnCtrls.TThemedDropDownButton.
	TThemedExpandBtn (see page 4566)	This is class ThemedActnCtrls.TThemedExpandBtn.
	TThemedMenuButton (see page 4567)	This is class ThemedActnCtrls.TThemedMenuButton.
	TThemedMenuItem (see page 4569)	This is class ThemedActnCtrls.TThemedMenuItem.
	TThemedPopupMenu (see page 4573)	This is class ThemedActnCtrls.TThemedPopupMenu.
	TThemedToolScrollBtn (see page 4575)	This is class ThemedActnCtrls.TThemedToolScrollBtn.

41.1.1 TThemedAddRemoveItem Class

Class Hierarchy

Pascal

```
TThemedAddRemoveItem = class(TCustomAddRemoveItem);
```

C++

```
class TThemedAddRemoveItem : public TCustomAddRemoveItem;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedAddRemoveItem.

41.1.1.1 TThemedAddRemoveItem Members

The following tables list the members exposed by TThemedAddRemoveItem.

Protected Methods

	Name	Description
	DrawBackground (see page 4557)	Draws a background image on the control.
	DrawGlyph (see page 4558)	Draws a symbol on the control.
	DrawSeparator (see page 4558)	This is DrawSeparator, a member of class TThemedAddRemoveItem.
	DrawText (see page 4558)	Draws text on the control.
	DrawUnusedEdges (see page 4559)	This is DrawUnusedEdges, a member of class TThemedAddRemoveItem.
	GetImageSize (see page 4559)	This is GetImageSize, a member of class TThemedAddRemoveItem.

Public Methods

	Name	Description
	CalcBounds (see page 4557)	Calculates the size of the add/remove menu item.

41.1.1.2 TThemedAddRemoveItem Methods

The methods of the TThemedAddRemoveItem class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4557)	Draws a background image on the control.
	DrawGlyph (see page 4558)	Draws a symbol on the control.
	DrawSeparator (see page 4558)	This is DrawSeparator, a member of class TThemedAddRemoveItem.
	DrawText (see page 4558)	Draws text on the control.
	DrawUnusedEdges (see page 4559)	This is DrawUnusedEdges, a member of class TThemedAddRemoveItem.
	GetImageSize (see page 4559)	This is GetImageSize, a member of class TThemedAddRemoveItem.

Public Methods

	Name	Description
	CalcBounds (see page 4557)	Calculates the size of the add/remove menu item.

41.1.1.2.1 TThemedAddRemoveItem.CalcBounds Method

Calculates the size of the add/remove menu item.

Pascal

```
procedure CalcBounds; override;
```

C++

```
virtual __fastcall CalcBounds();
```

Description

CalcBounds updates the Height, Width, and TextBounds properties to reflect current conditions (such as the item's caption and the current font).

See Also

Height

Width

TextBounds

41.1.1.2.2 TThemedAddRemoveItem.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.1.2.3 TThemedAddRemoveItem.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

41.1.1.2.4 TThemedAddRemoveItem.DrawSeparator Method

Pascal

```
procedure DrawSeparator(const Offset: Integer); override;
```

C++

```
virtual __fastcall DrawSeparator(const int Offset);
```

Description

This is DrawSeparator, a member of class TThemedAddRemoveItem.

41.1.1.2.5 TThemedAddRemoveItem.DrawText Method

Draws text on the control.

Pascal

```
procedure DrawText(var Rect: TRect; var Flags: Cardinal; Text: string); override;
```

C++

```
virtual __fastcall DrawText(TRect Rect, unsigned Flags, UnicodeString Text);
```

Description

Use DrawText to draw the text specified by Text on the control within the area specified by ARect.

See Also

DrawBackground

DrawGlyph

41.1.1.2.6 TThemedAddRemoveItem.DrawUnusedEdges Method

Pascal

```
procedure DrawUnusedEdges; override;
```

C++

```
virtual __fastcall DrawUnusedEdges();
```

Description

This is DrawUnusedEdges, a member of class TThemedAddRemoveItem.

41.1.1.2.7 TThemedAddRemoveItem.GetImageSize Method

Pascal

```
function GetImageSize: TPoint; override;
```

C++

```
virtual __fastcall TPoint GetImageSize();
```

Description

This is GetImageSize, a member of class TThemedAddRemoveItem.

41.1.2 TThemedButtonControl Class

Class Hierarchy

Pascal

```
TThemedButtonControl = class(TCustomButtonControl);
```

C++

```
class TThemedButtonControl : public TCustomButtonControl;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedButtonControl.

41.1.2.1 TThemedButtonControl Members

The following tables list the members exposed by TThemedButtonControl.

Protected Methods

	Name	Description
	DrawBackground (see page 4560)	Draws a background image on the control.
	DrawFrame (see page 4560)	This is DrawFrame, a member of class TThemedButtonControl.
	DrawGlyph (see page 4560)	Draws a symbol on the control.

	DrawLargeGlyph (see page 4561)	This is DrawLargeGlyph, a member of class TThemedButtonControl.
	DrawText (see page 4561)	Draws text on the control.

41.1.2.2 TThemedButtonControl Methods

The methods of the TThemedButtonControl class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4560)	Draws a background image on the control.
	DrawFrame (see page 4560)	This is DrawFrame, a member of class TThemedButtonControl.
	DrawGlyph (see page 4560)	Draws a symbol on the control.
	DrawLargeGlyph (see page 4561)	This is DrawLargeGlyph, a member of class TThemedButtonControl.
	DrawText (see page 4561)	Draws text on the control.

41.1.2.2.1 TThemedButtonControl.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.2.2.2 TThemedButtonControl.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TThemedButtonControl.

41.1.2.2.3 TThemedButtonControl.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

41.1.2.2.4 TThemedButtonControl.DrawLargeGlyph Method

Pascal

```
procedure DrawLargeGlyph(Location: TPoint); override;
```

C++

```
virtual __fastcall DrawLargeGlyph(TPoint Location);
```

Description

This is DrawLargeGlyph, a member of class TThemedButtonControl.

41.1.2.2.5 TThemedButtonControl.DrawText Method

Draws text on the control.

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: string); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

Use DrawText to draw the text specified by Text on the control within the area specified by ARect.

See Also

DrawBackground

DrawGlyph

41.1.3 TThemedCustomizePopup Class

Class Hierarchy

Pascal

```
TThemedCustomizePopup = class(TCustomizeActionToolBar);
```

C++

```
class TThemedCustomizePopup : public TCustomizeActionToolBar;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedCustomizePopup.

41.1.3.1 TThemedCustomizePopup Members

The following tables list the members exposed by TThemedCustomizePopup.

Protected Methods

	Name	Description
	GetAddRemoveItemClass (see page 4562)	This is GetAddRemoveItemClass, a member of class TThemedCustomizePopup.
	GetDefaultColorMapClass (see page 4563)	This is GetDefaultColorMapClass, a member of class TThemedCustomizePopup.
	NCPaint (see page 4563)	This is NCPaint, a member of class TThemedCustomizePopup.

Public Methods

	Name	Description
	Create (see page 4562)	Creates and initializes a TCustomActionPopupMenu instance.

41.1.3.2 TThemedCustomizePopup.Create Constructor

Creates and initializes a TCustomActionPopupMenu instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TThemedCustomizePopup(TComponent * AOwner);
```

Description

Create generates a TCustomActionPopupMenu and initializes its properties.

```
__fastcall virtual TCustomActionMenuBar (Classes::TComponentTComponent_Object* AOwner);
__fastcall TCustomActionMenuBar (HWND ParentWindow) :
Controls::TWinControlTWinControl_Create(ParentWindow) { }
```

41.1.3.3 TThemedCustomizePopup Methods

The methods of the TThemedCustomizePopup class are listed here.

Protected Methods

	Name	Description
	GetAddRemoveItemClass (see page 4562)	This is GetAddRemoveItemClass, a member of class TThemedCustomizePopup.
	GetDefaultColorMapClass (see page 4563)	This is GetDefaultColorMapClass, a member of class TThemedCustomizePopup.
	NCPaint (see page 4563)	This is NCPaint, a member of class TThemedCustomizePopup.

41.1.3.3.1 TThemedCustomizePopup.GetAddRemoveItemClass Method

Pascal

```
function GetAddRemoveItemClass: TCustomAddRemoveItemClass; override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass();
```

Description

This is GetAddRemoveItemClass, a member of class TThemedCustomizePopup.

41.1.3.3.2 TThemedCustomizePopup.GetDefaultColorMapClass Method

Pascal

```
function GetDefaultColorMapClass: TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetDefaultColorMapClass();
```

Description

This is GetDefaultColorMapClass, a member of class TThemedCustomizePopup.

41.1.3.3.3 TThemedCustomizePopup.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TThemedCustomizePopup.

41.1.4 TThemedDropDownButton Class

Class Hierarchy

Pascal

```
TThemedDropDownButton = class(TCustomDropDownButton);
```

C++

```
class TThemedDropDownButton : public TCustomDropDownButton;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedDropDownButton.

41.1.4.1 TThemedDropDownButton Members

The following tables list the members exposed by TThemedDropDownButton.

Protected Methods

	Name	Description
	DrawBackground (see page 4564)	Draws a background image on the control.
	DrawFrame (see page 4564)	This is DrawFrame, a member of class TThemedDropDownButton.
	DrawGlyph (see page 4565)	Draws a symbol on the control.
	DrawLargeGlyph (see page 4565)	This is DrawLargeGlyph, a member of class TThemedDropDownButton.
	GetDropDownButtonWidth (see page 4565)	This is GetDropDownButtonWidth, a member of class TThemedDropDownButton.
	GetPopupClass (see page 4565)	This is GetPopupClass, a member of class TThemedDropDownButton.

41.1.4.2 TThemedDropDownButton Methods

The methods of the TThemedDropDownButton class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4564)	Draws a background image on the control.
	DrawFrame (see page 4564)	This is DrawFrame, a member of class TThemedDropDownButton.
	DrawGlyph (see page 4565)	Draws a symbol on the control.
	DrawLargeGlyph (see page 4565)	This is DrawLargeGlyph, a member of class TThemedDropDownButton.
	GetDropDownButtonWidth (see page 4565)	This is GetDropDownButtonWidth, a member of class TThemedDropDownButton.
	GetPopupClass (see page 4565)	This is GetPopupClass, a member of class TThemedDropDownButton.

41.1.4.2.1 TThemedDropDownButton.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.4.2.2 TThemedDropDownButton.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TThemedDropDownButton.

41.1.4.2.3 TThemedDropDownButton.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

41.1.4.2.4 TThemedDropDownButton.DrawLargeGlyph Method

Pascal

```
procedure DrawLargeGlyph(Location: TPoint); override;
```

C++

```
virtual __fastcall DrawLargeGlyph(TPoint Location);
```

Description

This is DrawLargeGlyph, a member of class TThemedDropDownButton.

41.1.4.2.5 TThemedDropDownButton.GetDropDownButtonWidth Method

Pascal

```
function GetDropDownButtonWidth: Integer; override;
```

C++

```
virtual __fastcall int GetDropDownButtonWidth();
```

Description

This is GetDropDownButtonWidth, a member of class TThemedDropDownButton.

41.1.4.2.6 TThemedDropDownButton.GetPopupClass Method

Pascal

```
function GetPopupClass: TCustomActionBarClass; override;
```

C++

```
virtual __fastcall TCustomActionBarClass GetPopupClass();
```

Description

This is GetPopupClass, a member of class TThemedDropDownButton.

41.1.5 TThemedExpandBtn Class

Class Hierarchy

Pascal

```
TThemedExpandBtn = class(TCustomMenuExpandBtn);
```

C++

```
class TThemedExpandBtn : public TCustomMenuExpandBtn;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedExpandBtn.

41.1.5.1 TThemedExpandBtn Members

The following tables list the members exposed by TThemedExpandBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 4566)	Draws a background image on the control.
	DrawFrame (see page 4567)	This is DrawFrame, a member of class TThemedExpandBtn.
	GetImageSize (see page 4567)	This is GetImageSize, a member of class TThemedExpandBtn.

41.1.5.2 TThemedExpandBtn Methods

The methods of the TThemedExpandBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4566)	Draws a background image on the control.
	DrawFrame (see page 4567)	This is DrawFrame, a member of class TThemedExpandBtn.
	GetImageSize (see page 4567)	This is GetImageSize, a member of class TThemedExpandBtn.

41.1.5.2.1 TThemedExpandBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.5.2.2 TThemedExpandBtn.DrawFrame Method

Pascal

```
procedure DrawFrame(ARect: TRect; Down: Boolean); override;
```

C++

```
virtual __fastcall DrawFrame(TRect ARect, Boolean Down);
```

Description

This is DrawFrame, a member of class TThemedExpandBtn.

41.1.5.2.3 TThemedExpandBtn.GetImageSize Method

Pascal

```
function GetImageSize: TPoint; override;
```

C++

```
virtual __fastcall TPoint GetImageSize();
```

Description

This is GetImageSize, a member of class TThemedExpandBtn.

41.1.6 TThemedMenuButton Class

Class Hierarchy

Pascal

```
TThemedMenuButton = class(TCustomMenuButton);
```

C++

```
class TThemedMenuButton : public TCustomMenuButton;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedMenuButton.

41.1.6.1 TThemedMenuButton Members

The following tables list the members exposed by TThemedMenuButton.

Protected Methods

	Name	Description
	DrawBackground (see page 4568)	Draws a background image on the control.
	DrawText (see page 4569)	Draws text on the control.

Public Methods

	Name	Description
	CalcBounds (see page 4568)	Calculates the size of the control.

41.1.6.2 TThemedMenuButton Methods

The methods of the TThemedMenuButton class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4568)	Draws a background image on the control.
	DrawText (see page 4569)	Draws text on the control.

Public Methods

	Name	Description
	CalcBounds (see page 4568)	Calculates the size of the control.

41.1.6.2.1 TThemedMenuButton.CalcBounds Method

Calculates the size of the control.

Pascal

```
procedure CalcBounds; override;
```

C++

```
virtual __fastcall CalcBounds();
```

Description

This method is largely the same as CalcBounds (TCustomActionControl), with one minor exception. The width of the control is set to be one pixel wider. For more information, see the documentation for the inherited method.

See Also

CalcBounds

41.1.6.2.2 TThemedMenuButton.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.6.2.3 TThemedMenuButton.DrawText Method

Draws text on the control.

Pascal

```
procedure DrawText(var ARect: TRect; var Flags: Cardinal; Text: string); override;
```

C++

```
virtual __fastcall DrawText(TRect ARect, unsigned Flags, UnicodeString Text);
```

Description

Use DrawText to draw the text specified by Text on the control within the area specified by ARect.

See Also

DrawBackground

DrawGlyph

41.1.7 TThemedMenuItem Class

Class Hierarchy

Pascal

```
TThemedMenuItem = class(TCustomMenuItem);
```

C++

```
class TThemedMenuItem : public TCustomMenuItem;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedMenuItem.

41.1.7.1 TThemedMenuItem Members

The following tables list the members exposed by TThemedMenuItem.

Protected Methods

	Name	Description
	DrawBackground (see page 4570)	Draws a background image on the control.
	DrawGlyph (see page 4571)	Draws a symbol on the control.
	DrawLargeGlyph (see page 4571)	This is DrawLargeGlyph, a member of class TThemedMenuItem.
	DrawSeparator (see page 4571)	This is DrawSeparator, a member of class TThemedMenuItem.

	DrawShadowedText (see page 4572)	This is DrawShadowedText, a member of class TThemedMenuItem.
	DrawSubMenuGlyph (see page 4572)	This is DrawSubMenuGlyph, a member of class TThemedMenuItem.
	DrawText (see page 4572)	Draws text on the control.
	DrawUnusedEdges (see page 4572)	This is DrawUnusedEdges, a member of class TThemedMenuItem.
	GetImageSize (see page 4573)	This is GetImageSize, a member of class TThemedMenuItem.

Public Methods

	Name	Description
	CalcBounds (see page 4570)	Calculates the size of the menu item.

41.1.7.2 TThemedMenuItem Methods

The methods of the TThemedMenuItem class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4570)	Draws a background image on the control.
	DrawGlyph (see page 4571)	Draws a symbol on the control.
	DrawLargeGlyph (see page 4571)	This is DrawLargeGlyph, a member of class TThemedMenuItem.
	DrawSeparator (see page 4571)	This is DrawSeparator, a member of class TThemedMenuItem.
	DrawShadowedText (see page 4572)	This is DrawShadowedText, a member of class TThemedMenuItem.
	DrawSubMenuGlyph (see page 4572)	This is DrawSubMenuGlyph, a member of class TThemedMenuItem.
	DrawText (see page 4572)	Draws text on the control.
	DrawUnusedEdges (see page 4572)	This is DrawUnusedEdges, a member of class TThemedMenuItem.
	GetImageSize (see page 4573)	This is GetImageSize, a member of class TThemedMenuItem.

Public Methods

	Name	Description
	CalcBounds (see page 4570)	Calculates the size of the menu item.

41.1.7.2.1 TThemedMenuItem.CalcBounds Method

Calculates the size of the menu item.

Pascal

```
procedure CalcBounds; override;
```

C++

```
virtual __fastcall CalcBounds();
```

Description

The size of the control depends on many factors, such as whether or not the menu item is a separator or not. CalcBounds computes the boundaries of the menu item considering these kinds of factors. At the end, it calls SetBounds and other routines to ensure that the values are set properly.

See Also

SetBounds

41.1.7.2.2 TThemedMenuItem.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

See Also

DrawGlyph

DrawText

41.1.7.2.3 TThemedMenuItem.DrawGlyph Method

Draws a symbol on the control.

Pascal

```
procedure DrawGlyph(const Location: TPoint); override;
```

C++

```
virtual __fastcall DrawGlyph(const TPoint Location);
```

Description

Use DrawGlyph to draw a symbol on the control at the specified location.

See Also

DrawBackground

DrawText

41.1.7.2.4 TThemedMenuItem.DrawLargeGlyph Method

Pascal

```
procedure DrawLargeGlyph(Location: TPoint); override;
```

C++

```
virtual __fastcall DrawLargeGlyph(TPoint Location);
```

Description

This is DrawLargeGlyph, a member of class TThemedMenuItem.

41.1.7.2.5 TThemedMenuItem.DrawSeparator Method

Pascal

```
procedure DrawSeparator(const Offset: Integer); override;
```

C++

```
virtual __fastcall DrawSeparator(const int Offset);
```

Description

This is DrawSeparator, a member of class TThemedMenuItem.

41.1.7.2.6 TThemedMenuItem.DrawShadowedText Method

Pascal

```
procedure DrawShadowedText(Rect: TRect; Flags: Cardinal; Text: string; TextColor: TColor;
ShadowColor: TColor); override;
```

C++

```
virtual __fastcall DrawShadowedText(TRect Rect, unsigned Flags, UnicodeString Text, TColor
TextColor, TColor ShadowColor);
```

Description

This is DrawShadowedText, a member of class TThemedMenuItem.

41.1.7.2.7 TThemedMenuItem.DrawSubMenuGlyph Method

Pascal

```
procedure DrawSubMenuGlyph; override;
```

C++

```
virtual __fastcall DrawSubMenuGlyph();
```

Description

This is DrawSubMenuGlyph, a member of class TThemedMenuItem.

41.1.7.2.8 TThemedMenuItem.DrawText Method

Draws text on the control.

Pascal

```
procedure DrawText(var Rect: TRect; var Flags: Cardinal; Text: string); override;
```

C++

```
virtual __fastcall DrawText(TRect Rect, unsigned Flags, UnicodeString Text);
```

Description

Use DrawText to draw the text specified by Text on the control within the area specified by ARect.

See Also

DrawBackground

DrawGlyph

41.1.7.2.9 TThemedMenuItem.DrawUnusedEdges Method

Pascal

```
procedure DrawUnusedEdges; override;
```

C++

```
virtual __fastcall DrawUnusedEdges();
```

Description

This is DrawUnusedEdges, a member of class TThemedMenuItem.

41.1.7.2.10 TThemedMenuItem.GetImageSize Method

Pascal

```
function GetImageSize: TPoint; override;
```

C++

```
virtual __fastcall TPoint GetImageSize();
```

Description

This is GetImageSize, a member of class TThemedMenuItem.

41.1.8 TThemedPopupMenu Class

Class Hierarchy

Pascal

```
TThemedPopupMenu = class(TCustomActionPopupMenu);
```

C++

```
class TThemedPopupMenu : public TCustomActionPopupMenu;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedPopupMenu.

41.1.8.1 TThemedPopupMenu Members

The following tables list the members exposed by TThemedPopupMenu.

Protected Methods

	Name	Description
	GetExpandBtnClass (see page 4574)	This is GetExpandBtnClass, a member of class TThemedPopupMenu.
	NCPaint (see page 4574)	This is NCPaint, a member of class TThemedPopupMenu.
	PositionPopup (see page 4574)	This is PositionPopup, a member of class TThemedPopupMenu.
	VisibleChanging (see page 4575)	Provides the interface for a method that responds to changes in the control's visibility.

Public Methods

	Name	Description
	Create (see page 4573)	Creates and initializes a TCustomActionPopupMenu instance.

41.1.8.2 TThemedPopupMenu.Create Constructor

Creates and initializes a TCustomActionPopupMenu instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TThemedPopupMenu(TComponent * AOwner);
```

Description

Create generates a TCustomActionPopupMenu and initializes its properties.

```
__fastcall virtual TCustomActionMenuBar (Classes::TComponentTComponent_Object* AOwner);
__fastcall TCustomActionMenuBar (HWND ParentWindow) :
Controls::TWinControlTWinControl_Create(ParentWindow) { }
```

41.1.8.3 TThemedPopupMenu Methods

The methods of the TThemedPopupMenu class are listed here.

Protected Methods

	Name	Description
	GetExpandBtnClass (see page 4574)	This is GetExpandBtnClass, a member of class TThemedPopupMenu.
	NCPaint (see page 4574)	This is NCPaint, a member of class TThemedPopupMenu.
	PositionPopup (see page 4574)	This is PositionPopup, a member of class TThemedPopupMenu.
	VisibleChanging (see page 4575)	Provides the interface for a method that responds to changes in the control's visibility.

41.1.8.3.1 TThemedPopupMenu.GetExpandBtnClass Method

Pascal

```
function GetExpandBtnClass: TCustomMenuExpandBtnClass; override;
```

C++

```
virtual __fastcall TCustomMenuExpandBtnClass GetExpandBtnClass();
```

Description

This is GetExpandBtnClass, a member of class TThemedPopupMenu.

41.1.8.3.2 TThemedPopupMenu.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); override;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TThemedPopupMenu.

41.1.8.3.3 TThemedPopupMenu.PositionPopup Method

Pascal

```
procedure PositionPopup(AnOwner: TCustomActionBar; ParentItem: TCustomActionControl); override;
```

C++

```
virtual __fastcall PositionPopup(TCustomActionBar AnOwner, TCustomActionControl ParentItem);
```

Description

This is PositionPopup, a member of class TThemedPopupMenu.

41.1.8.3.4 TThemedPopupMenu.VisibleChanging Method

Provides the interface for a method that responds to changes in the control's visibility.

Pascal

```
procedure VisibleChanging; override;
```

C++

```
virtual __fastcall VisibleChanging();
```

Description

VisibleChanging is called before the value of a control's Visible property changes. As implemented in TControl, it does nothing. Override VisibleChanging to respond to changes in the control's visibility. For example, if a control should not change its visibility, override VisibleChanging to raise an exception when an attempt is made to alter the control's visibility.

Visible

41.1.9 TThemedToolScrollBtn Class

Class Hierarchy

Pascal

```
TThemedToolScrollBtn = class(TCustomToolScrollBtn);
```

C++

```
class TThemedToolScrollBtn : public TCustomToolScrollBtn;
```

File

ThemedActnCtrls

Description

This is class ThemedActnCtrls.TThemedToolScrollBtn.

41.1.9.1 TThemedToolScrollBtn Members

The following tables list the members exposed by TThemedToolScrollBtn.

Protected Methods

	Name	Description
	DrawBackground (see page 4576)	Draws a background image on the control.

41.1.9.2 TThemedToolScrollBtn Methods

The methods of the TThemedToolScrollBtn class are listed here.

Protected Methods

	Name	Description
	DrawBackground (see page 4576)	Draws a background image on the control.

41.1.9.2.1 TThemedToolScrollBtn.DrawBackground Method

Draws a background image on the control.

Pascal

```
procedure DrawBackground(var PaintRect: TRect); override;
```

C++

```
virtual __fastcall DrawBackground(TRect PaintRect);
```

Description

Use DrawBackground to draw a background image on the control within the area specified by PaintRect.

DrawText

42 Themes Namespace

This is namespace Themes.

Topics

Name	Description
Classes (see page 4579)	The following table lists classes in this documentation.
Functions (see page 4593)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 4595)	The following table lists structs, records, enums in this documentation.
Types (see page 4629)	The following table lists types in this documentation.
Variables (see page 4631)	The following table lists variables in this documentation.

Classes

	Name	Description
	TThemeServices (see page 4579)	TThemeServices is a class used for communicating with the OS theme engine.

Functions

	Name	Description
	ThemeControl (see page 4593)	Checks whether a control should be themed.
	ThemeServices (see page 4593)	Returns an instance of the TThemeServices (see page 4579) class.
	UnthemedDesigner (see page 4594)	Checks whether the VCL Forms designer supports theming for a control.

Structs, Records, Enums

	Name	Description
	TThemedButton (see page 4595)	TThemedButton describes the possible themable parts of a button.
	TThemedClock (see page 4598)	TThemedClock describes the possible themable parts of a clock.
	TThemedComboBox (see page 4598)	TThemedComboBox describes the possible themable parts of a combo box.
	TThemedEdit (see page 4599)	TThemedEdit describes the possible themable parts of an edit.
	TThemedElement (see page 4600)	TThemedElement describes the possible themed user interface elements.
	TThemedElementDetails (see page 4602)	TThemedElementDetails describes a themed user interface element.
	TThemedExplorerBar (see page 4603)	TThemedExplorerBar describes the possible themable parts of an explorer bar control.
	TThemedHeader (see page 4604)	TThemedHeader describes the possible themable parts of a header control.
	TThemedListview (see page 4605)	TThemedListview describes the possible themable parts of a list view.
	TThemedMenu (see page 4606)	TThemedMenu describes the possible themable parts of a menu.
	TThemedPage (see page 4607)	TThemedPage describes the possible themable parts of a tab page.
	TThemedProgress (see page 4608)	TThemedProgress describes the possible themable parts of a progress bar.

	TThemedRebar (see page 4609)	TThemedRebar describes the possible themable parts of a rebar control.
	TThemedScrollBar (see page 4610)	TThemedScrollBar describes the possible themable parts of a scroll bar.
	TThemedSpin (see page 4612)	TThemedSpin describes the possible themable parts of a spin control.
	TThemedStartPanel (see page 4613)	TThemedStartPanel describes the possible themable parts of a start panel.
	TThemedStatus (see page 4614)	TThemedStatus describes the possible themable parts of a status bar.
	TThemedTab (see page 4615)	TThemedTab describes the possible themable parts of a tab.
	TThemedTaskBand (see page 4616)	TThemedTaskBand describes the possible themable parts of a task band.
	TThemedTaskBar (see page 4617)	TThemedTaskBar describes the possible themable parts of a system task bar.
	TThemedToolBar (see page 4618)	TThemedToolBar describes the possible themable parts of a tool bar.
	TThemedToolTip (see page 4620)	TThemedToolTip describes the possible themable parts of a tool tip.
	TThemedTrackBar (see page 4621)	TThemedTrackBar describes the possible themable parts of a track bar.
	TThemedTrayNotify (see page 4622)	TThemedTrayNotify describes the possible themable parts of a system tray notification area.
	TThemedTreeview (see page 4623)	TThemedTreeview describes the possible themable parts of a tree view.
	TThemedWindow (see page 4624)	TThemedWindow describes the possible themable parts of a window.

Types

Name	Description
PThemedElementDetails (see page 4629)	PThemedElementDetails is pointer to a TThemedElementDetails (see page 4602) record.
TThemeData (see page 4629)	TThemeData is an array of theme handles.
TThemeServicesClass (see page 4630)	TThemeServicesClass defines the metaclass for TThemeServices (see page 4579).

Variables

Name	Description
ThemeServicesClass (see page 4631)	ThemeServicesClass contains the metaclass reference for TThemeServices (see page 4579).

42.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TThemeServices (see page 4579)	TThemeServices is a class used for communicating with the OS theme engine.

42.1.1 TThemeServices Class

TThemeServices is a class used for communicating with the OS theme engine.

Class Hierarchy

Pascal

```
TThemeServices = class(TObject);
```

C++

```
class TThemeServices : public TObject;
```

File

Themes

Description

Use properties and methods of TThemeServices to communicate with the theme engine of the underlying Operating System (see page 3159). Do not create instances of TThemeServices, since only one instance is allowed to be created in the VCL. Rather, use the ThemeServices (see page 4593) routine to retrieve a singleton instance of the TThemeServices class.

See Also

ThemeServices (see page 4593)

42.1.1.1 TThemeServices Members

The following tables list the members exposed by TThemeServices.

Protected Methods

	Name	Description
	DoOnThemeChange (see page 4583)	DoOnThemeChange triggers the OnThemeChange (see page 4592) event.
	UnloadThemeData (see page 4590)	Clears all the internal data for the current theme.

Public Events

	Name	Description
	OnThemeChange (see page 4592)	Occurs when the Operating System (see page 3159) theme changes.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	ApplyThemeChange (see page 4582)	Resets the application theme.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	ColorToRGB (see page 4582)	This is the overview for the ColorToRGB method overload.
	ContentRect (see page 4583)	Returns the rectangle of the background area of a themed control.
	Create (see page 4581)	Creates and initializes an instance of the TThemeServices (see page 4579) class.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 4581)	Destroys an instance of TThemeServices (see page 4579) class.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DrawEdge (see page 4584)	This is the overview for the DrawEdge method overload.
	DrawElement (see page 4584)	This is the overview for the DrawElement method overload.
	DrawIcon (see page 4585)	Draws an icon over a themed user interface element.
	DrawParentBackground (see page 4586)	This is the overview for the DrawParentBackground method overload.
	DrawText (see page 4586)	Draws text over a themed user interface element.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetElementDetails (see page 4587)	This is the overview for the GetElementDetails method overload.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	HasTransparentParts (see page 4589)	Checks whether a given user interface element has transparent parts.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintBorder (see page 4590)	Draws the border of a control.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.
	UpdateThemes (see page 4590)	Resets the application theme.

Public Properties

	Name	Description
	Theme (see page 4591)	Represents a set of handles associated with each user interface element type.

	ThemesAvailable (see page 4591)	Specifies whether the current Operation System (see page 3159) supports themes.
	ThemesEnabled (see page 4592)	Specifies whether the themes are enabled for this application.

42.1.1.2 TThemeServices.Create Constructor

Creates and initializes an instance of the TThemeServices (see page 4579) class.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TThemeServices();
```

Description

Use Create to create and initialize an instance of the TThemeServices (see page 4579) class. Do not call this method directly. TThemeServices (see page 4579) is designed as a singleton, which means that only one instance should be created at a time. Use ThemeServices (see page 4593) routine to retrieve the instance of the TThemeServices (see page 4579) class.

See Also

ThemeServices (see page 4593)

42.1.1.3 TThemeServices.Destroy Destructor

Destroys an instance of TThemeServices (see page 4579) class.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TThemeServices();
```

Description

Do not call Destroy. There is only one instance of TThemeServices (see page 4579) present at run-time. Calling Destroy destroys that instance and crashes the application.

See Also

System::TObject::Free (see page 3372)

42.1.1.4 TThemeServices Methods

The methods of the TThemeServices class are listed here.

Protected Methods

	Name	Description
	DoOnThemeChange (see page 4583)	DoOnThemeChange triggers the OnThemeChange (see page 4592) event.
	UnloadThemeData (see page 4590)	Clears all the internal data for the current theme.

Public Methods

	Name	Description
	ApplyThemeChange (see page 4582)	Resets the application theme.

	ColorToRGB (see page 4582)	This is the overview for the ColorToRGB method overload.
	ContentRect (see page 4583)	Returns the rectangle of the background area of a themed control.
	DrawEdge (see page 4584)	This is the overview for the DrawEdge method overload.
	DrawElement (see page 4584)	This is the overview for the DrawElement method overload.
	DrawIcon (see page 4585)	Draws an icon over a themed user interface element.
	DrawParentBackground (see page 4586)	This is the overview for the DrawParentBackground method overload.
	DrawText (see page 4586)	Draws text over a themed user interface element.
	GetElementDetails (see page 4587)	This is the overview for the GetElementDetails method overload.
	HasTransparentParts (see page 4589)	Checks whether a given user interface element has transparent parts.
	PaintBorder (see page 4590)	Draws the border of a control.
	UpdateThemes (see page 4590)	Resets the application theme.

42.1.1.4.1 TThemeServices.ApplyThemeChange Method

Resets the application theme.

Pascal

```
procedure ApplyThemeChange;
```

C++

```
__fastcall ApplyThemeChange();
```

Description

ApplyThemeChange is called automatically by the TApplication object whenever the Operating System (see page 3159) theme is changed.

Note: ApplyThemeChange is used internally by the VCL and should not be called manually by applications.

See Also

ThemeServices (see page 4593)

Application

42.1.1.4.2 ColorToRGB Method

This is the overview for the ColorToRGB method overload.

Overload List

	Name	Description
	TThemeServices.ColorToRGB (TColor) (see page 4582)	Converts a TColor to its RGB representation.
	TThemeServices.ColorToRGB (TColor, PThemedElementDetails) (see page 4582)	Converts a TColor to its RGB representation.

42.1.1.4.2.1 TThemeServices.ColorToRGB Method (TColor)

Converts a TColor to its RGB representation.

Pascal

```
function ColorToRGB(Color: TColor): COLORREF; overload;
function ColorToRGB(Color: TColor; Details: PThemedElementDetails): COLORREF; overload;
```

C++

```
__fastcall COLORREF ColorToRGB(TColor Color);
__fastcall COLORREF ColorToRGB(TColor Color, PThemedElementDetails Details);
```

Description

Call ColorToRGB to convert a TColor to its RGB representation. ColorToRGB is only useful to applications that require the colors of controls when theming is enabled; otherwise applications should use the ColorToRGB routine located in Graphics unit.

See Also

ThemeServices (see page 4593)

ColorToRGB

42.1.1.4.3 TThemeServices.ContentRect Method

Returns the rectangle of the background area of a themed control.

Pascal

```
function ContentRect(DC: HDC; Details: TThemedElementDetails; BoundingRect: TRect): TRect;
```

C++

```
__fastcall TRect ContentRect(HDC DC, TThemedElementDetails Details, TRect BoundingRect);
```

Description

Call ContentRect to retrieve the rectangle that contains the background area of a control in a themed environment. ContentRect expects a TThemedElementDetails (see page 4602) parameter that describes the user interface element from which the informations is being retrieved.

See Also

ThemeServices (see page 4593)

DrawEdge (see page 4584)

42.1.1.4.4 TThemeServices.DoOnThemeChange Method

DoOnThemeChange triggers the OnThemeChange (see page 4592) event.

Pascal

```
procedure DoOnThemeChange; virtual;
```

C++

```
virtual __fastcall DoOnThemeChange();
```

Description

DoOnThemeChange is called whenever the Operating System (see page 3159) theme is changed. DoOnThemeChange simply calls the user supplied OnThemeChange (see page 4592) event, otherwise nothing happens.

See Also

OnThemeChange (see page 4592)

TThemeServices (see page 4579)

42.1.1.4.5 DrawEdge Method

This is the overview for the DrawEdge method overload.

Overload List

	Name	Description
	TThemeServices.DrawEdge (HDC, TThemedElementDetails, TRect, Cardinal, Cardinal) (see page 4584)	Draws the edge of a themed user interface element.
	TThemeServices.DrawEdge (HDC, TThemedElementDetails, TRect, Cardinal, Cardinal, PRect) (see page 4584)	Draws the edge of a themed user interface element.

42.1.1.4.5.1 TThemeServices.DrawEdge Method (HDC, TThemedElementDetails, TRect, Cardinal, Cardinal)

Draws the edge of a themed user interface element.

Pascal

```
procedure DrawEdge(DC: HDC; Details: TThemedElementDetails; const R: TRect; Edge: Cardinal;
Flags: Cardinal); overload;
procedure DrawEdge(DC: HDC; Details: TThemedElementDetails; const R: TRect; Edge: Cardinal;
Flags: Cardinal; ContentRect: PRect); overload;
```

C++

```
__fastcall DrawEdge(HDC DC, TThemedElementDetails Details, const TRect R, unsigned Edge,
unsigned Flags);
__fastcall DrawEdge(HDC DC, TThemedElementDetails Details, const TRect R, unsigned Edge,
unsigned Flags, PRect ContentRect);
```

Description

Call DrawEdge to draw the edge of a themed user interface element. The area is drawn using the current Operation System (see page 3159) theme.

See Also

ThemeServices (see page 4593)

DrawElement (see page 4585)

DrawIcon (see page 4585)

42.1.1.4.6 DrawElement Method

This is the overview for the DrawElement method overload.

Overload List

	Name	Description
	TThemeServices.DrawElement (HDC, TThemedElementDetails, TRect) (see page 4585)	Draws a themed user interface element.

	TThemeServices.DrawElement (HDC, TThemedElementDetails, TRect, PRect) (see page 4585)	Draws a themed user interface element.
	TThemeServices.DrawElement (HDC, TThemedElementDetails, TRect, TRect) (see page 4585)	Draws a themed user interface element.

42.1.1.4.6.1 TThemeServices.DrawElement Method (HDC, TThemedElementDetails, TRect)

Draws a themed user interface element.

Pascal

```
procedure DrawElement(DC: HDC; Details: TThemedElementDetails; const R: TRect); overload;
procedure DrawElement(DC: HDC; Details: TThemedElementDetails; const R: TRect; ClipRect:
TRect); overload;
procedure DrawElement(DC: HDC; Details: TThemedElementDetails; const R: TRect; ClipRect:
PRect); overload;
```

C++

```
__fastcall DrawElement(HDC DC, TThemedElementDetails Details, const TRect R);
__fastcall DrawElement(HDC DC, TThemedElementDetails Details, const TRect R, TRect ClipRect);
__fastcall DrawElement(HDC DC, TThemedElementDetails Details, const TRect R, PRect ClipRect);
```

Description

Call DrawElement to draw a themed user interface element given by the `Details` parameter on a device context. The element is drawn using the current Operation System (see page 3159) theme.

See Also

ThemeServices (see page 4593)

DrawIcon (see page 4585)

DrawEdge (see page 4584)

42.1.1.4.7 TThemeServices.DrawIcon Method

Draws an icon over a themed user interface element.

Pascal

```
procedure DrawIcon(DC: HDC; Details: TThemedElementDetails; const R: TRect; himl: HIMAGELIST;
Index: Integer);
```

C++

```
__fastcall DrawIcon(HDC DC, TThemedElementDetails Details, const TRect R, HIMAGELIST himl, int
Index);
```

Description

Call DrawIcon to draw an icon over a themed user interface element. The icon is drawn using the current Operation System (see page 3159) theme constraints.

See Also

ThemeServices (see page 4593)

DrawElement (see page 4585)

DrawEdge (see page 4584)

42.1.1.4.8 DrawParentBackground Method

This is the overview for the DrawParentBackground method overload.

Overload List

	Name	Description
	TThemeServices.DrawParentBackground (HWND, HDC, PThemedElementDetails, Boolean, PRect) (see page 4586)	Draws the parent background of the themed user interface element.
	TThemeServices.DrawParentBackground (HWND, HDC, PThemedElementDetails, Boolean, TRect) (see page 4586)	Draws the parent background of the themed user interface element.
	TThemeServices.DrawParentBackground (HWND, HDC, TThemedElementDetails, Boolean, PRect) (see page 4586)	Draws the parent background of the themed user interface element.

42.1.1.4.8.1 TThemeServices.DrawParentBackground Method (HWND, HDC, PThemedElementDetails, Boolean, PRect)

Draws the parent background of the themed user interface element.

Pascal

```
procedure DrawParentBackground(Window: HWND; Target: HDC; Details: PThemedElementDetails;
OnlyIfTransparent: Boolean; Bounds: PRect = nil); overload;
procedure DrawParentBackground(Window: HWND; Target: HDC; Details: PThemedElementDetails;
OnlyIfTransparent: Boolean; const Bounds: TRect); overload;
procedure DrawParentBackground(Window: HWND; Target: HDC; const Details:
TThemedElementDetails; OnlyIfTransparent: Boolean; Bounds: PRect = nil); overload;
```

C++

```
__fastcall DrawParentBackground(HWND Window, HDC Target, PThemedElementDetails Details,
Boolean OnlyIfTransparent, PRect Bounds = nil);
__fastcall DrawParentBackground(HWND Window, HDC Target, PThemedElementDetails Details,
Boolean OnlyIfTransparent, const TRect Bounds);
__fastcall DrawParentBackground(HWND Window, HDC Target, const TThemedElementDetails Details,
Boolean OnlyIfTransparent, PRect Bounds = nil);
```

Description

Call DrawParentBackground to draw the background of a themed user interface element's parent. The area is drawn using the current Operation System (see page 3159) theme.

See Also

ThemeServices (see page 4593)

DrawElement (see page 4585)

DrawIcon (see page 4585)

DrawEdge (see page 4584)

42.1.1.4.9 TThemeServices.DrawText Method

Draws text over a themed user interface element.

Pascal

```
procedure DrawText(DC: HDC; Details: TThemedElementDetails; const S: WideString; R: TRect;
Flags: Cardinal; Flags2: Cardinal);
```

C++

```
__fastcall DrawText(HDC DC, TThemedElementDetails Details, const BSTR S, TRect R, unsigned
Flags, unsigned Flags2);
```

Description

Call DrawText to draw text over a themed user interface element. The text is drawn using the current Operation System (see page 3159) theme constraints.

DrawEdge (see page 4584)

DrawIcon (see page 4585)

42.1.1.4.10 GetElementDetails Method

This is the overview for the GetElementDetails method overload.

Overload List

	Name	Description
	TThemeServices.GetElementDetails (TThemedButton) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedClock) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedComboBox) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedEdit) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedExplorerBar) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedHeader) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedListView) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedMenu) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedPage) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedProgress) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedRebar) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedScrollBar) (see page 4588)	Retrieves the details of a themed user interface element.

	TThemeServices.GetElementDetails (TThemedSpin) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedStartPanel) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedStatus) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTab) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTaskBand) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTaskBar) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedToolBar) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedToolTip) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTrackBar) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTrayNotify) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedTreeview) (see page 4588)	Retrieves the details of a themed user interface element.
	TThemeServices.GetElementDetails (TThemedWindow) (see page 4588)	Retrieves the details of a themed user interface element.

42.1.1.4.10.1 TThemeServices.GetElementDetails Method (TThemedButton)

Retrieves the details of a themed user interface element.

Pascal

```
function GetElementDetails(Detail: TThemedButton): TThemedElementDetails; overload;
function GetElementDetails(Detail: TThemedClock): TThemedElementDetails; overload;
function GetElementDetails(Detail: TThemedComboBox): TThemedElementDetails; overload;

function GetElementDetails(Detail: TThemedTreeview): TThemedElementDetails; overload;
function GetElementDetails(Detail: TThemedWindow): TThemedElementDetails; overload;
```

C++

```
__fastcall TThemedElementDetails GetElementDetails(TThemedButton Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedClock Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedComboBox Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedEdit Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedExplorerBar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedHeader Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedListView Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedMenu Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedPage Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedProgress Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedRebar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedScrollBar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedSpin Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedStartPanel Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedStatus Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTab Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTaskBand Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTaskBar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedToolBar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedToolTip Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTrackBar Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTrayNotify Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedTreeview Detail);
__fastcall TThemedElementDetails GetElementDetails(TThemedWindow Detail);
```

Description

Call GetElementDetails to retrieve the details of a themed user interface element. Each overloaded variant of GetElementDetails retrieves the details for a different user interface element. The retrieved value is a TThemedElementDetails (see page 4602) record associated with the input element.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

DrawElement (see page 4585)

DrawIcon (see page 4585)

42.1.1.4.11 TThemeServices.HasTransparentParts Method

Checks whether a given user interface element has transparent parts.

Pascal

```
function HasTransparentParts(Details: TThemedElementDetails): Boolean;
```

C++

```
__fastcall Boolean HasTransparentParts(TThemedElementDetails Details);
```

Description

Call HasTransparentParts to check whether a given user interface element has transparent parts under the current Operating System (see page 3159) theme.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

GetElementDetails (see page 4588)

42.1.1.4.12 TThemeServices.PaintBorder Method

Draws the border of a control.

Pascal

```
procedure PaintBorder(Control: TWinControl; EraseLRCorner: Boolean);
```

C++

```
__fastcall PaintBorder(TWinControl * Control, Boolean EraseLRCorner);
```

Description

Call PaintBorder to draw the border of a control. The area is drawn using the current Operation System (see page 3159) theme.

See Also

ThemeServices (see page 4593)

DrawElement (see page 4585)

DrawIcon (see page 4585)

42.1.1.4.13 TThemeServices.UnloadThemeData Method

Clears all the internal data for the current theme.

Pascal

```
procedure UnloadThemeData;
```

C++

```
__fastcall UnloadThemeData();
```

Description

UnloadThemeData is automatically called by the TApplication object whenever the Operating System (see page 3159) theme is changed.

Note: UnloadThemeData is used internally by the VCL and should not be called manually by applications.

See Also

ThemeServices (see page 4593)

Application

42.1.1.4.14 TThemeServices.UpdateThemes Method

Resets the application theme.

Pascal

```
procedure UpdateThemes;
```

C++

```
__fastcall UpdateThemes();
```

Description

UpdateThemes is automatically called by the TApplication object whenever the Operating System (see page 3159) theme is changed.

Note: UpdateThemes is used internally by the VCL and should not be called manually by applications.

See Also

ThemeServices (see page 4593)

Application

42.1.1.5 TThemeServices Properties

The properties of the TThemeServices class are listed here.

Public Properties

	Name	Description
	Theme (see page 4591)	Represents a set of handles associated with each user interface element type.
	ThemesAvailable (see page 4591)	Specifies whether the current Operation System (see page 3159) supports themes.
	ThemesEnabled (see page 4592)	Specifies whether the themes are enabled for this application.

42.1.1.5.1 TThemeServices.Theme Property

Represents a set of handles associated with each user interface element type.

Pascal

```
property Theme [Element: TThemedElement]: HTHEME;
```

C++

```
__property HTHEME Theme[TThemedElement Element];
```

Description

Use Theme to retrieve Windows handles for each user interface element. Windows API uses the returned handles to draw specific UI elements. The property is only used internally, so normally you do not need to use it.

See Also

ThemeServices (see page 4593)

ThemesAvailable (see page 4591)

42.1.1.5.2 TThemeServices.ThemesAvailable Property

Specifies whether the current Operation System (see page 3159) supports themes.

Pascal

```
property ThemesAvailable: Boolean;
```

C++

```
__property Boolean ThemesAvailable;
```

Description

Use ThemesAvailable to check whether the current Operating System (see page 3159) support themes.

See Also

ThemeServices (see page 4593)

ThemesEnabled (see page 4592)

42.1.1.5.3 TThemeServices.ThemesEnabled Property

Specifies whether the themes are enabled for this application.

Pascal

```
property ThemesEnabled: Boolean;
```

C++

```
__property Boolean ThemesEnabled;
```

Description

Use ThemesEnabled to check whether the themes are enabled for this application.

See Also

ThemeServices (see page 4593)

ThemesAvailable (see page 4591)

42.1.1.6 TThemeServices Events

The events of the TThemeServices class are listed here.

Public Events

	Name	Description
	OnThemeChange (see page 4592)	Occurs when the Operating System (see page 3159) theme changes.

42.1.1.6.1 TThemeServices.OnThemeChange Event

Occurs when the Operating System (see page 3159) theme changes.

Pascal

```
property OnThemeChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnThemeChange;
```

Description

Use the OnThemeChange event to implement custom processing that should occur whenever the Operation System (see page 3159) theme changes.

See Also

ThemeServices (see page 4593)

DoOnThemeChange (see page 4583)

42.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	ThemeControl (see page 4593)	Checks whether a control should be themed.
	ThemeServices (see page 4593)	Returns an instance of the TThemeServices (see page 4579) class.
	UnthemedDesigner (see page 4594)	Checks whether the VCL Forms designer supports theming for a control.

42.2.1 Themes.ThemeControl Function

Checks whether a control should be themed.

Pascal

```
function ThemeControl(AControl: TControl): Boolean;
```

C++

```
Boolean ThemeControl(TControl * AControl);
```

File

Themes

Description

Call ThemeControl to check whether a control should be themed. `AControl` is the control that needs to be checked. ThemeControl returns **True** if the control can be themed and **False** otherwise.

Note: ThemeControl is used by the VCL Forms designer at design time. Applications should not call this routine directly.

See Also

UnthemedDesigner (see page 4594)

ThemeServices (see page 4593)

TThemeServices (see page 4579)

42.2.2 Themes.ThemeServices Function

Returns an instance of the TThemeServices (see page 4579) class.

Pascal

```
function ThemeServices: TThemeServices;
```

C++

```
TThemeServices ThemeServices();
```

File

Themes

Description

Call ThemeServices to obtain an instance of the TThemeServices (see page 4579) class. Normally, only one instance of TThemeServices (see page 4579) should be created at a time. ThemeServices makes sure that only one instance is created. If an instance that you want to create was already created, ThemeServices returns it.

See Also

TThemedElement (see page 4600)

TThemeServices (see page 4579)

42.2.3 Themes.UnthemedDesigner Function

Checks whether the VCL Forms designer supports theming for a control.

Pascal

```
function UnthemedDesigner(AControl: TControl): Boolean;
```

C++

```
Boolean UnthemedDesigner(TControl * AControl);
```

File

Themes

Description

Call UnthemedDesigner to check whether the VCL Forms designer supports theming for a control. `AControl` is the control that needs to be checked.

Note: UnthemedDesigner is used by the VCL Forms designer at design time. Applications should not call this routine directly.

See Also

ThemeControl (see page 4593)

ThemeServices (see page 4593)

TThemeServices (see page 4579)

42.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TThemedButton (see page 4595)	TThemedButton describes the possible themable parts of a button.
	TThemedClock (see page 4598)	TThemedClock describes the possible themable parts of a clock.
	TThemedComboBox (see page 4598)	TThemedComboBox describes the possible themable parts of a combo box.
	TThemedEdit (see page 4599)	TThemedEdit describes the possible themable parts of an edit.
	TThemedElement (see page 4600)	TThemedElement describes the possible themed user interface elements.
	TThemedExplorerBar (see page 4603)	TThemedExplorerBar describes the possible themable parts of an explorer bar control.
	TThemedHeader (see page 4604)	TThemedHeader describes the possible themable parts of a header control.
	TThemedListview (see page 4605)	TThemedListview describes the possible themable parts of a list view.
	TThemedMenu (see page 4606)	TThemedMenu describes the possible themable parts of a menu.
	TThemedPage (see page 4607)	TThemedPage describes the possible themable parts of a tab page.
	TThemedProgress (see page 4608)	TThemedProgress describes the possible themable parts of a progress bar.
	TThemedRebar (see page 4609)	TThemedRebar describes the possible themable parts of a rebar control.
	TThemedScrollBar (see page 4610)	TThemedScrollBar describes the possible themable parts of a scroll bar.
	TThemedSpin (see page 4612)	TThemedSpin describes the possible themable parts of a spin control.
	TThemedStartPanel (see page 4613)	TThemedStartPanel describes the possible themable parts of a start panel.
	TThemedStatus (see page 4614)	TThemedStatus describes the possible themable parts of a status bar.
	TThemedTab (see page 4615)	TThemedTab describes the possible themable parts of a tab.
	TThemedTaskBand (see page 4616)	TThemedTaskBand describes the possible themable parts of a task band.
	TThemedTaskBar (see page 4617)	TThemedTaskBar describes the possible themable parts of a system task bar.
	TThemedToolBar (see page 4618)	TThemedToolBar describes the possible themable parts of a tool bar.
	TThemedToolTip (see page 4620)	TThemedToolTip describes the possible themable parts of a tool tip.
	TThemedTrackBar (see page 4621)	TThemedTrackBar describes the possible themable parts of a track bar.
	TThemedTrayNotify (see page 4622)	TThemedTrayNotify describes the possible themable parts of a system tray notification area.
	TThemedTreeview (see page 4623)	TThemedTreeview describes the possible themable parts of a tree view.
	TThemedWindow (see page 4624)	TThemedWindow describes the possible themable parts of a window.

Records

	Name	Description
	TThemedElementDetails (see page 4602)	TThemedElementDetails describes a themed user interface element.

42.3.1 Themes.TThemedButton Enumeration

TThemedButton describes the possible themable parts of a button.

Pascal

```
TThemedButton = (
  tbButtonDontCare,
  tbButtonRoot,
  tbPushButtonNormal,
  tbPushButtonHot,
  tbPushButtonPressed,
  tbPushButtonDisabled,
```

```
    tbPushButtonDefaulted,
    tbRadioButtonUncheckedNormal,
    tbRadioButtonUncheckedHot,
    tbRadioButtonUncheckedPressed,
    tbRadioButtonUncheckedDisabled,
    tbRadioButtonCheckedNormal,
    tbRadioButtonCheckedHot,
    tbRadioButtonCheckedPressed,
    tbRadioButtonCheckedDisabled,
    tbCheckBoxUncheckedNormal,
    tbCheckBoxUncheckedHot,
    tbCheckBoxUncheckedPressed,
    tbCheckBoxUncheckedDisabled,
    tbCheckBoxCheckedNormal,
    tbCheckBoxCheckedHot,
    tbCheckBoxCheckedPressed,
    tbCheckBoxCheckedDisabled,
    tbCheckBoxMixedNormal,
    tbCheckBoxMixedHot,
    tbCheckBoxMixedPressed,
    tbCheckBoxMixedDisabled,
    tbGroupBoxNormal,
    tbGroupBoxDisabled,
    tbUserButton
  );
```

C++

```
  enum TThemedButton {
    tbButtonDontCare,
    tbButtonRoot,
    tbPushButtonNormal,
    tbPushButtonHot,
    tbPushButtonPressed,
    tbPushButtonDisabled,
    tbPushButtonDefaulted,
    tbRadioButtonUncheckedNormal,
    tbRadioButtonUncheckedHot,
    tbRadioButtonUncheckedPressed,
    tbRadioButtonUncheckedDisabled,
    tbRadioButtonCheckedNormal,
    tbRadioButtonCheckedHot,
    tbRadioButtonCheckedPressed,
    tbRadioButtonCheckedDisabled,
    tbCheckBoxUncheckedNormal,
    tbCheckBoxUncheckedHot,
    tbCheckBoxUncheckedPressed,
    tbCheckBoxUncheckedDisabled,
    tbCheckBoxCheckedNormal,
    tbCheckBoxCheckedHot,
    tbCheckBoxCheckedPressed,
    tbCheckBoxCheckedDisabled,
    tbCheckBoxMixedNormal,
    tbCheckBoxMixedHot,
    tbCheckBoxMixedPressed,
    tbCheckBoxMixedDisabled,
    tbGroupBoxNormal,
    tbGroupBoxDisabled,
    tbUserButton
  };
```

File

Themes

Description

TThemedButton describes the possible states of a themed button. The following table lists the possible values of

TThemedButton and their meaning.

Value	Description
tbButtonDontCare	The content that is shared across all the button parts.
tbButtonRoot	The content that is shared across all the button states.
tbPushButtonNormal	A push button in its normal state.
tbPushButtonHot	A push button in its hovered state.
tbPushButtonPressed	A push button in its pressed state.
tbPushButtonDisabled	A push button in its disabled state.
tbPushButtonDefaulted	A push button in its defaulted state.
tbRadioButtonUncheckedNormal	An unchecked radio button in its normal state.
tbRadioButtonUncheckedHot	An unchecked radio button in its hovered state.
tbRadioButtonUncheckedPressed	An unchecked radio button in its pressed state.
tbRadioButtonUncheckedDisabled	An unchecked radio button in its disabled state.
tbRadioButtonCheckedNormal	A checked radio button in its normal state.
tbRadioButtonCheckedHot	A checked radio button in its hovered state.
tbRadioButtonCheckedPressed	An unchecked radio button in its pressed state.
tbRadioButtonCheckedDisabled	An unchecked radio button in its disabled state.
tbCheckBoxUncheckedNormal	An unchecked check box in its normal state.
tbCheckBoxUncheckedHot	An unchecked check box in its hovered state.
tbCheckBoxUncheckedPressed	An unchecked check box in its pressed state.
tbCheckBoxUncheckedDisabled	An unchecked check box in its disabled state.
tbCheckBoxCheckedNormal	A checked check box in its normal state.
tbCheckBoxCheckedHot	A checked check box in its hovered state.
tbCheckBoxCheckedPressed	A checked check box in its pressed state.
tbCheckBoxCheckedDisabled	A checked check box in its disabled state.
tbCheckBoxMixedNormal	A mixed check box in its normal state.
tbCheckBoxMixedHot	A mixed check box in its hovered state.
tbCheckBoxMixedPressed	A mixed check box in its pressed state.
tbCheckBoxMixedDisabled	A mixed check box in its disabled state.
tbGroupBoxNormal	A group box in its normal state.
tbGroupBoxDisabled	A group box in its disabled state.
tbUserButton	An user-drawn button.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

TThemeData (see page 4629)

42.3.2 Themes.TThemedClock Enumeration

TThemedClock describes the possible themable parts of a clock.

Pascal

```
TThemedClock = (
  tcClockDontCare,
  tcClockRoot,
  tcTimeNormal
);
```

C++

```
enum TThemedClock {
  tcClockDontCare,
  tcClockRoot,
  tcTimeNormal
};
```

File

Themes

Description

TThemedClock describes the possible themable parts of a clock. The following table lists the possible values of TThemedClock and their meaning.

Value	Description
tcClockDontCare	The content that is shared across all the clock parts.
tcClockRoot	The content that is shared across all the clock states.
tcTimeNormal	A clock in its normal state.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

TThemeData (see page 4629)

42.3.3 Themes.TThemedComboBox Enumeration

TThemedComboBox describes the possible themable parts of a combo box.

Pascal

```
TThemedComboBox = (
  tcComboBoxDontCare,
  tcComboBoxRoot,
  tcDropDownButtonNormal,
  tcDropDownButtonHot,
  tcDropDownButtonPressed,
  tcDropDownButtonDisabled
);
```

C++

```
enum TThemedComboBox {
  tcComboBoxDontCare,
  tcComboBoxRoot,
  tcDropDownButtonNormal,
  tcDropDownButtonHot,
  tcDropDownButtonPressed,
  tcDropDownButtonDisabled
};
```

File

Themes

Description

TThemedComboBox describes the possible themable parts of a combo box. The following table lists the possible values of TThemedComboBox and their meaning.

Value	Description
tcComboBoxDontCare	The content that is shared across all the combo box parts.
tcComboBoxRoot	The content that is shared across all the combo box states.
tcDropDownButtonNormal	A combo box drop-down button in its normal state.
tcDropDownButtonHot	A combo box drop-down button in its hovered state.
tcDropDownButtonPressed	A combo box drop-down button in its pressed state.
tcDropDownButtonDisabled	A combo box drop-down button in its disabled state.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

TThemeData (see page 4629)

42.3.4 Themes.TThemedEdit Enumeration

TThemedEdit describes the possible themable parts of an edit.

Pascal

```
TThemedEdit = (
  teEditDontCare,
  teEditRoot,
  teEditTextNormal,
  teEditTextHot,
  teEditTextSelected,
  teEditTextDisabled,
  teEditTextFocused,
  teEditTextReadOnly,
  teEditTextAssist,
  teEditCaret
);
```

C++

```
enum TThemedEdit {
  teEditDontCare,
```

```
    teEditRoot,
    teEditTextNormal,
    teEditTextHot,
    teEditTextSelected,
    teEditTextDisabled,
    teEditTextFocused,
    teEditTextReadOnly,
    teEditTextAssist,
    teEditCaret
  };
```

File

Themes

Description

TThemedEdit describes the possible themable parts of an edit. The following table lists the possible values of TThemedEdit and their meaning.

Value	Description
teEditDontCare	The content that is shared across all edit parts.
teEditRoot	The content that is shared across all edit states.
teEditTextNormal	The text in the edit control in its normal state.
teEditTextHot	The text in the edit control in its hovered state.
teEditTextSelected	The text in the edit control in its selected state.
teEditTextDisabled	The text in the edit control in disabled state.
teEditTextFocused	The text in the edit control in focused state.
teEditTextReadOnly	The text in the edit control in read-only state.
teEditTextAssist	The text in the edit control in its accessible state.
teEditCaret	The caret of an edit control.

TThemeData (see page 4629)

42.3.5 Themes.TThemedElement Enumeration

TThemedElement describes the possible themed user interface elements.

Pascal

```
  TThemedElement = (
    teButton,
    teClock,
    teComboBox,
    teEdit,
    teExplorerBar,
    teHeader,
    teListView,
    teMenu,
    tePage,
```

```
    teProgress,
    teRebar,
    teScrollBar,
    teSpin,
    teStartPanel,
    teStatus,
    teTab,
    teTaskBand,
    teTaskBar,
    teToolBar,
    teToolTip,
    teTrackBar,
    teTrayNotify,
    teTreeview,
    teWindow
  );
```

C++

```
  enum TThemedElement {
    teButton,
    teClock,
    teComboBox,
    teEdit,
    teExplorerBar,
    teHeader,
    teListView,
    teMenu,
    tePage,
    teProgress,
    teRebar,
    teScrollBar,
    teSpin,
    teStartPanel,
    teStatus,
    teTab,
    teTaskBand,
    teTaskBar,
    teToolBar,
    teToolTip,
    teTrackBar,
    teTrayNotify,
    teTreeview,
    teWindow
  };
```

File

Themes

Description

TThemedElement describes the possible themed user interface elements. The following table lists the possible values of TThemedElement and their meaning.

Value	Description
teButton	Represents a button.
teClock	Represents a clock.
teComboBox	Represents a combo box.
teEdit	Represents an edit box.
teExplorerBar	Represents an explorer bar.
teHeader	Represents a list header.

teListView	Represents a list view.
teMenu	Represents a menu.
tePage	Represents a tab or a property page.
teProgress	Represents a progress bar.
teRebar	Represents a rebar.
teScrollBar	Represents a scroll bar.
teSpin	Represents a spin button.
teStartPanel	Represents a start panel.
teStatus	Represents a status bar.
teTab	Represents a tab in a tab control.
teTaskBand	Represents a task band.
teTaskBar	Represents a task bar.
teToolBar	Represents a tool bar.
teToolTip	Represents a tool tip.
teTrackBar	Represents a track bar.
teTrayNotify	Represents a tray notify area.
teTreeview	Represents a tree view.
teWindow	Represents a window.

42.3.6 Themes.TThemedElementDetails Record

TThemedElementDetails describes a themed user interface element.

Pascal

```
TThemedElementDetails = record
  Element: TThemedElement;
  Part: Integer;
  State: Integer;
end;
```

C++

```
struct TThemedElementDetails {
  TThemedElement Element;
  int Part;
  int State;
};
```

File

Themes

Description

TThemedElementDetails is a record that contains information useful when applying themes to a user interface element. The following table lists each member of TThemedElementDetails and its meaning.

Member	Description
`Element`	The type of the user interface element.
`Part`	The part of the control being themed.
`State`	The state of the user interface element.

42.3.7 Themes.TThemedExplorerBar Enumeration

TThemedExplorerBar describes the possible themable parts of an explorer bar control.

Pascal

```
TThemedExplorerBar = (
  tebExplorerBarDontCare,
  tebExplorerBarRoot,
  tebHeaderBackgroundNormal,
  tebHeaderBackgroundHot,
  tebHeaderBackgroundPressed,
  tebHeaderCloseNormal,
  tebHeaderCloseHot,
  tebHeaderClosePressed,
  tebHeaderPinNormal,
  tebHeaderPinHot,
  tebHeaderPinPressed,
  tebHeaderPinSelectedNormal,
  tebHeaderPinSelectedHot,
  tebHeaderPinSelectedPressed,
  tebIEBarMenuNormal,
  tebIEBarMenuHot,
  tebIEBarMenuPressed,
  tebNormalGroupBackground,
  tebNormalGroupCollapseNormal,
  tebNormalGroupCollapseHot,
  tebNormalGroupCollapsePressed,
  tebNormalGroupExpandNormal,
  tebNormalGroupExpandHot,
  tebNormalGroupExpandPressed,
  tebNormalGroupHead,
  tebSpecialGroupBackground,
  tebSpecialGroupCollapseSpecial,
  tebSpecialGroupCollapseHot,
  tebSpecialGroupCollapsePressed,
  tebSpecialGroupExpandSpecial,
  tebSpecialGroupExpandHot,
  tebSpecialGroupExpandPressed,
  tebSpecialGroupHead
);
```

C++

```
enum TThemedExplorerBar {

    ttnAnimBackground
  };
```

File

Themes

Description

TThemedTrayNotify describes the possible themable parts of a system tray notification area. The following table lists the possible values of TThemedTrayNotify and their meaning.

Value	Description
`ttnTrayNotifyDontCare`	The content that is shared across all the tray notification parts.
`ttnTrayNotifyRoot`	The content that is shared across all the tray notification states.
`ttnBackground`	The background of a tray notification area.
`ttnAnimBackground`	The background of a tray notification area when animating.

Description

TThemedTreeview describes the possible themable parts of a tree view. The following table lists the possible values of

TThemedTreeview and their meaning.

Value	Description
ttTreeviewDontCare	The content that is shared across all the tree view parts.
ttTreeviewRoot	The content that is shared across all the tree view states.
ttItemNormal	A tree view item in its normal state.
ttItemHot	A tree view item in its hovered state.
ttItemSelected	A tree view item in its selected state.
ttItemDisabled	A tree view item in its disabled state.
ttItemSelectedNotFocus	A tree view item in its selected, but not focused state.
ttGlyphClosed	The glyph representing a collapsed tree view node.
ttGlyphOpened	The glyph representing an expanded tree view node.
ttBranch	Tree view branch that links all nodes together.

File

Themes

Description

TThemedWindow describes the possible themable parts of a window.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

TThemeData (see page 4629)

42.4 Types

The following table lists types in this documentation.

Types

Name	Description
PThemedElementDetails (see page 4629)	PThemedElementDetails is pointer to a TThemedElementDetails (see page 4602) record.
TThemeData (see page 4629)	TThemeData is an array of theme handles.
TThemeServicesClass (see page 4630)	TThemeServicesClass defines the metaclass for TThemeServices (see page 4579).

42.4.1 Themes.PThemedElementDetails Type

PThemedElementDetails is pointer to a TThemedElementDetails (see page 4602) record.

Pascal

```
PThemedElementDetails = ^TThemedElementDetails;
```

C++

```
^TThemedElementDetails PThemedElementDetails;
```

File

Themes

Description

PThemedElementDetails is pointer to a TThemedElementDetails (see page 4602) record. PThemedElementDetails variables are used by the TThemeServices (see page 4579) class to store theme related information.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

TThemeData (see page 4629)

42.4.2 Themes.TThemeData Type

TThemeData is an array of theme handles.

Pascal

```
TThemeData = array[TThemedElement] of HTHEME;
```

C++

```
array[TThemedElement] of HTHEME TThemeData;
```

File

Themes

Description

TThemeData is an array used internally to hold theme element handles. Each element of TThemeData is a handle assigned to the specific user interface element supported by the theme engine. TThemeServices (see page 4579) instances use an array of this type.

See Also

ThemeServices (see page 4593)

TThemedElementDetails (see page 4602)

42.4.3 Themes.TThemeServicesClass Type

TThemeServicesClass defines the metaclass for TThemeServices (see page 4579).

Pascal

```
TThemeServicesClass = class of TThemeServices;
```

C++

```
TThemeServices TThemeServicesClass;
```

File

Themes

Description

TThemeServicesClass is the metaclass for TThemeServices (see page 4579). Its value is the class reference for TThemeServices (see page 4579) or for one of its descendants.

See Also

ThemeServicesClass (see page 4631)

TThemeServices (see page 4579)

ThemeServices (see page 4593)

Class References

42.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ThemeServicesClass (see page 4631)	ThemeServicesClass contains the metaclass reference for TThemeServices (see page 4579).

42.5.1 Themes.ThemeServicesClass Variable

ThemeServicesClass contains the metaclass reference for TThemeServices (see page 4579).

Pascal

```
ThemeServicesClass: TThemeServicesClass = TThemeServices;
```

C++

```
TThemeServicesClass ThemeServicesClass = TThemeServices;
```

File

Themes

Description

ThemeServicesClass is used internally by the theme services. When the singleton instance of TThemeServices (see page 4579) is created, ThemeServicesClass is used. You are allowed to change the value of ThemeServicesClass, but you must do that before the application loads any VCL unit. All VCL units invoke the ThemeServices (see page 4593) routine that creates the instance of TThemeServices (see page 4579). Changing the value of the ThemeServicesClass variable afterwards does not yield any result.

See Also

TThemeServices (see page 4579)

TThemeServicesClass (see page 4630)

ThemeServices (see page 4593)

43 ToolWin Namespace

This is namespace ToolWin.

Topics

Name	Description
Classes (see page 4634)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 4644)	The following table lists structs, records, enums in this documentation.
Types (see page 4647)	The following table lists types in this documentation.

Classes

	Name	Description
	TToolDockForm (see page 4634)	TToolDockForm is a default floating dock site class for tool buttons.
	TToolDockObject (see page 4637)	Handles drag-and-dock operations for toolbar controls.
	TToolWindow (see page 4639)	TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

Structs, Records, Enums

	Name	Description
	TEdgeBorder (see page 4644)	TEdgeBorders (see page 4647) is the type of the EdgeBorders property.
	TEdgeStyle (see page 4645)	TEdgeStyle describes the appearance of an edge border.
	TSizingOrientation (see page 4645)	TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

Types

Name	Description
TEdgeBorders (see page 4647)	This is type ToolWin.TEdgeBorders.

43.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TToolDockForm (see page 4634)	TToolDockForm is a default floating dock site class for tool buttons.
	TToolDockObject (see page 4637)	Handles drag-and-dock operations for toolbar controls.
	TToolWindow (see page 4639)	TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

43.1.1 TToolDockForm Class

TToolDockForm is a default floating dock site class for tool buttons.

Class Hierarchy

Pascal

```
TToolDockForm = class(TCustomDockForm);
```

C++

```
class TToolDockForm : public TCustomDockForm;
```

File

ToolWin

Description

Assign TToolDockForm to the FloatingDockSiteClass property of tool buttons to get appropriate docking behavior.

43.1.1.1 TToolDockForm Members

The following tables list the members exposed by TToolDockForm.

Protected Methods

	Name	Description
	CanResize (see page 4635)	Specifies whether the control can resize itself.
	CreateParams (see page 4636)	Initializes the window-creation parameter record when the form window is created.
	DoAddDockClient (see page 4636)	Performs actions when a control is docked to the form.
	WMNCCreate (see page 4636)	This is WMNCCreate, a member of class TToolDockForm.
	WMNCHitTest (see page 4636)	This is WMNCHitTest, a member of class TToolDockForm.
	WMNCLButtonDown (see page 4637)	This is WMNCLButtonDown, a member of class TToolDockForm.
	WMSize (see page 4637)	This is WMSize, a member of class TToolDockForm.
	WMSysCommand (see page 4637)	This is WMSysCommand, a member of class TToolDockForm.

Public Methods

	Name	Description
	Create (see page 4635)	Creates an instance of TToolDockForm (see page 4634).

43.1.1.2 TToolDockForm.Create Constructor

Creates an instance of TToolDockForm (see page 4634).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TToolDockForm(TComponent * AOwner);
```

Description

AOwner is the dock form's owner, which is responsible for freeing the tool dock form.

The constructor initializes the BorderWidth property to 1.

See Also

BorderWidth

Owner

43.1.1.3 TToolDockForm Methods

The methods of the TToolDockForm class are listed here.

Protected Methods

	Name	Description
	CanResize (see page 4635)	Specifies whether the control can resize itself.
	CreateParams (see page 4636)	Initializes the window-creation parameter record when the form window is created.
	DoAddDockClient (see page 4636)	Performs actions when a control is docked to the form.
	WMNCCreate (see page 4636)	This is WMNCCreate, a member of class TToolDockForm.
	WMNCHitTest (see page 4636)	This is WMNCHitTest, a member of class TToolDockForm.
	WMNCLButtonDown (see page 4637)	This is WMNCLButtonDown, a member of class TToolDockForm.
	WMSize (see page 4637)	This is WMSize, a member of class TToolDockForm.
	WMSysCommand (see page 4637)	This is WMSysCommand, a member of class TToolDockForm.

43.1.1.3.1 TToolDockForm.CanResize Method

Specifies whether the control can resize itself.

Pascal

```
function CanResize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanResize(int NewWidth, int NewHeight);
```

Description

CanResize is called automatically when an attempt is made to resize the control, after any autosizing has occurred. The NewWidth and NewHeight parameters specify the attempted new values for the control's height and width. CanResize optionally

adjusts the values of NewWidth and NewHeight, and returns true if the control can be resized to the returned values. CanResize returns false if the control can't be resized.

43.1.1.3.2 TToolDockForm.CreateParams Method

Initializes the window-creation parameter record when the form window is created.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams calls the inherited CreateParams method, and then adds WS_POPUP to the Style property.

43.1.1.3.3 TToolDockForm.DoAddDockClient Method

Performs actions when a control is docked to the form.

Pascal

```
procedure DoAddDockClient(Client: TControl; const ARect: TRect); override;
```

C++

```
virtual __fastcall DoAddDockClient(TControl * Client, const TRect ARect);
```

Description

DoAddDockClient sets the client's Align property to alNone and its BoundsRect property to ClientRect. Then DoAddDockClient calls the inherited DoAddDockClient method and sets the form's AutoSize property to true.

43.1.1.3.4 TToolDockForm.WMNCCreate Method

Pascal

```
procedure WMNCCreate(var Message: TWMNCCreate); message WM_NCCREATE;
```

C++

```
__fastcall WMNCCreate(TWMNCCreate Message);
```

Description

This is WMNCCreate, a member of class TToolDockForm.

43.1.1.3.5 TToolDockForm.WMNCHitTest Method

Pascal

```
procedure WMNCHitTest(var Message: TWMNCHitTest); message WM_NCHITTEST;
```

C++

```
__fastcall WMNCHitTest(TWMNCHitTest Message);
```

Description

This is WMNCHitTest, a member of class TToolDockForm.

43.1.1.3.6 TToolDockForm.WMNCLButtonDown Method

Pascal

```
procedure WMNCLButtonDown(var Message: TWMNCLButtonDown); message WM_NCLBUTTONDOWN;
```

C++

```
__fastcall WMNCLButtonDown(TWMNCLButtonDown Message);
```

Description

This is WMNCLButtonDown, a member of class TToolDockForm.

43.1.1.3.7 TToolDockForm.WMSize Method

Pascal

```
procedure WMSize(var Message: TWMSize); message WM_SIZE;
```

C++

```
__fastcall WMSize(TWMSize Message);
```

Description

This is WMSize, a member of class TToolDockForm.

43.1.1.3.8 TToolDockForm.WMSysCommand Method

Pascal

```
procedure WMSysCommand(var Message: TWMSysCommand); message WM_SYSCOMMAND;
```

C++

```
__fastcall WMSysCommand(TWMSysCommand Message);
```

Description

This is WMSysCommand, a member of class TToolDockForm.

43.1.2 TToolDockObject Class

Handles drag-and-dock operations for toolbar controls.

Class Hierarchy

Pascal

```
TToolDockObject = class(TDragDockObject);
```

C++

```
class TToolDockObject : public TDragDockObject;
```

File

ToolWin

Description

Use TToolDockObject to handle drag-and-dock operations for toolbar controls that are docked to a TControlBar object.

Note: TToolDockObject is designed for tool bars that are docked to TControlBar. It may not work as expected when the application is docking a tool bar to a form or panel.

See Also

TToolBar

TControlBar

43.1.2.1 TToolDockObject Members

The following tables list the members exposed by TToolDockObject.

Protected Methods

	Name	Description
	AdjustDockRect (see page 4638)	Adjusts the value of DockRect to reflect the dragged control's current status.
	DrawDragDockImage (see page 4639)	Called when the dock image for a toolbar control is drawn.
	EraseDragDockImage (see page 4639)	Called when the dock image for a toolbar control is erased.

Public Methods

	Name	Description
	Create (see page 4638)	Creates and initializes an instance of TDragDockObject.

43.1.2.2 TToolDockObject.Create Constructor

Creates and initializes an instance of TDragDockObject.

Pascal

```
constructor Create(AControl: TControl); override;
```

C++

```
virtual __fastcall TToolDockObject(TControl * AControl);
```

Description

Create calls the inherited constructor and allocates memory for the Brush property.

43.1.2.3 TToolDockObject Methods

The methods of the TToolDockObject class are listed here.

Protected Methods

	Name	Description
	AdjustDockRect (see page 4638)	Adjusts the value of DockRect to reflect the dragged control's current status.
	DrawDragDockImage (see page 4639)	Called when the dock image for a toolbar control is drawn.
	EraseDragDockImage (see page 4639)	Called when the dock image for a toolbar control is erased.

43.1.2.3.1 TToolDockObject.AdjustDockRect Method

Adjusts the value of DockRect to reflect the dragged control's current status.

Pascal

```
procedure AdjustDockRect(ARect: TRect); override;
```

C++

```
virtual __fastcall AdjustDockRect(TRect ARect);
```

Description

AdjustDockRect is called automatically at points during the drag operation to adjust the value of the DockRect property. The adjustment ensures that the position where the control is docked reflects the current mouse position, and, if the control is floating, reflects the size and shape of the control's floating dock site.

See Also

DockRect

Floating

43.1.2.3.2 TToolDockObject.DrawDragDockImage Method

Called when the dock image for a toolbar control is drawn.

Pascal

```
procedure DrawDragDockImage; override;
```

C++

```
virtual __fastcall DrawDragDockImage();
```

Description

DrawDragDockImage draws a control that is moved in a toolbar.

43.1.2.3.3 TToolDockObject.EraseDragDockImage Method

Called when the dock image for a toolbar control is erased.

Pascal

```
procedure EraseDragDockImage; override;
```

C++

```
virtual __fastcall EraseDragDockImage();
```

Description

EraseDragDockImage erases a control that is moved in a toolbar.

43.1.3 TToolWindow Class

TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

Class Hierarchy

Pascal

```
TToolWindow = class(TWinControl);
```

C++

```
class TToolWindow : public TWinControl;
```

File

ToolWin

Description

TToolWindow is the ancestor of the TCoolBar and TToolBar components, which facilitate the arrangement of buttons and other visual controls.

See Also

TCoolBar

TToolBar

43.1.3.1 TToolWindow Members

The following tables list the members exposed by TToolWindow.

Protected Methods

	Name	Description
	CMBorderChanged (see page 4641)	This is CMBorderChanged, a member of class TToolWindow.
	CMCtl3DChanged (see page 4641)	This is CMCtl3DChanged, a member of class TToolWindow.
V	NCPaint (see page 4641)	This is NCPaint, a member of class TToolWindow.
	WMNCCalcSize (see page 4641)	This is WMNCCalcSize, a member of class TToolWindow.
	WMNCPaint (see page 4642)	This is WMNCPaint, a member of class TToolWindow.

Public Methods

	Name	Description
V	Create (see page 4640)	Creates and initializes a TToolWindow (see page 4639) instance.

Public Properties

	Name	Description
	EdgeBorders (see page 4642)	Determines which sides of the control have visible borders.
	EdgeInner (see page 4642)	Determines the border style for the control's inner edge.
	EdgeOuter (see page 4643)	Determines the border style for the control's outer edge.

43.1.3.2 TToolWindow.Create Constructor

Creates and initializes a TToolWindow (see page 4639) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TToolWindow(TComponent * AOwner);
```

Description

Create generates a TToolWindow (see page 4639) and initializes its properties.

43.1.3.3 TToolWindow Methods

The methods of the TToolWindow class are listed here.

Protected Methods

	Name	Description
	CMBorderChanged (see page 4641)	This is CMBorderChanged, a member of class TToolWindow.
	CMCtl3DChanged (see page 4641)	This is CMCtl3DChanged, a member of class TToolWindow.
	NCPaint (see page 4641)	This is NCPaint, a member of class TToolWindow.
	WMNCCalcSize (see page 4641)	This is WMNCCalcSize, a member of class TToolWindow.
	WMNCPaint (see page 4642)	This is WMNCPaint, a member of class TToolWindow.

43.1.3.3.1 TToolWindow.CMBorderChanged Method

Pascal

```
procedure CMBorderChanged(var Message: TMessage); message CM_BORDERCHANGED;
```

C++

```
__fastcall CMBorderChanged(TMessage Message);
```

Description

This is CMBorderChanged, a member of class TToolWindow.

43.1.3.3.2 TToolWindow.CMCtl3DChanged Method

Pascal

```
procedure CMCtl3DChanged(var Message: TMessage); message CM_CTL3DCHANGED;
```

C++

```
__fastcall CMCtl3DChanged(TMessage Message);
```

Description

This is CMCtl3DChanged, a member of class TToolWindow.

43.1.3.3.3 TToolWindow.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); virtual;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TToolWindow.

43.1.3.3.4 TToolWindow.WMNCCalcSize Method

Pascal

```
procedure WMNCCalcSize(var Message: TWMNCCalcSize); message WM_NCCALCSIZE;
```

C++

```
__fastcall WMNCCalcSize(TWMNCCalcSize Message);
```

Description

This is WMNCCalcSize, a member of class TToolWindow.

43.1.3.3.5 TToolWindow.WMNCPaint Method

Pascal

```
procedure WMNCPaint(var Message: TWMNCPaint); message WM_NCPAINT;
```

C++

```
__fastcall WMNCPaint(TWMNCPaint Message);
```

Description

This is WMNCPaint, a member of class TToolWindow.

43.1.3.4 TToolWindow Properties

The properties of the TToolWindow class are listed here.

Public Properties

	Name	Description
	EdgeBorders (see page 4642)	Determines which sides of the control have visible borders.
	EdgeInner (see page 4642)	Determines the border style for the control's inner edge.
	EdgeOuter (see page 4643)	Determines the border style for the control's outer edge.

43.1.3.4.1 TToolWindow.EdgeBorders Property

Determines which sides of the control have visible borders.

Pascal

```
property EdgeBorders: TEdgeBorders;
```

C++

```
__property TEdgeBorders EdgeBorders;
```

Description

Use the EdgeBorders property to add or remove borders. The appearance of the borders can be set with the EdgeInner (see page 4642) and EdgeOuter (see page 4643) properties.

See Also

EdgeInner (see page 4642)

EdgeOuter (see page 4643)

43.1.3.4.2 TToolWindow.EdgeInner Property

Determines the border style for the control's inner edge.

Pascal

```
property EdgeInner: TEdgeStyle;
```

C++

```
__property TEdgeStyle EdgeInner;
```

Description

Use EdgeInner to provide the tool window with a three-dimensional beveled look. A tool window has two borders on each side, an outer border drawn next to the outer edge, and an inner border drawn inside the outer border. EdgeInner specifies the appearance of the inner border. It can be raised (esRaised), lowered (esLowered), or left off altogether (esNone).

Note: The EdgeInner property has an effect only on the sides specified by the EdgeBorders (see page 4642) property.

Use EdgeInner with EdgeOuter (see page 4643) to give the component a three-dimensional look.

See Also

EdgeBorders (see page 4642)

EdgeOuter (see page 4643)

43.1.3.4.3 TToolWindow.EdgeOuter Property

Determines the border style for the control's outer edge.

Pascal

```
property EdgeOuter: TEdgeStyle;
```

C++

```
__property TEdgeStyle EdgeOuter;
```

Description

Use EdgeOuter to provide the tool window with a three-dimensional beveled look. A tool window has two borders on each side, an outer border drawn next to the outer edge, and an inner border drawn inside the outer border. EdgeOuter specifies the appearance of the outer border. It can be raised (esRaised), lowered (esLowered), or left off altogether (esNone).

Note: The EdgeInner (see page 4642) property has an effect only on the sides specified by the EdgeBorders (see page 4642) property.

Use EdgeOuter with EdgeInner (see page 4642) to give the component a three-dimensional look.

See Also

EdgeBorders (see page 4642)

EdgeInner (see page 4642)

43.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TEdgeBorder (see page 4644)	TEdgeBorders (see page 4647) is the type of the EdgeBorders property.
	TEdgeStyle (see page 4645)	TEdgeStyle describes the appearance of an edge border.
	TSizingOrientation (see page 4645)	TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

43.2.1 ToolWin.TEdgeBorder Enumeration

TEdgeBorders (see page 4647) is the type of the EdgeBorders property.

Pascal

```
TEdgeBorder = (
  ebLeft,
  ebTop,
  ebRight,
  ebBottom
);
```

C++

```
enum TEdgeBorder {
  ebLeft,
  ebTop,
  ebRight,
  ebBottom
};
```

File

ToolWin

Description

TEdgeBorders (see page 4647) is a set of TEdgeBorder values. Each TEdgeBorder value indicates whether a beveled edge appears on a particular side of a control. The following table lists the TEdgeBorder values:

Value	Meaning
ebLeft	The control has a beveled left edge.
ebTop	The control has a beveled top edge.
ebRight	The control has a beveled right edge.
ebBottom	The control has a beveled bottom edge.

In addition to the values in the preceding table, the QGraphics unit defines the ebRect constant to represent all the edges of a control:

const ebRect = [ebLeft, ebTop, ebRight, ebBottom];

#define ebRect (System::Set<TEdgeBorder, ebLeft, ebBottom> () << TEdgeBorder(0) << TEdgeBorder(1) << TEdgeBorder(2)

<< TEdgeBorder(3))

43.2.2 ToolWin.TEdgeStyle Enumeration

TEdgeStyle describes the appearance of an edge border.

Pascal

```
TEdgeStyle = (
  esNone,
  esRaised,
  esLowered
);
```

C++

```
enum TEdgeStyle {
  esNone,
  esRaised,
  esLowered
};
```

File

ToolWin

Description

TEdgeStyle indicates the appearance of a particular border. The following table lists the possible values:

Value	Meaning
esNone	The border is not drawn.
esRaised	The border appears raised.
esLowered	The border appears lowered.

43.2.3 ToolWin.TSizingOrientation Enumeration

TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

Pascal

```
TSizingOrientation = (
  soNone,
  soHorizontal,
  soVertical
);
```

C++

```
enum TSizingOrientation {
  soNone,
  soHorizontal,
  soVertical
};
```

File

ToolWin

Description

TSizingOrientation can have one of the following values:

Value	Meaning
soNone	The control's size is not readjusted when it is docked.
soHorizontal	The control's width is adjusted when it is docked.
soVertical	The control's height is adjusted when it is docked.

43.3 Types

The following table lists types in this documentation.

Types

Name	Description
TEdgeBorders (see page 4647)	This is type ToolWin.TEdgeBorders.

43.3.1 ToolWin.TEdgeBorders Type

Pascal

```
TEdgeBorders = set of TEdgeBorder;
```

C++

```
TEdgeBorder TEdgeBorders;
```

File

ToolWin

Description

This is type ToolWin.TEdgeBorders.

44 Types Namespace

This is namespace Types.

Topics

Name	Description
Functions (see page 4651)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 4659)	The following table lists structs, records, enums in this documentation.
Types (see page 4663)	The following table lists types in this documentation.
Constants (see page 4675)	The following table lists constants in this documentation.

Constants

Name	Description
EqualsValue (see page 4675)	EqualsValue indicates that both values are equal in a comparison operation.
GreaterThanValue (see page 4675)	GreaterThanValue indicates that one value is greater than an other in a comparison operation.
LessThanValue (see page 4676)	LessThanValue indicates that one value is less than an other in a comparison operation.
RT_RCDATA (see page 4676)	This is constant Types.RT_RCDATA.

Functions

	Name	Description
	Bounds (see page 4651)	Returns the TRect (see page 4660) for a rectangle of given dimensions.
	CenteredRect (see page 4652)	This is function Types.CenteredRect.
	CenterPoint (see page 4652)	Returns the point in the center of a rectangle.
	EqualRect (see page 4652)	Indicates whether two TRect (see page 4660) values are the same.
	IntersectRect (see page 4653)	Returns the intersection of two rectangles
	IsRectEmpty (see page 4653)	Indicates wither a specified rectangle has a positive width and height.
	OffsetRect (see page 4654)	Changes the origin of a rectangle by a specified amount.
	Point (see page 4654)	Creates a TPoint (see page 4660) structure from a pair of coordinates.
	PtInRect (see page 4655)	Indicates whether a specified point lies inside a specified rectangle.
	Rect (see page 4655)	Creates a TRect (see page 4660) structure from a set of coordinates.
	RectHeight (see page 4656)	This is function Types.RectHeight.
	RectWidth (see page 4656)	This is function Types.RectWidth.
	SmallPoint (see page 4656)	Creates a TSmallPoint (see page 4661) structure from a pair of coordinates.
	SmallPoint (see page 4656)	Creates a TSmallPoint (see page 4661) structure from a pair of coordinates.
	SplitRect (see page 4657)	This is function Types.SplitRect.

	SplitRect (see page 4657)	This is function Types.SplitRect.
	UnionRect (see page 4658)	Returns the union of two rectangles

Structs, Records, Enums

	Name	Description
	tagSIZE (see page 4659)	tagSIZE is a record holding width and height values.
	TPoint (see page 4660)	TPoint type defines a pixel location onscreen.
	TRect (see page 4660)	TRect defines a rectangle.
	TSmallPoint (see page 4661)	TSmallPoint type defines a point with two 16-bit coordinates.
	TSplitRectType (see page 4662)	This is record Types.TSplitRectType.

Types

Name	Description
DWORD (see page 4663)	DWORD is equivalent to LongWord.
PByte (see page 4664)	PByte is a pointer to a `Byte` variable.
PDouble (see page 4664)	PDouble is a pointer to a `Double` variable.
PInteger (see page 4664)	PInteger is a pointer to a `Integer` variable.
PLongint (see page 4665)	PLongint is a pointer to a `LongInt` variable.
PPoint (see page 4665)	PPoint is a pointer to a TPoint (see page 4660) variable.
PRect (see page 4666)	PRect is a pointer to a TRect (see page 4660) variable.
PSize (see page 4666)	PSize is a pointer to a TSize (see page 4671) variable.
PSmallInt (see page 4666)	This is type Types.PSmallInt.
PSmallPoint (see page 4667)	This is type Types.PSmallPoint.
SIZE (see page 4667)	This is type Types.SIZE.
tagPOINT (see page 4667)	This is type Types.tagPOINT.
TBooleanDynArray (see page 4668)	TBooleanDynArray defines an array of Boolean elements.
TByteDynArray (see page 4668)	This is type Types.TByteDynArray.
TCardinalDynArray (see page 4668)	TCardinalDynArray defines an array of Cardinal elements.
TDoubleDynArray (see page 4669)	TDoubleDynArray defines an array of Double elements.
TInt64DynArray (see page 4669)	TInt64DynArray defines an array of Int64 elements.
TIntegerDynArray (see page 4670)	This is type Types.TIntegerDynArray.
TLongWordDynArray (see page 4670)	TLongWordDynArray defines an array of LongWord elements.
TShortIntDynArray (see page 4670)	TShortIntDynArray defines an array of ShortInt elements.
TSingleDynArray (see page 4671)	TSingleDynArray defines an array of Single elements.
TSize (see page 4671)	TSize represents a width and height.
TSmallIntDynArray (see page 4672)	TSmallIntDynArray defines an array of SmallInt elements.
TStringDynArray (see page 4672)	TStringDynArray defines an array of String elements.
TValueRelationship (see page 4673)	TValueRelationship defines value comparison possibilities.
TWideStringDynArray (see page 4673)	TWideStringDynArray defines an array of WideString (see page 3467) elements.
TWordDynArray (see page 4674)	TWordDynArray defines an array of Word elements.

44.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Bounds (see page 4651)	Returns the TRect (see page 4660) for a rectangle of given dimensions.
	CenteredRect (see page 4652)	This is function Types.CenteredRect.
	CenterPoint (see page 4652)	Returns the point in the center of a rectangle.
	EqualRect (see page 4652)	Indicates whether two TRect (see page 4660) values are the same.
	IntersectRect (see page 4653)	Returns the intersection of two rectangles
	IsRectEmpty (see page 4653)	Indicates wither a specified rectangle has a positive width and height.
	OffsetRect (see page 4654)	Changes the origin of a rectangle by a specified amount.
	Point (see page 4654)	Creates a TPoint (see page 4660) structure from a pair of coordinates.
	PtInRect (see page 4655)	Indicates whether a specified point lies inside a specified rectangle.
	Rect (see page 4655)	Creates a TRect (see page 4660) structure from a set of coordinates.
	RectHeight (see page 4656)	This is function Types.RectHeight.
	RectWidth (see page 4656)	This is function Types.RectWidth.
	SmallPoint (see page 4656)	Creates a TSmallPoint (see page 4661) structure from a pair of coordinates.
	SmallPoint (see page 4656)	Creates a TSmallPoint (see page 4661) structure from a pair of coordinates.
	SplitRect (see page 4657)	This is function Types.SplitRect.
	SplitRect (see page 4657)	This is function Types.SplitRect.
	UnionRect (see page 4658)	Returns the union of two rectangles

44.1.1 Types.Bounds Function

Returns the TRect (see page 4660) for a rectangle of given dimensions.

Pascal

```
function Bounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer): TRect;
```

C++

```
TRect Bounds(int ALeft, int ATop, int AWidth, int AHeight);
```

File

Types

Description

Call Bounds to obtain a TRect (see page 4660) for a rectangle with upper left corner at the point (ALeft, ATop) with width AWidth and height AHeight.

See Also

Rect (see page 4655)

44.1.2 Types.CenteredRect Function

Pascal

```
function CenteredRect(SourceRect: TRect; CenteredRect: TRect): TRect;
```

C++

```
TRect CenteredRect(TRect SourceRect, TRect CenteredRect);
```

File

Types

Description

This is function Types.CenteredRect.

44.1.3 Types.CenterPoint Function

Returns the point in the center of a rectangle.

Pascal

```
function CenterPoint(const Rect: TRect): TPoint;
```

C++

```
TPoint CenterPoint(const TRect Rect);
```

File

Types

Description

Call CenterPoint to obtain the point in the center of a rectangle.

Rect (see page 4655) is the rectangle whose center you want to locate.

See Also

PtInRect (see page 4655)

IsRectEmpty (see page 4653)

UnionRect (see page 4658)

IntersectRect (see page 4653)

44.1.4 Types.EqualRect Function

Indicates whether two TRect (see page 4660) values are the same.

Pascal

```
function EqualRect(const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean EqualRect(const TRect R1, const TRect R2);
```

File

Types

Description

Call EqualRect to compare two TRect (see page 4660) values. EqualRect returns true if R1 and R2 are identical (same position and size), false if they are different.

See Also

Rect (see page 4655)

Bounds (see page 4651)

IntersectRect (see page 4653)

44.1.5 Types.IntersectRect Function

Returns the intersection of two rectangles

Pascal

```
function IntersectRect(out Rect: TRect; const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean IntersectRect(TRect Rect, const TRect R1, const TRect R2);
```

File

Types

Description

Call IntersectRect to obtain the rectangle that is the intersection of R1 and R2. The intersection is returned as the Rect (see page 4655) parameter.

IntersectRect returns true if the two rectangles have a nonempty intersection. If R1 and R2 do not overlap, IntersectRect returns false, and the Rect (see page 4655) parameter is set to a rectangle at position (0,0) with 0 Width and 0 Height.

See Also

PtInRect (see page 4655)

IsRectEmpty (see page 4653)

UnionRect (see page 4658)

44.1.6 Types.IsRectEmpty Function

Indicates wither a specified rectangle has a positive width and height.

Pascal

```
function IsRectEmpty(const Rect: TRect): Boolean;
```

C++

```
Boolean IsRectEmpty(const TRect Rect);
```

File

Types

Description

Call IsRectEmpty to determine whether the rectangle specified by Rect (see page 4655) encloses a positive amount of space.

IsRectEmpty returns true if both the width and height of Rect (see page 4655) are greater than 0. If either the width or height is less than or equal to 0, IsRectEmpty returns false. Note that this means non-normalized rectangles (rectangles with negative height or width) are considered empty.

See Also

PtInRect (see page 4655)

IntersectRect (see page 4653)

44.1.7 Types.OffsetRect Function

Changes the origin of a rectangle by a specified amount.

Pascal

```
function OffsetRect(var Rect: TRect; DX: Integer; DY: Integer): Boolean;
```

C++

```
Boolean OffsetRect(TRect Rect, int DX, int DY);
```

File

Types

Description

Call OffsetRect to move the upper left corner of the rectangle specified by Rect (see page 4655) while maintaining the same width and height. The left of the rectangle moves by DX while the top moves by DY.

OffsetRect returns true if the Rect (see page 4655) parameter is not nil (Delphi) or NULL (C++), false if it can't return a new rectangle because Rect (see page 4655) is nil(Delphi) or NULL (C++).

See Also

Rect (see page 4655)

Bounds (see page 4651)

44.1.8 Types.Point Function

Creates a TPoint (see page 4660) structure from a pair of coordinates.

Pascal

```
function Point(X: Integer; Y: Integer): TPoint;
```

C++

```
TPoint Point(int X, int Y);
```

File

Types

Description

Call Point to create a TPoint (see page 4660) that represents the specified coordinates. Use Point to construct parameters for functions that require a point, rather than setting up local variables for each parameter.

See Also

SmallPoint (see page 4656)

Rect (see page 4655)

44.1.9 Types.PtInRect Function

Indicates whether a specified point lies inside a specified rectangle.

Pascal

```
function PtInRect(const Rect: TRect; const P: TPoint): Boolean;
```

C++

```
Boolean PtInRect(const TRect Rect, const TPoint P);
```

File

Types

Description

PtInRect returns true if the point, P, lies inside the rectangle, Rect (see page 4655), and false if P is not in Rect (see page 4655).

PtInRect does not consider a point inside a rectangle if the rectangle has a negative width or height. A point is considered inside a rectangle if it lies on the left or top edge, but not if it lies on the right or bottom edge.

See Also

IntersectRect (see page 4653)

IsRectEmpty (see page 4653)

CenterPoint (see page 4652)

44.1.10 Types.Rect Function

Creates a TRect (see page 4660) structure from a set of coordinates.

Pascal

```
function Rect(Left: Integer; Top: Integer; Right: Integer; Bottom: Integer): TRect;
```

C++

```
TRect Rect(int Left, int Top, int Right, int Bottom);
```

File

Types

Description

Call Rect to create a TRect (see page 4660) that represents the rectangle with the specified coordinates. Use Rect to construct parameters for functions that require TRect (see page 4660), rather than setting up local variables for each parameter.

See Also

Bounds (see page 4651)

Point (see page 4654)

44.1.11 Types.RectHeight Function

Pascal

```
function RectHeight(const Rect: TRect): Integer;
```

C++

```
int RectHeight(const TRect Rect);
```

File

Types

Description

This is function Types.RectHeight.

44.1.12 Types.RectWidth Function

Pascal

```
function RectWidth(const Rect: TRect): Integer;
```

C++

```
int RectWidth(const TRect Rect);
```

File

Types

Description

This is function Types.RectWidth.

44.1.13 Types.SmallPoint Function

Creates a TSmallPoint (see page 4661) structure from a pair of coordinates.

Pascal

```
function SmallPoint(X: Integer; Y: Integer): TSmallPoint; overload;
function SmallPoint(XY: LongWord): TSmallPoint; overload;
```

C++

```
TSmallPoint SmallPoint(int X, int Y);
TSmallPoint SmallPoint(LongWord XY);
```

File

Types

Description

Call SmallPoint to create a TSmallPoint (see page 4661) that represents the specified coordinates.

See Also

Point

44.1.14 Types.SplitRect Function

Pascal

```
function SplitRect(Rect: TRect; SplitType: TSplitRectType; Percent: Double): TRect; overload;
```

C++

```
TRect SplitRect(TRect Rect, TSplitRectType SplitType, Double Percent);
```

File

Types

Description

This is function Types.SplitRect.

44.1.15 Types.SplitRect Function

Pascal

```
function SplitRect(Rect: TRect; SplitType: TSplitRectType; Size: Integer): TRect; overload;
```

C++

```
TRect SplitRect(TRect Rect, TSplitRectType SplitType, int Size);
```

File

Types

Description

This is function Types.SplitRect.

44.1.16 Types.UnionRect Function

Returns the union of two rectangles

Pascal

```
function UnionRect(out Rect: TRect; const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean UnionRect(TRect Rect, const TRect R1, const TRect R2);
```

File

Types

Description

Call UnionRect to obtain the smallest rectangle that includes both R1 and R2. The union is returned as the Rect (see page 4655) parameter.

UnionRect returns true if the resulting rectangle is nonempty. If the resulting rectangle as a width or height that is less than or equal to 0, UnionRect returns false.

See Also

IntersectRect (see page 4653)

OffsetRect (see page 4654)

IsRectEmpty (see page 4653)

44.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TSplitRectType (see page 4662)	This is record Types.TSplitRectType.

Records

	Name	Description
	tagSIZE (see page 4659)	tagSIZE is a record holding width and height values.
	TPoint (see page 4660)	TPoint type defines a pixel location onscreen.
	TRect (see page 4660)	TRect defines a rectangle.
	TSmallPoint (see page 4661)	TSmallPoint type defines a point with two 16-bit coordinates.

44.2.1 Types.tagSIZE Record

tagSIZE is a record holding width and height values.

Pascal

```
tagSIZE = record
  cx: Longint;
  cy: Longint;
end;
```

C++

```
struct tagSIZE {
  Longint cx;
  Longint cy;
};
```

File

Types

Description

The SIZE (see page 4667) equates to a TSize (see page 4671) type, which in turn equates to a tagSIZE record.

tagSIZE holds the width (cx) and height (cy) of something, typically in pixels. For example, TextExtent returns the width and height, in pixels, of a string rendered in the current font.

See Also

SIZE (see page 4667)

TextExtent

TSize (see page 4671)

44.2.2 Types.TPoint Record

TPoint type defines a pixel location onscreen.

Pascal

```
TPoint = record
  X: Longint;
  Y: Longint;
end;
```

C++

```
struct TPoint {
  Longint X;
  Longint Y;
};
```

File

Types

Description

The TPoint type defines a pixel location onscreen, with the origin in the top left corner. X specifies the horizontal coordinate of the point, Y specifies the vertical coordinate.

C++ Examples:

```
/*
This example draws a polygon in the specified shape, and
fills it with the color teal.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPoint points[4];
  points[0] = Point(10,10);
  points[1] = Point(30,10);
  points[2] = Point(130,30);
  points[3] = Point(240,120);
  (dynamic_cast<TPaintBox *>(Sender))->Canvas->Brush->Color = clTeal;
  (dynamic_cast<TPaintBox *>(Sender))->Canvas->Polygon(points, 3);
}
```

See Also

Point (see page 4654)

44.2.3 Types.TRect Record

TRect defines a rectangle.

Pascal

```
TRect = record
  case Integer of
    0: (Bottom: Longint;
        Left: Longint;
        Right: Longint;
        Top: Longint;);
```

```
      1: (BottomRight: TPoint;
          TopLeft: TPoint;);
  end;
```

C++

```
  struct TRect {
    Longint Bottom;
    Longint Left;
    Longint Right;
    Longint Top;
    TPoint BottomRight;
    TPoint TopLeft;
  };
```

File

Types

Description

TRect represents the dimensions of a rectangle. The coordinates are specified as either four separate integers representing the left, top, right, and bottom sides, or as two points representing the locations of the top left and bottom right corners.

Typically, TRect values represent pixel locations, where the origin of the pixel coordinate system is in the top left corner of the screen (screen coordinates) or the top left corner of a control's client area (client coordinates). When a TRect value represents a rectangle on the screen, by convention the top and left edges are considered inside the rectangle and the bottom and right edges are considered outside the rectangle. This convention allows the width of the rectangle to be Right - Left and the height to be Bottom - Top.

44.2.4 Types.TSmallPoint Record

TSmallPoint type defines a point with two 16-bit coordinates.

Pascal

```
  TSmallPoint = record
    x: SmallInt;
    y: SmallInt;
  end;
```

C++

```
  struct TSmallPoint {
    SmallInt x;
    SmallInt y;
  };
```

File

Types

Description

The TSmallPoint type defines a point where each coordinate is a 16-bit integer. x specifies the horizontal coordinate of the point, y specifies the vertical coordinate.

44.2.5 Types.TSplitRectType Enumeration

Pascal

```
TSplitRectType = (
  srLeft,
  srRight,
  srTop,
  srBottom
);
```

C++

```
enum TSplitRectType {
  srLeft,
  srRight,
  srTop,
  srBottom
};
```

File

Types

Description

This is record Types.TSplitRectType.

44.3 Types

The following table lists types in this documentation.

Types

Name	Description
DWORD (see page 4663)	DWORD is equivalent to LongWord.
PByte (see page 4664)	PByte is a pointer to a `Byte` variable.
PDouble (see page 4664)	PDouble is a pointer to a `Double` variable.
PInteger (see page 4664)	PInteger is a pointer to a `Integer` variable.
PLongint (see page 4665)	PLongint is a pointer to a `LongInt` variable.
PPoint (see page 4665)	PPoint is a pointer to a TPoint (see page 4660) variable.
PRect (see page 4666)	PRect is a pointer to a TRect (see page 4660) variable.
PSize (see page 4666)	PSize is a pointer to a TSize (see page 4671) variable.
PSmallInt (see page 4666)	This is type Types.PSmallInt.
PSmallPoint (see page 4667)	This is type Types.PSmallPoint.
SIZE (see page 4667)	This is type Types.SIZE.
tagPOINT (see page 4667)	This is type Types.tagPOINT.
TBooleanDynArray (see page 4668)	TBooleanDynArray defines an array of Boolean elements.
TByteDynArray (see page 4668)	This is type Types.TByteDynArray.
TCardinalDynArray (see page 4668)	TCardinalDynArray defines an array of Cardinal elements.
TDoubleDynArray (see page 4669)	TDoubleDynArray defines an array of Double elements.
TInt64DynArray (see page 4669)	TInt64DynArray defines an array of Int64 elements.
TIntegerDynArray (see page 4670)	This is type Types.TIntegerDynArray.
TLongWordDynArray (see page 4670)	TLongWordDynArray defines an array of LongWord elements.
TShortIntDynArray (see page 4670)	TShortIntDynArray defines an array of ShortInt elements.
TSingleDynArray (see page 4671)	TSingleDynArray defines an array of Single elements.
TSize (see page 4671)	TSize represents a width and height.
TSmallIntDynArray (see page 4672)	TSmallIntDynArray defines an array of SmallInt elements.
TStringDynArray (see page 4672)	TStringDynArray defines an array of String elements.
TValueRelationship (see page 4673)	TValueRelationship defines value comparison possibilities.
TWideStringDynArray (see page 4673)	TWideStringDynArray defines an array of WideString (see page 3467) elements.
TWordDynArray (see page 4674)	TWordDynArray defines an array of Word elements.

44.3.1 Types.DWORD Type

DWORD is equivalent to LongWord.

Pascal

```
DWORD = LongWord;
```

C++

```
LongWord DWORD;
```

File

Types

Description

The DWORD holds positive integers up to a maximum value of 4,294,967,295.

44.3.2 Types.PByte Type

PByte is a pointer to a `Byte` variable.

Pascal

```
PByte = System.PByte;
```

C++

```
System.PByte PByte;
```

File

Types

Description

PByte is the same as PByte.

See Also

PByte (see page 3758)

44.3.3 Types.PDouble Type

PDouble is a pointer to a `Double` variable.

Pascal

```
PDouble = System.PDouble;
```

C++

```
System.PDouble PDouble;
```

File

Types

Description

PDouble is the same as PDouble.

See Also

PDouble (see page 3762)

44.3.4 Types.PInteger Type

PInteger is a pointer to a `Integer` variable.

Pascal

```
PInteger = System.PInteger;
```

C++

```
System.PInteger PInteger;
```

File

Types

Description

Types.PInteger is the same as PInteger.

See Also

PInteger (see page 3765)

44.3.5 Types.PLongint Type

PLongint is a pointer to a `LongInt` variable.

Pascal

```
PLongint = System.PLongint;
```

C++

```
System.PLongint PLongint;
```

File

Types

Description

PLongint is the same as PLongint.

See Also

PLongint (see page 3767)

44.3.6 Types.PPoint Type

PPoint is a pointer to a TPoint (see page 4660) variable.

Pascal

```
PPoint = ^TPoint;
```

C++

```
^TPoint PPoint;
```

File

Types

Description

The TPoint (see page 4660) type defines a pixel location onscreen, with the origin in the top left corner.

See Also

TPoint (see page 4660)

44.3.7 Types.PRect Type

PRect is a pointer to a TRect (see page 4660) variable.

Pascal

```
PRect = ^TRect;
```

C++

```
^TRect PRect;
```

File

Types

Description

The TRect (see page 4660) type represents the dimensions of a rectangle.

See Also

TRect (see page 4660)

44.3.8 Types.PSize Type

PSize is a pointer to a TSize (see page 4671) variable.

Pascal

```
PSize = ^TSize;
```

C++

```
^TSize PSize;
```

File

Types

Description

The TSize (see page 4671) type holds the width and height of something, typically in pixels.

See Also

TSize (see page 4671)

44.3.9 Types.PSmallInt Type

Pascal

```
PSmallInt = System.PSmallInt;
```

C++

```
System.PSmallInt PSmallInt;
```

File

Types

Description

This is type Types.PSmallInt.

44.3.10 Types.PSmallPoint Type

Pascal

```
PSmallPoint = ^TSmallPoint;
```

C++

```
^TSmallPoint PSmallPoint;
```

File

Types

Description

This is type Types.PSmallPoint.

44.3.11 Types.SIZE Type

Pascal

```
SIZE = tagSIZE;
```

C++

```
tagSIZE SIZE;
```

File

Types

Description

This is type Types.SIZE.

44.3.12 Types.tagPOINT Type

Pascal

```
tagPOINT = TPoint;
```

C++

```
TPoint tagPOINT;
```

File

Types

Description

This is type Types.tagPOINT.

44.3.13 Types.TBooleanDynArray Type

TBooleanDynArray defines an array of Boolean elements.

Pascal

```
TBooleanDynArray = array of Boolean;
```

C++

```
array of Boolean TBooleanDynArray;
```

File

Types

Description

The TBooleanDynArray defines a dynamic array of Boolean elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.14 Types.TByteDynArray Type

Pascal

```
TByteDynArray = array of Byte;
```

C++

```
array of Byte TByteDynArray;
```

File

Types

Description

This is type Types.TByteDynArray.

44.3.15 Types.TCardinalDynArray Type

TCardinalDynArray defines an array of Cardinal elements.

Pascal

```
TCardinalDynArray = array of Cardinal;
```

C++

```
array of Cardinal TCardinalDynArray;
```

File

Types

Description

The TCardinalDynArray defines a dynamic array of Cardinal elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.16 Types.TDoubleDynArray Type

TDoubleDynArray defines an array of Double elements.

Pascal

```
TDoubleDynArray = array of Double;
```

C++

```
array of Double TDoubleDynArray;
```

File

Types

Description

The TDoubleDynArray defines a dynamic array of Double elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.17 Types.TInt64DynArray Type

TInt64DynArray defines an array of Int64 elements.

Pascal

```
TInt64DynArray = array of Int64;
```

C++

```
array of Int64 TInt64DynArray;
```

File

Types

Description

The TInt64DynArray defines a dynamic array of Int64 elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.18 Types.TIntegerDynArray Type

Pascal

```
TIntegerDynArray = array of Integer;
```

C++

```
array of Integer TIntegerDynArray;
```

File

Types

Description

This is type Types.TIntegerDynArray.

44.3.19 Types.TLongWordDynArray Type

TLongWordDynArray defines an array of LongWord elements.

Pascal

```
TLongWordDynArray = array of LongWord;
```

C++

```
array of LongWord TLongWordDynArray;
```

File

Types

Description

The TLongWordDynArray defines a dynamic array of LongWord elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.20 Types.TShortIntDynArray Type

TShortIntDynArray defines an array of ShortInt elements.

Pascal

```
TShortIntDynArray = array of ShortInt;
```

C++

```
array of ShortInt TShortIntDynArray;
```

File

Types

Description

The TShortIntDynArray defines a dynamic array of ShortInt elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.21 Types.TSingleDynArray Type

TSingleDynArray defines an array of Single elements.

Pascal

```
TSingleDynArray = array of Single;
```

C++

```
array of Single TSingleDynArray;
```

File

Types

Description

The TSingleDynArray defines a dynamic array of Single elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.22 Types.TSize Type

TSize represents a width and height.

Pascal

```
TSize = tagSIZE;
```

C++

```
tagSIZE TSize;
```

File

Types

Description

TSize represents the size of something. Typically, the implied units of measurement are pixels.

cx is the width.

cy is the height.

44.3.23 Types.TSmallIntDynArray Type

TSmallIntDynArray defines an array of SmallInt elements.

Pascal

```
TSmallIntDynArray = array of SmallInt;
```

C++

```
array of SmallInt TSmallIntDynArray;
```

File

Types

Description

The TSmallIntDynArray defines a dynamic array of SmallInt elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.24 Types.TStringDynArray Type

TStringDynArray defines an array of String elements.

Pascal

```
TStringDynArray = array of string;
```

C++

```
array of string TStringDynArray;
```

File

Types

Description

The TStringDynArray defines a dynamic array of String elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.25 Types.TValueRelationship Type

TValueRelationship defines value comparison possibilities.

Pascal

```
TValueRelationship = -1..1;
```

C++

```
-1..1 TValueRelationship;
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship value as follows :

Value	Associated constant	Meaning
-1	LessThanValue (see page 4676)	The first value is less than the second value.
0	EqualsValue (see page 4675)	The two values are equal.
+1	GreaterThanValue (see page 4675)	The first value is greater than the second value.

See Also

LessThanValue (see page 4676)

EqualsValue (see page 4675)

GreaterThanValue (see page 4675)

44.3.26 Types.TWideStringDynArray Type

TWideStringDynArray defines an array of WideString (see page 3467) elements.

Pascal

```
TWideStringDynArray = array of WideString;
```

C++

```
array of WideString TWideStringDynArray;
```

File

Types

Description

The TWideStringDynArray defines a dynamic array of WideString (see page 3467) elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.3.27 Types.TWordDynArray Type

TWordDynArray defines an array of Word elements.

Pascal

```
TWordDynArray = array of Word;
```

C++

```
array of Word TWordDynArray;
```

File

Types

Description

The TWordDynArray defines a dynamic array of Word elements.

Use SetLength (see page 3657) to allocate storage for such an array.

See Also

TSize (see page 4671)

44.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
EqualsValue (see page 4675)	EqualsValue indicates that both values are equal in a comparison operation.
GreaterThanValue (see page 4675)	GreaterThanValue indicates that one value is greater than an other in a comparison operation.
LessThanValue (see page 4676)	LessThanValue indicates that one value is less than an other in a comparison operation.
RT_RCDATA (see page 4676)	This is constant Types.RT_RCDATA.

44.4.1 Types.EqualsValue Constant

EqualsValue indicates that both values are equal in a comparison operation.

Pascal

```
EqualsValue = 0;
```

C++

```
EqualsValue = 0;
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 4673) value. If the first value is equal to the second, the value is EqualsValue

See Also

CompareValue

GreaterThanValue (see page 4675)

LessThanValue (see page 4676)

TValueRelationship (see page 4673)

44.4.2 Types.GreaterThanValue Constant

GreaterThanValue indicates that one value is greater than an other in a comparison operation.

Pascal

```
GreaterThanValue = High(TValueRelationship);
```

C++

```
GreaterThanValue = High(TValueRelationship);
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 4673) value. If the first value is greater than the second, the value is GreaterThanValue

See Also

EqualsValue (see page 4675)

CompareValue

LessThanValue (see page 4676)

TValueRelationship (see page 4673)

44.4.3 Types.LessThanValue Constant

LessThanValue indicates that one value is less than an other in a comparison operation.

Pascal

```
LessThanValue = Low(TValueRelationship);
```

C++

```
LessThanValue = Low(TValueRelationship);
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 4673) value. If the first value is less than the second, the value is LessThanValue

See Also

EqualsValue (see page 4675)

CompareValue

GreaterThanValue (see page 4675)

TValueRelationship (see page 4673)

44.4.4 Types.RT_RCDATA Constant

Pascal

```
RT_RCDATA = PChar(10);
```

C++

```
RT_RCDATA = PChar(10);
```

File

Types

Description

This is constant Types.RT_RCDATA.

45 TypeTrans Namespace

This is namespace TypeTrans.

Topics

Name	Description
Classes (see page 4680)	The following table lists classes in this documentation.
Functions (see page 4684)	The following table lists functions in this documentation.
Variables (see page 4687)	The following table lists variables in this documentation.

Classes

	Name	Description
	ETypeTransException (see page 4680)	ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.
	TTypeTranslator (see page 4680)	This is class TypeTrans.TTypeTranslator.

Functions

	Name	Description
	FloatToStrEx (see page 4684)	This is function TypeTrans.FloatToStrEx.
	GetEnumValueEx (see page 4684)	This is function TypeTrans.GetEnumValueEx.
	GetEnumValueExW (see page 4685)	This is function TypeTrans.GetEnumValueExW.
	SetEnumPropEx (see page 4685)	This is function TypeTrans.SetEnumPropEx.
	SetEnumPropExW (see page 4685)	This is function TypeTrans.SetEnumPropExW.
	StrToFloatEx (see page 4686)	This is function TypeTrans.StrToFloatEx.

Variables

Name	Description
TypeTranslator (see page 4687)	This is variable TypeTrans.TypeTranslator.

45.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ETypeTransException (see page 4680)	ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.
	TTypeTranslator (see page 4680)	This is class TypeTrans.TTypeTranslator.

45.1.1 ETypeTransException Class

ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.

Class Hierarchy

Pascal

```
ETypeTransException = class(Exception);
```

C++

```
class ETypeTransException : public Exception;
```

File

TypeTrans

Description

ETypeTransException is thrown when an application attempts to convert a type in a SOAP packet to an Object Pascal type and fails for some reason.

See Also

TOPToSoapDomConvert

45.1.2 TTypeTranslator Class

Class Hierarchy

Pascal

```
TTypeTranslator = class;
```

C++

```
class TTypeTranslator;
```

File

TypeTrans

Description

This is class TypeTrans.TTypeTranslator.

45.1.2.1 TTypeTranslator Members

The following tables list the members exposed by TTypeTranslator.

Public Methods

	Name	Description
	Base64ToVar (see page 4682)	This is the overview for the Base64ToVar method overload.
	CastNativeToSoap (see page 4682)	This is CastNativeToSoap, a member of class TTypeTranslator.
	CastSoapToNative (see page 4683)	This is CastSoapToNative, a member of class TTypeTranslator.
	CastSoapToVariant (see page 4683)	This is the overview for the CastSoapToVariant method overload.
	Create (see page 4681)	This is Create, a member of class TTypeTranslator.
	Destroy (see page 4681)	This is Destroy, a member of class TTypeTranslator.

45.1.2.2 TTypeTranslator.Create Constructor

Pascal

```
constructor Create;
```

C++

```
__fastcall TTypeTranslator();
```

Description

This is Create, a member of class TTypeTranslator.

45.1.2.3 TTypeTranslator.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTypeTranslator();
```

Description

This is Destroy, a member of class TTypeTranslator.

45.1.2.4 TTypeTranslator Methods

The methods of the TTypeTranslator class are listed here.

Public Methods

	Name	Description
	Base64ToVar (see page 4682)	This is the overview for the Base64ToVar method overload.

	CastNativeToSoap (see page 4682)	This is CastNativeToSoap, a member of class TTypeTranslator.
	CastSoapToNative (see page 4683)	This is CastSoapToNative, a member of class TTypeTranslator.
	CastSoapToVariant (see page 4683)	This is the overview for the CastSoapToVariant method overload.

45.1.2.4.1 Base64ToVar Method

This is the overview for the Base64ToVar method overload.

Overload List

	Name	Description
	TTypeTranslator.Base64ToVar (Pointer, InvString) (see page 4682)	This is Base64ToVar, a member of class TTypeTranslator.
	TTypeTranslator.Base64ToVar (Variant, InvString) (see page 4682)	This is Base64ToVar, a member of class TTypeTranslator.

45.1.2.4.1.1 TTypeTranslator.Base64ToVar Method (Pointer, InvString)

Pascal

```
procedure Base64ToVar(NatData: Pointer; const SoapData: InvString); overload;
```

C++

```
__fastcall Base64ToVar(void * NatData, const InvString SoapData);
```

Description

This is Base64ToVar, a member of class TTypeTranslator.

45.1.2.4.1.2 TTypeTranslator.Base64ToVar Method (Variant, InvString)

Pascal

```
procedure Base64ToVar(var V: Variant; const SoapData: InvString); overload;
```

C++

```
__fastcall Base64ToVar(Variant V, const InvString SoapData);
```

Description

This is Base64ToVar, a member of class TTypeTranslator.

45.1.2.4.2 TTypeTranslator.CastNativeToSoap Method

Pascal

```
procedure CastNativeToSoap(Info: PTypeInfo; var SoapData: InvString; NatData: Pointer; var
IsNull: Boolean);
```

C++

```
__fastcall CastNativeToSoap(PTypeInfo Info, InvString SoapData, void * NatData, Boolean
IsNull);
```

Description

This is CastNativeToSoap, a member of class TTypeTranslator.

45.1.2.4.3 TTypeTranslator.CastSoapToNative Method

Pascal

```
function CastSoapToNative(Info: PTypeInfo; const SoapData: InvString; NatData: Pointer;
IsNull: Boolean): Boolean;
```

C++

```
__fastcall Boolean CastSoapToNative(PTypeInfo Info, const InvString SoapData, void * NatData,
Boolean IsNull);
```

Description

This is CastSoapToNative, a member of class TTypeTranslator.

45.1.2.4.4 CastSoapToVariant Method

This is the overview for the CastSoapToVariant method overload.

Overload List

	Name	Description
	TTypeTranslator.CastSoapToVariant (PTypeInfo, InvString) (see page 4683)	This is CastSoapToVariant, a member of class TTypeTranslator.
	TTypeTranslator.CastSoapToVariant (PTypeInfo, InvString, Pointer) (see page 4683)	This is CastSoapToVariant, a member of class TTypeTranslator.

45.1.2.4.4.1 TTypeTranslator.CastSoapToVariant Method (PTypeInfo, InvString)

Pascal

```
function CastSoapToVariant(SoapInfo: PTypeInfo; const SoapData: InvString): Variant; overload;
```

C++

```
__fastcall Variant CastSoapToVariant(PTypeInfo SoapInfo, const InvString SoapData);
```

Description

This is CastSoapToVariant, a member of class TTypeTranslator.

45.1.2.4.4.2 TTypeTranslator.CastSoapToVariant Method (PTypeInfo, InvString, Pointer)

Pascal

```
procedure CastSoapToVariant(SoapInfo: PTypeInfo; const SoapData: InvString; NatData: Pointer);
overload;
```

C++

```
__fastcall CastSoapToVariant(PTypeInfo SoapInfo, const InvString SoapData, void * NatData);
```

Description

This is CastSoapToVariant, a member of class TTypeTranslator.

45.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FloatToStrEx (see page 4684)	This is function TypeTrans.FloatToStrEx.
	GetEnumValueEx (see page 4684)	This is function TypeTrans.GetEnumValueEx.
	GetEnumValueExW (see page 4685)	This is function TypeTrans.GetEnumValueExW.
	SetEnumPropEx (see page 4685)	This is function TypeTrans.SetEnumPropEx.
	SetEnumPropExW (see page 4685)	This is function TypeTrans.SetEnumPropExW.
	StrToFloatEx (see page 4686)	This is function TypeTrans.StrToFloatEx.

45.2.1 TypeTrans.FloatToStrEx Function

Pascal

```
function FloatToStrEx(Value: Extended): string;
```

C++

```
UnicodeString FloatToStrEx(Extended Value);
```

File

TypeTrans

Description

This is function TypeTrans.FloatToStrEx.

45.2.2 TypeTrans.GetEnumValueEx Function

Pascal

```
function GetEnumValueEx(TypInfo: PTypeInfo; const Name: string): Integer; deprecated;
```

C++

```
int GetEnumValueEx(PTypeInfo TypInfo, const UnicodeString Name);
```

File

TypeTrans

Description

This is function TypeTrans.GetEnumValueEx.

45.2.3 TypeTrans.GetEnumValueExW Function

Pascal

```
function GetEnumValueExW(TypInfo: PTypeInfo; const Name: InvString): Integer;
```

C++

```
int GetEnumValueExW(PTypeInfo TypInfo, const InvString Name);
```

File

TypeTrans

Description

This is function TypeTrans.GetEnumValueExW.

45.2.4 TypeTrans.SetEnumPropEx Function

Pascal

```
procedure SetEnumPropEx(Instance: TObject; PropInfo: PPropInfo; const Value: string);
deprecated;
```

C++

```
SetEnumPropEx(TObject * Instance, PPropInfo PropInfo, const UnicodeString Value);
```

File

TypeTrans

Description

This is function TypeTrans.SetEnumPropEx.

45.2.5 TypeTrans.SetEnumPropExW Function

Pascal

```
procedure SetEnumPropExW(Instance: TObject; PropInfo: PPropInfo; const Value: InvString);
```

C++

```
SetEnumPropExW(TObject * Instance, PPropInfo PropInfo, const InvString Value);
```

File

TypeTrans

Description

This is function TypeTrans.SetEnumPropExW.

45.2.6 TypeTrans.StrToFloatEx Function

Pascal

```
function StrToFloatEx(const S: string): Extended;
```

C++

```
Extended StrToFloatEx(const UnicodeString S);
```

File

TypeTrans

Description

This is function TypeTrans.StrToFloatEx.

45.3 Variables

The following table lists variables in this documentation.

Variables

Name	Description
TypeTranslator (see page 4687)	This is variable TypeTrans.TypeTranslator.

45.3.1 TypeTrans.TypeTranslator Variable

Pascal

```
TypeTranslator: TTypeTranslator;
```

C++

```
TTypeTranslator TypeTranslator;
```

File

TypeTrans

Description

This is variable TypeTrans.TypeTranslator.

46 TypInfo Namespace

This is namespace TypInfo.

Topics

Name	Description
Classes (see page 4693)	The following table lists classes in this documentation.
Functions (see page 4701)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 4747)	The following table lists structs, records, enums in this documentation.
Types (see page 4762)	The following table lists types in this documentation.
Variables (see page 4774)	The following table lists variables in this documentation.
Constants (see page 4775)	The following table lists constants in this documentation.

Classes

	Name	Description
	EPropertyConvertError (see page 4693)	EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.
	EPropertyError (see page 4693)	EPropertyError is the exception class for unsuccessful attempts to set the value of a property.
	TPublishableVariantType (see page 4694)	TPublishableVariantType is the base class for custom Variant (see page 3421) types that surface the published properties of an object that represents the Variant (see page 3421)'s data.

Constants

Name	Description
tkAny (see page 4775)	tkAny is a set that contains all values defined by the TTypeKind (see page 4760) enumeration.
tkMethods (see page 4775)	tkMethods is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent a method kind.
tkProperties (see page 4776)	tkProperties is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent types that can be published.

Functions

	Name	Description
	FreeAndNilProperties (see page 4703)	Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).
	GetAnsiStrProp (see page 4703)	Returns the value of a component property that is of AnsiString type.
	GetAnsiStrProp (see page 4703)	Returns the value of a component property that is of AnsiString type.
	GetDynArrayProp (see page 4704)	Returns the value of a component property that is a dynamic array type.

	GetDynArrayProp (see page 4704)	Returns the value of a component property that is a dynamic array type.
	GetEnumName (see page 4705)	Returns the name of a Delphi enumerated type constant given its value.
	GetEnumProp (see page 4708)	Returns the value of a component property that is an enumerated type.
	GetEnumProp (see page 4708)	Returns the value of a component property that is an enumerated type.
	GetEnumValue (see page 4710)	Returns the value of an enumerated type constant given its string representation.
	GetFloatProp (see page 4711)	Returns the value of a component property that is a float type.
	GetFloatProp (see page 4711)	Returns the value of a component property that is a float type.
	GetInt64Prop (see page 4712)	Returns the value of a component property that is an Int64 type.
	GetInt64Prop (see page 4712)	Returns the value of a component property that is an Int64 type.
	GetInterfaceProp (see page 4712)	Returns the value of a component property that is an interface type.
	GetInterfaceProp (see page 4712)	Returns the value of a component property that is an interface type.
	GetMethodProp (see page 4713)	Returns the value of a component property that is a method type.
	GetMethodProp (see page 4713)	Returns the value of a component property that is a method type.
	GetObjectProp (see page 4714)	Returns the value of a component property that is an object type.
	GetObjectProp (see page 4714)	Returns the value of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetOrdProp (see page 4716)	Returns the value of a component property that is an ordinal type.
	GetOrdProp (see page 4716)	Returns the value of a component property that is an ordinal type.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfos (see page 4717)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropName (see page 4719)	Returns the name of a component property identified by a given PPropInfo (see page 4762).
	GetPropValue (see page 4719)	Retrieves a component's property value as a variant.
	GetPropValue (see page 4719)	Retrieves a component's property value as a variant.
	GetSetElementName (see page 4720)	Returns the string representation of a given constant.
	GetSetElementValue (see page 4721)	Returns the integer representation of a given constant identified by it's name.
	GetSetProp (see page 4722)	Returns the value of a component property that is a set type.
	GetSetProp (see page 4722)	Returns the value of a component property that is a set type.
	GetStrProp (see page 4722)	Returns the value of a component property that is a string type.
	GetStrProp (see page 4722)	Returns the value of a component property that is a string type.
	GetTypeData (see page 4723)	Returns a pointer to information about a type.
	GetTypeName (see page 4724)	Returns the name of the type from it's type information record.
	GetUnicodeStrProp (see page 4724)	Returns the value of a component property that is of UnicodeString (see page 3381) type.
	GetUnicodeStrProp (see page 4724)	Returns the value of a component property that is of UnicodeString (see page 3381) type.
	GetVariantProp (see page 4725)	Returns the value of a component property that is a variant type.
	GetVariantProp (see page 4725)	Returns the value of a component property that is a variant type.
	GetWideStrProp (see page 4726)	Returns the value of a component property that is a WideString (see page 3467) type.
	GetWideStrProp (see page 4726)	Returns the value of a component property that is a WideString (see page 3467) type.
	IsPublishedProp (see page 4727)	Determines if a specified component property is a published property.
	IsPublishedProp (see page 4727)	Determines if a specified component property is a published property.
	IsStoredProp (see page 4727)	Determines if a specified component property has the stored attribute.
	IsStoredProp (see page 4727)	Determines if a specified component property has the stored attribute.
	PropIsType (see page 4728)	Determines if a component property is of a particular data type.
	PropIsType (see page 4728)	Determines if a component property is of a particular data type.

	PropType (see page 4729)	Retrieves a component's property type.
	PropType (see page 4729)	Retrieves a component's property type.
	SamePropTypeName (see page 4729)	Checks whether the two given property names are equal.
	SetAnsiStrProp (see page 4730)	Sets the value of a component property that is of AnsiString type.
	SetAnsiStrProp (see page 4730)	Sets the value of a component property that is of AnsiString type.
	SetDynArrayProp (see page 4731)	Sets the value of a component property that is a dynamic array type.
	SetDynArrayProp (see page 4731)	Sets the value of a component property that is a dynamic array type.
	SetEnumProp (see page 4732)	Sets the value of a component property that is an enumerated type.
	SetEnumProp (see page 4732)	Sets the value of a component property that is an enumerated type.
	SetFloatProp (see page 4734)	Sets the value of a component property that is a float type.
	SetFloatProp (see page 4734)	Sets the value of a component property that is a float type.
	SetInt64Prop (see page 4735)	Sets the value of a component property that is an Int64 type.
	SetInt64Prop (see page 4735)	Sets the value of a component property that is an Int64 type.
	SetInterfaceProp (see page 4736)	Sets the value of a component property that is an Interface type.
	SetInterfaceProp (see page 4736)	Sets the value of a component property that is an Interface type.
	SetMethodProp (see page 4737)	Sets the value of a component property that is a method type.
	SetMethodProp (see page 4737)	Sets the value of a component property that is a method type.
	SetObjectProp (see page 4737)	Sets the value of a component property that is an object type.
	SetObjectProp (see page 4737)	Sets the value of a component property that is an object type.
	SetOrdProp (see page 4738)	Sets the value of a component property that is an ordinal type.
	SetOrdProp (see page 4738)	Sets the value of a component property that is an ordinal type.
	SetPropValue (see page 4739)	Sets the value of a component property using a variant value.
	SetPropValue (see page 4739)	Sets the value of a component property using a variant value.
	SetSetProp (see page 4740)	Sets the value of a component property that is a set type.
	SetSetProp (see page 4740)	Sets the value of a component property that is a set type.
	SetStrProp (see page 4741)	Sets the value of a component property that is a string type.
	SetStrProp (see page 4741)	Sets the value of a component property that is a string type.
	SetToString (see page 4742)	Returns one or more of the set values of a component's property.
	SetUnicodeStrProp (see page 4742)	Sets the value of a component property that is of UnicodeString (see page 3381) type.
	SetUnicodeStrProp (see page 4742)	Sets the value of a component property that is of UnicodeString (see page 3381) type.
	SetVariantProp (see page 4743)	Sets the value of a component property that is a variant type.
	SetVariantProp (see page 4743)	Sets the value of a component property that is a variant type.
	SetWideStrProp (see page 4744)	Sets the value of a component property that is a WideString (see page 3467) type.
	SetWideStrProp (see page 4744)	Sets the value of a component property that is a WideString (see page 3467) type.
	SortPropList (see page 4745)	Sorts a list of component properties into alphanumeric sequence.
	StringToSet (see page 4746)	Returns a bit mask of set values for a set type component property.

Structs, Records, Enums

	Name	Description
	TFloatType (see page 4747)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TIntfFlag (see page 4751)	This is record TypInfo.TIntfFlag.
	TManagedField (see page 4751)	This is record TypInfo.TManagedField.
	TMethodKind (see page 4751)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TOrdType (see page 4753)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TParamFlag (see page 4756)	TParamFlag and TParamFlags (see page 4772) indicates the attributes of a method parameter.
	TPropData (see page 4757)	This is record TypInfo.TPropData.
	TPropInfo (see page 4757)	TPropInfo is a record of component property type information.
	TTypeData (see page 4758)	TTypeData is used internally to represent type information.
	TTypeInfo (see page 4759)	Holds information for a data type as returned by TypeInfo.

	TTypeKind (see page 4760)	These types describe a type that is manipulated in the forms designer.

Types

Name	Description
PPropInfo (see page 4762)	PPropInfo points to a TPropInfo (see page 4757) record that holds component property information.
PPropList (see page 4763)	Defines a pointer to a TPropList (see page 4773) array.
PPTypeInfo (see page 4763)	Holds a pointer to a pointer to information for a data type as returned by TypeInfo.
PTypeData (see page 4764)	PTypeData points to a TTypeData (see page 4758) record that holds component property type information.
PTypeInfo (see page 4767)	Holds a pointer to information for a data type as returned by TypeInfo.
ShortStringBase (see page 4770)	Defines a fixed length string for general use in the TTypeData (see page 4758) record.
TIntfFlags (see page 4770)	Enumerates interface flag types in the TTypeData (see page 4758) record.
TIntfFlagsBase (see page 4771)	Set of interface flag types in the TTypeData (see page 4758) record.
TParamFlags (see page 4772)	This is type TypInfo.TParamFlags.
TParamFlagsBase (see page 4772)	This is type TypInfo.TParamFlagsBase.
TPropInfoProc (see page 4772)	This is type TypInfo.TPropInfoProc.
TPropList (see page 4773)	Defines an array of PPropInfo (see page 4762) values.
TTypeKinds (see page 4773)	Defines a set of TTypeKind (see page 4760) values.

Variables

Name	Description
BooleanIdents (see page 4774)	An array of string representations of true and false.
DotSep (see page 4774)	This is variable TypInfo.DotSep.

46.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EPropertyConvertError (see page 4693)	EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.
	EPropertyError (see page 4693)	EPropertyError is the exception class for unsuccessful attempts to set the value of a property.
	TPublishableVariantType (see page 4694)	TPublishableVariantType is the base class for custom Variant (see page 3421) types that surface the published properties of an object that represents the Variant (see page 3421)'s data.

46.1.1 EPropertyConvertError Class

EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.

Class Hierarchy

Pascal

```
EPropertyConvertError = class(Exception);
```

C++

```
class EPropertyConvertError : public Exception;
```

File

TypInfo

Description

EPropertyConvertError is raised when an application tries to set a property to a value of the wrong type or to read a property that has invalid type information.

See Also

EPropertyError (see page 4693)

TPropertyEditor

46.1.2 EPropertyError Class

EPropertyError is the exception class for unsuccessful attempts to set the value of a property.

Class Hierarchy

Pascal

```
EPropertyError = class(Exception);
```

C++

```
class EPropertyError : public Exception;
```

File

TypInfo

Description

EPropertyError is raised by the SetValue (or Edit) methods of property-editor objects when they cannot set a requested property value. This usually occurs because the requested value is out of range or of an invalid data type.

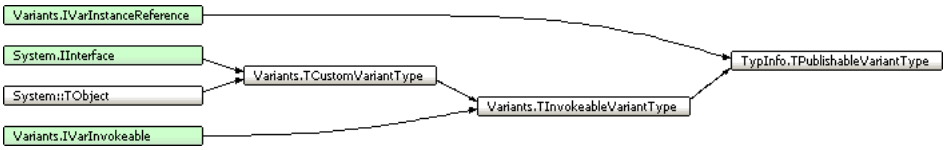
See Also

TPropertyEditor

46.1.3 TPublishableVariantType Class

TPublishableVariantType is the base class for custom Variant (see page 3421) types that surface the published properties of an object that represents the Variant (see page 3421)'s data.

Class Hierarchy



Pascal

```
TPublishableVariantType = class(TInvokeableVariantType, IVarInstanceReference);
```

C++

```
class TPublishableVariantType : public TInvokeableVariantType, public IVarInstanceReference;
```

File

TypInfo

Description

TPublishableVariantType is the base class for new data types for Variants (see page 4973) that have properties and methods. TPublishableVariantType descendants do not represent the Variants (see page 4973) themselves. Rather, they act as utility classes that the custom Variants (see page 4973) call on to perform their operations. TPublishableVariantType adds to its ancestor's ability to implement properties and methods on Variants (see page 4973) of the custom type by automatically implementing all published properties of the object it uses to store its data.

Note: To create a Variant (see page 3421) type that descends from TPublishableVariantType,

Note: 1. Map the storage of the Variant (see page 3421)'s data on to the TVarData (see page 3740) record.

Note: 2. Write (see page 3707) a method that creates instances of your custom Variant (see page 3421). This fills in the

Variant (see page 3421)'s data as defined in step 1.

Note: 3. Declare a class that descends from TPublishableVariantType.

Note: 4. Override the GetInstance (see page 4698) method to return the object that stores the custom Variant (see page 3421)'s data.

Note: 5. Implement all other required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically DoFunction, DoProcedure, BinaryOp, UnaryOp, CompareOp or Compare, Cast, CastTo, Clear, Copy (see page 3547), IsClear, LeftPromotion, and RightPromotion).

Note: 6. In the initialization section of the unit that defines your TPublishableVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the Variant (see page 3421)-handling system so that the new Variant (see page 3421) type is enabled.

Note: 7. In the finalization section of the unit that defines your TPublishableVariantType descendant, free the instance of your class. This automatically unregisters the Variant (see page 3421) type.

Note: For an example, see the VarCmplx (see page 4899) (Windows) or FMTBcd (Linux) unit, which implements a custom Variant (see page 3421) type for complex (Windows) or binary-coded decimal (Linux) numbers.

Note: Do not create your own custom Variant (see page 3421) types in C++. They are only supported in Delphi.

See Also

TInvokeableVariantType (see page 5014)

Supporting Properties and Methods in Custom Variants

46.1.3.1 TPublishableVariantType Members

The following tables list the members exposed by TPublishableVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 4993)	Responds when the caller acquires a reference to this object's interface.
	_Release (see page 4993)	Responds when the caller releases a reference to this object's interface.
V	DispInvoke (see page 4999)	Invokes a method call when the System::Variant (see page 3421) supports such operations.
V	DispInvoke (see page 5018)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 5014) method.
V	FixupIdent (see page 5020)	Fixes up dispatch identifier.
A	GetInstance (see page 4698)	Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.
V	LeftPromotion (see page 5000)	Indicates whether the left argument to a binary operation should be coerced to a different type.

	OlePromotion (see page 5001)	Indicates the type to which a System::Variant (see page 3421) value must be cast to make it Automation-compatible.
	QueryInterface (see page 5002)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 5002)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 5003)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 5003)	Generates a system error indicating an invalid operation.
	RightPromotion (see page 5004)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 5005)	Clears a TVarData (see page 3740) record by re-initializing it.
	SimplisticCopy (see page 5005)	Performs a simple block copy of one TVarData (see page 3740) record to another.
	VarDataCast (see page 5006)	Performs a cast from one System::Variant (see page 3421) type to another.
	VarDataCastTo (see page 5007)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 5007)	Performs a cast to a System::Variant (see page 3421) type of varOleStr (see page 3869).
	VarDataClear (see page 5008)	Clears the data from a built-in System::Variant (see page 3421) type.
	VarDataCopy (see page 5008)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataCopyNoInd (see page 5009)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataFromOleStr (see page 5009)	Creates a TVarData (see page 3740) record to represent a Unicode string.
	VarDataFromStr (see page 5010)	Creates a TVarData (see page 3740) record to represent a string.
	VarDataInit (see page 5010)	Initializes a TVarData (see page 3740) record.
	VarDataIsArray (see page 5010)	Indicates whether a TVarData (see page 3740) record represents the data from a System::Variant (see page 3421) array.
	VarDataIsByRef (see page 5011)	Indicates whether a TVarData (see page 3740) record stores its data indirectly.
	VarDataIsEmptyParam (see page 5011)	Indicates whether a TVarData (see page 3740) record represents an unassigned optional parameter.
	VarDataIsFloat (see page 5011)	Indicates whether a TVarData (see page 3740) record represents a floating-point value.
	VarDataIsNumeric (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a numeric value.
	VarDataIsOrdinal (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a ordinal value.
	VarDataIsStr (see page 5013)	Indicates whether a TVarData (see page 3740) record represents a string (normal or Unicode).
	VarDataToStr (see page 5013)	Returns a string that represents the value from a TVarData (see page 3740) record.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	BinaryOp (see page 4994)	Implements any binary operations of which the custom System::Variant (see page 3421) type is capable.
	Cast (see page 4995)	Converts the data from another System::Variant (see page 3421) type so that it represents this custom type's data format.
	CastTo (see page 4995)	Converts data in the format of this TCustomVariantType (see page 4987) to the format of another System::Variant (see page 3421) type.
	CastToOle (see page 4996)	Converts data in the format of this custom System::Variant (see page 3421) type to a format that can be used by COM Variants (see page 4973).
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.

	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 4996)	Sets the data for this custom System::Variant (see page 3421) type to a blank or unassigned value.
	Compare (see page 4997)	Implements comparisons that involve the custom System::Variant (see page 3421) type.
	CompareOp (see page 4998)	Implements any comparison operations of which the custom System::Variant (see page 3421) type is capable.
	Copy (see page 4999)	Copies the data from a System::Variant (see page 3421) of this custom type.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 4990)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 4991)	Frees an instance of TCustomVariantType (see page 4987).
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoFunction (see page 5024)	Implements all the methods that return values.
	DoFunction (see page 5018)	Implements all methods that return values.
	DoProcedure (see page 5025)	Implements all methods that do not return values.
	DoProcedure (see page 5019)	Implements all methods that do not return values.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetProperty (see page 4698)	Returns the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	IsClear (see page 5000)	Indicates whether the data from a custom System::Variant (see page 3421) represents a blank or unassigned value.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	SetProperty (see page 4699)	Sets the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).
	ToString (see page 3380)	Returns a string containing the class name.
	UnaryOp (see page 5006)	Implements any unary operations of which the custom System::Variant (see page 3421) type is capable.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	VarType (see page 5014)	Indicates the System::Variant (see page 3421) type code for the custom System::Variant (see page 3421) type.

46.1.3.2 TPublishableVariantType Methods

The methods of the TPublishableVariantType class are listed here.

Protected Methods

	Name	Description
	GetInstance (see page 4698)	Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.

Public Methods

	Name	Description
	GetProperty (see page 4698)	Returns the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).
	SetProperty (see page 4699)	Sets the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).

46.1.3.2.1 TPublishableVariantType.GetInstance Method

Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.

Pascal

```
function GetInstance(const V: TVarData): TObject; virtual; abstract;
```

C++

```
virtual __fastcall TObject * GetInstance(const TVarData V) = 0;
```

Description

Override GetInstance to return the object that represents the data from a Variant (see page 3421) of the custom Type. TPublishableVariantType (see page 4694) implements all the published properties of that object so that they are published properties of the Variant (see page 3421).

V is the data from a Variant (see page 3421) of the custom type. This data must include a reference to an object that represents the Variant (see page 3421)'s data, and which GetInstance returns.

GetInstance is abstract or, in C++ terminology, pure virtual in TPublishableVariantType (see page 4694), which means it has no implementation. Descendant classes override this method to enable Variants (see page 4973) to publish the properties from the object that implements their data.

See Also

GetProperty (see page 4698)

SetProperty (see page 4699)

Supporting Properties and Methods in Custom Variants

46.1.3.2.2 TPublishableVariantType.GetProperty Method

Returns the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
override;
```

C++

```
virtual __fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const UnicodeString
Name);
```

Description

GetProperty enables an application to read the properties of instances of the publishable Variant (see page 3421) type. It implements all the properties that are published by the object that GetInstance (see page 4698) returns.

When the application contains a line such as

```
PropValue := MyVariant.SpecialProperty;
```

(Delphi) or calls the Exec method of the Variant (see page 3421) (C++), a call is automatically generated to GetProperty. If SpecialProperty is a published property on the object that implements the Variant (see page 3421)'s data, GetProperty fills in the Dest parameter with the property value.

Dest is a TVarData (see page 3740) record (Delphi) or structure (C++) that receives the property value.

V is the TVarData (see page 3740) record or structure from the Variant (see page 3421) instance whose property is being read.

Name is the name of the property.

GetProperty returns true if it returns a property value, and raises an exception if it does not implement the specified property.

See Also

DoFunction (see page 5018)

DoProcedure (see page 5019)

GetInstance (see page 4698)

System::Variant::Exec

46.1.3.2.3 TPublishableVariantType.SetProperty Method

Sets the value of a published property on the object that GetInstance (see page 4698) returns, so that it is available in custom Variants (see page 4973).

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
override;
```

C++

```
virtual __fastcall Boolean SetProperty(const TVarData V, const UnicodeString Name, const
TVarData Value);
```

Description

SetProperty enables an application to set the properties of instances of the publishable Variant (see page 3421) type. It implements all the settable properties that are published by the object that GetInstance (see page 4698) returns.

When the application contains a line such as

```
MyVariant.SpecialProperty := NewValue;
```

(Delphi) or calls the Exec method of the Variant (see page 3421) (C++), a call is automatically generated to SetProperty. If SpecialProperty is a published settable property on the object that implements the Variant (see page 3421)'s data, SetProperty sets the property on the object included in V so that the Variant (see page 3421)'s value is changed accordingly.

V is the TVarData (see page 3740) record (Delphi) or structure (C++) from the Variant (see page 3421) instance whose

property is being set. It includes the object that the GetInstance (see page 4698) method returns.

Name is the name of the property.

Value is a TVarData (see page 3740) record or structure that contains the new property value.

GetProperty (see page 4698) returns true if it sets a property value, and raises an exception of Name does not specify a published settable property on the object that GetInstance (see page 4698) returns.

46.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FreeAndNilProperties (see page 4703)	Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).
	GetAnsiStrProp (see page 4703)	Returns the value of a component property that is of AnsiString type.
	GetAnsiStrProp (see page 4703)	Returns the value of a component property that is of AnsiString type.
	GetDynArrayProp (see page 4704)	Returns the value of a component property that is a dynamic array type.
	GetDynArrayProp (see page 4704)	Returns the value of a component property that is a dynamic array type.
	GetEnumName (see page 4705)	Returns the name of a Delphi enumerated type constant given its value.
	GetEnumProp (see page 4708)	Returns the value of a component property that is an enumerated type.
	GetEnumProp (see page 4708)	Returns the value of a component property that is an enumerated type.
	GetEnumValue (see page 4710)	Returns the value of an enumerated type constant given its string representation.
	GetFloatProp (see page 4711)	Returns the value of a component property that is a float type.
	GetFloatProp (see page 4711)	Returns the value of a component property that is a float type.
	GetInt64Prop (see page 4712)	Returns the value of a component property that is an Int64 type.
	GetInt64Prop (see page 4712)	Returns the value of a component property that is an Int64 type.
	GetInterfaceProp (see page 4712)	Returns the value of a component property that is an interface type.
	GetInterfaceProp (see page 4712)	Returns the value of a component property that is an interface type.
	GetMethodProp (see page 4713)	Returns the value of a component property that is a method type.
	GetMethodProp (see page 4713)	Returns the value of a component property that is a method type.
	GetObjectProp (see page 4714)	Returns the value of a component property that is an object type.
	GetObjectProp (see page 4714)	Returns the value of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 4715)	Returns the class type of a component property that is an object type.
	GetOrdProp (see page 4716)	Returns the value of a component property that is an ordinal type.
	GetOrdProp (see page 4716)	Returns the value of a component property that is an ordinal type.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfo (see page 4717)	Retrieves information about a component's property.
	GetPropInfos (see page 4717)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropList (see page 4718)	Retrieves a list of component properties.
	GetPropName (see page 4719)	Returns the name of a component property identified by a given PPropInfo (see page 4762).
	GetPropValue (see page 4719)	Retrieves a component's property value as a variant.
	GetPropValue (see page 4719)	Retrieves a component's property value as a variant.
	GetSetElementName (see page 4720)	Returns the string representation of a given constant.
	GetSetElementValue (see page 4721)	Returns the integer representation of a given constant identified by it's name.
	GetSetProp (see page 4722)	Returns the value of a component property that is a set type.
	GetSetProp (see page 4722)	Returns the value of a component property that is a set type.
	GetStrProp (see page 4722)	Returns the value of a component property that is a string type.
	GetStrProp (see page 4722)	Returns the value of a component property that is a string type.
	GetTypeData (see page 4723)	Returns a pointer to information about a type.
	GetTypeName (see page 4724)	Returns the name of the type from it's type information record.

	GetUnicodeStrProp (see page 4724)	Returns the value of a component property that is of UnicodeString (see page 3381) type.
	GetUnicodeStrProp (see page 4724)	Returns the value of a component property that is of UnicodeString (see page 3381) type.
	GetVariantProp (see page 4725)	Returns the value of a component property that is a variant type.
	GetVariantProp (see page 4725)	Returns the value of a component property that is a variant type.
	GetWideStrProp (see page 4726)	Returns the value of a component property that is a WideString (see page 3467) type.
	GetWideStrProp (see page 4726)	Returns the value of a component property that is a WideString (see page 3467) type.
	IsPublishedProp (see page 4727)	Determines if a specified component property is a published property.
	IsPublishedProp (see page 4727)	Determines if a specified component property is a published property.
	IsStoredProp (see page 4727)	Determines if a specified component property has the stored attribute.
	IsStoredProp (see page 4727)	Determines if a specified component property has the stored attribute.
	PropIsType (see page 4728)	Determines if a component property is of a particular data type.
	PropIsType (see page 4728)	Determines if a component property is of a particular data type.
	PropType (see page 4729)	Retrieves a component's property type.
	PropType (see page 4729)	Retrieves a component's property type.
	SamePropTypeName (see page 4729)	Checks whether the two given property names are equal.
	SetAnsiStrProp (see page 4730)	Sets the value of a component property that is of AnsiString type.
	SetAnsiStrProp (see page 4730)	Sets the value of a component property that is of AnsiString type.
	SetDynArrayProp (see page 4731)	Sets the value of a component property that is a dynamic array type.
	SetDynArrayProp (see page 4731)	Sets the value of a component property that is a dynamic array type.
	SetEnumProp (see page 4732)	Sets the value of a component property that is an enumerated type.
	SetEnumProp (see page 4732)	Sets the value of a component property that is an enumerated type.
	SetFloatProp (see page 4734)	Sets the value of a component property that is a float type.
	SetFloatProp (see page 4734)	Sets the value of a component property that is a float type.
	SetInt64Prop (see page 4735)	Sets the value of a component property that is an Int64 type.
	SetInt64Prop (see page 4735)	Sets the value of a component property that is an Int64 type.
	SetInterfaceProp (see page 4736)	Sets the value of a component property that is an Interface type.
	SetInterfaceProp (see page 4736)	Sets the value of a component property that is an Interface type.
	SetMethodProp (see page 4737)	Sets the value of a component property that is a method type.
	SetMethodProp (see page 4737)	Sets the value of a component property that is a method type.
	SetObjectProp (see page 4737)	Sets the value of a component property that is an object type.
	SetObjectProp (see page 4737)	Sets the value of a component property that is an object type.
	SetOrdProp (see page 4738)	Sets the value of a component property that is an ordinal type.
	SetOrdProp (see page 4738)	Sets the value of a component property that is an ordinal type.
	SetPropValue (see page 4739)	Sets the value of a component property using a variant value.
	SetPropValue (see page 4739)	Sets the value of a component property using a variant value.
	SetSetProp (see page 4740)	Sets the value of a component property that is a set type.
	SetSetProp (see page 4740)	Sets the value of a component property that is a set type.
	SetStrProp (see page 4741)	Sets the value of a component property that is a string type.
	SetStrProp (see page 4741)	Sets the value of a component property that is a string type.
	SetToString (see page 4742)	Returns one or more of the set values of a component's property.
	SetUnicodeStrProp (see page 4742)	Sets the value of a component property that is of UnicodeString (see page 3381) type.
	SetUnicodeStrProp (see page 4742)	Sets the value of a component property that is of UnicodeString (see page 3381) type.
	SetVariantProp (see page 4743)	Sets the value of a component property that is a variant type.
	SetVariantProp (see page 4743)	Sets the value of a component property that is a variant type.
	SetWideStrProp (see page 4744)	Sets the value of a component property that is a WideString (see page 3467) type.
	SetWideStrProp (see page 4744)	Sets the value of a component property that is a WideString (see page 3467) type.
	SortPropList (see page 4745)	Sorts a list of component properties into alphanumeric sequence.
	StringToSet (see page 4746)	Returns a bit mask of set values for a set type component property.

46.2.1 TypInfo.FreeAndNilProperties Function

Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).

Pascal

```
procedure FreeAndNilProperties(AObject: TObject);
```

C++

```
FreeAndNilProperties(TObject * AObject);
```

File

TypInfo

Description

Call FreeAndNilProperties from a destructor to free all internally created objects and set the corresponding property values to nil (Delphi) or NULL (C++). FreeAndNilProperties searches the properties of AObject, identifying any that are objects. It frees those objects, and sets the corresponding property to nil (Delphi) or NULL (C++).

. By default, all persistent objects (TPersistent and descendants) are compiled with RTTI. Other TObject (see page 3354) descendants can be compiled with RTTI by using the $M+ compiler switch in Delphi or the __declspec(delphirtti) directive in C++.

Warning: Calling FreeAndNilProperties frees all object properties, which may lead to unintended results. FreeAndNilProperties can't distinguish between objects that were created by AObject (and typically stored in a class member) from objects that are created independently and which should not be freed with AObject. To avoid unintentionally freeing independently-created objects, set properties that refer to external objects to nil (Delphi) or NULL (C++) before calling FreeAndNilProperties.

See Also

FreeAndNil (see page 4201)

46.2.2 TypInfo.GetAnsiStrProp Function

Returns the value of a component property that is of AnsiString type.

Pascal

```
function GetAnsiStrProp(Instance: TObject; const PropName: string): AnsiString; overload;
function GetAnsiStrProp(Instance: TObject; PropInfo: PPropInfo): AnsiString; overload;
```

C++

```
AnsiString GetAnsiStrProp(TObject * Instance, const UnicodeString PropName);
AnsiString GetAnsiStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetAnsiStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is an AnsiString. An empty string is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and

GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetAnsiStrProp (see page 4730)

46.2.3 TypInfo.GetDynArrayProp Function

Returns the value of a component property that is a dynamic array type.

Pascal

```
function GetDynArrayProp(Instance: TObject; const PropName: string): Pointer; overload;
function GetDynArrayProp(Instance: TObject; PropInfo: PPropInfo): Pointer; overload;
```

C++

```
void * GetDynArrayProp(TObject * Instance, const UnicodeString PropName);
void * GetDynArrayProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetDynArrayProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a dynamic array type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a pointer to the array.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetDynArrayProp (see page 4731)

46.2.4 TypInfo.GetEnumName Function

Returns the name of a Delphi enumerated type constant given its value.

Pascal

```
function GetEnumName(TypeInfo: PTypeInfo; Value: Integer): string;
```

C++

```
UnicodeString GetEnumName(PTypeInfo TypeInfo, int Value);
```

File

TypInfo

Description

Use GetEnumName to convert a Delphi enumerated value into the symbolic name that represents it in code.

TypeInfo is the type information record that describes the enumerated type. You can obtain the type information for a type by calling the TypeInfo function in Delphi or the __delphirtti operator in C++.

Value is the enumerated value, represented as an integer.

GetEnumName returns the string that represents the specified value.

C++ Examples:

```
/*
Add the Delphi source file that appears on this Help page into
a CPP Builder project that includes a CPP module containing the
following code.  An hpp file will be generated for the Delphi
code when you build the project.  Add the include line for
that hpp file at the top of the CPP module.  The FormCreates
for both forms will execute and the following generics code
will work.  Remember to give the forms different names!
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Prints type info for string type
  TGenericClass__1<System::UnicodeString> *GString = new
TGenericClass__1<System::UnicodeString>();
  GString->PrintTypeInfo(Memo1);

  // Prints type info for Byte type
  TGenericClass__1<Byte> *GByte = new TGenericClass__1<Byte>();
  GByte->PrintTypeInfo(Memo1);
```

```
  // Prints type info for Double type
  TGenericClass__1<Double> *GDouble = new TGenericClass__1<Double>();
  GDouble->PrintTypeInfo(Memo1);

  // Prints type info for "array of String" type
  // TGenericClass__1<array of string> *GStringArray = new TGenericClass__1<array of string>();
  // GStringArray->PrintTypeInfo(Memo1);
}
```

Delphi Examples:

```
{
This example demostrates the methods to retreive of
Run-time Type Information (RTTI) information.
This example will print useful information about any given
type including it's name, size, kind and sub-kind.
}

GetEnumValue (see page 4710)

46.2.5 TypInfo.GetEnumProp Function

Returns the value of a component property that is an enumerated type.

Pascal

```
function GetEnumProp(Instance: TObject; const PropName: string): string; overload;
function GetEnumProp(Instance: TObject; PropInfo: PPropInfo): string; overload;
```

C++

```
UnicodeString GetEnumProp(TObject * Instance, const UnicodeString PropName);
UnicodeString GetEnumProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetEnumProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is an enumerated type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

C++ Examples:

```
/*
This example shows how to use GetEnumProp and SetEnumProp in order to
check for visual components properties and to change them.
This example uses two buttons, Button1 and Button2.
*/
```

```
void __fastcall TForm2::Button1Click(TObject *Sender)
{
    //getting the current color of the workspace
    String currentPropColor = GetEnumProp(this,"Color");
    int currentColorInt = StrToInt(currentPropColor);

    //getting the first button align enum and if different,
    //setting it to alLeft
    String currentAlignProp = GetEnumProp(Button1, "Align");
    if (currentAlignProp != "alLeft")
    {
        SetEnumProp(Button1, "Align", "alLeft");
     }

    //checking if the form background color was set.
    if(currentColorInt < 0)
    {
       currentColorInt = GetSysColor(COLOR_APPWORKSPACE);
    }

    //setting the form background color as the negative value
    //of the current background color
    SetEnumProp(this, "Color",
                IntToStr((int)(clWhite - currentColorInt)));
}

void __fastcall TForm2::Button2Click(TObject *Sender)
{
    int p[5] = {clYellow, clGreen, clRed, clBlue, clBlack};
    SetEnumProp(this, "Color", IntToStr(p[random(5)]));

    //getting the second button align enum and if different,
    //setting it to alRight
    String currentAlignProp = GetEnumProp(Button2, "Align");
    if (currentAlignProp != "alRight")
    {
        SetEnumProp(Button2, "Align", "alRight");
     }
}
```

Delphi Examples:

```
{
This example shows how to use GetEnumProp and SetEnumProp in order to
check for visual components properties and to change them.
This example uses two buttons, Button1 and Button2.
}
procedure TForm3.Button1Click(Sender: TObject);
var
  currentPropColor : String;
  currentAlignProp : String;
  currentColorInt : Integer;
begin
  //getting the current color of the workspace
  currentPropColor := GetEnumProp(Self,'Color');
  currentColorInt := StrToInt(currentPropColor);

  //getting the first button align enum and if different,
  //setting it to alLeft
  currentAlignProp := GetEnumProp(Button1, 'Align');
  if GetEnumValue(TypeInfo(TAlign), currentAlignProp) <> Ord(alLeft) then
     SetEnumProp(Button1, 'Align', 'alLeft');

  //checking if the form background color was set.
    if currentColorInt < 0 then
    begin
        currentColorInt := GetSysColor(COLOR_APPWORKSPACE);
```

```
    end;

  //setting the form background color as the negative value
  // of the current background color
  currentColorInt := clWhite - currentColorInt;

  SetEnumProp(Self, 'Color', IntToStr(currentColorInt));
end;

procedure TForm3.Button2Click(Sender: TObject);
var
  p : array [0..4] of Integer;
  currentAlignProp : String;
begin
  p[0] := clYellow;
  p[1] := clRed;
  p[2] := clBlue;
  p[3] := clBlack;
  p[4] := clGreen;

    SetEnumProp(Self, 'Color', IntToStr(p[random(5)]));

  //getting the second button align enum and if different,
  //setting it to alRight
  currentAlignProp := GetEnumProp(Button2, 'Align');
  if GetEnumValue(TypeInfo(TAlign), currentAlignProp) <> Ord(alRight) then
     SetEnumProp(Button2, 'Align', 'alRight');

end;
```

46.2.6 TypInfo.GetEnumValue Function

Returns the value of an enumerated type constant given its string representation.

Pascal

```
function GetEnumValue(TypeInfo: PTypeInfo; const Name: string): Integer;
```

C++

```
int GetEnumValue(PTypeInfo TypeInfo, const UnicodeString Name);
```

File

TypInfo

Description

Use GetEnumValue to convert the string that represents an enumerated value into the corresponding integer that is its implemented value.

TypeInfo is the type information record that describes the enumerated type. You can obtain the type information for a type by

calling the TypeInfo function in Delphi or using the __delphirtti operator in C++.

Name is the string that is used in code to represent the enumerated value.

GetEnumValue returns the corresponding integer value.

IdentToInt

GetEnumName (see page 4705)

46.2.7 TypInfo.GetFloatProp Function

Returns the value of a component property that is a float type.

Pascal

```
function GetFloatProp(Instance: TObject; const PropName: string): Extended; overload;
function GetFloatProp(Instance: TObject; PropInfo: PPropInfo): Extended; overload;
```

C++

```
Extended GetFloatProp(TObject * Instance, const UnicodeString PropName);
Extended GetFloatProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetFloatProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a floating point number type. 0.0 is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a float value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.8 TypInfo.GetInt64Prop Function

Returns the value of a component property that is an Int64 type.

Pascal

```
function GetInt64Prop(Instance: TObject; const PropName: string): Int64; overload;
function GetInt64Prop(Instance: TObject; PropInfo: PPropInfo): Int64; overload;
```

C++

```
Int64 GetInt64Prop(TObject * Instance, const UnicodeString PropName);
Int64 GetInt64Prop(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetInt64Prop utilises Delphi's RTTI (Run Time see page 4297) Type Information) to return the current value of a component's property where that property is an Int64 type. 0 is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an Int64 value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.9 TypInfo.GetInterfaceProp Function

Returns the value of a component property that is an interface type.

Pascal

```
function GetInterfaceProp(Instance: TObject; const PropName: string): IInterface; overload;
function GetInterfaceProp(Instance: TObject; PropInfo: PPropInfo): IInterface; overload;
```

C++

```
IInterface GetInterfaceProp(TObject * Instance, const UnicodeString PropName);
IInterface GetInterfaceProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetInterfaceProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is an interface type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an interface value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.10 TypInfo.GetMethodProp Function

Returns the value of a component property that is a method type.

Pascal

```
function GetMethodProp(Instance: TObject; const PropName: string): TMethod; overload;
function GetMethodProp(Instance: TObject; PropInfo: PPropInfo): TMethod; overload;
```

C++

```
TMethod GetMethodProp(TObject * Instance, const UnicodeString PropName);
TMethod GetMethodProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetMethodProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a method type : an event routine.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a method value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.11 TypInfo.GetObjectProp Function

Returns the value of a component property that is an object type.

Pascal

```
function GetObjectProp(Instance: TObject; const PropName: string; MinClass: TClass = nil):
TObject; overload;
function GetObjectProp(Instance: TObject; PropInfo: PPropInfo; MinClass: TClass = nil):
TObject; overload;
```

C++

```
TObject * GetObjectProp(TObject * Instance, const UnicodeString PropName, TClass MinClass =
nil);
TObject * GetObjectProp(TObject * Instance, PPropInfo PropInfo, TClass MinClass = nil);
```

File

TypInfo

Description

GetObjectProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is an object type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an object, or nil if the property is not an object type.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.12 TypInfo.GetObjectPropClass Function

Returns the class type of a component property that is an object type.

Pascal

```
function GetObjectPropClass(Instance: TObject; const PropName: string): TClass; overload;
function GetObjectPropClass(Instance: TObject; PropInfo: PPropInfo): TClass; overload;
function GetObjectPropClass(PropInfo: PPropInfo): TClass; overload;
```

C++

```
TClass GetObjectPropClass(TObject * Instance, const UnicodeString PropName);
TClass GetObjectPropClass(TObject * Instance, PPropInfo PropInfo);
TClass GetObjectPropClass(PPropInfo PropInfo);
```

File

TypInfo

Description

GetObjectPropClass utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the class type of a component's property where that property is an object.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the class type of the property object value is returned.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.13 TypInfo.GetOrdProp Function

Returns the value of a component property that is an ordinal type.

Pascal

```
function GetOrdProp(Instance: TObject; const PropName: string): Longint; overload;
function GetOrdProp(Instance: TObject; PropInfo: PPropInfo): Longint; overload;
```

C++

```
Longint GetOrdProp(TObject * Instance, const UnicodeString PropName);
Longint GetOrdProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetOrdProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is an Integer, Char, WideChar, or Class type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an LongInt value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetOrdProp (see page 4738)

46.2.14 TypInfo.GetPropInfo Function

Retrieves information about a component's property.

Pascal

```
function GetPropInfo(Instance: TObject; const PropName: string; AKinds: TTypeKinds = []):
PPropInfo; overload;
function GetPropInfo(AClass: TClass; const PropName: string; AKinds: TTypeKinds = []):
PPropInfo; overload;
function GetPropInfo(TypeInfo: PTypeInfo; const PropName: string): PPropInfo; overload;
function GetPropInfo(TypeInfo: PTypeInfo; const PropName: string; AKinds: TTypeKinds):
PPropInfo; overload;
```

C++

```
PPropInfo GetPropInfo(TObject * Instance, const UnicodeString PropName, TTypeKinds AKinds =
[]);
PPropInfo GetPropInfo(TClass AClass, const UnicodeString PropName, TTypeKinds AKinds = []);
PPropInfo GetPropInfo(PTypeInfo TypeInfo, const UnicodeString PropName);
PPropInfo GetPropInfo(PTypeInfo TypeInfo, const UnicodeString PropName, TTypeKinds AKinds);
```

File

TypInfo

Description

GetPropInfo utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to retrieve a pointer to a property information record for a component.

In the first form of this function, **TypeInfo** specifies the component type whose property you want to retrieve. **PropName** specifies the property name as a string. You may optionally specify a **AKinds** set of TTypeKind (see page 4760) property value types that the property must belong to.

The second form of the function is similar to the first, with **AClass** replacing **TypeInfo** as the means of specifying the component type. **AKinds** is now a required value.

The final form of the function is like the second form, with **Instance** specifying a component instance.

In all forms of the function, the returned value is a pointer to a TPropInfo (see page 4757) value. This provides rich data about the property being investigated at run time. This enables more elegant component processing than can be achieved with hard coded component names/properties.

Note: If the specified property does not exist, a nil pointer is returned.

See Also

PTypeInfo (see page 4767)

PPropInfo (see page 4762)

TTypeKinds (see page 4773)

46.2.15 TypInfo.GetPropInfos Function

Retrieves a list of component properties.

Pascal

```
procedure GetPropInfos(TypeInfo: PTypeInfo; PropList: PPropList);
```

C++

```
GetPropInfos(PTypeInfo TypeInfo, PPropList PropList);
```

File

TypInfo

Description

GetPropInfos utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to retrieve a list of property information records for a component or component type.

The **TypeInfo** defines the component type and **PropList** defines a variable to receive the list of properties : a pointer to a TPropList (see page 4773) variable

The Delphi inbuilt TypeInfo function may be used to provide the **TypeInfo** value.

Note: If you want the count of properties returned in PropList

, use GetPropList (see page 4718) instead.

See Also

GetPropList (see page 4718)

PTypeInfo (see page 4767)

PPropList (see page 4763)

TPropList (see page 4773)

TTypeKinds (see page 4773)

46.2.16 TypInfo.GetPropList Function

Retrieves a list of component properties.

Pascal

```
function GetPropList(TypeInfo: PTypeInfo; TypeKinds: TTypeKinds; PropList: PPropList;
SortList: Boolean = True): Integer; overload;
function GetPropList(TypeInfo: PTypeInfo; out PropList: PPropList): Integer; overload;
function GetPropList(AObject: TObject; out PropList: PPropList): Integer; overload;
```

C++

```
int GetPropList(PTypeInfo TypeInfo, TTypeKinds TypeKinds, PPropList PropList, Boolean SortList
= True);
int GetPropList(PTypeInfo TypeInfo, PPropList PropList);
int GetPropList(TObject * AObject, PPropList PropList);
```

File

TypInfo

Description

GetPropList utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to retrieve a list of property information records for a component or component type.

In one form of this function, **TypeInfo** defines the component type, **PropList** defines a variable to receive the list of properties : a pointer to a TPropList (see page 4773) variable, and **TypeKinds** defines the type of properties that will be returned. Use tkAny (see page 4775) to return all types. The list may optionally be sorted by setting **SortList** true.

The Delphi inbuilt TypeInfo function may be used to provide the **TypeInfo** value.

In the other form of this function, you specify a component instance rather than component type. The **TypeKinds** and **SortList** parameters can no longer be specified.

In both forms of the function, the returned value is the number of properties in **PropList**.

Note: If you do not need the count of properties returned, use GetPropInfos (see page 4717).

See Also

GetPropInfos (see page 4717)

PTypeInfo (see page 4767)

PPropList (see page 4763)

TPropList (see page 4773)

TTypeKinds (see page 4773)

46.2.17 TypInfo.GetPropName Function

Returns the name of a component property identified by a given PPropInfo (see page 4762).

Pascal

```
function GetPropName(PropInfo: PPropInfo): string;
```

C++

```
UnicodeString GetPropName(PPropInfo PropInfo);
```

File

TypInfo

Description

Use GetPropName to obtain the qualified property name of a component's property identified by a given PPropInfo (see page 4762) parameter.

PropInfo is the type information record that describes the property. You can obtain the type information for a component property by calling the GetPropInfo (see page 4717) function.

See Also

GetPropInfo (see page 4717)

TPropInfo (see page 4757)

46.2.18 TypInfo.GetPropValue Function

Retrieves a component's property value as a variant.

Pascal

```
function GetPropValue(Instance: TObject; const PropName: string; PreferStrings: Boolean =
True): Variant; overload;
function GetPropValue(Instance: TObject; PropInfo: PPropInfo; PreferStrings: Boolean = True):
Variant; overload;
```

C++

```
Variant GetPropValue(TObject * Instance, const UnicodeString PropName, Boolean PreferStrings =
True);
Variant GetPropValue(TObject * Instance, PPropInfo PropInfo, Boolean PreferStrings = True);
```

File

TypInfo

Description

GetPropValue utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to retrieve a a component property as a variant.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the returned value the property value as a variant.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

PTypeInfo (see page 4767)

PPropInfo (see page 4762)

TTypeKinds (see page 4773)

SetPropValue (see page 4739)

46.2.19 TypInfo.GetSetElementName Function

Returns the string representation of a given constant.

Pascal

```
function GetSetElementName(TypeInfo: PTypeInfo; Value: Integer): string;
```

C++

```
UnicodeString GetSetElementName(PTypeInfo TypeInfo, int Value);
```

File

TypInfo

Description

Use GetSetElementName to convert a constant into the symbolic name that represents it in code.

TypeInfo is the type information record that describes the type for which the constant has a meaning. You can obtain the type information for a type by calling the TypeInfo function in Delphi or the __delphirtti operator in C++.

Value is the constant, represented as an integer.

GetSetElementName returns the string that represents the specified value.

If TypeInfo describes an Integer type, Value is assumed to be a simple integer and is converted to its numerical string representation. If TypeInfo describes a char type, a string containing the Pascal character notation of Value is returned. If TypeInfo describes an enumerated type, GetEnumName (see page 4705) returns the string representation of Value.

See Also

GetSetElementValue (see page 4721)

GetEnumName (see page 4705)

GetEnumValue (see page 4710)

TTypeInfo (see page 4759)

46.2.20 TypInfo.GetSetElementValue Function

Returns the integer representation of a given constant identified by it's name.

Pascal

```
function GetSetElementValue(TypeInfo: PTypeInfo; const Name: string): Integer;
```

C++

```
int GetSetElementValue(PTypeInfo TypeInfo, const UnicodeString Name);
```

File

TypInfo

Description

Use GetSetElementValue to convert a constant identified by it's symbolic name to an integer.

TypeInfo is the type information record that describes the type for which the constant has a meaning. You can obtain the type information for a type by calling the TypeInfo function in Delphi or the __delphirtti operator in C++.

Value is the constant, represented as a string.

GetSetElementValue returns the integer that represents the specified value.

If TypeInfo describes an Integer type, Value is assumed to be a string representation of an integer and is converted to an integer. If TypeInfo describes a char type, an integer containing the character code is returned. If TypeInfo describes an enumerated type, GetEnumValue (see page 4710) returns the integer representation of Value.

See Also

GetSetElementName (see page 4720)

GetEnumName (see page 4705)

GetEnumValue (see page 4710)

TTypeInfo (see page 4759)

46.2.21 TypInfo.GetSetProp Function

Returns the value of a component property that is a set type.

Pascal

```
function GetSetProp(Instance: TObject; const PropName: string; Brackets: Boolean = False):
string; overload;
function GetSetProp(Instance: TObject; PropInfo: PPropInfo; Brackets: Boolean = False):
string; overload;
```

C++

```
UnicodeString GetSetProp(TObject * Instance, const UnicodeString PropName, Boolean Brackets =
False);
UnicodeString GetSetProp(TObject * Instance, PPropInfo PropInfo, Boolean Brackets = False);
```

File

TypInfo

Description

GetSetProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a set of values type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the list if set values is returned as a comma separated string. You may optionally set **Brackets** true so as to enclose this within square brackets, as shown in the IDE for the property.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetSetProp (see page 4740)

46.2.22 TypInfo.GetStrProp Function

Returns the value of a component property that is a string type.

Pascal

```
function GetStrProp(Instance: TObject; const PropName: string): string; overload;
function GetStrProp(Instance: TObject; PropInfo: PPropInfo): string; overload;
```

C++

```
UnicodeString GetStrProp(TObject * Instance, const UnicodeString PropName);
UnicodeString GetStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a String, LongString or WideString (see page 3467) type. An empty string is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetStrProp (see page 4741)

46.2.23 TypInfo.GetTypeData Function

Returns a pointer to information about a type.

Pascal

```
function GetTypeData(TypeInfo: PTypeInfo): PTypeData;
```

C++

```
PTypeData GetTypeData(PTypeInfo TypeInfo);
```

File

TypInfo

Description

GetTypeData utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a pointer to TTypeData (see page 4758) record.

The TTypeData (see page 4758) record is a variant type, but does not contain the variant as a tag. To identify which variant applies to a particular type, you should retrieve the TTypeKind (see page 4760) value using the TypeInfo routine.

The TTypeData (see page 4758) record holds meta data about a property. For example, the name of the unit a class type is stored in.

See Also

PTypeData (see page 4764)

TTypeData (see page 4758)

TTypeKind (see page 4760)

46.2.24 TypInfo.GetTypeName Function

Returns the name of the type from it's type information record.

Pascal

```
function GetTypeName(TypeInfo: PTypeInfo): string;
```

C++

```
UnicodeString GetTypeName(PTypeInfo TypeInfo);
```

File

TypInfo

Description

GetTypeName utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the name of a type as defined in the code.

TypeInfo is the type information record that describes the type for which the name must be obtained. You can obtain the type information for a type by calling the TypeInfo function in Delphi or the __delphirtti operator in C++.

See Also

TTypeInfo (see page 4759)

GetTypeData (see page 4723)

46.2.25 TypInfo.GetUnicodeStrProp Function

Returns the value of a component property that is of UnicodeString (see page 3381) type.

Pascal

```
function GetUnicodeStrProp(Instance: TObject; const PropName: string): UnicodeString; overload;
function GetUnicodeStrProp(Instance: TObject; PropInfo: PPropInfo): UnicodeString; overload;
```

C++

```
UnicodeString GetUnicodeStrProp(TObject * Instance, const UnicodeString PropName);
UnicodeString GetUnicodeStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetUnicodeStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a UnicodeString (see page 3381). An empty string is returned if the property is not of this type.

In one form of this function, the property is looked up by using the data in the **PropInfo** parameter. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetUnicodeStrProp (see page 4742)

46.2.26 TypInfo.GetVariantProp Function

Returns the value of a component property that is a variant type.

Pascal

```
function GetVariantProp(Instance: TObject; const PropName: string): Variant; overload;
function GetVariantProp(Instance: TObject; PropInfo: PPropInfo): Variant; overload;
```

C++

```
Variant GetVariantProp(TObject * Instance, const UnicodeString PropName);
Variant GetVariantProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetVariantProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a

component's property that is a variant type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a variant.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown. If the property is not a variant type, an EVariantBadVarTypeError (see page 4980) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetVariantProp (see page 4743)

46.2.27 TypInfo.GetWideStrProp Function

Returns the value of a component property that is a WideString (see page 3467) type.

Pascal

```
function GetWideStrProp(Instance: TObject; const PropName: string): WideString; overload;
function GetWideStrProp(Instance: TObject; PropInfo: PPropInfo): WideString; overload;
```

C++

```
BSTR GetWideStrProp(TObject * Instance, const UnicodeString PropName);
BSTR GetWideStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetWideStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the current value of a component's property where that property is a WideString (see page 3467) type. A string or LongString type is returned via a call to the GetWideStrProp routine. Otherwise, for other types, an empty string is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a WideString (see page 3467).

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 4719) to retrieve a property value where the type is unknown - it is returned in a Variant (see page 3421) type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropList (see page 4718)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

SetWideStrProp (see page 4744)

46.2.28 TypInfo.IsPublishedProp Function

Determines if a specified component property is a published property.

Pascal

```
function IsPublishedProp(Instance: TObject; const PropName: string): Boolean; overload;
function IsPublishedProp(AClass: TClass; const PropName: string): Boolean; overload;
```

C++

```
Boolean IsPublishedProp(TObject * Instance, const UnicodeString PropName);
Boolean IsPublishedProp(TClass AClass, const UnicodeString PropName);
```

File

TypInfo

Description

IsPublishedProp returns true if the specified property is published. Delphi's RTTI (Run Time (see page 4297) Type Information) facility requires that properties are published.

In one form of this function, the component is defined by the **TClass (see page 3785)** parameter.

In the other form of this function, an **Instance** of the component is used.

In both forms of the function, **PropName** specifies the property as a string.

See Also

GetPropInfo (see page 4717)

GetPropValue (see page 4719)

46.2.29 TypInfo.IsStoredProp Function

Determines if a specified component property has the stored attribute.

Pascal

```
function IsStoredProp(Instance: TObject; const PropName: string): Boolean; overload;
function IsStoredProp(Instance: TObject; PropInfo: PPropInfo): Boolean; overload;
```

C++

```
Boolean IsStoredProp(TObject * Instance, const UnicodeString PropName);
Boolean IsStoredProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

IsStoredProp returns true if the specified property is saved in the form file. The stored attribute is set true by default : only those that have the keyword stored defined as false do not.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the value of the stored attribute is returned.

See Also

GetPropInfo (see page 4717)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

46.2.30 TypInfo.PropIsType Function

Determines if a component property is of a particular data type.

Pascal

```
function PropIsType(Instance: TObject; const PropName: string; TypeKind: TTypeKind): Boolean;
overload;
function PropIsType(AClass: TClass; const PropName: string; TypeKind: TTypeKind): Boolean;
overload;
```

C++

```
Boolean PropIsType(TObject * Instance, const UnicodeString PropName, TTypeKind TypeKind);
Boolean PropIsType(TClass AClass, const UnicodeString PropName, TTypeKind TypeKind);
```

File

TypInfo

Description

PropIsType returns true if the property is of the specified data type.

In the first form of this function, **AClass** specifies the component class whose property you want to look at.

The second form of the function a class **Instance** replaces **AClass**.

In both forms of the function, **PropName** specifies the property name as a string. If the property has the **TypeKind** data type, then true is returned. Otherwise false is returned.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropInfo (see page 4717)

GetPropValue (see page 4719)

PPropInfo (see page 4762)

TTypeKinds (see page 4773)

46.2.31 TypInfo.PropType Function

Retrieves a component's property type.

Pascal

```
function PropType(Instance: TObject; const PropName: string): TTypeKind; overload;
function PropType(AClass: TClass; const PropName: string): TTypeKind; overload;
```

C++

```
TTypeKind PropType(TObject * Instance, const UnicodeString PropName);
TTypeKind PropType(TClass AClass, const UnicodeString PropName);
```

File

TypInfo

Description

PropType utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return the type of a component property in a TTypeKind (see page 4760) value.

In the first form of this function, **AClass** specifies the component class whose property you want to retrieve. **PropName** specifies the property name as a string.

The second form of the function is similar to the first, with **Instance** replacing **AClass** as the means of specifying the component.

In both forms of the function, the returned value is a TTypeKind (see page 4760) value.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

PTypeInfo (see page 4767)

PPropInfo (see page 4762)

TTypeKind (see page 4760)

46.2.32 TypInfo.SamePropTypeName Function

Checks whether the two given property names are equal.

Pascal

```
function SamePropTypeName(const Name1: ShortString; const Name2: ShortString): Boolean;
```

C++

```
Boolean SamePropTypeName(const ShortString Name1, const ShortString Name2);
```

File

TypInfo

Description

SamePropTypeName compares the two given property names represented as ShortStrings. Use this function rather than the equality operator, because the internal format in which these names are stored might be changed in the future.

See Also

GetPropName (see page 4719)

TPropInfo (see page 4757)

46.2.33 TypInfo.SetAnsiStrProp Function

Sets the value of a component property that is of AnsiString type.

Pascal

```
procedure SetAnsiStrProp(Instance: TObject; const PropName: string; const Value: AnsiString);
overload;
procedure SetAnsiStrProp(Instance: TObject; PropInfo: PPropInfo; const Value: AnsiString);
overload;
```

C++

```
SetAnsiStrProp(TObject * Instance, const UnicodeString PropName, const AnsiString Value);
SetAnsiStrProp(TObject * Instance, PPropInfo PropInfo, const AnsiString Value);
```

File

TypInfo

Description

SetAnsiStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an AnsiString.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetAnsiStrProp (see page 4703)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.34 TypInfo.SetDynArrayProp Function

Sets the value of a component property that is a dynamic array type.

Pascal

```
procedure SetDynArrayProp(Instance: TObject; const PropName: string; const Value: Pointer);
overload;
procedure SetDynArrayProp(Instance: TObject; PropInfo: PPropInfo; const Value: Pointer);
overload;
```

C++

```
SetDynArrayProp(TObject * Instance, const UnicodeString PropName, const void * Value);
SetDynArrayProp(TObject * Instance, PPropInfo PropInfo, const void * Value);
```

File

TypInfo

Description

SetDynArrayProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a dynamic array type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetEnumProp (see page 4708)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.35 TypInfo.SetEnumProp Function

Sets the value of a component property that is an enumerated type.

Pascal

```
procedure SetEnumProp(Instance: TObject; const PropName: string; const Value: string);
overload;
procedure SetEnumProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetEnumProp(TObject * Instance, const UnicodeString PropName, const UnicodeString Value);
SetEnumProp(TObject * Instance, PPropInfo PropInfo, const UnicodeString Value);
```

File

TypInfo

Description

SetEnumProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an enumerated type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

C++ Examples:

```
/*
This example shows how to use GetEnumProp and SetEnumProp in order to
check for visual components properties and to change them.
This example uses two buttons, Button1 and Button2.
*/
void __fastcall TForm2::Button1Click(TObject *Sender)
{
    //getting the current color of the workspace
    String currentPropColor = GetEnumProp(this,"Color");
    int currentColorInt = StrToInt(currentPropColor);

    //getting the first button align enum and if different,
    //setting it to alLeft
    String currentAlignProp = GetEnumProp(Button1, "Align");
    if (currentAlignProp != "alLeft")
    {
         SetEnumProp(Button1, "Align", "alLeft");
     }
```

```
    //checking if the form background color was set.
    if(currentColorInt < 0)
    {
        currentColorInt = GetSysColor(COLOR_APPWORKSPACE);
    }

    //setting the form background color as the negative value
    //of the current background color
    SetEnumProp(this, "Color",
                IntToStr((int)(clWhite - currentColorInt)));
}

void __fastcall TForm2::Button2Click(TObject *Sender)
{
    int p[5] = {clYellow, clGreen, clRed, clBlue, clBlack};
    SetEnumProp(this, "Color", IntToStr(p[random(5)]));

    //getting the second button align enum and if different,
    //setting it to alRight
    String currentAlignProp = GetEnumProp(Button2, "Align");
    if (currentAlignProp != "alRight")
    {
         SetEnumProp(Button2, "Align", "alRight");
     }
}
```

Delphi Examples:

```
{
This example shows how to use GetEnumProp and SetEnumProp in order to
check for visual components properties and to change them.
This example uses two buttons, Button1 and Button2.
}
procedure TForm3.Button1Click(Sender: TObject);
var
  currentPropColor : String;
  currentAlignProp : String;
  currentColorInt : Integer;
begin
  //getting the current color of the workspace
  currentPropColor := GetEnumProp(Self,'Color');
  currentColorInt := StrToInt(currentPropColor);

  //getting the first button align enum and if different,
  //setting it to alLeft
  currentAlignProp := GetEnumProp(Button1, 'Align');
  if GetEnumValue(TypeInfo(TAlign), currentAlignProp) <> Ord(alLeft) then
     SetEnumProp(Button1, 'Align', 'alLeft');

  //checking if the form background color was set.
    if currentColorInt < 0 then
    begin
        currentColorInt := GetSysColor(COLOR_APPWORKSPACE);
    end;

  //setting the form background color as the negative value
  // of the current background color
  currentColorInt := clWhite - currentColorInt;

  SetEnumProp(Self, 'Color', IntToStr(currentColorInt));
end;

procedure TForm3.Button2Click(Sender: TObject);
var
  p : array [0..4] of Integer;
  currentAlignProp : String;
begin
```

```
    p[0] := clYellow;
    p[1] := clRed;
    p[2] := clBlue;
    p[3] := clBlack;
    p[4] := clGreen;

      SetEnumProp(Self, 'Color', IntToStr(p[random(5)]));

    //getting the second button align enum and if different,
    //setting it to alRight
    currentAlignProp := GetEnumProp(Button2, 'Align');
    if GetEnumValue(TypeInfo(TAlign), currentAlignProp) <> Ord(alRight) then
       SetEnumProp(Button2, 'Align', 'alRight');

  end;
```

46.2.36 TypInfo.SetFloatProp Function

Sets the value of a component property that is a float type.

Pascal

```
procedure SetFloatProp(Instance: TObject; const PropName: string; const Value: Extended);
overload;
procedure SetFloatProp(Instance: TObject; PropInfo: PPropInfo; const Value: Extended);
overload;
```

C++

```
SetFloatProp(TObject * Instance, const UnicodeString PropName, const Extended Value);
SetFloatProp(TObject * Instance, PPropInfo PropInfo, const Extended Value);
```

File

TypInfo

Description

SetFloatProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a floating point number.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when

using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.37 TypInfo.SetInt64Prop Function

Sets the value of a component property that is an Int64 type.

Pascal

```
procedure SetInt64Prop(Instance: TObject; const PropName: string; const Value: Int64);
overload;
procedure SetInt64Prop(Instance: TObject; PropInfo: PPropInfo; const Value: Int64); overload;
```

C++

```
SetInt64Prop(TObject * Instance, const UnicodeString PropName, const Int64 Value);
SetInt64Prop(TObject * Instance, PPropInfo PropInfo, const Int64 Value);
```

File

TypInfo

Description

SetInt64Prop utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an Int64 number.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.38 TypInfo.SetInterfaceProp Function

Sets the value of a component property that is an Interface type.

Pascal

```
procedure SetInterfaceProp(Instance: TObject; const PropName: string; const Value:
IInterface); overload;
procedure SetInterfaceProp(Instance: TObject; PropInfo: PPropInfo; const Value: IInterface);
overload;
```

C++

```
SetInterfaceProp(TObject * Instance, const UnicodeString PropName, const IInterface Value);
SetInterfaceProp(TObject * Instance, PPropInfo PropInfo, const IInterface Value);
```

File

TypInfo

Description

SetInterfaceProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an Interface.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.39 TypInfo.SetMethodProp Function

Sets the value of a component property that is a method type.

Pascal

```
procedure SetMethodProp(Instance: TObject; const PropName: string; const Value: TMethod);
overload;
procedure SetMethodProp(Instance: TObject; PropInfo: PPropInfo; const Value: TMethod);
overload;
```

C++

```
SetMethodProp(TObject * Instance, const UnicodeString PropName, const TMethod Value);
SetMethodProp(TObject * Instance, PPropInfo PropInfo, const TMethod Value);
```

File

TypInfo

Description

SetMethodProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an Event (Method property).

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.40 TypInfo.SetObjectProp Function

Sets the value of a component property that is an object type.

Pascal

```
procedure SetObjectProp(Instance: TObject; const PropName: string; Value: TObject); overload;
procedure SetObjectProp(Instance: TObject; PropInfo: PPropInfo; Value: TObject; ValidateClass:
Boolean = True); overload;
```

C++

```
SetObjectProp(TObject * Instance, const UnicodeString PropName, TObject * Value);
SetObjectProp(TObject * Instance, PPropInfo PropInfo, TObject * Value, Boolean ValidateClass =
True);
```

File

TypInfo

Description

SetObjectProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an object.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.41 TypInfo.SetOrdProp Function

Sets the value of a component property that is an ordinal type.

Pascal

```
procedure SetOrdProp(Instance: TObject; const PropName: string; Value: Longint); overload;
procedure SetOrdProp(Instance: TObject; PropInfo: PPropInfo; Value: Longint); overload;
```

C++

```
SetOrdProp(TObject * Instance, const UnicodeString PropName, Longint Value);
SetOrdProp(TObject * Instance, PPropInfo PropInfo, Longint Value);
```

File

TypInfo

Description

SetOrdProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is an Integer, Char, WideChar, or Class type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetOrdProp (see page 4716)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

PPropInfo (see page 4762)

46.2.42 TypInfo.SetPropValue Function

Sets the value of a component property using a variant value.

Pascal

```
procedure SetPropValue(Instance: TObject; const PropName: string; const Value: Variant);
overload;
procedure SetPropValue(Instance: TObject; PropInfo: PPropInfo; const Value: Variant); overload;
```

C++

```
SetPropValue(TObject * Instance, const UnicodeString PropName, const Variant Value);
SetPropValue(TObject * Instance, PPropInfo PropInfo, const Variant Value);
```

File

TypInfo

Description

SetPropValue utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property using a variant value.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**. Note that only certain property assignments are possible using variants. It is normally be used when using GetPropValue (see page 4719) from another property.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetPropValue (see page 4719)

46.2.43 TypInfo.SetSetProp Function

Sets the value of a component property that is a set type.

Pascal

```
procedure SetSetProp(Instance: TObject; const PropName: string; const Value: string); overload;
procedure SetSetProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetSetProp(TObject * Instance, const UnicodeString PropName, const UnicodeString Value);
SetSetProp(TObject * Instance, PPropInfo PropInfo, const UnicodeString Value);
```

File

TypInfo

Description

SetSetProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a set type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**. You specify the set of values as a comma separated string. You may optionally enclose these in square brackets. This allows the returned value from one GetSetProp (see page 4722) call to be used as the assignment value in a SetSetProp call.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetSetProp (see page 4722)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.44 TypInfo.SetStrProp Function

Sets the value of a component property that is a string type.

Pascal

```
procedure SetStrProp(Instance: TObject; const PropName: string; const Value: string); overload;
procedure SetStrProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetStrProp(TObject * Instance, const UnicodeString PropName, const UnicodeString Value);
SetStrProp(TObject * Instance, PPropInfo PropInfo, const UnicodeString Value);
```

File

TypInfo

Description

SetStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a String, LongString or WideString (see page 3467) type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetStrProp (see page 4722)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

SetPropValue (see page 4739)

PPropInfo (see page 4762)

46.2.45 TypInfo.SetToString Function

Returns one or more of the set values of a component's property.

Pascal

```
function SetToString(PropInfo: PPropInfo; Value: Integer; Brackets: Boolean = False): string;
```

C++

```
UnicodeString SetToString(PPropInfo PropInfo, int Value, Boolean Brackets = False);
```

File

TypInfo

Description

SetToString utilises Delphi's RTTI (Run Time see page 4297) Type Information) to retrieve one or more of the values of a component property that is of the set type.

The property to interrogate is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

Value defines a bit mask that selects the possible values of this property. Each bit corresponds to a set value. The low order bit corresponds to the first set value. A string is returned with the selected set values as a comma separated value string. Note that the current property set values are not taken into account - the set values selected by **Value** are those in the complete set.

You may optionally set **Brackets** true so as to enclose this returned string within square brackets, as shown in the IDE for the property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

See Also

GetSetProp (see page 4722)

GetPropInfo (see page 4717)

GetPropList (see page 4718)

PPropInfo (see page 4762)

SetPropValue (see page 4739)

SetSetProp (see page 4740)

46.2.46 TypInfo.SetUnicodeStrProp Function

Sets the value of a component property that is of UnicodeString (see page 3381) type.

Pascal

```
procedure SetUnicodeStrProp(Instance: TObject; const PropName: string; const Value:
UnicodeString); overload;
procedure SetUnicodeStrProp(Instance: TObject; PropInfo: PPropInfo; const Value:
UnicodeString); overload;
```

C++

```
SetUnicodeStrProp(TObject * Instance, const UnicodeString PropName, const UnicodeString Value);
SetUnicodeStrProp(TObject * Instance, PPropInfo PropInfo, const UnicodeString Value);
```

File

TypInfo

Description

SetUnicodeStrProp uses Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a UnicodeString (see page 3381).

In one form of this function, the property is looked up by using the data in the **PropInfo** parameter. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.47 TypInfo.SetVariantProp Function

Sets the value of a component property that is a variant type.

Pascal

```
procedure SetVariantProp(Instance: TObject; const PropName: string; const Value: Variant);
overload;
procedure SetVariantProp(Instance: TObject; PropInfo: PPropInfo; const Value: Variant);
overload;
```

C++

```
SetVariantProp(TObject * Instance, const UnicodeString PropName, const Variant Value);
SetVariantProp(TObject * Instance, PPropInfo PropInfo, const Variant Value);
```

File

TypInfo

Description

SetVariantProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a variant type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.48 TypInfo.SetWideStrProp Function

Sets the value of a component property that is a WideString (see page 3467) type.

Pascal

```
procedure SetWideStrProp(Instance: TObject; const PropName: string; const Value: WideString);
overload;
procedure SetWideStrProp(Instance: TObject; PropInfo: PPropInfo; const Value: WideString);
overload;
```

C++

```
SetWideStrProp(TObject * Instance, const UnicodeString PropName, const BSTR Value);
SetWideStrProp(TObject * Instance, PPropInfo PropInfo, const BSTR Value);
```

File

TypInfo

Description

SetWideStrProp utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to set the value of a component's property where that property is a WideString (see page 3467) type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 4739) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 4719) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 4693) exception is thrown.

46.2.49 TypInfo.SortPropList Function

Sorts a list of component properties into alphanumeric sequence.

Pascal

```
procedure SortPropList(PropList: PPropList; PropCount: Integer);
```

C++

```
SortPropList(PPropList PropList, int PropCount);
```

File

TypInfo

Description

SortPropList is used to sort a PPropList (see page 4763) that was originally created in natural rather than sorted sequence (by GetPropList (see page 4718)).

PropList defines a pointer to the array of TPropInfo (see page 4757) pointers (normally obtained using GetPropList (see page 4718)). **Count** specifies the number of TPropList (see page 4773)

See Also

GetPropList (see page 4718)

46.2.50 TypInfo.StringToSet Function

Returns a bit mask of set values for a set type component property.

Pascal

```
function StringToSet(PropInfo: PPropInfo; const Value: string): Integer;
```

C++

```
int StringToSet(PPropInfo PropInfo, const UnicodeString Value);
```

File

TypInfo

Description

StringToSet utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a bit mask of set indices for component's property where that property is a set type.

The property is defined by the **PropInfo** pointer. (GetPropInfo (see page 4717) and GetPropList (see page 4718) can be used to obtain such a record).

Value defines a comma separated string of set values the property may have.

The resulting integer value is a bit mask. The 0 bit relates to the 1st set value for the property. If that property value is included in the **Value** string, it is set to 1, otherwise 0. This continues for bits 1, 2 and so on referring to set positions 2, 3 and so on.

46.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TFloatType (see page 4747)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TIntfFlag (see page 4751)	This is record TypInfo.TIntfFlag.
	TMethodKind (see page 4751)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TOrdType (see page 4753)	Enumerates floating point number types in the TTypeData (see page 4758) record.
	TParamFlag (see page 4756)	TParamFlag and TParamFlags (see page 4772) indicates the attributes of a method parameter.
	TTypeKind (see page 4760)	These types describe a type that is manipulated in the forms designer.

Records

	Name	Description
	TManagedField (see page 4751)	This is record TypInfo.TManagedField.
	TPropData (see page 4757)	This is record TypInfo.TPropData.
	TPropInfo (see page 4757)	TPropInfo is a record of component property type information.
	TTypeData (see page 4758)	TTypeData is used internally to represent type information.
	TTypeInfo (see page 4759)	Holds information for a data type as returned by TypeInfo.

46.3.1 TypInfo.TFloatType Enumeration

Enumerates floating point number types in the TTypeData (see page 4758) record.

Pascal

```
TFloatType = (
  ftSingle,
  ftDouble,
  ftExtended,
  ftComp,
  ftCurr
);
```

C++

```
enum TFloatType {
  ftSingle,
  ftDouble,
  ftExtended,
  ftComp,
  ftCurr
};
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a

pointer to TTypeData (see page 4758) record that describes a component property data type.

TTypeData (see page 4758) is a variant record : the layout depends on the property TTypeKind (see page 4760) value. When it is tkFloat, the data is one of the TFloatType enumerated values.

The TFloatType value meanings are as follows :

Value	Meaning
ftSingle	Single data type. (-1.5 x 10^45 .. 3.4 x 10^38)
ftDouble	Double data type. (-5.0 x 10^324 .. 1.7 x 10^308)
ftExtended	Extended data type. (-3.6 x 10^4951 .. 1.1 x 10^4932)
ftComp	Comp data type. (-2^63+1 .. 2^63-1)
ftCurr	Currency (see page 3235) data type. (20 significant digits, 4 decimal places)

C++ Examples:

```
/*
Add the Delphi source file that appears on this Help page into
a CPP Builder project that includes a CPP module containing the
following code.  An hpp file will be generated for the Delphi
code when you build the project.  Add the include line for
that hpp file at the top of the CPP module.  The FormCreates
for both forms will execute and the following generics code
will work.  Remember to give the forms different names!
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Prints type info for string type
  TGenericClass__1<System::UnicodeString> *GString = new
TGenericClass__1<System::UnicodeString>();
  GString->PrintTypeInfo(Memo1);

  // Prints type info for Byte type
  TGenericClass__1<Byte> *GByte = new TGenericClass__1<Byte>();
  GByte->PrintTypeInfo(Memo1);

  // Prints type info for Double type
  TGenericClass__1<Double> *GDouble = new TGenericClass__1<Double>();
  GDouble->PrintTypeInfo(Memo1);

  // Prints type info for "array of String" type
  // TGenericClass__1<array of string> *GStringArray = new TGenericClass__1<array of string>();
  // GStringArray->PrintTypeInfo(Memo1);
}
```

Delphi Examples:

```
{
This example demostrates the methods to retreive of
Run-time Type Information (RTTI) information.
This example will print useful information about any given
type including it's name, size, kind and sub-kind.
}

type
  TForm2 = class(TForm)
    Memo1: TMemo;
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
  public
```

```
    { Public declarations }
  end;
{ Defining a generic type that contains a single class (static)
  method that will print information about the type it operates on.
}
  TGenericClass<T> = class(TList<T>)  // TList is a class in Generics.Collections
  public
    procedure PrintTypeInfo(memo: TMemo);
  end;
  TGenericString = class(TGenericClass<UnicodeString>)
  end;
  TGenericByte = class(TGenericClass<Byte>)
  end;
  TGenericDouble = class(TGenericClass<Double>)
  end;

var
  Form2: TForm2;

implementation

{$R *.dfm}

{ Method defintition }
procedure TGenericClass<T>.PrintTypeInfo(memo: TMemo);
var
  Info     : PTypeInfo;
  Data     : PTypeData;
  KindName : String;
  SubName  : String;
begin
  { Get type info for the "yet unknown type" }
  Info := System.TypeInfo(T);

  { There is no RTTI attached for some types like Records for example. }
  if Info <> nil then
  begin
    memo.Lines.Add('Type name: ' + Info^.Name);

    { Find out the name of an enum item from it's ordinal value }
    KindName := TypInfo.GetEnumName(System.TypeInfo(TTypeKind), Ord(Info^.Kind));

    memo.Lines.Add('Type kind: ' + KindName);

    Data := GetTypeData(Info);

    if Info^.Kind = tkInteger then
    begin
      { In case of integer let's see the actual sub-type name }
      SubName := TypInfo.GetEnumName(System.TypeInfo(TOrdType), Ord(Data^.OrdType));
      memo.Lines.Add('Integer kind: ' + SubName);
    end;

    if Info^.Kind = tkFloat then
    begin
      { In case of float let's see the actual sub-type name }
      SubName := TypInfo.GetEnumName(System.TypeInfo(TFloatType), Ord(Data^.FloatType));

Description

This is record TypInfo.TIntfFlag.

46.3.3 TypInfo.TManagedField Record

Pascal

```
TManagedField = record
  TypeRef: PTypeInfo;
  FldOffset: Integer;
end;
```

C++

```
struct TManagedField {
  PTypeInfo TypeRef;
  int FldOffset;
};
```

File

TypInfo

Description

This is record TypInfo.TManagedField.

46.3.4 TypInfo.TMethodKind Enumeration

Enumerates floating point number types in the TTypeData (see page 4758) record.

Pascal

```
TMethodKind = (
```

```
    mkProcedure,
    mkFunction,
    mkConstructor,
    mkDestructor,
    mkClassProcedure,
    mkClassFunction,
    mkClassConstructor,
    mkOperatorOverload,
    mkSafeProcedure,
    mkSafeFunction
  );
```

C++

```
  enum TMethodKind {
    mkProcedure,
    mkFunction,
    mkConstructor,
    mkDestructor,
    mkClassProcedure,
    mkClassFunction,
    mkClassConstructor,
    mkOperatorOverload,
    mkSafeProcedure,
    mkSafeFunction
  };
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a pointer to TTypeData (see page 4758) record that describes a component property data type.

TTypeData (see page 4758) is a variant record : the layout depends on the property TTypeKind (see page 4760) value. When it is tkMethod, the data is one of the TMethodKind enumerated values.

The TMethodKind value meanings are as follows :

Value	Meaning
mkProcedure	Stand alone procedure.
mkFunction	Stand alone function.
mkDestructor	Destructor.
mkConstructor	Constructor.
mkClassProcedure	Class procedure.
mkClassFunction	Class function.
mkClassConstructor	Class constructor.
mkOperatorOverload	Operator overload.
mkSafeProcedure	Safe procedure.
mkSafeFunction	Safe function.

46.3.5 TypInfo.TOrdType Enumeration

Enumerates floating point number types in the TTypeData (see page 4758) record.

Pascal

```
TOrdType = (
  otSByte,
  otUByte,
  otSWord,
  otUWord,
  otSLong,
  otULong
);
```

C++

```
enum TOrdType {
  otSByte,
  otUByte,
  otSWord,
  otUWord,
  otSLong,
  otULong
};
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a pointer to TTypeData (see page 4758) record that describes a component property data type.

TTypeData (see page 4758) is a variant record : the layout depends on the property TTypeKind (see page 4760) value. When it is tkWChar, the data is one of the TOrdType enumerated values.

The TOrdType value meanings are as follows :

Value	Meaning
otSByte	Signed byte.
otUByte	Unsigned byte
otSWord	Signed Word
otUWord	Unsigned Word
otSLong	Signed Long
otULong	Unsigned Long

C++ Examples:

```
/*

TTypeKind (see page 4760)

46.3.6 TypInfo.TParamFlag Enumeration

TParamFlag and TParamFlags (see page 4772) indicates the attributes of a method parameter.

Pascal

```
TParamFlag = (
  pfVar,
  pfConst,
  pfArray,
  pfAddress,
  pfReference,
  pfOut
);
```

C++

```
enum TParamFlag {
  pfVar,
  pfConst,
  pfArray,
  pfAddress,
  pfReference,
  pfOut
};
```

File

TypInfo

Description

TParamFlags (see page 4772) indicates the attributes of a parameter on a Delphi language function or procedure. It is a set of TParamFlag values:

Value	Meaning
pfVar	The parameter is input/output. Caller must supply a variable to receive output.
pfConst	The parameter can't be changed by the function or procedure.
pfArray	The parameter represents an open array of values.
pfAddress	The parameter is a memory address (pointer).
pfReference	The parameter is passed by reference.
pfOut	The parameter is output. Caller supplies a variable to receive the output.

46.3.7 TypInfo.TPropData Record

Pascal

```
TPropData = packed record
  PropCount: Word;
  PropList: record;
end;
```

C++

```
struct TPropData {
  Word PropCount;
  record PropList;
};
```

File

TypInfo

Description

This is record TypInfo.TPropData.

46.3.8 TypInfo.TPropInfo Record

TPropInfo is a record of component property type information.

Pascal

```
TPropInfo = packed record
  PropType: PPTypeInfo;
  GetProc: Pointer;
  SetProc: Pointer;
  StoredProc: Pointer;
  Index: Integer;
  Default: Longint;
  NameIndex: SmallInt;
  Name: ShortString;
end;
```

C++

```
struct TPropInfo {
  PPTypeInfo PropType;
  void * GetProc;
  void * SetProc;
```

```
    void * StoredProc;
    int Index;
    Longint Default;
    SmallInt NameIndex;
    ShortString Name;
  };
```

File

TypInfo

Description

TPropInfo is principally used to hold the results of a call to GetPropInfo (see page 4717). It provides meta details about a component property as part of Delphi's RTTI (Run Time (see page 4297) Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values.

The TPropInfo fields have the foillowing meanings :

Field	Meaning
PropType	Points to a data structure that gives information about the property type.
GetProc	Method pointer for the method that gets the component property value.
SetProc	Method pointer for the method that sets the component property value.
Index	The index of the property. It is used as a parameter to the GetProc and SetProc methods on indexed properties.
Default	The default value of the property.
NameIndex	The offset into the Name field where the property's name starts.
Name	The qualified property name.

See Also

GetPropInfo (see page 4717)

PPropInfo (see page 4762)

46.3.9 TypInfo.TTypeData Record

TTypeData is used internally to represent type information.

Pascal

```
TTypeData = packed record
  case TTypeKind of
    tkClass: (ClassType: TClass;
              ParentInfo: PPTypeInfo;
              PropCount: SmallInt;
              UnitName: ShortStringBase;);
    tkDynArray: (elSize: Longint;
                 elType: PPTypeInfo;
                 varType: Integer;
                 elType2: PPTypeInfo;
                 DynUnitName: ShortStringBase;);
    tkEnumeration: (BaseType: PPTypeInfo;
                    NameList: ShortStringBase;
                    EnumUnitName: ShortStringBase;);
    tkFloat: (FloatType: TFloatType;);
    tkInt64: (MaxInt64Value: Int64;
```

```
                MinInt64Value: Int64;);
      tkLString: (CodePage: Word;);
      tkMethod: (MethodKind: TMethodKind;
                 ParamCount: Byte;
                 ParamList: array[0..1023] of AnsiChar );
                 tkInterface: ( IntfParent : PPTypeInfo; IntfFlags : TIntfFlagsBase; Guid :
  TGUID; IntfUnit : ShortStringBase;;);
      tkRecord: (RecSize: Integer;
                 ManagedFldCount: Integer;);
      tkSet: (CompType: PPTypeInfo;);
      tkString: (MaxLength: Byte;);
      tkWChar: (OrdType: TOrdType;
                MinValue: Longint;
                MaxValue: Longint;);
  end;
```

C++

```
  struct TTypeData {
    Word CodePage;
    TOrdType OrdType;
    Longint MinValue;
    Longint MaxValue;
    PPTypeInfo BaseType;
    ShortStringBase NameList;
    ShortStringBase EnumUnitName;
    PPTypeInfo CompType;
    TFloatType FloatType;
    Byte MaxLength;
    TClass ClassType;
    PPTypeInfo ParentInfo;
    SmallInt PropCount;
    ShortStringBase UnitName;
    TMethodKind MethodKind;
    Byte ParamCount;
    array[0..1023] of AnsiChar ) ParamList;
    ( IntfParent : PPTypeInfo; IntfFlags : TIntfFlagsBase; Guid : TGUID; IntfUnit :
  ShortStringBase; tkInterface;
    Int64 MaxInt64Value;
    Int64 MinInt64Value;
    Longint elSize;
    PPTypeInfo elType;
    int varType;
    PPTypeInfo elType2;
    ShortStringBase DynUnitName;
    int RecSize;
    int ManagedFldCount;
  };
```

File

TypInfo

Description

A TTypeData structure represents a category of properties, events, or methods in parameters passed to several routines in the TypInfo (see page 4689) unit.

46.3.10 TypInfo.TTypeInfo Record

Holds information for a data type as returned by TypeInfo.

Pascal

```
TTypeInfo = record
  Kind: TTypeKind;
  Name: ShortString;
end;
```

C++

```
struct TTypeInfo {
  TTypeKind Kind;
  ShortString Name;
};
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time (see page 4297) Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo (see page 4767) pointer to a TTypeInfo value.

The TTypeInfo holds the following fields :

Field	Meaning
Kind	The kind of type in RTTI terms. This value is required to select the appropriate variant section in the TTypeData (see page 4758) returned by the GetTypeData (see page 4723).
Name	The name of the data type.

See Also

GetTypeData (see page 4723)

PTypeInfo (see page 4767)

PPTypeInfo (see page 4763)

TTypeKind (see page 4760)

TTypeData (see page 4758)

46.3.11 TypInfo.TTypeKind Enumeration

These types describe a type that is manipulated in the forms designer.

Pascal

```
TTypeKind = (
  tkUnknown,
  tkInteger,
  tkChar,
  tkEnumeration,
  tkFloat,
  tkString,
  tkSet,
  tkClass,
  tkMethod,
  tkWChar,
  tkLString,
  tkWString,
  tkVariant,
```

```
    tkArray,
    tkRecord,
    tkInterface,
    tkInt64,
    tkDynArray,
    tkUString
  );
```

C++

```
  enum TTypeKind {
    tkUnknown,
    tkInteger,
    tkChar,
    tkEnumeration,
    tkFloat,
    tkString,
    tkSet,
    tkClass,
    tkMethod,
    tkWChar,
    tkLString,
    tkWString,
    tkVariant,
    tkArray,
    tkRecord,
    tkInterface,
    tkInt64,
    tkDynArray,
    tkUString
  };
```

File

TypInfo

Description

TTypeKind is an enumerated type that classifies a type.

TTypeInfo (see page 4759) describes a type by giving its classification and its name.

PTypeInfo (see page 4767) is a pointer to a TTypeInfo (see page 4759) value.

PPTypeInfo (see page 4763) is a pointer to a PTypeInfo (see page 4767) pointer.

46.4 Types

The following table lists types in this documentation.

Types

Name	Description
PPropInfo (see page 4762)	PPropInfo points to a TPropInfo (see page 4757) record that holds component property information.
PPropList (see page 4763)	Defines a pointer to a TPropList (see page 4773) array.
PPTypeInfo (see page 4763)	Holds a pointer to a pointer to information for a data type as returned by TypeInfo.
PTypeData (see page 4764)	PTypeData points to a TTypeData (see page 4758) record that holds component property type information.
PTypeInfo (see page 4767)	Holds a pointer to information for a data type as returned by TypeInfo.
ShortStringBase (see page 4770)	Defines a fixed length string for general use in the TTypeData (see page 4758) record.
TIntfFlags (see page 4770)	Enumerates interface flag types in the TTypeData (see page 4758) record.
TIntfFlagsBase (see page 4771)	Set of interface flag types in the TTypeData (see page 4758) record.
TParamFlags (see page 4772)	This is type TypInfo.TParamFlags.
TParamFlagsBase (see page 4772)	This is type TypInfo.TParamFlagsBase.
TPropInfoProc (see page 4772)	This is type TypInfo.TPropInfoProc.
TPropList (see page 4773)	Defines an array of PPropInfo (see page 4762) values.
TTypeKinds (see page 4773)	Defines a set of TTypeKind (see page 4760) values.

46.4.1 TypInfo.PPropInfo Type

PPropInfo points to a TPropInfo (see page 4757) record that holds component property information.

Pascal

```
PPropInfo = ^TPropInfo;
```

C++

```
^TPropInfo PPropInfo;
```

File

TypInfo

Description

TPropInfo (see page 4757) is principally used to hold the results of a call to GetPropInfo (see page 4717). It provides meta details about a component property as part of Delphi's RTTI (Run Time (see page 4297) Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values. PPropInfo is a pointer to a TPropInfo (see page 4757) record.

See Also

GetPropInfo (see page 4717)

TPropInfo (see page 4757)

46.4.2 TypInfo.PPropList Type

Defines a pointer to a TPropList (see page 4773) array.

Pascal

```
PPropList = ^TPropList;
```

C++

```
^TPropList PPropList;
```

File

TypInfo

Description

PPropList defines a pointer to an array of PPropInfo (see page 4762) values. This TPropList (see page 4773) array is principally used to hold the results of a call to GetPropList (see page 4718). This list (array) holds pointers to TPropInfo (see page 4757) records that describe the nature of the properties of the component provided to GetPropList (see page 4718).

See Also

GetPropList (see page 4718)

PPropInfo (see page 4762)

TPropInfo (see page 4757)

TPropList (see page 4773)

46.4.3 TypInfo.PPTypeInfo Type

Holds a pointer to a pointer to information for a data type as returned by TypeInfo.

Pascal

```
PPTypeInfo = ^PTypeInfo;
```

C++

```
^PTypeInfo PPTypeInfo;
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time (see page 4297) Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo (see page 4767) pointer to a TTypeInfo (see page 4759) value. PPTypeInfo is a PTypeInfo (see page 4767) pointer.

See Also

GetTypeData (see page 4723)

PTypeInfo (see page 4767)

TTypeInfo (see page 4759)

TTypeKind (see page 4760)

TTypeData (see page 4758)

46.4.4 TypInfo.PTypeData Type

PTypeData points to a TTypeData (see page 4758) record that holds component property type information.

Pascal

```
PTypeData = ^TTypeData;
```

C++

```
^TTypeData PTypeData;
```

File

TypInfo

Description

TTypeData (see page 4758) is principally used to hold the results of a call to GetTypeData (see page 4723). It provides meta details about a component property type as part of Delphi's RTTI (Run Time (see page 4297) Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values. PTypeData is a pointer to a TTypeData (see page 4758) record.

C++ Examples:

```
/*
Add the Delphi source file that appears on this Help page into
a CPP Builder project that includes a CPP module containing the
following code.  An hpp file will be generated for the Delphi
code when you build the project.  Add the include line for
that hpp file at the top of the CPP module.  The FormCreates
for both forms will execute and the following generics code
will work.  Remember to give the forms different names!
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  // Prints type info for string type
  TGenericClass__1<System::UnicodeString> *GString = new
TGenericClass__1<System::UnicodeString>();
  GString->PrintTypeInfo(Memo1);

  // Prints type info for Byte type
  TGenericClass__1<Byte> *GByte = new TGenericClass__1<Byte>();
  GByte->PrintTypeInfo(Memo1);

  // Prints type info for Double type
  TGenericClass__1<Double> *GDouble = new TGenericClass__1<Double>();
  GDouble->PrintTypeInfo(Memo1);

  // Prints type info for "array of String" type
  // TGenericClass__1<array of string> *GStringArray = new TGenericClass__1<array of string>();
  // GStringArray->PrintTypeInfo(Memo1);
}
```

Delphi Examples:

```
{
This example demostrates the methods to retreive of
Run-time Type Information (RTTI) information.
```

```
  This example will print useful information about any given
  type including it's name, size, kind and sub-kind.
  }

  type
    TForm2 = class(TForm)
      Memo1: TMemo;
      procedure FormCreate(Sender: TObject);
    private
      { Private declarations }
    public
      { Public declarations }
    end;
  { Defining a generic type that contains a single class (static)
    method that will print information about the type it operates on.
  }
    TGenericClass<T> = class(TList<T>)  // TList is a class in Generics.Collections
    public
      procedure PrintTypeInfo(memo: TMemo);
    end;
    TGenericString = class(TGenericClass<UnicodeString>)
    end;

  Size of type: 4

  Type name: Byte
  Type kind: tkInteger
  Integer kind: otUByte
  Size of type: 1

  Type name: Double
  Type kind: tkFloat
  Float kind: ftDouble
  Size of type: 8

  Type name: .1
  Type kind: tkDynArray
  Array element type name: string
  Array element type size: 4
  Size of type: 4
  }
```

See Also

GetTypeData (see page 4723)

TTypeData (see page 4758)

46.4.5 TypInfo.PTypeInfo Type

Holds a pointer to information for a data type as returned by TypeInfo.

Pascal

```
PTypeInfo = ^TTypeInfo;
```

C++

```
^TTypeInfo PTypeInfo;
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time (see page 4297) Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo pointer to a TTypeInfo (see page 4759) value.

The TTypeInfo (see page 4759) holds the following fields :

Field	Meaning
Kind	The kind of type in RTTI terms. This value is required to select the appropriate variant section in the TTypeData (see page 4758) returned by the GetTypeData (see page 4723).
Name	The name of the data type.

C++ Examples:

```
/*
Add the Delphi source file that appears on this Help page into
a CPP Builder project that includes a CPP module containing the
following code.  An hpp file will be generated for the Delphi
code when you build the project.  Add the include line for
that hpp file at the top of the CPP module.  The FormCreates
for both forms will execute and the following generics code
will work.  Remember to give the forms different names!
*/

void __fastcall TForm1::FormCreate(TObject *Sender)

TTypeKind (see page 4760)

TTypeData (see page 4758)

46.4.6 TypInfo.ShortStringBase Type

Defines a fixed length string for general use in the TTypeData (see page 4758) record.

Pascal

```
ShortStringBase = string[255];
```

C++

```
string[255] ShortStringBase;
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a pointer to TTypeData (see page 4758) record that describes a component property data type.

A number of the variant data sections in the TTypeData (see page 4758) record use the ShortStringBase to define a 255 character string to hold Name values such as UnitName for a class data type.

See Also

GetTypeData (see page 4723)

TTypeData (see page 4758)

46.4.7 TypInfo.TIntfFlags Type

Enumerates interface flag types in the TTypeData (see page 4758) record.

Pascal

```
TIntfFlags = set of TIntfFlag;
```

C++

```
TIntfFlag TIntfFlags;
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a

pointer to TTypeData (see page 4758) record that describes a component property data type.

TTypeData (see page 4758) is a variant record : the layout depends on the property TTypeKind (see page 4760) value. When it is tkInterface, the data contains a TIntfFlagsBase (see page 4771) set of TIntfFlags values.

The TIntfFlags value meanings are as follows :

Value	Meaning
ifHasGuid	Interface has a GUID (Globally Unique IDentifier).
ifDispInterface	Is a dispatch interface.
ifDispatch	Can be dispatched.

See Also

GetTypeData (see page 4723)

TIntfFlagsBase (see page 4771)

TTypeData (see page 4758)

TTypeKind (see page 4760)

46.4.8 TypInfo.TIntfFlagsBase Type

Set of interface flag types in the TTypeData (see page 4758) record.

Pascal

```
TIntfFlagsBase = set of TIntfFlag;
```

C++

```
TIntfFlag TIntfFlagsBase;
```

File

TypInfo

Description

The GetTypeData (see page 4723) routine utilises Delphi's RTTI (Run Time (see page 4297) Type Information) to return a pointer to TTypeData (see page 4758) record that describes a component property data type.

TTypeData (see page 4758) is a variant record : the layout depends on the property TTypeKind (see page 4760) value. When it is tkInterface, the data contains a TIntfFlagsBase set of TIntfFlag (see page 4751) values.

The TIntfFlag (see page 4751) value meanings are as follows :

Value	Meaning
ifHasGuid	Interface has a GUID (Globally Unique IDentifier).
ifDispInterface	Is a dispatch interface.
ifDispatch	Can be dispatched.

See Also

GetTypeData (see page 4723)

TIntfFlag (see page 4751)

TTypeData (see page 4758)

TTypeKind (see page 4760)

46.4.9 TypInfo.TParamFlags Type

Pascal

```
TParamFlags = set of TParamFlag;
```

C++

```
TParamFlag TParamFlags;
```

File

TypInfo

Description

This is type TypInfo.TParamFlags.

46.4.10 TypInfo.TParamFlagsBase Type

Pascal

```
TParamFlagsBase = set of TParamFlag;
```

C++

```
TParamFlag TParamFlagsBase;
```

File

TypInfo

Description

This is type TypInfo.TParamFlagsBase.

46.4.11 TypInfo.TPropInfoProc Type

Pascal

```
TPropInfoProc = procedure (PropInfo: PPropInfo) of object;
```

C++

```
(PropInfo: PPropInfo) ( TPropInfoProc)();
```

File

TypInfo

Description

This is type TypInfo.TPropInfoProc.

46.4.12 TypInfo.TPropList Type

Defines an array of PPropInfo (see page 4762) values.

Pascal

```
TPropList = array[0..16379] of PPropInfo;
```

C++

```
array[0..16379] of PPropInfo TPropList;
```

File

TypInfo

Description

TPropList is principally used to hold the results of a call to GetPropList (see page 4718). This list (array) holds pointers to TPropInfo (see page 4757) records that describe the nature of the properties of the component provided to GetPropList (see page 4718).

See Also

GetPropList (see page 4718)

TPropInfo (see page 4757)

46.4.13 TypInfo.TTypeKinds Type

Defines a set of TTypeKind (see page 4760) values.

Pascal

```
TTypeKinds = set of TTypeKind;
```

C++

```
TTypeKind TTypeKinds;
```

File

TypInfo

Description

TTypeKinds defines a set of TTypeKind (see page 4760) values. It is used to select which component property types to use in various routines, such as GetPropInfo (see page 4717).

See Also

GetPropInfo (see page 4717)

TTypeKind (see page 4760)

46.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
BooleanIdents (see page 4774)	An array of string representations of true and false.
DotSep (see page 4774)	This is variable TypInfo.DotSep.

46.5.1 TypInfo.BooleanIdents Variable

An array of string representations of true and false.

Pascal

```
BooleanIdents: array [Boolean] of string = ('False', 'True');
```

C++

```
array [Boolean] of string BooleanIdents = ('False', 'True');
```

File

TypInfo

Description

The GetEnumName (see page 4705) routine is part of Delphi's RTTI (Run Time (see page 4297) Type Information). It returns a string representation of an enumerated type value. If that type is true or false, BooleanIdents is used internally.

See Also

GetEnumName (see page 4705)

46.5.2 TypInfo.DotSep Variable

Pascal

```
DotSep: string = '.';
```

C++

```
UnicodeString DotSep = '.';
```

File

TypInfo

Description

This is variable TypInfo.DotSep.

46.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
tkAny (see page 4775)	tkAny is a set that contains all values defined by the TTypeKind (see page 4760) enumeration.
tkMethods (see page 4775)	tkMethods is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent a method kind.
tkProperties (see page 4776)	tkProperties is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent types that can be published.

46.6.1 TypInfo.tkAny Constant

tkAny is a set that contains all values defined by the TTypeKind (see page 4760) enumeration.

Pascal

```
tkAny = [Low(TTypeKind)..High(TTypeKind)];
```

C++

```
tkAny = [Low(TTypeKind)..High(TTypeKind)];
```

File

TypInfo

Description

tkAny set is not particularly useful because it contains all the values defined by TTypeKind (see page 4760) enumeration.

It is primarily used by other more restricted sets, but can also be passed as a parameter to routines like GetPropInfo (see page 4717).

See Also

TTypeKinds (see page 4773)

tkMethods (see page 4775)

tkProperties (see page 4776)

46.6.2 TypInfo.tkMethods Constant

tkMethods is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent a method kind.

Pascal

```
tkMethods = [tkMethod];
```

C++

```
tkMethods = [tkMethod];
```

File

TypInfo

Description

tkMethods set can be used when you need to identify a type kind as being a method.

Use this constant in conjunction with routines such as GetPropInfo (see page 4717) that require a TTypeKind (see page 4760) set as a parameter.

See Also

TTypeKinds (see page 4773)

tkAny (see page 4775)

tkProperties (see page 4776)

46.6.3 TypInfo.tkProperties Constant

tkProperties is a set that contains values, defined by the TTypeKind (see page 4760) enumeration, that represent types that can be published.

Pascal

```
tkProperties = tkAny - tkMethods - [tkUnknown];
```

C++

```
tkProperties = tkAny - tkMethods - [tkUnknown];
```

File

TypInfo

Description

tkProperties is useful in cases when you need to select only the type kinds which represent data types that can be published in a TObject (see page 3354)-derived class.

See Also

TTypeKinds (see page 4773)

tkAny (see page 4775)

tkMethods (see page 4775)

47 ValEdit Namespace

This is namespace ValEdit.

Topics

Name	Description
Classes (see page 4778)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 4892)	The following table lists structs, records, enums in this documentation.
Types (see page 4894)	The following table lists types in this documentation.

Classes

	Name	Description
	TItemProp (see page 4778)	TItemProp configures how users can edit the item values in a value list editor.
	TValueListEditor (see page 4784)	TValueListEditor provides a simple way to edit string lists that contain name/value pairs.
	TValueListStrings (see page 4882)	This is class ValEdit.TValueListStrings.

Structs, Records, Enums

	Name	Description
	TDisplayOption (see page 4892)	TDisplayOption and TDisplayOptions (see page 4894) control the appearance of a value list editor.
	TKeyOption (see page 4893)	TKeyOption and TKeyOptions (see page 4895) indicate the response of a value list editor to certain keystrokes.

Types

Name	Description
TDisplayOptions (see page 4894)	TDisplayOptions and TDisplayOption (see page 4892) control the appearance of a value list editor.
TGetPickListEvent (see page 4895)	TGetPickListEvent is the type for event handlers that supply pick list values to a value list editor.
TItemProps (see page 4895)	This is type ValEdit.TItemProps.
TKeyOptions (see page 4895)	TKeyOptions and TKeyOption (see page 4893) indicate the response of a value list editor to certain keystrokes.
TOnValidateEvent (see page 4896)	TOnValidateEvent is the type for event handlers that validate the values a user types into a value list editor.

47.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TItemProp (see page 4778)	TItemProp configures how users can edit the item values in a value list editor.
	TValueListEditor (see page 4784)	TValueListEditor provides a simple way to edit string lists that contain name/value pairs.
	TValueListStrings (see page 4882)	This is class ValEdit.TValueListStrings.

47.1.1 TItemProp Class

TItemProp configures how users can edit the item values in a value list editor.

Class Hierarchy

Pascal

```
TItemProp = class(TPersistent);
```

C++

```
class TItemProp : public TPersistent;
```

File

ValEdit

Description

For each item that it allows users to edit, the TValueListEditor (see page 4784) component maintains a TItemProp object. This object's properties govern how users can edit the value in the value list editor.

TItemProp objects are created and owned by the value list editor that uses them to represent properties of item values (such as an edit mask or maximum length) or to supply a fixed pick list of values that users can assign to the item.

See Also

TValueListEditor (see page 4784)

47.1.1.1 TItemProp Members

The following tables list the members exposed by TItemProp.

Protected Methods

	Name	Description
	AssignTo (see page 4780)	Copies the properties of an object to a destination object.
	UpdateEdit (see page 4781)	This is UpdateEdit, a member of class TItemProp.

Public Methods

	Name	Description
	Create (see page 4779)	Creates an instance of TItemProp (see page 4778).
	Destroy (see page 4779)	Frees the memory associated with the TItemProp (see page 4778) object.
	HasPickList (see page 4781)	Indicates whether the PickList (see page 4783) property provides a static set of values for this item.

Published Properties

	Name	Description
	EditMask (see page 4781)	Restricts the value that can be entered for the associated item.
	EditStyle (see page 4782)	Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.
	KeyDesc (see page 4783)	Specifies the name of the item, which appears in the names column of the Value list editor.
	MaxLength (see page 4783)	Specifies the maximum number of characters that users can enter for the item's value.
	PickList (see page 4783)	Lists the items that appear in the drop-down pick list for the item.
	ReadOnly (see page 4784)	Indicates whether users can edit the item's value by typing in a new value.

47.1.1.2 TItemProp.Create Constructor

Creates an instance of TItemProp (see page 4778).

Pascal

```
constructor Create(AEditor: TValueListEditor);
```

C++

```
__fastcall TItemProp(TValueListEditor AEditor);
```

Description

Do not call Create directly in an application. TValueListEditor (see page 4784) creates TItemProp (see page 4778) instances as needed when you make assignments to its ItemProps property.

The AEditor parameter is the value list editor that creates the TItemProp (see page 4778) instance to represent the properties of one of its items.

See Also

ItemProps (see page 4821)

47.1.1.3 TItemProp.Destroy Destructor

Frees the memory associated with the TItemProp (see page 4778) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TItemProp();
```

Description

Do not call Destroy. The TValueListEditor (see page 4784) that owns this TItemProp (see page 4778) object destroys the object when it is no longer needed.

See Also

Create (see page 4779)

System::TObject::Free (see page 3372)

47.1.1.4 TItemProp Methods

The methods of the TItemProp class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 4780)	Copies the properties of an object to a destination object.
	UpdateEdit (see page 4781)	This is UpdateEdit, a member of class TItemProp.

Public Methods

	Name	Description
	HasPickList (see page 4781)	Indicates whether the PickList (see page 4783) property provides a static set of values for this item.

47.1.1.4.1 TItemProp.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign

EConvertError (see page 3919)

47.1.1.4.2 TItemProp.HasPickList Method

Indicates whether the PickList (see page 4783) property provides a static set of values for this item.

Pascal

```
function HasPickList: Boolean;
```

C++

```
__fastcall Boolean HasPickList();
```

Description

Call PickList (see page 4783) to determine whether this TItemProp (see page 4778) object supplies values using the PickList (see page 4783) property. HasPickList returns true if the PickList (see page 4783) property contains a nonempty list of values.

See Also

PickList (see page 4783)

47.1.1.4.3 TItemProp.UpdateEdit Method

Pascal

```
procedure UpdateEdit;
```

C++

```
__fastcall UpdateEdit();
```

Description

This is UpdateEdit, a member of class TItemProp.

47.1.1.5 TItemProp Properties

The properties of the TItemProp class are listed here.

Published Properties

	Name	Description
	EditMask (see page 4781)	Restricts the value that can be entered for the associated item.
	EditStyle (see page 4782)	Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.
	KeyDesc (see page 4783)	Specifies the name of the item, which appears in the names column of the Value list editor.
	MaxLength (see page 4783)	Specifies the maximum number of characters that users can enter for the item's value.
	PickList (see page 4783)	Lists the items that appear in the drop-down pick list for the item.
	ReadOnly (see page 4784)	Indicates whether users can edit the item's value by typing in a new value.

47.1.1.5.1 TItemProp.EditMask Property

Restricts the value that can be entered for the associated item.

Pascal

```
property EditMask: string;
```

C++

```
__property UnicodeString EditMask;
```

Description

Use EditMask to restrict the characters a user can enter. If the user attempts to enter a character that is not valid, the character is not accepted. Validation using the EditMask property is performed on a character-by-character basis.

A mask consists of three fields with semicolons separating the fields. The first part of the mask is the mask itself. The second part is the character that determines whether the literal characters of a mask are included as part of the data. The third part of the mask is the character used to represent unentered characters in the mask.

Setting EditMask to an empty string removes the mask.

For more information on using edit masks, see the TEditMask type.

See Also

Values (see page 4835)

OnSetEditText

47.1.1.5.2 TItemProp.EditStyle Property

Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.

Pascal

```
property EditStyle: TEditStyle;
```

C++

```
__property TEditStyle EditStyle;
```

Description

Set EditStyle to specify whether the cell in the value list editor that contains the associated value should allow users to drop down a pick list or to launch a dialog to edit the value.

When EditStyle is esSimple, the value cell is a simple edit box that lets users edit the associated value directly (unless the ReadOnly (see page 4784) property is true).

When EditStyle is esEllipsis, the value cell contains an ellipsis button that users can click to generate an OnEditButtonClick event. Typically, applications use this event to launch a dialog that edits the value.

When EditStyle is esPickList, the value cell contains a drop-down arrow that users can click to display a list of values from which to select. This value must be supplied by the PickList (see page 4783) property or in an OnGetPickList event handler (or supplied by the PickList (see page 4783) property and modified in an OnGetPickList event handler).

See Also

PickList (see page 4783)

OnGetPickList (see page 4860)

OnEditButtonClick (see page 4849)

ReadOnly (see page 4784)

KeyOptions (see page 4821)

DisplayOptions (see page 4812)

47.1.1.5.3 TItemProp.KeyDesc Property

Specifies the name of the item, which appears in the names column of the Value list editor.

Pascal

```
property KeyDesc: string;
```

C++

```
__property UnicodeString KeyDesc;
```

Description

Set KeyDesc to specify a name for this item. This name appears in the names column of the Value list editor.

If ItemProp is not set, then the name that appears in the key column of the Value list editor is the corresponding value of the Keys property.

See Also

Keys (see page 4822)

47.1.1.5.4 TItemProp.MaxLength Property

Specifies the maximum number of characters that users can enter for the item's value.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be typed when assigning a value to the item. A value of 0 indicates that there is no application-defined limit on the length.

Note: Setting MaxLength will not truncate the existing value, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered.

See Also

Values (see page 4835)

EditMask (see page 4781)

47.1.1.5.5 TItemProp.PickList Property

Lists the items that appear in the drop-down pick list for the item.

Pascal

```
property PickList: TStrings;
```

C++

```
__property TStrings PickList;
```

Description

Use PickList to supply the values that appear in the drop-down pick list for the associated item. PickList lets you supply a static set of items that appear in the drop-down list for the associated item when EditStyle (see page 4782) is esPickList. These items can be subsequently modified by an OnGetPickList event handler.

Note: PickList is only used when the EditStyle (see page 4782) property is esPickList. If EditStyle (see page 4782) is esPickList, and PickList does list a set of values, you must supply an OnGetPickList event handler to supply the items.

See Also

EditStyle (see page 4782)

OnGetPickList (see page 4860)

DropDownRows (see page 4816)

47.1.1.5.6 TItemProp.ReadOnly Property

Indicates whether users can edit the item's value by typing in a new value.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set ReadOnly to true to prevent users from typing in a new value for the associated item. For example, to force users to select item values only from a pick list, you can set the EditStyle (see page 4782) to esPickList and set ReadOnly to true. Similarly, to force users to enter values only using a property editor, you can set EditStyle (see page 4782) to esEllipsis and set ReadOnly to true.

See Also

EditStyle (see page 4782)

47.1.2 TValueListEditor Class

TValueListEditor provides a simple way to edit string lists that contain name/value pairs.

Class Hierarchy

Pascal

```
TValueListEditor = class(TCustomDrawGrid);
```

C++

```
class TValueListEditor : public TCustomDrawGrid;
```

File

ValEdit

Description

Use TValueListEditor to let users edit string lists that consist of strings with the form Name=Value. By default, the names appear

in a column headed "Key", and the values in a column headed "Value", although you can customize these labels. You can control whether users can select, add, or edit the strings in the Key column. For each entry in the Value column, you can let users edit the string, supply a drop-down list from which they can select values, or provide a dialog in which they can edit values.

TStrings

Value List Editors (VCL Only)

47.1.2.1 TValueListEditor Members

The following tables list the members exposed by TValueListEditor.

Protected Methods

	Name	Description
	AdjustColWidths (see page 4789)	This is AdjustColWidths, a member of class TValueListEditor.
	AdjustRowCount (see page 4789)	This is AdjustRowCount, a member of class TValueListEditor.
	CanEditModify (see page 4790)	Indicates whether the current cell in the grid can be edited.
	ColWidthsChanged (see page 4790)	Responds when the column widths change.
	CreateEditor (see page 4790)	Creates the inplace editor control.
	CreateWnd (see page 4791)	Creates the underlying window.
	DoExit (see page 4792)	Hides the inplace editor when selection moves to another control in a form.
	DoOnValidate (see page 4792)	This is DoOnValidate, a member of class TValueListEditor.
	DrawCell (see page 4792)	Generates an OnDrawCell event.
	EditListGetItems (see page 4793)	This is EditListGetItems, a member of class TValueListEditor.
	GetCell (see page 4794)	This is GetCell, a member of class TValueListEditor.
	GetColCount (see page 4794)	This is GetColCount, a member of class TValueListEditor.
	GetEditLimit (see page 4794)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 4794)	Generates an OnGetEditMask event.
	GetEditStyle (see page 4795)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 4795)	This is GetEditText, a member of class TValueListEditor.
	GetPickList (see page 4795)	This is GetPickList, a member of class TValueListEditor.
	GetRowCount (see page 4795)	This is GetRowCount, a member of class TValueListEditor.
	IsEmptyRow (see page 4796)	This is IsEmptyRow, a member of class TValueListEditor.
	KeyDown (see page 4797)	Provides special processing when the user presses a key.
	MouseDown (see page 4797)	Provides special processing when the user presses a mouse button.
	Resize (see page 4798)	Respond to control resize.
	RowMoved (see page 4799)	Generates an OnRowMoved event.
	SelectCell (see page 4799)	Determines whether a particular cell in the grid can be selected.
	SetCell (see page 4799)	This is SetCell, a member of class TValueListEditor.
	SetEditText (see page 4800)	This is SetEditText, a member of class TValueListEditor.
	SetStrings (see page 4800)	This is SetStrings, a member of class TValueListEditor.
	StringsChanging (see page 4800)	This is StringsChanging, a member of class TValueListEditor.
	TitleCaptionsStored (see page 4800)	This is TitleCaptionsStored, a member of class TValueListEditor.

Protected Properties

	Name	Description
	EditList (see page 4817)	This is EditList, a member of class TValueListEditor.

Public Methods

	Name	Description
	Create (see page 4788)	Creates and initializes new TValueListEditor (see page 4784) object.
	DeleteRow (see page 4791)	Deletes a row in the value list editor and a corresponding string from the associated TStrings object.
	Destroy (see page 4788)	Frees the memory associated with the TValueListEditor (see page 4784) object.
	FindRow (see page 4793)	Locates the row that corresponds to a specified key name.
	InsertRow (see page 4796)	Inserts a row in the value list editor and a corresponding string into the associated TStrings object.
	Refresh (see page 4798)	Updates the display to reflect the current value of the Strings (see page 4834) property.
	RestoreCurrentRow (see page 4798)	Undoes all edits to the current row.

Public Properties

	Name	Description
	Cells (see page 4806)	Lists the strings for each cell in the editor.
	ColCount (see page 4807)	Indicates the number of columns in the value list editor.
	ItemProps (see page 4821)	Specifies various constraints on the way users can enter a value for each item in the list.
	Keys (see page 4822)	Lists the strings for each cell in the name (key) column.
	RowCount (see page 4831)	Indicates the number of rows in the value list editor.
	Values (see page 4835)	Lists the strings for each value from the value column.
	VisibleColCount (see page 4837)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 4838)	Indicates the number of scrollable rows visible in the grid.

Published Events

	Name	Description
	OnClick (see page 4839)	Occurs when the user clicks the control.
	OnContextPopup (see page 4841)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 4841)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 4842)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 4845)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 4848)	Occurs when a cell in the grid needs to be drawn.
	OnEditButtonClick (see page 4849)	Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.
	OnEndDock (see page 4850)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 4850)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 4851)	Occurs when a control receives the input focus.
	OnExit (see page 4854)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 4858)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 4859)	Occurs when the in-place editor requests the value of a cell.
	OnGetPickList (see page 4860)	Supplies a pick list for values associated with a particular key.
	OnKeyDown (see page 4861)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 4864)	Occurs when a key is pressed.
	OnKeyUp (see page 4865)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 4867)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 4868)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 4870)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 4871)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 4871)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 4873)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 4875)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 4876)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 4876)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 4877)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 4879)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 4879)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 4880)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnStringsChange (see page 4881)	Occurs immediately after the names or values in the string list change.
	OnStringsChanging (see page 4881)	Occurs immediately before the names or values in the string list change.
	OnTopLeftChanged (see page 4882)	Occurs immediately after the TopRow property or the LeftCol property changes.
	OnValidate (see page 4882)	Occurs when focus shifts away from a cell in the value list editor.

Published Properties

	Name	Description
	Align (see page 4802)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4805)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 4806)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 4806)	Determines whether a single line border is drawn around the grid.
	Color (see page 4807)	Specifies the background color of the control.
	Constraints (see page 4808)	Specifies the size constraints for the control.
	Ctl3D (see page 4809)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 4809)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 4811)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 4811)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DisplayOptions (see page 4812)	Controls aspects of the value list editor's appearance.
	DoubleBuffered (see page 4812)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 4814)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 4814)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 4814)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownRows (see page 4816)	Limits the length of the drop-down list that appears for values that use a pick list.
	Enabled (see page 4817)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 4817)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 4818)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	Font (see page 4818)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 4819)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	KeyOptions (see page 4821)	Controls the way the value list editor responds to user keystrokes.
	Options (see page 4822)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 4824)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 4824)	Determines where a control looks for its color information.
	ParentCtl3D (see page 4825)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 4825)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 4825)	Determines where a control looks for its font information.
	ParentShowHint (see page 4826)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4826)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 4832)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 4832)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Strings (see page 4834)	Provides access to the string list that is being edited.

	TabOrder (see page 4834)	Indicates the position of the control in its parent's tab order.
	TitleCaptions (see page 4835)	Specifies the captions that label the columns of the value list editor.
	Visible (see page 4836)	Determines whether the component appears onscreen.

47.1.2.2 TValueListEditor.Create Constructor

Creates and initializes new TValueListEditor (see page 4784) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TValueListEditor(TComponent * AOwner);
```

Description

Call Create to create a value list editor component at runtime. TValueListEditor (see page 4784) components added to forms at design time are created automatically.

The AOwner parameter specifies another component (typically the form) that is responsible for freeing the TValueListEditor (see page 4784) instance.

See Also

Owner

47.1.2.3 TValueListEditor.Destroy Destructor

Frees the memory associated with the TValueListEditor (see page 4784) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TValueListEditor();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the value list editor reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free (see page 3372)

47.1.2.4 TValueListEditor Methods

The methods of the TValueListEditor class are listed here.

Protected Methods

	Name	Description
	AdjustColWidths (see page 4789)	This is AdjustColWidths, a member of class TValueListEditor.
	AdjustRowCount (see page 4789)	This is AdjustRowCount, a member of class TValueListEditor.
	CanEditModify (see page 4790)	Indicates whether the current cell in the grid can be edited.
	ColWidthsChanged (see page 4790)	Responds when the column widths change.
	CreateEditor (see page 4790)	Creates the inplace editor control.

	CreateWnd (see page 4791)	Creates the underlying window.
	DoExit (see page 4792)	Hides the inplace editor when selection moves to another control in a form.
	DoOnValidate (see page 4792)	This is DoOnValidate, a member of class TValueListEditor.
	DrawCell (see page 4792)	Generates an OnDrawCell event.
	EditListGetItems (see page 4793)	This is EditListGetItems, a member of class TValueListEditor.
	GetCell (see page 4794)	This is GetCell, a member of class TValueListEditor.
	GetColCount (see page 4794)	This is GetColCount, a member of class TValueListEditor.
	GetEditLimit (see page 4794)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 4794)	Generates an OnGetEditMask event.
	GetEditStyle (see page 4795)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 4795)	This is GetEditText, a member of class TValueListEditor.
	GetPickList (see page 4795)	This is GetPickList, a member of class TValueListEditor.
	GetRowCount (see page 4795)	This is GetRowCount, a member of class TValueListEditor.
	IsEmptyRow (see page 4796)	This is IsEmptyRow, a member of class TValueListEditor.
	KeyDown (see page 4797)	Provides special processing when the user presses a key.
	MouseDown (see page 4797)	Provides special processing when the user presses a mouse button.
	Resize (see page 4798)	Respond to control resize.
	RowMoved (see page 4799)	Generates an OnRowMoved event.
	SelectCell (see page 4799)	Determines whether a particular cell in the grid can be selected.
	SetCell (see page 4799)	This is SetCell, a member of class TValueListEditor.
	SetEditText (see page 4800)	This is SetEditText, a member of class TValueListEditor.
	SetStrings (see page 4800)	This is SetStrings, a member of class TValueListEditor.
	StringsChanging (see page 4800)	This is StringsChanging, a member of class TValueListEditor.
	TitleCaptionsStored (see page 4800)	This is TitleCaptionsStored, a member of class TValueListEditor.

Public Methods

	Name	Description
	DeleteRow (see page 4791)	Deletes a row in the value list editor and a corresponding string from the associated TStrings object.
	FindRow (see page 4793)	Locates the row that corresponds to a specified key name.
	InsertRow (see page 4796)	Inserts a row in the value list editor and a corresponding string into the associated TStrings object.
	Refresh (see page 4798)	Updates the display to reflect the current value of the Strings (see page 4834) property.
	RestoreCurrentRow (see page 4798)	Undoes all edits to the current row.

47.1.2.4.1 TValueListEditor.AdjustColWidths Method

Pascal

```
procedure AdjustColWidths; virtual;
```

C++

```
virtual __fastcall AdjustColWidths();
```

Description

This is AdjustColWidths, a member of class TValueListEditor.

47.1.2.4.2 TValueListEditor.AdjustRowCount Method

Pascal

```
procedure AdjustRowCount; virtual;
```

C++

```
virtual __fastcall AdjustRowCount();
```

Description

This is AdjustRowCount, a member of class TValueListEditor.

47.1.2.4.3 TValueListEditor.CanEditModify Method

Indicates whether the current cell in the grid can be edited.

Pascal

```
function CanEditModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean CanEditModify();
```

Description

Grid components use CanEditModify internally to determine whether to allow the user to edit the current cell. CanEditModify returns true unless the inplace editor has disallowed editing for the cell.

See Also

CanEditShow

InplaceEditor

47.1.2.4.4 TValueListEditor.ColWidthsChanged Method

Responds when the column widths change.

Pascal

```
procedure ColWidthsChanged; override;
```

C++

```
virtual __fastcall ColWidthsChanged();
```

Description

ColWidthsChanged is called immediately after the column widths change. The change can result from setting the ColWidths property, from setting the DefaultColWidth property, from moving one of the columns, or from resizing the columns with the mouse.

ColWidthsChanged adjusts the scroll bar and the position of the inplace editor to take into account the new column size and positions of the columns.

See Also

ColWidths

DefaultColWidth

InplaceEditor

ScrollBars

47.1.2.4.5 TValueListEditor.CreateEditor Method

Creates the inplace editor control.

Pascal

```
function CreateEditor: TInplaceEdit; override;
```

C++

```
virtual __fastcall TInplaceEdit CreateEditor();
```

Description

Grid controls call CreateEditor internally the first time the grid goes into edit mode. CreateEditor is exposed as a protected method so that descendants of TCustomGrid can substitute a specialized descendant of TInplaceEdit to handle cell editing.

See Also

EditorMode

InplaceEditor

ShowEditor

47.1.2.4.6 TValueListEditor.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

47.1.2.4.7 TValueListEditor.DeleteRow Method

Deletes a row in the value list editor and a corresponding string from the associated TStrings object.

Pascal

```
procedure DeleteRow(ARow: Integer); override;
```

C++

```
virtual __fastcall DeleteRow(int ARow);
```

Description

Call DeleteRow to remove the row specified by the ARow parameter. Delete (see page 3552) removes the corresponding string from the TStrings object being edited and updates the display.

ARow must be the index of a row that displays a name/value pair. That is, it can't be less than 0 or greater than the number of

rows. If DisplayOptions (see page 4812) includes doColumnTitles, ARow can't be 0, because that is the title row, not a name/value pair in the associated TStrings object.

Note: DeleteRow deletes the specified row regardless of the value of KeyOptions (see page 4821). The keyDelete member of KeyOptions (see page 4821) controls only whether the user can delete a row by pressing the Delete (see page 3552) key.

See Also

Cells (see page 4806)

Strings (see page 4834)

KeyOptions (see page 4821)

DisplayOptions (see page 4812)

47.1.2.4.8 TValueListEditor.DoExit Method

Hides the inplace editor when selection moves to another control in a form.

Pascal

```
procedure DoExit; override;
```

C++

```
virtual __fastcall DoExit();
```

Description

After calling the inherited method, which generates an OnExit event, DoExit hides the inplace editor unless the Options property includes goAlwaysShowEditor.

See Also

HideEditor

Options

OnExit

47.1.2.4.9 TValueListEditor.DoOnValidate Method

Pascal

```
procedure DoOnValidate; virtual;
```

C++

```
virtual __fastcall DoOnValidate();
```

Description

This is DoOnValidate, a member of class TValueListEditor.

47.1.2.4.10 TValueListEditor.DrawCell Method

Generates an OnDrawCell event.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell is called automatically whenever a cell in the grid is drawn. If the DefaultDrawing property is true, the background of the cell is painted before DrawCell is called, and the 3D effects of the fixed cells or the focus rectangle around the focused cell are drawn after DrawCell. Descendants of TCustomDrawGrid can override this method to draw the contents of the cell or to block the OnDrawCell event.

See Also

DefaultDrawing

FixedCols

FixedRows

OnDrawCell

47.1.2.4.11 TValueListEditor.EditListGetItems Method

Pascal

```
procedure EditListGetItems(ACol: Integer; ARow: Integer; Items: TStrings);
```

C++

```
__fastcall EditListGetItems(int ACol, int ARow, TStrings Items);
```

Description

This is EditListGetItems, a member of class TValueListEditor.

47.1.2.4.12 TValueListEditor.FindRow Method

Locates the row that corresponds to a specified key name.

Pascal

```
function FindRow(const KeyName: string; var Row: Integer): Boolean;
```

C++

```
__fastcall Boolean FindRow(const UnicodeString KeyName, int Row);
```

Description

Call FindRow to locate the row in the value list editor that has the value specified by KeyName in the first column. This corresponds to a name/value pair in the string list where the name part is KeyName.

If a row in the value list editor has the specified key name, FindRow returns true and the Row parameter returns the index of the first row found with the specified name. If the specified name does not correspond to any of the rows in the value list editor, FindRow returns false.

See Also

Keys (see page 4822)

47.1.2.4.13 TValueListEditor.GetCell Method

Pascal

```
function GetCell(ACol: Integer; ARow: Integer): string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetCell(int ACol, int ARow);
```

Description

This is GetCell, a member of class TValueListEditor.

47.1.2.4.14 TValueListEditor.GetColCount Method

Pascal

```
function GetColCount: Integer;
```

C++

```
__fastcall int GetColCount();
```

Description

This is GetColCount, a member of class TValueListEditor.

47.1.2.4.15 TValueListEditor.GetEditLimit Method

Provides the interface for a method that limits the number of characters the user can type into cells.

Pascal

```
function GetEditLimit: Integer; override;
```

C++

```
virtual __fastcall int GetEditLimit();
```

Description

The inplace editor calls GetEditLimit to determine if a limit should be placed on the number of characters a user can type into a cell. GetEditLimit sets no limits. Descendants of TCustomGrid override this method to limit the text for certain cells.

See Also

InplaceEditor

47.1.2.4.16 TValueListEditor.GetEditMask Method

Generates an OnGetEditMask event.

Pascal

```
function GetEditMask(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall UnicodeString GetEditMask(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditMask to obtain any input mask associated with the cell specified by the ACol and ARow parameters. GetEditMask returns the Value parameter set by the OnGetEditMask event handler. If there is no OnGetEditMask

event handler, GetEditMask returns an empty string, indicating that there is no edit mask.

See Also

OnGetEditMask

47.1.2.4.17 TValueListEditor.GetEditStyle Method

Indicates whether a specified cell has an ellipsis button or drop-down arrow.

Pascal

```
function GetEditStyle(ACol: Longint; ARow: Longint): TEditStyle; override;
```

C++

```
virtual __fastcall TEditStyle GetEditStyle(Longint ACol, Longint ARow);
```

Description

GetEditStyle indicates whether the specified cell can only be edited directly (esSimple), whether it has an ellipsis button that users can click to launch an editor for modifying field values (esEllipsis), or whether it has a drop-down arrow that users can click to display a pick list of possible values (esPickList).

ACol is the column that contains the cell. ARow is the row that contains the cell.

In TCustomGrid, GetEditStyle always returns esSimple, indicating that there is no ellipsis button or drop-down arrow. Descendant classes can override this methods if they provide a way to add pick lists or ellipsis buttons to cells.

47.1.2.4.18 TValueListEditor.GetEditText Method

Pascal

```
function GetEditText(ACol: Integer; ARow: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString GetEditText(int ACol, int ARow);
```

Description

This is GetEditText, a member of class TValueListEditor.

47.1.2.4.19 TValueListEditor.GetPickList Method

Pascal

```
function GetPickList(Values: TStrings; ClearFirst: Boolean = True): Boolean;
```

C++

```
__fastcall Boolean GetPickList(TStrings Values, Boolean ClearFirst = True);
```

Description

This is GetPickList, a member of class TValueListEditor.

47.1.2.4.20 TValueListEditor.GetRowCount Method

Pascal

```
function GetRowCount: Integer;
```

C++

```
__fastcall int GetRowCount();
```

Description

This is GetRowCount, a member of class TValueListEditor.

47.1.2.4.21 TValueListEditor.InsertRow Method

Inserts a row in the value list editor and a corresponding string into the associated TStrings object.

Pascal

```
function InsertRow(const KeyName: string; const Value: string; Append: Boolean): Integer;
```

C++

```
__fastcall int InsertRow(const UnicodeString KeyName, const UnicodeString Value, Boolean
Append);
```

Description

Call InsertRow to add a name/value pair to the value list editor and the TStrings object it is editing.

InsertRow adds a string of the form

`KeyName=Value`

to the Strings (see page 4834) property and updates the display to reflect the change.

If the current row of the value list editor is empty (has no name or value portion), InsertRow assigns the new KeyName and Value to the current row. Otherwise, if the Append (see page 3520) parameter is true, the new string appears after the currently selected row, while if Append (see page 3520) is false, the new string appears before the currently selected row.

Note: InsertRow inserts the specified row regardless of the value of KeyOptions (see page 4821). The keyAdd member of KeyOptions (see page 4821) controls only whether the user can add new rows by pressing the Insert (see page 3601) key or navigating past the last row.

See Also

Cells (see page 4806)

Strings (see page 4834)

KeyOptions (see page 4821)

DisplayOptions (see page 4812)

47.1.2.4.22 TValueListEditor.IsEmptyRow Method

Pascal

```
function IsEmptyRow: Boolean;
```

C++

```
__fastcall Boolean IsEmptyRow();
```

Description

This is IsEmptyRow, a member of class TValueListEditor.

47.1.2.4.23 TValueListEditor.KeyDown Method

Provides special processing when the user presses a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

After generating an OnKeyDown event, KeyDown calls CanGridAcceptKey to screen out problematic key combinations. KeyDown moves to the appropriate cell in response to navigational key combinations, or sets the EditorMode property to true when the user presses F2.

See Also

CanGridAcceptKey

EditorMode

KeyPress

OnKeyDown

47.1.2.4.24 TValueListEditor.MouseDown Method

Provides special processing when the user presses a mouse button.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseDown hides the editor window so that it can move selection to the cell that receives the mouse click. If the mouse lands in the hot region for beginning a move or resize of a row or column, MouseDown starts the move or resize, and provides visual feedback by changing the cursor. If the editor window was hidden, it is brought back up in its new location. Finally, MouseDown generates an OnMouseDown event.

OnMouseDown

47.1.2.4.25 TValueListEditor.Refresh Method

Updates the display to reflect the current value of the Strings (see page 4834) property.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh to ensure that the value list editor accurately reflects the value of the Strings (see page 4834) property. For example, call Refresh after programmatically editing the value of the Strings (see page 4834) property.

See Also

RestoreCurrentRow (see page 4798)

Repaint

Strings (see page 4834)

47.1.2.4.26 TValueListEditor.Resize Method

Respond to control resize.

Pascal

```
procedure Resize; override;
```

C++

```
virtual __fastcall Resize();
```

Description

Resize is called automatically immediately after the control's dimensions change. As implemented in TControl, Resize calls the control's OnResize event handler if it is assigned.

See Also

OnResize

47.1.2.4.27 TValueListEditor.RestoreCurrentRow Method

Undoes all edits to the current row.

Pascal

```
function RestoreCurrentRow: Boolean;
```

C++

```
__fastcall Boolean RestoreCurrentRow();
```

Description

Call RestoreCurrentRow to back out edits to the current cell in the value list editor. RestoreCurrentRow backs out edits to the current cell if it is still in edit mode, or deletes a newly inserted row.

The user can accomplish the same effect by pressing the Escape key.

See Also

Cells (see page 4806)

InsertRow (see page 4796)

47.1.2.4.28 TValueListEditor.RowMoved Method

Generates an OnRowMoved event.

Pascal

```
procedure RowMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall RowMoved(Longint FromIndex, Longint ToIndex);
```

Description

RowMoved is called immediately after a row in the grid changes position. It overrides the inherited method to generate an OnRowMoved event. Descendants of TCustomDrawGrid can override this method to make internal adjustments or to block the OnRowMoved event.

See Also

OnRowMoved

47.1.2.4.29 TValueListEditor.SelectCell Method

Determines whether a particular cell in the grid can be selected.

Pascal

```
function SelectCell(ACol: Longint; ARow: Longint): Boolean; override;
```

C++

```
virtual __fastcall Boolean SelectCell(Longint ACol, Longint ARow);
```

Description

Grid controls call SelectCell internally before attempting to move selection to a the cell identified by the ACol and ARow parameters. ACol and ARow are the column and row indexes for the cell, where the first column has index 0, and the top row has index 0.

SelectCell generates an OnSelectCell event. This method then returns true, unless the OnSelectCell event handler indicates that the cell should not be selected. Descendants of TCustomDrawGrid can override this method to check the properties of the information displayed in the cell or block the OnSelectCell event.

See Also

OnSelectCell

47.1.2.4.30 TValueListEditor.SetCell Method

Pascal

```
procedure SetCell(ACol: Integer; ARow: Integer; const Value: string); virtual;
```

C++

```
virtual __fastcall SetCell(int ACol, int ARow, const UnicodeString Value);
```

Description

This is SetCell, a member of class TValueListEditor.

47.1.2.4.31 TValueListEditor.SetEditText Method

Pascal

```
procedure SetEditText(ACol: Integer; ARow: Integer; const Value: string); override;
```

C++

```
virtual __fastcall SetEditText(int ACol, int ARow, const UnicodeString Value);
```

Description

This is SetEditText, a member of class TValueListEditor.

47.1.2.4.32 TValueListEditor.SetStrings Method

Pascal

```
procedure SetStrings(const Value: TStrings); virtual;
```

C++

```
virtual __fastcall SetStrings(const TStrings Value);
```

Description

This is SetStrings, a member of class TValueListEditor.

47.1.2.4.33 TValueListEditor.StringsChanging Method

Pascal

```
procedure StringsChanging; dynamic;
```

C++

```
__fastcall StringsChanging();
```

Description

This is StringsChanging, a member of class TValueListEditor.

47.1.2.4.34 TValueListEditor.TitleCaptionsStored Method

Pascal

```
function TitleCaptionsStored: Boolean;
```

C++

```
__fastcall Boolean TitleCaptionsStored();
```

Description

This is TitleCaptionsStored, a member of class TValueListEditor.

47.1.2.5 TValueListEditor Properties

The properties of the TValueListEditor class are listed here.

Protected Properties

	Name	Description
R	EditList (see page 4817)	This is EditList, a member of class TValueListEditor.

Public Properties

	Name	Description
	Cells (see page 4806)	Lists the strings for each cell in the editor.
R	ColCount (see page 4807)	Indicates the number of columns in the value list editor.
	ItemProps (see page 4821)	Specifies various constraints on the way users can enter a value for each item in the list.
	Keys (see page 4822)	Lists the strings for each cell in the name (key) column.
R	RowCount (see page 4831)	Indicates the number of rows in the value list editor.
	Values (see page 4835)	Lists the strings for each value from the value column.
	VisibleColCount (see page 4837)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 4838)	Indicates the number of scrollable rows visible in the grid.

Published Properties

	Name	Description
	Align (see page 4802)	Determines how the control aligns within its container (parent control).
	Anchors (see page 4805)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 4806)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 4806)	Determines whether a single line border is drawn around the grid.
	Color (see page 4807)	Specifies the background color of the control.
	Constraints (see page 4808)	Specifies the size constraints for the control.
	Ctl3D (see page 4809)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 4809)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 4811)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 4811)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DisplayOptions (see page 4812)	Controls aspects of the value list editor's appearance.
	DoubleBuffered (see page 4812)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 4814)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 4814)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 4814)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownRows (see page 4816)	Limits the length of the drop-down list that appears for values that use a pick list.
	Enabled (see page 4817)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 4817)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 4818)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	Font (see page 4818)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 4819)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	KeyOptions (see page 4821)	Controls the way the value list editor responds to user keystrokes.
	Options (see page 4822)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 4824)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 4824)	Determines where a control looks for its color information.
	ParentCtl3D (see page 4825)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 4825)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 4825)	Determines where a control looks for its font information.
	ParentShowHint (see page 4826)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 4826)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 4832)	Specifies whether the grid includes horizontal and vertical scroll bars.

	ShowHint (see page 4832)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Strings (see page 4834)	Provides access to the string list that is being edited.
	TabOrder (see page 4834)	Indicates the position of the control in its parent's tab order.
	TitleCaptions (see page 4835)	Specifies the captions that label the columns of the value list editor.
	Visible (see page 4836)	Determines whether the component appears onscreen.

47.1.2.5.1 TValueListEditor.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);
```

```
  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
```

```
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;

Anchors

47.1.2.5.2 TValueListEditor.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

47.1.2.5.3 TValueListEditor.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

47.1.2.5.4 TValueListEditor.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle;
```

C++

```
__property BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

47.1.2.5.5 TValueListEditor.Cells Property

Lists the strings for each cell in the editor.

Pascal

```
property Cells [ACol, ARow: Integer]: string;
```

C++

```
__property UnicodeString Cells[int ACol, ARow];
```

Description

Use Cells to access the string in a particular cell. ACol is the column coordinate of the cell, and ARow is the row coordinate of the cell. ACol can be 0 (for the name column) or 1 (for the value column). ARow can range from 0 (for the title row) to the number of strings in the associated TStrings descendant.

To access the strings in the name column, use the Keys (see page 4822) property instead. To access the strings in the value column, use the Values (see page 4835) property instead. To access the underlying string list, use the Strings (see page 4834) property.

See Also

Keys (see page 4822)

Values (see page 4835)

Strings (see page 4834)

47.1.2.5.6 TValueListEditor.ColCount Property

Indicates the number of columns in the value list editor.

Pascal

```
property ColCount;
```

C++

```
__property ColCount;
```

Description

TValueListEditor (see page 4784) redeclares the ColCount property, which it inherits from TCustomGrid, to change it to a read-only property. The value of ColCount is always 2 plus the number of fixed columns, because the value list editor is designed to display only the name and value of the strings in the associated string list.

See Also

Cells (see page 4806)

RowCount (see page 4831)

FixedCols

47.1.2.5.7 TValueListEditor.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

47.1.2.5.8 TValueListEditor.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

47.1.2.5.9 TValueListEditor.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

47.1.2.5.10 TValueListEditor.DefaultColWidth Property

Determines the width (in pixels) of all columns that have not been explicitly resized.

Pascal

```
property DefaultColWidth;
```

C++

```
__property DefaultColWidth;
```

Description

Set DefaultColWidth to change the size of all columns in the grid. When DefaultColWidth is set, columns that have been resized using the mouse or by setting the ColWidths property are given the DefaultColWidth as well.

When new columns are added to the grid using the ColCount property, they are created with a width of DefaultColWidth.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
```

```
to values the cause the button click to do something.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (DrawGrid1->DefaultColWidth > 90)
    DrawGrid1->GridLineWidth = 2;
  else
    DrawGrid1->GridLineWidth = 1;
}

void __fastcall TForm1::DrawGrid1DrawCell(TObject *Sender, int ACol, int ARow, TRect &Rect,
          TGridDrawState State)
{
  int index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
  }
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow, bool
&CanSelect)

{
  CanSelect = True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
```

```
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

DefaultRowHeight

47.1.2.5.11 TValueListEditor.DefaultDrawing Property

Determines whether the Cells are painted when the grid is drawn.

Pascal

```
property DefaultDrawing;
```

C++

```
__property DefaultDrawing;
```

Description

Set DefaultDrawing to true to have the grid automatically paint the cells in the grid, including adding the background color, the 3-D effects on the fixed cells, and the focus rectangle around the selected cell. Set DefaultDrawing to false to skip the painting of the cells when the grid is drawn.

When DefaultDrawing is false, the cells should be painted using the DrawCell method. For TCustomGrid, DrawCell is an abstract method. Descendants of TCustomGrid use DrawCell to provide their own customized drawing code, or to generate an OnDrawCell event.

DrawCell

OnDrawCell

47.1.2.5.12 TValueListEditor.DefaultRowHeight Property

Specifies the height (in pixels) of all rows that have not been explicitly resized.

Pascal

```
property DefaultRowHeight;
```

C++

```
__property DefaultRowHeight;
```

Description

Set DefaultRowHeight to change the size of all rows in the grid. When DefaultRowHeight is set, rows that have been resized using the mouse or by setting the RowHeights property are given the DefaultRowHeight as well.

When new rows are added to the grid using the RowCount property, they are created with a height of DefaultRowHeight.

DefaultColWidth

RowCount

RowHeights

47.1.2.5.13 TValueListEditor.DisplayOptions Property

Controls aspects of the value list editor's appearance.

Pascal

```
property DisplayOptions: TDisplayOptions;
```

C++

```
__property TDisplayOptions DisplayOptions;
```

Description

Use DisplayOptions to control whether titles appear at the top of the columns in the value list editor and how the control responds when it is resized.

See Also

KeyOptions (see page 4821)

Options

TitleCaptions (see page 4835)

47.1.2.5.14 TValueListEditor.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
```

```
    Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
```

```
      end;
    end;
  end;
```

47.1.2.5.15 TValueListEditor.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

47.1.2.5.16 TValueListEditor.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

47.1.2.5.17 TValueListEditor.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
```

```
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

47.1.2.5.18 TValueListEditor.DropDownRows Property

Limits the length of the drop-down list that appears for values that use a pick list.

Pascal

```
property DropDownRows: Integer;
```

C++

```
__property int DropDownRows;
```

Description

Use DropDownRows to indicate the maximum height of the drop-down list that appears when the user clicks the drop-down button on values that have a pick list. DropDownRows is an upper limit: if the pick list has fewer entries that DropDownRows, the drop-down list includes only a line for every item in the list.

DropDownRows is ignored for values that do not have a pick list. To provide a value in the value list editor with a drop-down button and pick list, you do either of the following:

For the appropriate entry in the ItemProps (see page 4821) property, set the EditStyle property to esPickList and set the PickList property to the list of items.

Write (see page 3707) an OnGetPickList (see page 4860) event handler that supplies the items in the list.

See Also

OnGetPickList (see page 4860)

Values (see page 4835)

47.1.2.5.19 TValueListEditor.EditList Property

Pascal

```
property EditList: TInplaceEditList;
```

C++

```
__property TInplaceEditList EditList;
```

Description

This is EditList, a member of class TValueListEditor.

47.1.2.5.20 TValueListEditor.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to False. Some disabled controls appear dimmed (for example: buttons, check boxes, labels), while others (container controls) simply lose their functionality without changing their appearance. If Enabled is set to False, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to True.

Note: This property applies to all TControl descendants.

47.1.2.5.21 TValueListEditor.FixedColor Property

Specifies the background color of the fixed rows and columns in the grid.

Pascal

```
property FixedColor;
```

C++

```
__property FixedColor;
```

Description

Set FixedColor to specify the color for the nonscrolling cells in the grid. The scrolling region of the grid is drawn using the Color property.

See Also

Color

FixedCols

FixedRows

47.1.2.5.22 TValueListEditor.FixedCols Property

Specifies the number of columns on the left of the grid that cannot be scrolled.

Pascal

```
property FixedCols;
```

C++

```
__property FixedCols;
```

Description

Set FixedCols to create or get rid of nonscrolling columns. Nonscrolling columns appear at the left of the grid, and are always visible, even when the user scrolls the other columns in the grid. Use nonscrolling columns for displaying row titles or row numbers, or to implement a scroll lock that the user can set.

Nonscrolling columns are visually distinct from the scrollable columns in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids must include at least one scrolling column. Do not set FixedCols to a value greater than ColCount - 1.

47.1.2.5.23 TValueListEditor.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
```

```
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

47.1.2.5.24 TValueListEditor.GridLineWidth Property

Specifies the width (in pixels) of the lines that separate the cells of the grid.

Pascal

```
property GridLineWidth;
```

C++

```
__property GridLineWidth;
```

Description

Set GridLineWidth to make the lines that separate the cells in the grid heavier or lighter. When GridLineWidth is zero, no separators are drawn between the cells of the grid.

GridLineWidth will have no effect if the Options property does not include goFixedHorzLine, goFixedVertLine, goHorzLine, or goVertLine.

Note: Values greater than 3 pixels are not recommended for applications that run on Windows 9x or Windows ME because of distortions that can appear.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (DrawGrid1->DefaultColWidth > 90)
    DrawGrid1->GridLineWidth = 2;
  else
    DrawGrid1->GridLineWidth = 1;
}

void __fastcall TForm1::DrawGrid1DrawCell(TObject *Sender, int ACol, int ARow, TRect &Rect,
          TGridDrawState State)
{
  int index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
  }
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow, bool
&CanSelect)

{
  CanSelect = True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
```

```
    index: Integer;
  begin
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clBackground;
    DrawGrid1.Canvas.FillRect(Rect);
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
    end;
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

Options

47.1.2.5.25 TValueListEditor.ItemProps Property

Specifies various constraints on the way users can enter a value for each item in the list.

Pascal

```
property ItemProps [const KeyOrIndex: Variant]: TItemProp;
```

C++

```
__property TItemProp ItemProps[Variant const KeyOrIndex];
```

Description

Use ItemProps to indicate, for each item:

- Whether the item is read only.
- The maximum length of strings the user can enter.
- An edit mask that limits the strings the user can enter as a value.
- Whether the item lets users drop down a pick list or launch a dialog to enter values.
- A fixed set of values from which users select (a pick list).

OnGetPickList (see page 4860)

Values (see page 4835)

47.1.2.5.26 TValueListEditor.KeyOptions Property

Controls the way the value list editor responds to user keystrokes.

Pascal

```
property KeyOptions: TKeyOptions;
```

C++

```
__property TKeyOptions KeyOptions;
```

Description

Use KeyOptions to control how users can edit name/value pairs using the value list editor.

See Also

Keys (see page 4822)

Strings (see page 4834)

47.1.2.5.27 TValueListEditor.Keys Property

Lists the strings for each cell in the name (key) column.

Pascal

```
property Keys [Index: Integer]: string;
```

C++

```
__property UnicodeString Keys[int Index];
```

Description

Use Keys to access the name (or key) value for a particular row. That is, Keys assumes the strings in the associated string list have the form Name=Value, and returns the Name portion.

Index identifies the Row of the value list editor. It takes a value from 0 to the number of rows. When DisplayOptions (see page 4812) includes doColumnTitles, the value of Keys is the title of the first column when Index is 0, and is the Name portion of the string when Index is greater than 0. When DisplayOptions (see page 4812) does not include doColumnTitles, the value of Keys is the Name portion of the string in the specified row.

To access the strings in the value column, use the Values (see page 4835) property instead. To access the underlying string list, use the Strings (see page 4834) property.

Names

47.1.2.5.28 TValueListEditor.Options Property

Specifies various display and behavioral properties of the grid.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TGridOptions Options;
```

Description

Set Options to include the desired properties for the grid. See the type Grids.TGridOptions for definitions of these properties.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

47.1.2.5.29 TValueListEditor.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

47.1.2.5.30 TValueListEditor.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

47.1.2.5.31 TValueListEditor.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

47.1.2.5.32 TValueListEditor.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

47.1.2.5.33 TValueListEditor.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own

Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

47.1.2.5.34 TValueListEditor.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

47.1.2.5.35 TValueListEditor.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
```

```
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
```

```
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else

47.1.2.5.36 TValueListEditor.RowCount Property

Indicates the number of rows in the value list editor.

Pascal

```
property RowCount: Integer;
```

C++

```
__property int RowCount;
```

Description

TValueListEditor (see page 4784) redeclares the RowCount property, which it inherits from TCustomGrid, to change it to a read-only property. The value of RowCount is the number of strings in the Strings (see page 4834) property plus the number of fixed rows (typically one, for the column titles).

See Also

Strings (see page 4834)

ColCount (see page 4807)

FixedRows

47.1.2.5.37 TValueListEditor.ScrollBars Property

Specifies whether the grid includes horizontal and vertical scroll bars.

Pascal

```
property ScrollBars;
```

C++

```
__property ScrollBars;
```

Description

Use ScrollBars to give the grid horizontal or vertical scroll bars.

Note: If all the cells in the grid fit in the ClientWidth, no horizontal scroll bar appears, even if ScrollBars is ssHorizontal or ssBoth. If all the cells fit in the ClientHeight, no vertical scroll bar appears, even if ScrollBars is ssVertical or ssBoth.

ClientHeight

ClientWidth

47.1.2.5.38 TValueListEditor.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint

property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

47.1.2.5.39 TValueListEditor.Strings Property

Provides access to the string list that is being edited.

Pascal

```
property Strings: TStrings;
```

C++

```
__property TStrings Strings;
```

Description

Use Strings to access the string list that the value list editor displays. Strings should be a TStrings descendant that contains strings of the form Name=Value.

At design time, add values to the Strings property using the string list editor. At runtime, you can use the methods of TStrings to add strings to the list one by one, or assign an existing TStrings descendant to the Strings property. When you set Strings at runtime, TValueListEditor (see page 4784) copies the strings from the TStrings object you assign: it does not take ownership of the object itself.

When Strings is assigned, the value list editor displays the name portion (TStrings . ::Names) of the strings in its key column and the value portion (TStrings . ::Values (see page 4835)) in the value column.

Names

Values

KeyOptions (see page 4821)

47.1.2.5.40 TValueListEditor.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

TabStop

47.1.2.5.41 TValueListEditor.TitleCaptions Property

Specifies the captions that label the columns of the value list editor.

Pascal

```
property TitleCaptions: TStrings;
```

C++

```
__property TStrings TitleCaptions;
```

Description

Use TitleCaptions to provide titles for the columns of the value list editor. TitleCaptions is a TStrings descendant that contains two strings: the first string labels the name (key) column, and the second string labels the value column. If TitleCaptions contains less than two strings, missing captions are treated as empty strings. If TitleCaptions contains more than two strings, all strings except the first two are ignored.

Note: TitleCaptions is only used when the DisplayOptions (see page 4812) property includes doColumnTitles.

See Also

DisplayOptions (see page 4812)

47.1.2.5.42 TValueListEditor.Values Property

Lists the strings for each value from the value column.

Pascal

```
property Values [const Key: string]: string;
```

C++

```
__property UnicodeString Values[UnicodeString const Key];
```

Description

Use Values to access the value associated with a specified name from the first (key) column. Key specifies a string that appears in the first column of the value list editor. Values is the corresponding string from the second (value) column.

To access the strings in the key column, use the Keys (see page 4822) property instead. To access the underlying string list, use the Strings (see page 4834) property.

Note: Setting Values with Key set to a name that is not in the list adds a new string to Strings (see page 4834) and a new row to the value list editor.

Values

47.1.2.5.43 TValueListEditor.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
```

```
  form OnCreate event handler populates each sheet with an
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;

47.1.2.5.44 TValueListEditor.VisibleColCount Property

Indicates the number of scrollable columns visible in the grid.

Pascal

```
property VisibleColCount;
```

C++

```
__property VisibleColCount;
```

Description

Use VisibleColCount to determine the number of scrollable columns fully visible in the grid. VisibleColCount does not include the fixed columns counted by the FixedCols property. It does not include any partially visible columns on the right edge of the grid.

ColCount

FixedCols

VisibleRowCount

47.1.2.5.45 TValueListEditor.VisibleRowCount Property

Indicates the number of scrollable rows visible in the grid.

Pascal

```
property VisibleRowCount;
```

C++

```
__property VisibleRowCount;
```

Description

Use VisibleRowCount to determine the number of scrollable rows fully visible in the grid. VisibleRowCount does not include the fixed rows counted by the FixedRows property. It does not include any partially visible rows on the bottom of the grid.

47.1.2.6 TValueListEditor Events

The events of the TValueListEditor class are listed here.

Published Events

	Name	Description
	OnClick (see page 4839)	Occurs when the user clicks the control.
	OnContextPopup (see page 4841)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 4841)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 4842)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 4845)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 4848)	Occurs when a cell in the grid needs to be drawn.
	OnEditButtonClick (see page 4849)	Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.
	OnEndDock (see page 4850)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 4850)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 4851)	Occurs when a control receives the input focus.
	OnExit (see page 4854)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 4858)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 4859)	Occurs when the in-place editor requests the value of a cell.
	OnGetPickList (see page 4860)	Supplies a pick list for values associated with a particular key.
	OnKeyDown (see page 4861)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 4864)	Occurs when a key is pressed.
	OnKeyUp (see page 4865)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 4867)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 4868)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 4870)	Occurs when the user moves the mouse into a control.

	OnMouseLeave (see page 4871)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 4871)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 4873)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 4875)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 4876)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 4876)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 4877)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 4879)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 4879)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 4880)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnStringsChange (see page 4881)	Occurs immediately after the names or values in the string list change.
	OnStringsChanging (see page 4881)	Occurs immediately before the names or values in the string list change.
	OnTopLeftChanged (see page 4882)	Occurs immediately after the TopRow property or the LeftCol property changes.
	OnValidate (see page 4882)	Occurs when focus shifts away from a cell in the value list editor.

47.1.2.6.1 TValueListEditor.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

47.1.2.6.2 TValueListEditor.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

47.1.2.6.3 TValueListEditor.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

47.1.2.6.4 TValueListEditor.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

TDragObject

47.1.2.6.5 TValueListEditor.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

47.1.2.6.6 TValueListEditor.OnDrawCell Event

Occurs when a cell in the grid needs to be drawn.

Pascal

```
property OnDrawCell;
```

C++

```
__property OnDrawCell;
```

Description

Write an OnDrawCell event handler to draw the contents of all the cells in the grid. Draw on the cell using the methods of the Canvas property. The Rect parameter indicates the location of the cell on the canvas. The Col and Row parameters indicate the column and row indexes of the cell that should be drawn. The State parameter indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (nonscrolling) cell.

If the OnDrawCell event handler is not assigned, all cells in the draw grid will appear empty. If the DefaultDrawing property is true, the draw grid paints the background color of the cell before the OnDrawCell event, and draws a focus rectangle around the selected cell after the OnDrawCell event handler finishes drawing the contents of the cell. If the DefaultDrawing property is false, the OnDrawCell event handler should paint the background of the cell and provide all visual indication of selection and focus.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  if (State.Contains(gdFocused))
  {
```

```
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

47.1.2.6.7 TValueListEditor.OnEditButtonClick Event

Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.

Pascal

```
property OnEditButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEditButtonClick;
```

Description

Write (see page 3707) an OnEditButtonClick to display a dialog that lets users edit a value in the Values (see page 4835) column. This event only occurs for items for which the ItemProps (see page 4821) property has an EditStyle of esEllipsis.

In the event handler, you can use the Row property to identify the row that the user is editing. The event handler (or the dialog that the event handler displays) can use the Keys (see page 4822) property to identify the current key value, and use that to get and set the corresponding entry in the Values (see page 4835) property that is being edited.

47.1.2.6.8 TValueListEditor.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock;
```

C++

```
__property OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

47.1.2.6.9 TValueListEditor.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
```

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

47.1.2.6.10 TValueListEditor.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
```

```
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also

47.1.2.6.11 TValueListEditor.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255 ,
as this validation test cannot be accomplished
using the edit mask property alone.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

ActiveControl

47.1.2.6.12 TValueListEditor.OnGetEditMask Event

Occurs when the in-place editor requests an edit mask.

Pascal

```
property OnGetEditMask;
```

C++

```
__property OnGetEditMask;
```

Description

Write an OnGetEditMask event handler to provide the in-place editor with an edit mask that describes the valid input strings a user can type into a cell. Set the Value parameter to the string that describes the edit mask for the cell specified by the ACol and ARow parameters. If the cell does not have an edit mask, set the Value parameter to an empty string.

OnGetEditMask does not occur unless the Options property includes goEditing.

C++ Examples:

```
/*
This example specifies an edit mask in a string grid to
limit the cells that contain telephone numbers, as indicated
by a label cell in the first row.  Include goEditing in the
TStringGrid Options property.  Set the title of one of the
columns to 'Phone Number'.  Set the DefaultColWidth large
enough to see a phone number.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[2][0] = "Phone Number";
}

void __fastcall TForm1::StringGrid1GetEditMask(TObject *Sender, int ACol, int ARow,
          UnicodeString &Value)
{
  if (StringGrid1->Cells[ACol][0] == "Phone Number")
    Value =  "!\(999\)000-0000;1";
}
```

Delphi Examples:

```
{
This example specifies an edit mask in a string grid to
limit the cells that contain telephone numbers, as indicated
by a label cell in the first row.  Include goEditing in the
TStringGrid Options property.  Set the title of one of the
columns to 'Phone Number'.  Set the DefaultColWidth large
enough to see a phone number.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[2, 0]:= 'Phone Number';
```

```
end;

procedure TForm1.StringGrid1GetEditMask(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  if StringGrid1.Cells[ACol, 0] = 'Phone Number' then
    Value :=  '!\(999\)000-0000;1';
end;
```

EditMask

47.1.2.6.13 TValueListEditor.OnGetEditText Event

Occurs when the in-place editor requests the value of a cell.

Pascal

```
property OnGetEditText;
```

C++

```
__property OnGetEditText;
```

Description

Write an OnGetEditText event handler to provide the in-place editor with a string representing the contents of the cell. Set the Value parameter to the string for the cell specified by the ACol and ARow parameters. When the cell enters edit mode, the contents of the cell are drawn as the Value string returned by the OnGetEditText event handler. This image need not match the appearance of the cell when it is not in edit mode, which is drawn using the OnDrawCell event handler.

OnGetEditText does not occur unless the Options property includes goEditing.

C++ Examples:

```
/*
The following code lowercases the text for a string grid
cell when the user begins to edit it.
*/
void __fastcall TForm1::StringGrid1GetEditText(TObject *Sender, int ACol, int ARow,
          UnicodeString &Value)
{
  Value = AnsiLowerCase(Value);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[2][0] = "Phone Number";
  StringGrid1->Cells[2][1] = "(408)984-1234";
  StringGrid1->Cells[2][2] = "(415)434-6789";
  StringGrid1->Cells[2][3] = "(650)696-2345";
  StringGrid1->Cells[2][4] = "(831)431-2422";
  StringGrid1->Cells[2][5] = "(408)506-9876";
  StringGrid1->Cells[1][0] = "Name";
  StringGrid1->Cells[1][1] = "Clem Myers";
  StringGrid1->Cells[1][2] = "Ed Satchel";
  StringGrid1->Cells[1][3] = "Johanna Mills";
  StringGrid1->Cells[1][4] = "Stella Gables";
  StringGrid1->Cells[1][5] = "Ted Thompson";
  StringGrid1->Cells[3][0] = "POB";
  StringGrid1->Cells[3][1] = "Detroit";
  StringGrid1->Cells[3][2] = "Memphis";
  StringGrid1->Cells[3][3] = "New Orleans";
```

```
  StringGrid1->Cells[3][4] = "Lander";
  StringGrid1->Cells[3][5] = "Round Pond";
  StringGrid1->Cells[4][0] = "State";
  StringGrid1->Cells[4][1] = "Michigan";
  StringGrid1->Cells[4][2] = "Tennessee";
  StringGrid1->Cells[4][3] = "Lousiana";
  StringGrid1->Cells[4][4] = "Wyoming";
  StringGrid1->Cells[4][5] = "Maine";
  StringGrid1->Cells[5][0] = "Last Graduated";
  StringGrid1->Cells[5][1] = "Michigan State";
  StringGrid1->Cells[5][2] = "Univ-> Colorado";
  StringGrid1->Cells[5][3] = "Univ-> Washington";
  StringGrid1->Cells[5][4] = "USC";
  StringGrid1->Cells[5][5] = "Bowdoin";
}
```

Delphi Examples:

```
{
The following code lowercases the text for a string grid
cell when the user begins to edit it.
}
procedure TForm1.StringGrid1GetEditText(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  Value := AnsiLowerCase(Value);
end;
```

OnSetEditText

47.1.2.6.14 TValueListEditor.OnGetPickList Event

Supplies a pick list for values associated with a particular key.

Pascal

```
property OnGetPickList: TGetPickListEvent;
```

C++

```
__property TGetPickListEvent OnGetPickList;
```

Description

Write (see page 3707) an OnGetPickList event handler to provide a drop-down list of values for specific names from the first (key) column. OnGetPickList is called when the value column gets focus and the name (key) column contains the string specified by KeyName.

If the ItemProps (see page 4821) property has an EditStyle of esPickList for this item, The Values (see page 4835) parameter of the event handler is initialized to the value of its PickList property for this item. Otherwise, Values (see page 4835) is initialized to an empty list. In either case, the event handler can change the list of values that appear in the drop-down pick list.

If the OnGetPickList event handler exits with a non-empty string list as the value of the Values (see page 4835) parameter, a drop-down arrow appears in the value column. The user can click this arrow button to display the pick list you supplied as the value of Values (see page 4835). This makes the Value column behave like a drop-down combo box: the user can select items from the list or type in an entirely different value.

47.1.2.6.15 TValueListEditor.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
```

```
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
/*
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
*/
#include <Printers.hpp>

OnKeyPress

OnKeyUp

47.1.2.6.16 TValueListEditor.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

47.1.2.6.18 TValueListEditor.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no

control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

47.1.2.6.19 TValueListEditor.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
```

```
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
```

```
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

47.1.2.6.20 TValueListEditor.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

47.1.2.6.21 TValueListEditor.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

47.1.2.6.22 TValueListEditor.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

47.1.2.6.23 TValueListEditor.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

47.1.2.6.24 TValueListEditor.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown;
```

C++

```
__property OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

OnMouseWheelDown

OnMouseWheel

47.1.2.6.26 TValueListEditor.OnRowMoved Event

Occurs immediately after the position of a row changes.

Pascal

```
property OnRowMoved;
```

C++

```
__property OnRowMoved;
```

Description

Write an OnRowMoved event handler to provide special processing whenever a row in the grid changes position. Rows can be moved programmatically or by user manipulation. OnRowMoved does not occur unless the Options property includes goRowMoving.

C++ Examples:

```
/*
The following code displays the number of rows a row was
moved in the first cell of the row.  To move rows in a
TStringGrid, goRowMoving must be included in the Options property.
*/
void __fastcall TForm1::StringGrid1RowMoved(TObject *Sender, int FromIndex, int ToIndex)

{
```

```
  int delta = (FromIndex > ToIndex) ? (FromIndex-ToIndex) : (ToIndex-FromIndex);
  StringGrid1->Cells[0][ToIndex] = IntToStr(delta);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[2][0] = "Phone Number";
  StringGrid1->Cells[2][1] = "(408)984-1234";
  StringGrid1->Cells[2][2] = "(415)434-6789";
  StringGrid1->Cells[2][3] = "(650)696-2345";
  StringGrid1->Cells[2][4] = "(831)431-2422";
  StringGrid1->Cells[2][5] = "(408)506-9876";
  StringGrid1->Cells[1][0] = "Name";
  StringGrid1->Cells[1][1] = "Clem Myers";
  StringGrid1->Cells[1][2] = "Ed Satchel";
  StringGrid1->Cells[1][3] = "Johanna Mills";
  StringGrid1->Cells[1][4] = "Stella Gables";
  StringGrid1->Cells[1][5] = "Ted Thompson";
  StringGrid1->Cells[3][0] = "POB";
  StringGrid1->Cells[3][1] = "Detroit";
  StringGrid1->Cells[3][2] = "Memphis";
  StringGrid1->Cells[3][3] = "New Orleans";
  StringGrid1->Cells[3][4] = "Lander";
  StringGrid1->Cells[3][5] = "Round Pond";
  StringGrid1->Cells[4][0] = "State";
  StringGrid1->Cells[4][1] = "Michigan";
  StringGrid1->Cells[4][2] = "Tennessee";
  StringGrid1->Cells[4][3] = "Lousiana";
  StringGrid1->Cells[4][4] = "Wyoming";
  StringGrid1->Cells[4][5] = "Maine";
  StringGrid1->Cells[5][0] = "Last Graduated";
  StringGrid1->Cells[5][1] = "Michigan State";
  StringGrid1->Cells[5][2] = "Univ-> Colorado";
  StringGrid1->Cells[5][3] = "Univ-> Washington";
  StringGrid1->Cells[5][4] = "USC";
  StringGrid1->Cells[5][5] = "Bowdoin";
}
```

Delphi Examples:

```
{
The following code displays the number of rows a row was
moved in a label.  To move rows in a TStringGrid, goRowMoving
must be included in the Options property.
}
procedure TForm1.StringGrid1RowMoved(Sender: TObject; FromIndex, ToIndex: Longint);
begin
  Label1.Caption := IntToStr(Abs(FromIndex-ToIndex));
end;
```

OnColumnMoved

Options

47.1.2.6.27 TValueListEditor.OnSelectCell Event

Occurs before a cell in the grid is selected.

Pascal

```
property OnSelectCell;
```

C++

```
__property OnSelectCell;
```

Description

Write an OnSelectCell event handler to specify whether any particular cell in the grid can be selected. The Col and Row parameters indicate the column and row indexes of the cell that is about to be selected. Set the CanSelect parameter to false to prevent the cell being selected.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code ensures that the user cannot select a cell
unless it is empty.
*/
void __fastcall TForm1::StringGrid1SelectCell(TObject *Sender, int ACol, int ARow,
          bool &CanSelect)
{
  CanSelect = (StringGrid1->Cells[ACol][ARow]== "");
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
```

```
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
  {
  The following code ensures that the user cannot select a cell
  unless it is empty.
  }
  procedure TForm1.StringGrid1SelectCell(Sender: TObject; ACol, ARow: Longint; var CanSelect:
  Boolean);
  begin
    CanSelect := (StringGrid1.Cells[ACol, ARow]='')
  end;

47.1.2.6.28 TValueListEditor.OnSetEditText Event

Occurs when the user edits the value of a cell.

Pascal

```
property OnSetEditText;
```

C++

```
__property OnSetEditText;
```

Description

Write an OnSetEditText event handler to perform any special processing of the text edited by the user in an in-place editor. For example, use the OnSetEditText event to retrieve and store the value of a cell so that it can be displayed in an OnDrawCell event handler. OnSetEditText occurs every time the user changes the text.

The Value parameter is the new value for the cell specified by the ACol and ARow parameters.

OnSetEditText does not occur unless the Options property includes goEditing.

OnGetEditText

Options

47.1.2.6.29 TValueListEditor.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnEndDock

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

47.1.2.6.30 TValueListEditor.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

47.1.2.6.31 TValueListEditor.OnStringsChange Event

Occurs immediately after the names or values in the string list change.

Pascal

```
property OnStringsChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStringsChange;
```

Description

Write (see page 3707) an OnStringsChange event handler to respond when the strings in the list change. For example, you can use the OnStringsChange event to update your display to reflect the new values of the strings in the value list editor.

OnStringsChange occurs after the change is complete. The properties of the value list editor reflect the new values of the strings.

OnStringsChanging (see page 4881)

Strings (see page 4834)

OnSetEditText

47.1.2.6.32 TValueListEditor.OnStringsChanging Event

Occurs immediately before the names or values in the string list change.

Pascal

```
property OnStringsChanging: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStringsChanging;
```

Description

Write (see page 3707) an OnStringsChanging event handler to prepare for changes in the list of strings. For example, you can use the OnStringsChanging event to disable repaints until the OnStringsChange (see page 4881) event when the list has finished changing..

OnStringsChanging occurs before the change occurs. The properties of the value list editor reflect the old values of the strings.

See Also

OnStringsChange (see page 4881)

Strings (see page 4834)

OnSetEditText

47.1.2.6.33 TValueListEditor.OnTopLeftChanged Event

Occurs immediately after the TopRow property or the LeftCol property changes.

Pascal

```
property OnTopLeftChanged;
```

C++

```
__property OnTopLeftChanged;
```

Description

Use OnTopLeftChanged to perform special processing when the non-fixed cells in the grid are scrolled.

See Also

LeftCol

TopRow

47.1.2.6.34 TValueListEditor.OnValidate Event

Occurs when focus shifts away from a cell in the value list editor.

Pascal

```
property OnValidate: TOnValidateEvent;
```

C++

```
__property TOnValidateEvent OnValidate;
```

Description

Write (see page 3707) an OnValidate event handler to validate any edits the user enters in a cell before focus leaves it. OnValidate gives applications an opportunity to provide more validation than the EditMask property of the corresponding TItemProp (see page 4778) object can supply.

OnValidate only occurs if the user edited the value of the cell that is about to lose focus. The OnValidate event handler can verify the value the user supplied, and if it is not acceptable, raise an exception.

47.1.3 TValueListStrings Class

Class Hierarchy

Pascal

```
TValueListStrings = class(TStringList);
```

C++

```
class TValueListStrings : public TStringList;
```

File

ValEdit

Description

This is class ValEdit.TValueListStrings.

47.1.3.1 TValueListStrings Members

The following tables list the members exposed by TValueListStrings.

Protected Methods

	Name	Description
	Changed (see page 4887)	This is Changed, a member of class TValueListStrings.
	Changing (see page 4887)	This is Changing, a member of class TValueListStrings.
	FindItemProp (see page 4889)	This is FindItemProp, a member of class TValueListStrings.
	InsertItem (see page 4889)	This is InsertItem, a member of class TValueListStrings.
	Put (see page 4890)	This is Put, a member of class TValueListStrings.

Protected Properties

	Name	Description
	UpdateCount (see page 4890)	Indicates the number of calls to BeginUpdate that have not been matched by a call to EndUpdate.

Public Methods

	Name	Description
	Assign (see page 4884)	Sets the strings in the list, and possibly associated objects, from a source object.
	Clear (see page 4887)	Deletes all the strings from the list.
	Create (see page 4883)	This is Create, a member of class TValueListStrings.
	CustomSort (see page 4888)	Sorts the strings in the list in a customized order.
	Delete (see page 4888)	Removes the string specified by the `Index` parameter.
	Destroy (see page 4884)	Destroys an instance of TStringList.
	Exchange (see page 4889)	Swaps the position of two strings in the list.
	KeyIsValid (see page 4890)	This is KeyIsValid, a member of class TValueListStrings.

Public Properties

	Name	Description
	ItemProps (see page 4890)	This is ItemProps, a member of class TValueListStrings.

47.1.3.2 TValueListStrings.Create Constructor

Pascal

```
constructor Create(AEditor: TValueListEditor); reintroduce;
```

C++

```
__fastcall TValueListStrings(TValueListEditor AEditor);
```

Description

This is Create, a member of class TValueListStrings.

47.1.3.3 TValueListStrings.Destroy Destructor

Destroys an instance of TStringList.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TValueListStrings();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TStringList reference is not nil and only then calls Destroy.

Destroy frees the memory allocated to hold the list of strings and object references before calling the inherited destructor.

See Also

System::TObject::Free (see page 3372)

47.1.3.4 TValueListStrings Methods

The methods of the TValueListStrings class are listed here.

Protected Methods

	Name	Description
	Changed (see page 4887)	This is Changed, a member of class TValueListStrings.
	Changing (see page 4887)	This is Changing, a member of class TValueListStrings.
	FindItemProp (see page 4889)	This is FindItemProp, a member of class TValueListStrings.
	InsertItem (see page 4889)	This is InsertItem, a member of class TValueListStrings.
	Put (see page 4890)	This is Put, a member of class TValueListStrings.

Public Methods

	Name	Description
	Assign (see page 4884)	Sets the strings in the list, and possibly associated objects, from a source object.
	Clear (see page 4887)	Deletes all the strings from the list.
	CustomSort (see page 4888)	Sorts the strings in the list in a customized order.
	Delete (see page 4888)	Removes the string specified by the `Index` parameter.
	Exchange (see page 4889)	Swaps the position of two strings in the list.
	KeyIsValid (see page 4890)	This is KeyIsValid, a member of class TValueListStrings.

47.1.3.4.1 TValueListStrings.Assign Method

Sets the strings in the list, and possibly associated objects, from a source object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to set the value of the TStrings object from another object. If Source is of type TStrings, the list is set to the list of the

source TStrings object, and if associated objects are supported, any associated objects are copied from the Source as well.

If Source is not of type TStrings, the inherited Assign will set the value of the list from any object that supports TStrings in its AssignTo method.

C++ Examples:

```
/*
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
*/
void __fastcall TForm1::Add_a_fileClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    int index = TabControl1->Tabs->Add(OpenDialog1->FileName);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[index]);
    TabControl1Change(Sender);
  }
}

void __fastcall TForm1::Assign_filesClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TabControl1->Tabs->Assign(OpenDialog1->Files);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[TabControl1->TabIndex]);
  }
}
/*
Place the following code in the tab control's OnChange event
handler:
*/
void __fastcall TForm1::TabControl1Change(TObject *Sender)
{
    Memo1->Lines->LoadFromFile(
      TabControl1->Tabs->Strings[TabControl1->TabIndex]);
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  std::auto_ptr<TStrings> StringList(new TStringList());
  StringList->Add("This example uses A string List. ");
  StringList->Add("It is the easiest way to add strings");
  StringList->Add("to a combobox's list of strings. ");
  StringList->Add("Always remember TStrings is abstract,");
  StringList->Add("So create a TStringList instead.");
  ComboBox1->Width = 210;
  ComboBox1->Items->Assign(StringList.get());
  ComboBox1->ItemIndex = 0;
```

```
}
```

Delphi Examples:

```
{
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
}
procedure TForm1.Add_a_fileClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
    index:= TabControl1.Tabs.Add(OpenDialog1.FileName);
    Memo1.Lines.LoadFromFile(TabControl1.Tabs[index]);
    TabControl1Change(Sender);
  end;
end;

procedure TForm1.Assign_filesClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
    TabControl1.Tabs.Assign(OpenDialog1.Files);
    Memo1.Lines.LoadFromFile(
      TabControl1.Tabs[TabControl1.TabIndex]);
  end;
end;

{
Place the following code in the tab control's OnChange event
handler:
}
procedure TForm1.TabControl1Change(Sender: TObject);
begin
  with TabControl1 do
    Memo1.Lines.LoadFromFile(Tabs[TabIndex]);
end;
{
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  StringList: TStringList;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
      Add('This example uses A string List.');
      Add('It is the easiest way to add strings');
      Add('to a combobox''s list of strings.');
      Add('Always remember TStrings.Create method');
      Add('is abstract; So use TStringList.Create');
```

```
        Add('method instead.');
      end;
      with ComboBox1 do begin
        Width := 210;
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

47.1.3.4.2 TValueListStrings.Changed Method

Pascal

```
procedure Changed; override;
```

C++

```
virtual __fastcall Changed();
```

Description

This is Changed, a member of class TValueListStrings.

47.1.3.4.3 TValueListStrings.Changing Method

Pascal

```
procedure Changing; override;
```

C++

```
virtual __fastcall Changing();
```

Description

This is Changing, a member of class TValueListStrings.

47.1.3.4.4 TValueListStrings.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete

Objects

Strings

47.1.3.4.5 TValueListStrings.CustomSort Method

Sorts the strings in the list in a customized order.

Pascal

```
procedure CustomSort(Compare: TStringListSortCompare); override;
```

C++

```
virtual __fastcall CustomSort(TStringListSortCompare Compare);
```

Description

Use CustomSort to sort the strings in the list, where the sort order is defined by the Compare parameter.

Supply a value for the Compare function that compares two strings in the string list. The `List` parameter provides access to the string list, while the Index1 and Index2 parameters identify the strings to be compared.

Do not pass nil (Delphi) or NULL (C++) as the value of the Compare parameter.

Note: You must explicitly call the CustomSort method. Setting the Sorted property only sorts strings using ANSI (Windows) or UTF-8 (Linux) order, as implemented in the Sort method.

See Also

Sort

Strings

Sorted

47.1.3.4.6 TValueListStrings.Delete Method

Removes the string specified by the `Index` parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add

AddObject

Clear

IndexOf

InsertObject

Objects

Strings

47.1.3.4.7 TValueListStrings.Exchange Method

Swaps the position of two strings in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer); override;
```

C++

```
virtual __fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to rearrange the strings in the list. The strings are specified by their index values in the Index1 and Index2 parameters. Indexes are zero-based, so the first string in the list has an index value of 0, the second has an index value of 1, and so on.

If either string has an associated object, Exchange changes the index of the object as well.

Warning: Do not call Exchange on a sorted list except to swap two identical strings with different associated objects. Exchange does not check whether the list is sorted, and can destroy the sort order of a sorted list.

47.1.3.4.8 TValueListStrings.FindItemProp Method

Pascal

```
function FindItemProp(const KeyOrIndex: Variant; Create: Boolean = False): TItemProp;
```

C++

```
__fastcall TItemProp FindItemProp(const Variant KeyOrIndex, Boolean Create = False);
```

Description

This is FindItemProp, a member of class TValueListStrings.

47.1.3.4.9 TValueListStrings.InsertItem Method

Pascal

```
procedure InsertItem(Index: Integer; const S: string; AObject: TObject); override;
```

C++

```
virtual __fastcall InsertItem(int Index, const UnicodeString S, TObject * AObject);
```

Description

This is InsertItem, a member of class TValueListStrings.

47.1.3.4.10 TValueListStrings.KeyIsValid Method

Pascal

```
function KeyIsValid(const Key: string; RaiseError: Boolean = True): Boolean;
```

C++

```
__fastcall Boolean KeyIsValid(const UnicodeString Key, Boolean RaiseError = True);
```

Description

This is KeyIsValid, a member of class TValueListStrings.

47.1.3.4.11 TValueListStrings.Put Method

Pascal

```
procedure Put(Index: Integer; const S: String); override;
```

C++

```
virtual __fastcall Put(int Index, const UnicodeString S);
```

Description

This is Put, a member of class TValueListStrings.

47.1.3.5 TValueListStrings Properties

The properties of the TValueListStrings class are listed here.

Protected Properties

	Name	Description
	UpdateCount (see page 4890)	Indicates the number of calls to BeginUpdate that have not been matched by a call to EndUpdate.

Public Properties

	Name	Description
	ItemProps (see page 4890)	This is ItemProps, a member of class TValueListStrings.

47.1.3.5.1 TValueListStrings.ItemProps Property

Pascal

```
property ItemProps [const KeyOrIndex: Variant]: TItemProp;
```

C++

```
__property TItemProp ItemProps[Variant const KeyOrIndex];
```

Description

This is ItemProps, a member of class TValueListStrings.

47.1.3.5.2 TValueListStrings.UpdateCount Property

Indicates the number of calls to BeginUpdate that have not been matched by a call to EndUpdate.

Pascal

```
property UpdateCount;
```

C++

```
__property UpdateCount;
```

Description

TStrings uses UpdateCount to keep track of calls to the BeginUpdate and EndUpdate methods. Every time a call is made to BeginUpdate, TStrings increments the value of UpdateCount. Every call to EndUpdate causes TStrings to decrement UpdateCount.

When UpdateCount changes from 0 to 1, TStrings calls the SetUpdateState method with a parameter of true. When UpdateCount changes from 1 to 0, TStrings calls the SetUpdateState method with a parameter of false. This allows descendant classes to perform optimizations when handling multiple updates.

47.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TDisplayOption (see page 4892)	TDisplayOption and TDisplayOptions (see page 4894) control the appearance of a value list editor.
	TKeyOption (see page 4893)	TKeyOption and TKeyOptions (see page 4895) indicate the response of a value list editor to certain keystrokes.

47.2.1 ValEdit.TDisplayOption Enumeration

TDisplayOption and TDisplayOptions (see page 4894) control the appearance of a value list editor.

Pascal

```
TDisplayOption = (
  doColumnTitles,
  doAutoColResize,
  doKeyColFixed
);
```

C++

```
enum TDisplayOption {
  doColumnTitles,
  doAutoColResize,
  doKeyColFixed
};
```

File

ValEdit

Description

TDisplayOption is a set of TDisplayOptions (see page 4894) values. The possible values of TDisplayOptions (see page 4894) are

Option	Meaning
doColumnTitles	The first row of the value list editor is a fixed (nonscrolling) row that displays the captions specified by the TitleCaptions property.
doAutoColResize	When the editor is resized, the column widths automatically adjust so that they completely fill the new width of the editor. If DisplayOptions does not include doKeyColFixed, each column has a width equal to half the width of the editor. Otherwise, the value column takes up any space left over after the fixed (key) column.
doKeyColFixed	The first (key) column of the value list editor is fixed in width. When the value list editor is resized, only the second (value) column resizes. This option is only used when DisplayOptions includes doAutoColResize.

47.2.2 ValEdit.TKeyOption Enumeration

TKeyOption and TKeyOptions (see page 4895) indicate the response of a value list editor to certain keystrokes.

Pascal

```
TKeyOption = (
  keyEdit,
  keyAdd,
  keyDelete,
  keyUnique
);
```

C++

```
enum TKeyOption {
  keyEdit,
  keyAdd,
  keyDelete,
  keyUnique
};
```

File

ValEdit

Description

TKeyOption is a set of TKeyOptions (see page 4895) values. The possible values of TKeyOptions (see page 4895) are

Option	Meaning
keyEdit	The user can select and edit values in the first (key) column. That is, the user can specify the name in a name/value pair.
keyAdd	The user can add new name/value pairs. When included, the user can create new entries by pressing the Insert (see page 3601) key or using the down arrow key when positioned on the last name/value pair. keyAdd requires that keyEdit is also included.
keyDelete	The user can delete the selected name/value pair by pressing the Delete (see page 3552) key.
keyUnique	The user can't create name/value pairs where the name portion is the same as the name in another name/value pair. Attempting to add a duplicate name causes the value list editor to raise an exception. keyUnique requires that keyEdit is also included.

47.3 Types

The following table lists types in this documentation.

Types

Name	Description
TDisplayOptions (see page 4894)	TDisplayOptions and TDisplayOption (see page 4892) control the appearance of a value list editor.
TGetPickListEvent (see page 4895)	TGetPickListEvent is the type for event handlers that supply pick list values to a value list editor.
TItemProps (see page 4895)	This is type ValEdit.TItemProps.
TKeyOptions (see page 4895)	TKeyOptions and TKeyOption (see page 4893) indicate the response of a value list editor to certain keystrokes.
TOnValidateEvent (see page 4896)	TOnValidateEvent is the type for event handlers that validate the values a user types into a value list editor.

47.3.1 ValEdit.TDisplayOptions Type

TDisplayOptions and TDisplayOption (see page 4892) control the appearance of a value list editor.

Pascal

```
TDisplayOptions = set of TDisplayOption;
```

C++

```
TDisplayOption TDisplayOptions;
```

File

ValEdit

Description

TDisplayOptions is a set of TDisplayOption (see page 4892) values. The following table lists the possible values of TDisplayOption (see page 4892).

Option	Meaning
doColumnTitles	The first row of the value list editor is a fixed (nonscrolling) row that displays the captions specified by the TitleCaptions property.
doAutoColResize	When the editor is resized, the column widths automatically adjust so that they completely fill the new width of the editor. If DisplayOptions does not include doKeyColFixed, each column has a width equal to half the width of the editor. Otherwise, the value column takes up any space left over after the fixed (key) column.
doKeyColFixed	The first (key) column of the value list editor is fixed in width. When the value list editor is resized, only the second (value) column resizes. This option is only used when DisplayOptions includes doAutoColResize.

See Also

TDisplayOption (see page 4892)

TValueListEditor (see page 4784)

47.3.2 ValEdit.TGetPickListEvent Type

TGetPickListEvent is the type for event handlers that supply pick list values to a value list editor.

Pascal

```
TGetPickListEvent = procedure (Sender: TObject; const KeyName: string; Values: TStrings) of object;
```

C++

```
(Sender: TObject; const KeyName: string; Values: TStrings) ( TGetPickListEvent)();
```

File

ValEdit

Description

`Sender` is the value list editor that uses the drop-down list of values. `KeyName` is the name of a string that appears in the first column of the current row. `Values` is a string list that you can fill with candidates for the second (value) column of the value list editor.

See Also

OnGetPickList (see page 4860)

Creating events

47.3.3 ValEdit.TItemProps Type

Pascal

```
TItemProps = array of TItemProp;
```

C++

```
array of TItemProp TItemProps;
```

File

ValEdit

Description

This is type ValEdit.TItemProps.

47.3.4 ValEdit.TKeyOptions Type

TKeyOptions and TKeyOption (see page 4893) indicate the response of a value list editor to certain keystrokes.

Pascal

```
TKeyOptions = set of TKeyOption;
```

C++

```
TKeyOption TKeyOptions;
```

File

ValEdit

Description

TKeyOptions is a set of TKeyOption (see page 4893) values. The possible values of TKeyOption (see page 4893) are listed in the following table.

Option	Meaning
keyEdit	The user can select and edit values in the first (key) column. That is, the user can specify the name in a name/value pair.
keyAdd	The user can add new name/value pairs. When included, the user can create new entries by pressing the Insert (see page 3601) key or using the down arrow key when positioned on the last name/value pair. keyAdd requires that keyEdit is also included.
keyDelete	The user can delete the selected name/value pair by pressing the Delete (see page 3552) key.
keyUnique	The user cannot create name/value pairs where the name portion is the same as the name in another name/value pair. Attempting to add a duplicate name causes the value list editor to raise an exception. keyUnique requires that keyEdit is also included.

See Also

TKeyOption (see page 4893)

TValueListEditor (see page 4784)

47.3.5 ValEdit.TOnValidateEvent Type

TOnValidateEvent is the type for event handlers that validate the values a user types into a value list editor.

Pascal

```
TOnValidateEvent = procedure (Sender: TObject; ACol, ARow: Longint; const KeyName, KeyValue:
string) of object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; const KeyName, KeyValue: string) ( TOnValidateEvent)();
```

File

ValEdit

Description

Sender is the value list editor that contains the edited cell.

ACol and ARow identify the cell by its column and row numbers, respectively. The first row or column has an index of 0, the second has an index of 1, and so on.

KeyName is the current value of in the key column for ARow. This value includes any edits that have not yet been committed.

KeyValue is the current value of the value column for ARow. This value includes any edits that have not yet been committed.

Topics

Name	Description
Functions (see page 4901)	The following table lists functions in this documentation.
Variables (see page 4944)	The following table lists variables in this documentation.

Functions

	Name	Description
	VarAsComplex (see page 4902)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a complex number.
	VarComplex (see page 4903)	Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent complex numbers.
	VarComplexAbs (see page 4903)	Returns the absolute value of a complex number.
	VarComplexAbsSqr (see page 4904)	Returns the square of the absolute value of a complex number.
	VarComplexAngle (see page 4905)	Returns the angle made by a complex number.
	VarComplexArcCos (see page 4905)	Returns the inverse cosine of a complex number.
	VarComplexArcCosH (see page 4906)	Returns the hyperbolic inverse cosine of a complex number.
	VarComplexArcCot (see page 4907)	Returns the inverse cotangent of a complex number.
	VarComplexArcCotH (see page 4908)	Returns the hyperbolic inverse cotangent of a complex number.
	VarComplexArcCsc (see page 4909)	Returns the inverse cosecant of a complex number.
	VarComplexArcCscH (see page 4911)	Returns the hyperbolic inverse cosecant of a complex number.
	VarComplexArcSec (see page 4912)	Returns the inverse secant of a complex number.
	VarComplexArcSecH (see page 4913)	Returns the hyperbolic inverse secant of a complex number.
	VarComplexArcSin (see page 4914)	Returns the inverse sine of a complex number.
	VarComplexArcSinH (see page 4915)	Returns the hyperbolic inverse sine of a complex number.
	VarComplexArcTan (see page 4916)	Returns the inverse tangent of a complex number.
	VarComplexArcTanH (see page 4917)	Returns the hyperbolic inverse tangent of a complex number.
	VarComplexConjugate (see page 4918)	Returns the conjugate of a complex number.
	VarComplexCos (see page 4919)	Returns the cosine of a complex number.
	VarComplexCosH (see page 4920)	Returns the hyperbolic cosine of a complex number.
	VarComplexCot (see page 4921)	Returns the cotangent of a complex number.
	VarComplexCotH (see page 4922)	Returns the hyperbolic cotangent of a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.

	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCsc (see page 4924)	Returns the cosecant of a complex number.
	VarComplexCscH (see page 4925)	Returns the hyperbolic cosecant of a complex number.
	VarComplexExp (see page 4926)	Returns the exponential of a complex number.
	VarComplexFromPolar (see page 4927)	Converts a set of polar coordinates to a complex number.
	VarComplexInverse (see page 4927)	Returns the inverse of a complex number.
	VarComplexLn (see page 4928)	Returns the natural log of a complex number.
	VarComplexLog10 (see page 4929)	Returns the log base 10 of a complex number.
	VarComplexLog2 (see page 4929)	Returns the log base 2 of a complex number.
	VarComplexLogN (see page 4930)	Returns the log base N of a complex number.
	VarComplexPower (see page 4930)	Returns the value of a complex number raised to a specified power.
	VarComplexSec (see page 4931)	Returns the secant of a complex number.
	VarComplexSecH (see page 4932)	Returns the hyperbolic secant of a complex number.
	VarComplexSign (see page 4933)	This is function VarCmplx.VarComplexSign.
	VarComplexSimplify (see page 4934)	Reduces a Variant (see page 3421) that represents a complex number to one that represents a real value, if possible.
	VarComplexSin (see page 4934)	Returns the sine of a complex number.
	VarComplexSinH (see page 4935)	Returns the hyperbolic sine of a complex number.
	VarComplexSqr (see page 4936)	Returns the square of a complex number.
	VarComplexSqrt (see page 4937)	Returns the square root of a complex number.
	VarComplexTan (see page 4938)	Returns the tangent of a complex number.
	VarComplexTanH (see page 4939)	Returns the hyperbolic tangent of a complex number.
	VarComplexTimesImaginary (see page 4940)	Returns the value of a complex number multiplied by an imaginary number.
	VarComplexTimesNegI (see page 4940)	Returns the value of a complex number multiplied by –i.
	VarComplexTimesPosI (see page 4941)	Returns the value of a complex number multiplied by i.
	VarComplexTimesReal (see page 4941)	Returns the value of a complex number multiplied by a real number.
	VarComplexToPolar (see page 4942)	Computes the polar coordinates that correspond to a custom Variant (see page 3421) that represents a complex number.
	VarIsComplex (see page 4942)	Indicates whether a Variant (see page 3421) stores its data internally as a complex number.

Variables

Name	Description
ComplexNumberDefuzzAtZero (see page 4944)	This is variable VarCmplx.ComplexNumberDefuzzAtZero.
ComplexNumberSymbol (see page 4944)	Indicates the symbol used to represent the imaginary part of a complex number.
ComplexNumberSymbolBeforeImaginary (see page 4945)	Indicates the placement of the symbol that represents the imaginary part of a complex number.

48.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsComplex (see page 4902)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a complex number.
	VarComplex (see page 4903)	Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent complex numbers.
	VarComplexAbs (see page 4903)	Returns the absolute value of a complex number.
	VarComplexAbsSqr (see page 4904)	Returns the square of the absolute value of a complex number.
	VarComplexAngle (see page 4905)	Returns the angle made by a complex number.
	VarComplexArcCos (see page 4905)	Returns the inverse cosine of a complex number.
	VarComplexArcCosH (see page 4906)	Returns the hyperbolic inverse cosine of a complex number.
	VarComplexArcCot (see page 4907)	Returns the inverse cotangent of a complex number.
	VarComplexArcCotH (see page 4908)	Returns the hyperbolic inverse cotangent of a complex number.
	VarComplexArcCsc (see page 4909)	Returns the inverse cosecant of a complex number.
	VarComplexArcCscH (see page 4911)	Returns the hyperbolic inverse cosecant of a complex number.
	VarComplexArcSec (see page 4912)	Returns the inverse secant of a complex number.
	VarComplexArcSecH (see page 4913)	Returns the hyperbolic inverse secant of a complex number.
	VarComplexArcSin (see page 4914)	Returns the inverse sine of a complex number.
	VarComplexArcSinH (see page 4915)	Returns the hyperbolic inverse sine of a complex number.
	VarComplexArcTan (see page 4916)	Returns the inverse tangent of a complex number.
	VarComplexArcTanH (see page 4917)	Returns the hyperbolic inverse tangent of a complex number.
	VarComplexConjugate (see page 4918)	Returns the conjugate of a complex number.
	VarComplexCos (see page 4919)	Returns the cosine of a complex number.
	VarComplexCosH (see page 4920)	Returns the hyperbolic cosine of a complex number.
	VarComplexCot (see page 4921)	Returns the cotangent of a complex number.
	VarComplexCotH (see page 4922)	Returns the hyperbolic cotangent of a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCreate (see page 4923)	Returns a custom Variant (see page 3421) that represents a complex number.
	VarComplexCsc (see page 4924)	Returns the cosecant of a complex number.
	VarComplexCscH (see page 4925)	Returns the hyperbolic cosecant of a complex number.
	VarComplexExp (see page 4926)	Returns the exponential of a complex number.
	VarComplexFromPolar (see page 4927)	Converts a set of polar coordinates to a complex number.
	VarComplexInverse (see page 4927)	Returns the inverse of a complex number.
	VarComplexLn (see page 4928)	Returns the natural log of a complex number.
	VarComplexLog10 (see page 4929)	Returns the log base 10 of a complex number.
	VarComplexLog2 (see page 4929)	Returns the log base 2 of a complex number.
	VarComplexLogN (see page 4930)	Returns the log base N of a complex number.
	VarComplexPower (see page 4930)	Returns the value of a complex number raised to a specified power.
	VarComplexSec (see page 4931)	Returns the secant of a complex number.
	VarComplexSecH (see page 4932)	Returns the hyperbolic secant of a complex number.
	VarComplexSign (see page 4933)	This is function VarCmplx.VarComplexSign.
	VarComplexSimplify (see page 4934)	Reduces a Variant (see page 3421) that represents a complex number to one that represents a real value, if possible.
	VarComplexSin (see page 4934)	Returns the sine of a complex number.
	VarComplexSinH (see page 4935)	Returns the hyperbolic sine of a complex number.

	VarComplexSqr (see page 4936)	Returns the square of a complex number.
	VarComplexSqrt (see page 4937)	Returns the square root of a complex number.
	VarComplexTan (see page 4938)	Returns the tangent of a complex number.
	VarComplexTanH (see page 4939)	Returns the hyperbolic tangent of a complex number.
	VarComplexTimesImaginary (see page 4940)	Returns the value of a complex number multiplied by an imaginary number.
	VarComplexTimesNegI (see page 4940)	Returns the value of a complex number multiplied by –i.
	VarComplexTimesPosI (see page 4941)	Returns the value of a complex number multiplied by i.
	VarComplexTimesReal (see page 4941)	Returns the value of a complex number multiplied by a real number.
	VarComplexToPolar (see page 4942)	Computes the polar coordinates that correspond to a custom Variant (see page 3421) that represents a complex number.
	VarIsComplex (see page 4942)	Indicates whether a Variant (see page 3421) stores its data internally as a complex number.

48.1.1 VarCmplx.VarAsComplex Function

Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a complex number.

Pascal

```
function VarAsComplex(const AValue: Variant): Variant;
```

C++

```
Variant VarAsComplex(const Variant AValue);
```

File

VarCmplx

Description

VarAsComplex converts the Variant (see page 3421) specified by AValue to a custom Variant (see page 3421) representing the corresponding complex number. It returns the custom Variant (see page 3421).

If VarAsComplex can't perform the conversion, it raises an EInvalidCast exception.

Complex Variants (see page 4973) are custom Variants (see page 4973) that represent complex numbers. The Variant (see page 3421) type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime (see page 3323) values, and boolean values. In addition, the VarCmplx (see page 4899) unit implements a number of global functions for operating on complex Variants (see page 4973).

EInvalidCast (see page 3935)

VarIsComplex (see page 4942)

VarComplexCreate (see page 4923)

VarComplexSimplify (see page 4934)

VarAsType (see page 5073)

48.1.2 VarCmplx.VarComplex Function

Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent complex numbers.

Pascal

```
function VarComplex: TVarType;
```

C++

```
TVarType VarComplex();
```

File

VarCmplx

Description

Use VarComplex to obtain the variant type code for custom Variants (see page 4973) that represent complex numbers. The Variant (see page 3421) type codes for custom Variants (see page 4973) are dynamically allocated when the application loads the unit that implements them. VarComplex allows the application to identify the Variant (see page 3421) type code that is currently used for custom Variants (see page 4973) that represent complex numbers. This type code, however, may not match the type code used by another application that uses a different set of custom Variant (see page 3421) types.

Complex Variants (see page 4973) are custom Variants (see page 4973) that represent complex numbers. The Variant (see page 3421) type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime (see page 3323) values, and boolean values. In addition, the VarCmplx (see page 4899) unit implements a number of global functions for operating on complex Variants (see page 4973).

See Also

VarType (see page 5090)

48.1.3 VarCmplx.VarComplexAbs Function

Returns the absolute value of a complex number.

Pascal

```
function VarComplexAbs(const AValue: Variant): Double;
```

C++

```
Double VarComplexAbs(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAbs to take the absolute value (length) of a complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexAbs returns the absolute value of AValue.

See Also

VarComplexAbsSqr (see page 4904)

VarComplexAngle (see page 4905)

VarComplexConjugate (see page 4918)

VarComplexInverse (see page 4927)

VarComplexTimesPosI (see page 4941)

VarComplexTimesNegI (see page 4940)

48.1.4 VarCmplx.VarComplexAbsSqr Function

Returns the square of the absolute value of a complex number.

Pascal

```
function VarComplexAbsSqr(const AValue: Variant): Double;
```

C++

```
Double VarComplexAbsSqr(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAbsSqr to obtain the square of a complex number's absolute value.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexAbs (see page 4903) returns the absolute value of AValue, squared.

See Also

VarComplexAbs (see page 4903)

VarComplexAngle (see page 4905)

VarComplexConjugate (see page 4918)

VarComplexInverse (see page 4927)

VarComplexTimesPosI (see page 4941)

VarComplexTimesNegI (see page 4940)

VarComplexLn (see page 4928)

VarComplexExp (see page 4926)

VarComplexSqr (see page 4936)

VarComplexSqrt (see page 4937)

VarComplexPower (see page 4930)

48.1.5 VarCmplx.VarComplexAngle Function

Returns the angle made by a complex number.

Pascal

```
function VarComplexAngle(const AValue: Variant): Double;
```

C++

```
Double VarComplexAngle(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAngle to obtain the angle of a complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexAbs (see page 4903) returns the angle that corresponds to AValue.

See Also

VarComplexToPolar (see page 4942)

VarComplexAbs (see page 4903)

48.1.6 VarCmplx.VarComplexArcCos Function

Returns the inverse cosine of a complex number.

Pascal

```
function VarComplexArcCos(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCos(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCos computes the inverse cosine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCos returns a Variant (see page 3421) whose value is the inverse cosine of AValue.

See Also

VarComplexArcCosH (see page 4906)

VarComplexArcTanH (see page 4917)
VarComplexCos (see page 4919)
VarComplexCosH (see page 4920)
VarComplexCot (see page 4921)
VarComplexCotH (see page 4922)
VarComplexCsc (see page 4924)
VarComplexCscH (see page 4925)
VarComplexSec (see page 4931)
VarComplexSecH (see page 4932)
VarComplexSin (see page 4934)
VarComplexSinH (see page 4935)
VarComplexTan (see page 4938)
VarComplexTanH (see page 4939)

48.1.7 VarCmplx.VarComplexArcCosH Function

Returns the hyperbolic inverse cosine of a complex number.

Pascal

```
function VarComplexArcCosH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCosH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCosH computes the hyperbolic inverse cosine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCosH returns a Variant (see page 3421) whose value is the hyperbolic inverse cosine of AValue.

VarComplexSinH (see page 4935)
VarComplexTan (see page 4938)
VarComplexTanH (see page 4939)

48.1.8 VarCmplx.VarComplexArcCot Function

Returns the inverse cotangent of a complex number.

Pascal

```
function VarComplexArcCot(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCot(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCot computes the inverse cotangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCot returns a Variant (see page 3421) whose value is the inverse cotangent of AValue.

VarComplexTanH (see page 4939)

48.1.9 VarCmplx.VarComplexArcCotH Function

Returns the hyperbolic inverse cotangent of a complex number.

Pascal

```
function VarComplexArcCotH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCotH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCot (see page 4907) computes the hyperbolic inverse cotangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCot (see page 4907) returns a Variant (see page 3421) whose value is the hyperbolic inverse cotangent of AValue.

VarComplexTan (see page 4938)

VarComplexTanH (see page 4939)

48.1.10 VarCmplx.VarComplexArcCsc Function

Returns the inverse cosecant of a complex number.

Pascal

```
function VarComplexArcCsc(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCsc(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCsc computes the inverse cosecant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCsc returns a Variant (see page 3421) whose value is the inverse cosecant of AValue.

See Also

VarComplexArcCosH (see page 4906)

48.1.11 VarCmplx.VarComplexArcCscH Function

Returns the hyperbolic inverse cosecant of a complex number.

Pascal

```
function VarComplexArcCscH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCscH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCsc (see page 4909) computes the hyperbolic inverse cosecant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcCsc (see page 4909) returns a Variant (see page 3421) whose value is the hyperbolic inverse cosecant of AValue.

See Also

48.1.12 VarCmplx.VarComplexArcSec Function

Returns the inverse secant of a complex number.

Pascal

```
function VarComplexArcSec(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSec(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSec computes the inverse secant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcSec returns a Variant (see page 3421) whose value is the inverse secant of AValue.

VarComplexTanH (see page 4939)

48.1.13 VarCmplx.VarComplexArcSecH Function

Returns the hyperbolic inverse secant of a complex number.

Pascal

```
function VarComplexArcSecH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSecH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSec (see page 4912) computes the hyperbolic inverse secant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcSec (see page 4912) returns a Variant (see page 3421) whose value is the hyperbolic inverse secant of AValue.

48.1.14 VarCmplx.VarComplexArcSin Function

Returns the inverse sine of a complex number.

Pascal

```
function VarComplexArcSin(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSin(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSin computes the inverse sine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcSin returns a Variant (see page 3421) whose value is the inverse sine of AValue.

48.1.15 VarCmplx.VarComplexArcSinH Function

Returns the hyperbolic inverse sine of a complex number.

Pascal

```
function VarComplexArcSinH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSinH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSinH computes the hyperbolic inverse sine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcSinH returns a Variant (see page 3421) whose value is the hyperbolic inverse sine of AValue.

48.1.16 VarCmplx.VarComplexArcTan Function

Returns the inverse tangent of a complex number.

Pascal

```
function VarComplexArcTan(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcTan(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcTan computes the inverse tangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcTan returns a Variant (see page 3421) whose value is the inverse tangent of AValue.

48.1.17 VarCmplx.VarComplexArcTanH Function

Returns the hyperbolic inverse tangent of a complex number.

Pascal

```
function VarComplexArcTanH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcTanH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcTanH computes the hyperbolic inverse tangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexArcTanH returns a Variant (see page 3421) whose value is the hyperbolic inverse tangent of AValue.

48.1.18 VarCmplx.VarComplexConjugate Function

Returns the conjugate of a complex number.

Pascal

```
function VarComplexConjugate(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexConjugate(const Variant AValue);
```

File

VarCmplx

Description

VarComplexConjugate returns the conjugate of a complex number. The conjugate is the value that has the same real part and the inverse of the imaginary part.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexConjugate returns a Variant (see page 3421) whose value is the conjugate of AValue.

48.1.19 VarCmplx.VarComplexCos Function

Returns the cosine of a complex number.

Pascal

```
function VarComplexCos(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCos(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCos computes the cosine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCos returns a Variant (see page 3421) whose value is the cosine of AValue.

48.1.20 VarCmplx.VarComplexCosH Function

Returns the hyperbolic cosine of a complex number.

Pascal

```
function VarComplexCosH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCosH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCosH computes the hyperbolic cosine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCosH returns a Variant (see page 3421) whose value is the hyperbolic cosine of AValue.

48.1.21 VarCmplx.VarComplexCot Function

Returns the cotangent of a complex number.

Pascal

```
function VarComplexCot(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCot(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCot computes the cotangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCot returns a Variant (see page 3421) whose value is the cotangent of AValue.

48.1.22 VarCmplx.VarComplexCotH Function

Returns the hyperbolic cotangent of a complex number.

Pascal

```
function VarComplexCotH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCotH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCot (see page 4921) computes the hyperbolic cotangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCot (see page 4921) returns a Variant (see page 3421) whose value is the hyperbolic cotangent of AValue.

48.1.23 VarCmplx.VarComplexCreate Function

Returns a custom Variant (see page 3421) that represents a complex number.

Pascal

```
function VarComplexCreate: Variant; overload;
function VarComplexCreate(const AReal: Double): Variant; overload;
function VarComplexCreate(const AReal: Double; const AImaginary: Double): Variant; overload;
function VarComplexCreate(const AText: string): Variant; overload;
```

C++

```
Variant VarComplexCreate();
Variant VarComplexCreate(const Double AReal);
Variant VarComplexCreate(const Double AReal, const Double AImaginary);
Variant VarComplexCreate(const UnicodeString AText);
```

File

VarCmplx

Description

Call VarComplexCreate to create a Variant (see page 3421) whose value is a complex number.

AReal is the real part of the complex number.

AImaginary is the imaginary part of the complex number.

Using the first three versions of the constructor, omitting AReal or AImaginary results in a real or imaginary part of 0.

Using the last syntax, AText is parsed using the ComplexNumberSymbol (see page 4944) and

ComplexNumberSymbolBeforeImaginary (see page 4945) global variables and, if the string represents a complex value, that becomes the value of the new Variant (see page 3421). If the string can't be parsed into a complex number, VarComplexCreate raises an EConvertError exception.

Complex Variants (see page 4973) are custom Variants (see page 4973) that represent complex numbers. The Variant (see page 3421) type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime (see page 3323) values, and boolean values. In addition, the VarCmplx (see page 4899) unit implements a number of global functions for operating on complex Variants (see page 4973).

48.1.24 VarCmplx.VarComplexCsc Function

Returns the cosecant of a complex number.

Pascal

```
function VarComplexCsc(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCsc(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCsc computes the cosecant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCsc returns a Variant (see page 3421) whose value is the cosecant of AValue.

48.1.25 VarCmplx.VarComplexCscH Function

Returns the hyperbolic cosecant of a complex number.

Pascal

```
function VarComplexCscH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCscH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCsc (see page 4924) computes the hyperbolic cosecant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexCsc (see page 4924) returns a Variant (see page 3421) whose value is the hyperbolic cosecant of AValue.

48.1.26 VarCmplx.VarComplexExp Function

Returns the exponential of a complex number.

Pascal

```
function VarComplexExp(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexExp(const Variant AValue);
```

File

VarCmplx

Description

VarComplexExp returns value of e raised to the power of a specified complex number, where e is the base of the natural logarithms.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexExp returns a Variant (see page 3421) whose value is the exponential of AValue.

See Also

48.1.27 VarCmplx.VarComplexFromPolar Function

Converts a set of polar coordinates to a complex number.

Pascal

```
function VarComplexFromPolar(const ARadius: Double; const ATheta: Double): Variant;
```

C++

```
Variant VarComplexFromPolar(const Double ARadius, const Double ATheta);
```

File

VarCmplx

Description

VarComplexFromPolar returns the complex number that corresponds to the radius (length) and angle specified by the ARadius and ATheta parameters, respectively. The result is returned as a Variant (see page 3421) whose value is the corresponding complex number.

See Also

VarComplexCreate (see page 4923)

VarComplexToPolar (see page 4942)

48.1.28 VarCmplx.VarComplexInverse Function

Returns the inverse of a complex number.

Pascal

```
function VarComplexInverse(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexInverse(const Variant AValue);
```

File

VarCmplx

Description

VarComplexInverse returns the inverse of a complex number. The inverse is the value that results when you divide 1 by the complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexInverse returns a Variant (see page 3421) whose value is the inverse of AValue.

See Also

VarComplexAbs (see page 4903)

VarComplexAngle (see page 4905)

VarComplexAbsSqr (see page 4904)

VarComplexConjugate (see page 4918)

VarComplexTimesPosI (see page 4941)

VarComplexTimesNegI (see page 4940)

VarComplexLn (see page 4928)

VarComplexExp (see page 4926)

VarComplexSqr (see page 4936)

VarComplexSqrt (see page 4937)

VarComplexPower (see page 4930)

48.1.29 VarCmplx.VarComplexLn Function

Returns the natural log of a complex number.

Pascal

```
function VarComplexLn(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLn(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLn returns the natural logarithm of a complex number. The natural logarithm is the power to which you must raise e to get the complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexLn returns a Variant (see page 3421) whose value is the natural log of AValue.

See Also

VarComplexAbs (see page 4903)

VarComplexAngle (see page 4905)

VarComplexAbsSqr (see page 4904)

VarComplexConjugate (see page 4918)

VarComplexTimesNegI (see page 4940)

VarComplexInverse (see page 4927)

VarComplexExp (see page 4926)

VarComplexSqr (see page 4936)

VarComplexSqrt (see page 4937)

VarComplexPower (see page 4930)

48.1.30 VarCmplx.VarComplexLog10 Function

Returns the log base 10 of a complex number.

Pascal

```
function VarComplexLog10(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLog10(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLog10 returns the base 10 logarithm of a complex number. The base 10 logarithm is the power to which you must raise 10 to get the complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexLog10 returns a Variant (see page 3421) whose value is the log base 10 of AValue.

See Also

VarComplexLn (see page 4928)

VarComplexLog2 (see page 4929)

VarComplexLogN (see page 4930)

48.1.31 VarCmplx.VarComplexLog2 Function

Returns the log base 2 of a complex number.

Pascal

```
function VarComplexLog2(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLog2(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLog2 returns the base 2 logarithm of a complex number. The base 2 logarithm is the power to which you must raise 2 to get the complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexLog2 returns a Variant (see page 3421) whose value is the log base 2 of AValue.

See Also

VarComplexLn (see page 4928)

VarComplexLog10 (see page 4929)

VarComplexLogN (see page 4930)

48.1.32 VarCmplx.VarComplexLogN Function

Returns the log base N of a complex number.

Pascal

```
function VarComplexLogN(const AValue: Variant; const X: Double): Variant;
```

C++

```
Variant VarComplexLogN(const Variant AValue, const Double X);
```

File

VarCmplx

Description

VarComplexLogN returns the base N logarithm of a complex number. The base N logarithm is the power to which you must raise an exponent N to get the complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

X is the logarithm exponent.

VarComplexLogN returns a Variant (see page 3421) whose value is the log base N of AValue.

See Also

VarComplexLn (see page 4928)

VarComplexLog2 (see page 4929)

VarComplexLog10 (see page 4929)

48.1.33 VarCmplx.VarComplexPower Function

Returns the value of a complex number raised to a specified power.

Pascal

```
function VarComplexPower(const AValue: Variant; const APower: Variant): Variant;
```

C++

```
Variant VarComplexPower(const Variant AValue, const Variant APower);
```

File

VarCmplx

Description

VarComplexPower returns the result of raising AValue to the power APower.

AValue is a Variant (see page 3421) whose value represents the complex number.

APower is a Variant (see page 3421) that specifies the power to which you want to raise AValue. It can also be a complex number.

VarComplexPower returns a Variant (see page 3421) whose value is AValue raised to the APower power.

48.1.34 VarCmplx.VarComplexSec Function

Returns the secant of a complex number.

Pascal

```
function VarComplexSec(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSec(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSec computes the secant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexSec returns a Variant (see page 3421) whose value is the secant of AValue.

48.1.35 VarCmplx.VarComplexSecH Function

Returns the hyperbolic secant of a complex number.

Pascal

```
function VarComplexSecH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSecH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSec (see page 4931) computes the hyperbolic secant of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexSec (see page 4931) returns a Variant (see page 3421) whose value is the hyperbolic secant of AValue.

48.1.36 VarCmplx.VarComplexSign Function

Pascal

```
function VarComplexSign(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSign(const Variant AValue);
```

File

VarCmplx

Description

This is function VarCmplx.VarComplexSign.

48.1.37 VarCmplx.VarComplexSimplify Function

Reduces a Variant (see page 3421) that represents a complex number to one that represents a real value, if possible.

Pascal

```
function VarComplexSimplify(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSimplify(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexSimplify to convert a complex number to a real value when possible. VarComplexSimplify checks whether the Variant (see page 3421) specified by AValue represents a complex number that has no imaginary part. If so, it returns a Variant (see page 3421) whose value is simply a real number. If AValue does not represent a complex number, or if AValue represents a complex number with a nonzero imaginary part, VarComplexSimplify returns AValue.

VarAsType (see page 5073)

48.1.38 VarCmplx.VarComplexSin Function

Returns the sine of a complex number.

Pascal

```
function VarComplexSin(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSin(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSin computes the sine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexSin returns a Variant (see page 3421) whose value is the sine of AValue.

48.1.39 VarCmplx.VarComplexSinH Function

Returns the hyperbolic sine of a complex number.

Pascal

```
function VarComplexSinH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSinH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSinH computes the hyperbolic sine of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexSinH returns a Variant (see page 3421) whose value is the hyperbolic sine of AValue.

48.1.40 VarCmplx.VarComplexSqr Function

Returns the square of a complex number.

Pascal

```
function VarComplexSqr(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSqr(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSqr returns the square of AValue.

AValue is a Variant (see page 3421) whose value represents the complex number.

See Also

VarComplexAbs (see page 4903)

VarComplexAngle (see page 4905)

VarComplexAbsSqr (see page 4904)

VarComplexSqrt (see page 4937)

VarComplexPower (see page 4930)

48.1.41 VarCmplx.VarComplexSqrt Function

Returns the square root of a complex number.

Pascal

```
function VarComplexSqrt(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSqrt(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSqrt returns the square root of AValue.

AValue is a Variant (see page 3421) whose value represents the complex number.

See Also

VarComplexAbs (see page 4903)

VarComplexAngle (see page 4905)

VarComplexAbsSqr (see page 4904)

48.1.42 VarCmplx.VarComplexTan Function

Returns the tangent of a complex number.

Pascal

```
function VarComplexTan(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTan(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTan computes the tangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexTan returns a Variant (see page 3421) whose value is the tangent of AValue.

48.1.43 VarCmplx.VarComplexTanH Function

Returns the hyperbolic tangent of a complex number.

Pascal

```
function VarComplexTanH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTanH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTanH computes the hyperbolic tangent of a complex number and returns the result.

AValue is a Variant (see page 3421) whose value represents the complex number.

VarComplexTanH returns a Variant (see page 3421) whose value is the hyperbolic tangent of AValue.

See Also

VarComplexArcTan (see page 4916)

48.1.44 VarCmplx.VarComplexTimesImaginary Function

Returns the value of a complex number multiplied by an imaginary number.

Pascal

```
function VarComplexTimesImaginary(const AValue: Variant; const AFactor: Double): Variant;
```

C++

```
Variant VarComplexTimesImaginary(const Variant AValue, const Double AFactor);
```

File

VarCmplx

Description

VarComplexTimesImaginary returns a complex value times an imaginary number.

AValue is a Variant (see page 3421) whose value represents the complex number.

AFactor is a real number that represents the imaginary number. That is, the imaginary number is AFactor times i.

VarComplexTimesImaginary returns a variant whose value is AValue times AFactor times i.

See Also

VarComplexTimesNegI (see page 4940)

VarComplexTimesPosI (see page 4941)

VarComplexTimesReal (see page 4941)

48.1.45 VarCmplx.VarComplexTimesNegI Function

Returns the value of a complex number multiplied by –i.

Pascal

```
function VarComplexTimesNegI(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTimesNegI(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTimesNegI returns AValue times –i.

AValue is a Variant (see page 3421) whose value represents the complex number.

See Also

VarComplexTimesImaginary (see page 4940)

VarComplexTimesPosI (see page 4941)

VarComplexTimesReal (see page 4941)

48.1.46 VarCmplx.VarComplexTimesPosI Function

Returns the value of a complex number multiplied by i.

Pascal

```
function VarComplexTimesPosI(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTimesPosI(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTimesPosI returns AValue times i.

AValue is a Variant (see page 3421) whose value represents the complex number.

See Also

VarComplexTimesNegI (see page 4940)

VarComplexTimesImaginary (see page 4940)

VarComplexTimesReal (see page 4941)

48.1.47 VarCmplx.VarComplexTimesReal Function

Returns the value of a complex number multiplied by a real number.

Pascal

```
function VarComplexTimesReal(const AValue: Variant; const AFactor: Double): Variant;
```

C++

```
Variant VarComplexTimesReal(const Variant AValue, const Double AFactor);
```

File

VarCmplx

Description

VarComplexTimesReal returns a complex value times a real number.

AValue is a Variant (see page 3421) whose value represents the complex number.

AFactor is a real number.

VarComplexTimesReal returns a variant whose value is AValue times AFactor.

See Also

VarComplexTimesNegI (see page 4940)

VarComplexTimesPosI (see page 4941)

48.1.48 VarCmplx.VarComplexToPolar Function

Computes the polar coordinates that correspond to a custom Variant (see page 3421) that represents a complex number.

Pascal

```
procedure VarComplexToPolar(const AValue: Variant; var ARadius: Double; var ATheta: Double;
AFixTheta: Boolean = True);
```

C++

```
VarComplexToPolar(const Variant AValue, Double ARadius, Double ATheta, Boolean AFixTheta =
True);
```

File

VarCmplx

Description

Call VarComplexToPolar to obtain the polar coordinates for a complex number.

AValue is a Variant (see page 3421) whose value represents the complex number.

ARadius returns the radius of the corresponding polar coordinates.

ATheta returns the angle (Theta) of the corresponding polar coordinates.

AFixTheta indicates whether VarComplexToPolar should normalize the angle (ATheta). When AFixTheta is true, VarComplexToPolar always returns an angle between – pi and pi.

See Also

VarComplexAngle (see page 4905)

VarComplexFromPolar (see page 4927)

VarComplexAbs (see page 4903)

48.1.49 VarCmplx.VarIsComplex Function

Indicates whether a Variant (see page 3421) stores its data internally as a complex number.

Pascal

```
function VarIsComplex(const AValue: Variant): Boolean;
```

C++

```
Boolean VarIsComplex(const Variant AValue);
```

File

VarCmplx

Description

VarIsComplex returns true if AValue represents a complex number (that is, if it has a VarType (see page 5090) of VarComplex (see page 4903)).

Complex Variants (see page 4973) are custom Variants (see page 4973) that represent complex numbers. The Variant (see page 3421) type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime (see page 3323) values, and boolean values. In addition, the VarCmplx (see page 4899) unit implements a number of global functions for operating on complex Variants (see page 4973).

See Also

VarAsComplex (see page 4902)

VarComplexCreate (see page 4923)

VarComplexSimplify (see page 4934)

VarComplex (see page 4903)

VarType (see page 5090)

48.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ComplexNumberDefuzzAtZero (see page 4944)	This is variable VarCmplx.ComplexNumberDefuzzAtZero.
ComplexNumberSymbol (see page 4944)	Indicates the symbol used to represent the imaginary part of a complex number.
ComplexNumberSymbolBeforeImaginary (see page 4945)	Indicates the placement of the symbol that represents the imaginary part of a complex number.

48.2.1 VarCmplx.ComplexNumberDefuzzAtZero Variable

Pascal

```
ComplexNumberDefuzzAtZero: Boolean = True;
```

C++

```
Boolean ComplexNumberDefuzzAtZero = True;
```

File

VarCmplx

Description

This is variable VarCmplx.ComplexNumberDefuzzAtZero.

48.2.2 VarCmplx.ComplexNumberSymbol Variable

Indicates the symbol used to represent the imaginary part of a complex number.

Pascal

```
ComplexNumberSymbol: string = 'i';
```

C++

```
UnicodeString ComplexNumberSymbol = 'i';
```

File

VarCmplx

Description

Custom Variants (see page 4973) that represent complex numbers use ComplexNumberSymbol when converting between complex values and strings. This identifies the symbol used to signal the imaginary part of a complex number. By default, this value is 'i'. This allows the custom Variant (see page 3421) for complex numbers to interpret or produce strings such as '3.4 + 2i'.

See Also

ComplexNumberSymbolBeforeImaginary (see page 4945)

48.2.3 VarCmplx.ComplexNumberSymbolBeforeImaginary Variable

Indicates the placement of the symbol that represents the imaginary part of a complex number.

Pascal

```
ComplexNumberSymbolBeforeImaginary: Boolean = False;
```

C++

```
Boolean ComplexNumberSymbolBeforeImaginary = False;
```

File

VarCmplx

Description

Custom Variants (see page 4973) that represent complex numbers use ComplexNumberSymbolBeforeImaginary when converting between complex values and strings.

When ComplexNumberSymbolBeforeImaginary is false (the default), the symbol appears after the imaginary part, as in '3.4 + 2i'.

When ComplexNumberSymbolBeforeImaginary is true, the symbol appears before the imaginary part, as in '3.4 + i2'.

See Also

ComplexNumberSymbol (see page 4944)

49 VarConv Namespace

This is namespace VarConv.

Topics

Name	Description
Functions (see page 4948)	The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsConvert (see page 4948)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a measurement.
	VarAsConvert (see page 4948)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a measurement.
	VarConvert (see page 4949)	Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent measurements.
	VarConvertCreate (see page 4950)	Returns a custom Variant (see page 3421) that represents a measurement.
	VarConvertCreate (see page 4950)	Returns a custom Variant (see page 3421) that represents a measurement.
	VarIsConvert (see page 4951)	Indicates whether a Variant (see page 3421) is a custom Variant (see page 3421) that represents a measurement.

49.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsConvert (see page 4948)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a measurement.
	VarAsConvert (see page 4948)	Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a measurement.
	VarConvert (see page 4949)	Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent measurements.
	VarConvertCreate (see page 4950)	Returns a custom Variant (see page 3421) that represents a measurement.
	VarConvertCreate (see page 4950)	Returns a custom Variant (see page 3421) that represents a measurement.
	VarIsConvert (see page 4951)	Indicates whether a Variant (see page 3421) is a custom Variant (see page 3421) that represents a measurement.

49.1.1 VarConv.VarAsConvert Function

Casts an arbitrary Variant (see page 3421) so that it is a custom Variant (see page 3421) representing a measurement.

Pascal

```
function VarAsConvert(const AValue: Variant): Variant; overload;
function VarAsConvert(const AValue: Variant; const AType: TConvType): Variant; overload;
```

C++

```
Variant VarAsConvert(const Variant AValue);
Variant VarAsConvert(const Variant AValue, const TConvType AType);
```

File

VarConv

Description

VarAsConvert converts the Variant (see page 3421) specified by AValue to a VarConvert (see page 4949) custom Variant (see page 3421).

Using the first syntax, AValue is interpreted as the numeric portion (the number of units), and AType identifies the units.

Using the second syntax, AValue should be a Variant (see page 3421) that can be parsed into a VarConv (see page 4947) custom Variant (see page 3421) (for example, a variant whose value is a string such as '1.5 miles').

If VarAsConvert can't perform the conversion, it raises an EInvalidCast (see page 3935) exception.

VarConvert (see page 4949) custom Variants (see page 4973) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils unit. You can use the negation operator on VarConv (see page 4947) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 4947) Variant (see page 3421) with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 4947) Variants (see page 4973). VarConv (see page 4947) custom Variants (see page 4973) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant (see page 3421) has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

EInvalidCast (see page 3935)

VarIsConvert (see page 4951)

VarConvertCreate (see page 4950)

VarAsType (see page 5073)

TVarData (see page 3740)

49.1.2 VarConv.VarConvert Function

Returns the Variant (see page 3421) type code for custom Variants (see page 4973) that represent measurements.

Pascal

```
function VarConvert: TVarType;
```

C++

```
TVarType VarConvert();
```

File

VarConv

Description

Use VarConvert to obtain the variant type code for custom Variants (see page 4973) that represent measurements. The Variant (see page 3421) type codes for custom Variants (see page 4973) are dynamically allocated when the application loads the unit that implements them. VarConvert allows the application to identify the Variant (see page 3421) type code that is currently used for custom Variants (see page 4973) that represent VarConvert custom Variants (see page 4973). This type code, however, may not match the type code used by another application that uses a different set of custom Variant (see page 3421) types.

VarConvert custom Variants (see page 4973) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils unit. You can use the negation operator on VarConv (see page 4947) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 4947) Variant (see page 3421) with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 4947) Variants (see page 4973). VarConv (see page 4947) custom Variants (see page 4973) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant (see page 3421) has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

See Also

VarType (see page 5090)

49.1.3 VarConv.VarConvertCreate Function

Returns a custom Variant (see page 3421) that represents a measurement.

Pascal

```
function VarConvertCreate(const AValue: Double; const AType: TConvType): Variant; overload;
function VarConvertCreate(const AValue: string): Variant; overload;
```

C++

```
Variant VarConvertCreate(const Double AValue, const TConvType AType);
Variant VarConvertCreate(const UnicodeString AValue);
```

File

VarConv

Description

Call VarConvertCreate to create a Variant (see page 3421) whose value is a measurement.

Using the first syntax, AType indicates the measurement units, and AValue is the number of those units. AType must represent a registered conversion unit.

Using the second syntax, AValue is a string that can be parsed by the TryStrToConvUnit function. (For example '1.5 liters'.)

If the string can't be parsed into a measurement, VarConvertCreate raises an EInvalidCast (see page 3935) exception.

VarConvert (see page 4949) custom Variants (see page 4973) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils unit. You can use the negation operator on VarConv (see page 4947) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 4947) Variant (see page 3421) with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 4947) Variants (see page 4973). VarConv (see page 4947) custom Variants (see page 4973) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant (see page 3421) has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

See Also

VarIsConvert (see page 4951)

VarAsConvert (see page 4948)

EInvalidCast (see page 3935)

49.1.4 VarConv.VarIsConvert Function

Indicates whether a Variant (see page 3421) is a custom Variant (see page 3421) that represents a measurement.

Pascal

```
function VarIsConvert(const AValue: Variant): Boolean;
```

C++

```
Boolean VarIsConvert(const Variant AValue);
```

File

VarConv

Description

VarIsConvert returns true if AValue represents a measurement (that is, if it has a VarType (see page 5090) of VarConvert (see page 4949)).

VarConvert (see page 4949) custom Variants (see page 4973) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils unit. You can use the negation operator on VarConv (see page 4947) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 4947) Variant (see page 3421) with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 4947) Variants (see page 4973). VarConv (see page 4947) custom Variants (see page 4973) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant (see page 3421) has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

50 VarHlpr Namespace

This is namespace VarHlpr.

Topics

Name	Description
Functions (see page 4955)	The following table lists functions in this documentation.

Functions

	Name	Description
	VariantAdd (see page 4955)	Adds two Variants (see page 4973).
	VariantAdd2 (see page 4956)	Adds two Variants (see page 4973).
	VariantAnd (see page 4956)	Performs an **and** operation between two Variant (see page 3421) values.
	VariantAnd2 (see page 4957)	Performs an **and** operation between two Variants (see page 4973).
	VariantArrayRedim (see page 4957)	Resizes a Variant (see page 3421) array.
	VariantCast (see page 4958)	Performs a type-cast on a Variant (see page 3421).
	VariantClear (see page 4958)	Empties a Variant (see page 3421), so that it is unassigned.
	VariantCpy (see page 4959)	Copies a Variant (see page 3421).
	VariantDiv (see page 4959)	Divides two Variants (see page 4973).
	VariantDiv2 (see page 4960)	Divides two Variants (see page 4973).
	VariantFromUnicodeString (see page 4960)	Assigns an Unicode string to a Variant (see page 3421).
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantMod (see page 4962)	Returns the remainder on division of two Variants (see page 4973).
	VariantMod2 (see page 4962)	Returns the remainder on division of two Variants (see page 4973).
	VariantMul (see page 4963)	Multiplies two Variants (see page 4973).
	VariantMul2 (see page 4963)	Multiplies two Variants (see page 4973).
	VariantNeg (see page 4964)	Inverts the sign of a Variant (see page 3421).
	VariantNot (see page 4964)	Performs a **not** operation on a Variant (see page 3421).
	VariantOr (see page 4964)	Performs an **or** operation between two Variants (see page 4973).
	VariantOr2 (see page 4965)	Performs an **or** operation between two Variants (see page 4973).
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.

	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantShl (see page 4966)	Performs an **shl** (shift left) operation between two Variants (see page 4973).
	VariantShl2 (see page 4967)	Performs an **shl** (shift left) operation between two Variants (see page 4973).
	VariantShr (see page 4967)	Performs an **shr** (shift right) operation between two Variants (see page 4973).
	VariantShr2 (see page 4968)	Performs an **shr** (shift right) operation between two Variants (see page 4973).
	VariantSub (see page 4968)	Subtracts two Variants (see page 4973).
	VariantSub2 (see page 4969)	Subtracts two Variants (see page 4973).
	VariantToUnicodeString (see page 4969)	Converts a Variant (see page 3421) to an Unicode string.
	VariantXor (see page 4970)	Performs a **xor** (exclusive or) operation between two Variants (see page 4973).
	VariantXor2 (see page 4970)	Performs a **xor** (exclusive or) operation between two Variants (see page 4973).

50.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	VariantAdd (see page 4955)	Adds two Variants (see page 4973).
	VariantAdd2 (see page 4956)	Adds two Variants (see page 4973).
	VariantAnd (see page 4956)	Performs an **and** operation between two Variant (see page 3421) values.
	VariantAnd2 (see page 4957)	Performs an **and** operation between two Variants (see page 4973).
	VariantArrayRedim (see page 4957)	Resizes a Variant (see page 3421) array.
	VariantCast (see page 4958)	Performs a type-cast on a Variant (see page 3421).
	VariantClear (see page 4958)	Empties a Variant (see page 3421), so that it is unassigned.
	VariantCpy (see page 4959)	Copies a Variant (see page 3421).
	VariantDiv (see page 4959)	Divides two Variants (see page 4973).
	VariantDiv2 (see page 4960)	Divides two Variants (see page 4973).
	VariantFromUnicodeString (see page 4960)	Assigns an Unicode string to a Variant (see page 3421).
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantGetElement (see page 4961)	Returns an element from a Variant (see page 3421) array.
	VariantMod (see page 4962)	Returns the remainder on division of two Variants (see page 4973).
	VariantMod2 (see page 4962)	Returns the remainder on division of two Variants (see page 4973).
	VariantMul (see page 4963)	Multiplies two Variants (see page 4973).
	VariantMul2 (see page 4963)	Multiplies two Variants (see page 4973).
	VariantNeg (see page 4964)	Inverts the sign of a Variant (see page 3421).
	VariantNot (see page 4964)	Performs a **not** operation on a Variant (see page 3421).
	VariantOr (see page 4964)	Performs an **or** operation between two Variants (see page 4973).
	VariantOr2 (see page 4965)	Performs an **or** operation between two Variants (see page 4973).
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantPutElement (see page 4966)	Sets the value of an element in a Variant (see page 3421) array.
	VariantShl (see page 4966)	Performs an **shl** (shift left) operation between two Variants (see page 4973).
	VariantShl2 (see page 4967)	Performs an **shl** (shift left) operation between two Variants (see page 4973).
	VariantShr (see page 4967)	Performs an **shr** (shift right) operation between two Variants (see page 4973).
	VariantShr2 (see page 4968)	Performs an **shr** (shift right) operation between two Variants (see page 4973).
	VariantSub (see page 4968)	Subtracts two Variants (see page 4973).
	VariantSub2 (see page 4969)	Subtracts two Variants (see page 4973).
	VariantToUnicodeString (see page 4969)	Converts a Variant (see page 3421) to an Unicode string.
	VariantXor (see page 4970)	Performs a **xor** (exclusive or) operation between two Variants (see page 4973).
	VariantXor2 (see page 4970)	Performs a **xor** (exclusive or) operation between two Variants (see page 4973).

50.1.1 VarHlpr.VariantAdd Function

Adds two Variants (see page 4973).

Pascal

```
procedure VariantAdd(const src: Variant; var dst: Variant);
```

C++

```
VariantAdd(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantAdd adds **src** to **dst** and returns the result as **dst**.

The input values must have compatible types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantAdd2 (see page 4956)

VariantSub (see page 4968)

VariantSub2 (see page 4969)

50.1.2 VarHlpr.VariantAdd2 Function

Adds two Variants (see page 4973).

Pascal

```
function VariantAdd2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantAdd2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantAdd2 adds **V1** to **V2** and returns a new Variant (see page 3421) holding the result.

The input values must have compatible types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantAdd (see page 4955)

VariantSub (see page 4968)

VariantSub2 (see page 4969)

50.1.3 VarHlpr.VariantAnd Function

Performs an **and** operation between two Variant (see page 3421) values.

Pascal

```
procedure VariantAnd(const src: Variant; var dst: Variant);
```

C++

```
VariantAnd(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantAnd performs a bit-wise or a logical **and** operation between **src** and **dst** and returns the result as **dst**.

The input values must be convertible to numerical or boolean types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantAnd2 (see page 4957)

VariantOr (see page 4964)

VariantOr2 (see page 4965)

50.1.4 VarHlpr.VariantAnd2 Function

Performs an **and** operation between two Variants (see page 4973).

Pascal

```
function VariantAnd2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantAnd2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantAnd2 performs a bit-wise or a logical **and** operation between **V1** and **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical or boolean types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantAnd (see page 4956)

VariantOr (see page 4964)

VariantOr2 (see page 4965)

50.1.5 VarHlpr.VariantArrayRedim Function

Resizes a Variant (see page 3421) array.

Pascal

```
procedure VariantArrayRedim(var V: Variant; High: Integer);
```

C++

```
VariantArrayRedim(Variant V, int High);
```

File

VarHlpr

Description

VariantArrayRedim resizes the given Variant (see page 3421) array by changing the high bound of the rightmost dimension to the given value.

The input value must be a Variant (see page 3421) array; otherwise an EVariantInvalidArgError exception will be raised.

See Also

VariantGetElement (see page 4961)

VariantPutElement (see page 4966)

50.1.6 VarHlpr.VariantCast Function

Performs a type-cast on a Variant (see page 3421).

Pascal

```
procedure VariantCast(const src: Variant; var dst: Variant; vt: Integer);
```

C++

```
VariantCast(const Variant src, Variant dst, int vt);
```

File

VarHlpr

Description

VariantCast type-casts **src** to the desired type and returns the resulted Variant (see page 3421) as **dst**. **vt** is a value which identifies the type of the destination Variant (see page 3421).

An EVariantTypeCastError exception will be raised if the source cannot be type-casted to the desired type.

See Also

VariantClear (see page 4958)

VarClear (see page 3704)

50.1.7 VarHlpr.VariantClear Function

Empties a Variant (see page 3421), so that it is unassigned.

Pascal

```
procedure VariantClear(var V: Variant);
```

C++

```
VariantClear(Variant V);
```

File

VarHlpr

Description

Calling VariantClear is equivalent to assigning the Unassigned constant to the Variant (see page 3421). After calling VariantClear, the VarIsEmpty function returns true, and the VarType function returns varEmpty (see page 3865). Using an unassigned variant in an expression causes an exception to be thrown. Likewise, if you attempt to convert an unassigned Variant (see page 3421) to another type (using VariantCast (see page 4958)), an exception is thrown.

Note: Do not confuse clearing a Variant (see page 3421), which leaves it unassigned, with assigning a Null value. A Null Variant (see page 3421) is still assigned, but has the value Null. Unlike unassigned Variants (see page 4973), Null Variants (see page 4973) can be used in expressions and can be converted to other types of Variants (see page 4973).

See Also

VariantCast (see page 4958)

VarClear (see page 3704)

50.1.8 VarHlpr.VariantCpy Function

Copies a Variant (see page 3421).

Pascal

```
procedure VariantCpy(const src: Variant; var dst: Variant);
```

C++

```
VariantCpy(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantCpy copies the Variant (see page 3421) value contained in **src** to **dst**.

See Also

VariantClear (see page 4958)

VariantCast (see page 4958)

50.1.9 VarHlpr.VariantDiv Function

Divides two Variants (see page 4973).

Pascal

```
procedure VariantDiv(const src: Variant; var dst: Variant);
```

C++

```
VariantDiv(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantDiv divides **src** to **dst** and returns the result as **dst**.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantDiv2 (see page 4960)

VariantMul (see page 4963)

VariantMul2 (see page 4963)

50.1.10 VarHlpr.VariantDiv2 Function

Divides two Variants (see page 4973).

Pascal

```
function VariantDiv2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantDiv2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantDiv2 divides **V1** to **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantDiv (see page 4959)

VariantMul (see page 4963)

VariantMul2 (see page 4963)

50.1.11 VarHlpr.VariantFromUnicodeString Function

Assigns an Unicode string to a Variant (see page 3421).

Pascal

```
procedure VariantFromUnicodeString(var V: Variant; const Str: UnicodeString);
```

C++

```
VariantFromUnicodeString(Variant V, const UnicodeString Str);
```

File

VarHlpr

Description

VariantFromUnicodeString assigns an Unicode string to a given Variant (see page 3421) parameter. The old value, if there was one, of the Variant (see page 3421) will be lost.

See Also

VariantToUnicodeString (see page 4969)

VariantClear (see page 4958)

VariantCast (see page 4958)

50.1.12 VarHlpr.VariantGetElement Function

Returns an element from a Variant (see page 3421) array.

Pascal

```
function VariantGetElement(const V: Variant; i1: integer): Variant; overload;
function VariantGetElement(const V: Variant; i1: integer; i2: integer): Variant; overload;
function VariantGetElement(const V: Variant; i1: integer; i2: integer; i3: integer): Variant;
overload;
function VariantGetElement(const V: Variant; i1: integer; i2: integer; i3: integer; i4:
integer): Variant; overload;
function VariantGetElement(const V: Variant; i1: integer; i2: integer; i3: integer; i4:
integer; i5: integer): Variant; overload;
```

C++

```
Variant VariantGetElement(const Variant V, int i1);
Variant VariantGetElement(const Variant V, int i1, int i2);
Variant VariantGetElement(const Variant V, int i1, int i2, int i3);
Variant VariantGetElement(const Variant V, int i1, int i2, int i3, int i4);
Variant VariantGetElement(const Variant V, int i1, int i2, int i3, int i4, int i5);
```

File

VarHlpr

Description

VariantGetElement returns the Variant (see page 3421) value located at the specified indices in the Variant (see page 3421) array **V**.

This function comes in five forms. Each form accepts a Variant (see page 3421) array and a number of indices in that array, one for each dimension.

See Also

VariantPutElement (see page 4966)

VarArrayGet (see page 5063)

VarArrayPut (see page 5069)

50.1.13 VarHlpr.VariantMod Function

Returns the remainder on division of two Variants (see page 4973).

Pascal

```
procedure VariantMod(const src: Variant; var dst: Variant);
```

C++

```
VariantMod(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantMod calculates the remainder on division of **src** by **dst** and returns the result as **dst**.

The input values must be convertible to integer numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantMod2 (see page 4962)

VariantDiv (see page 4959)

VariantDiv2 (see page 4960)

50.1.14 VarHlpr.VariantMod2 Function

Returns the remainder on division of two Variants (see page 4973).

Pascal

```
function VariantMod2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantMod2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantMod2 calculates the remainder on division of **V1** by **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to integer numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantMod (see page 4962)

VariantDiv (see page 4959)

VariantDiv2 (see page 4960)

50.1.15 VarHlpr.VariantMul Function

Multiplies two Variants (see page 4973).

Pascal

```
procedure VariantMul(const src: Variant; var dst: Variant);
```

C++

```
VariantMul(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantMul multiplies **src** to **dst** and returns the result as **dst**.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantMul2 (see page 4963)

VariantDiv (see page 4959)

VariantDiv2 (see page 4960)

50.1.16 VarHlpr.VariantMul2 Function

Multiplies two Variants (see page 4973).

Pascal

```
function VariantMul2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantMul2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantMul2 multiplies **V1** to **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantMul (see page 4963)

VariantDiv (see page 4959)

VariantDiv2 (see page 4960)

50.1.17 VarHlpr.VariantNeg Function

Inverts the sign of a Variant (see page 3421).

Pascal

```
function VariantNeg(const V1: Variant): Variant;
```

C++

```
Variant VariantNeg(const Variant V1);
```

File

VarHlpr

Description

VariantNeg will invert the sign of **V1** from positive to negative and vice-versa.

The input parameter must be convertible to a numerical type; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantNot (see page 4964)

50.1.18 VarHlpr.VariantNot Function

Performs a **not** operation on a Variant (see page 3421).

Pascal

```
function VariantNot(const V1: Variant): Variant;
```

C++

```
Variant VariantNot(const Variant V1);
```

File

VarHlpr

Description

VariantNot performs a bit-wise or a logical **not** operation on **V1** and returns a new Variant (see page 3421) holding the result.

The input value must be convertible to a numerical or boolean type; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantNeg (see page 4964)

50.1.19 VarHlpr.VariantOr Function

Performs an **or** operation between two Variants (see page 4973).

Pascal

```
procedure VariantOr(const src: Variant; var dst: Variant);
```

C++

```
VariantOr(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantOr performs a bit-wise or a logical **or** operation between **src** and **dst** and returns the result as **dst**.

Given input values must be convertible to numerical or boolean types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantOr2 (see page 4965)

VariantAnd (see page 4956)

VariantAnd2 (see page 4957)

50.1.20 VarHlpr.VariantOr2 Function

Performs an **or** operation between two Variants (see page 4973).

Pascal

```
function VariantOr2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantOr2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantOr2 performs a bit-wise or a logical **or** operation between **V1** and **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical or boolean types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantOr (see page 4964)

VariantAnd (see page 4956)

VariantAnd2 (see page 4957)

50.1.21 VarHlpr.VariantPutElement Function

Sets the value of an element in a Variant (see page 3421) array.

Pascal

```
procedure VariantPutElement(var V: Variant; const data: Variant; i1: integer); overload;
procedure VariantPutElement(var V: Variant; const data: Variant; i1: integer; i2: integer);
overload;
procedure VariantPutElement(var V: Variant; const data: Variant; i1: integer; i2: integer; i3:
integer); overload;
procedure VariantPutElement(var V: Variant; const data: Variant; i1: integer; i2: integer; i3:
integer; i4: integer); overload;
procedure VariantPutElement(var V: Variant; const data: Variant; i1: integer; i2: integer; i3:
integer; i4: integer; i5: integer); overload;
```

C++

```
VariantPutElement(Variant V, const Variant data, int i1);
VariantPutElement(Variant V, const Variant data, int i1, int i2);
VariantPutElement(Variant V, const Variant data, int i1, int i2, int i3);
VariantPutElement(Variant V, const Variant data, int i1, int i2, int i3, int i4);
VariantPutElement(Variant V, const Variant data, int i1, int i2, int i3, int i4, int i5);
```

File

VarHlpr

Description

VariantPutElement sets the Variant (see page 3421) value located at the specified indices in the Variant (see page 3421) array **V**.

This function comes in five forms. Each form accepts a Variant (see page 3421) array, a Variant (see page 3421) value to assign, and a number of indices in that array, one for each dimension.

See Also

VariantGetElement (see page 4961)

VarArrayGet (see page 5063)

VarArrayPut (see page 5069)

50.1.22 VarHlpr.VariantShl Function

Performs an **shl** (shift left) operation between two Variants (see page 4973).

Pascal

```
procedure VariantShl(const src: Variant; var dst: Variant);
```

C++

```
VariantShl(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantShl performs a bit-wise **shl** (shift left) operation between **src** and **dst** and returns the result as **dst**.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantShr (see page 4967)

VariantShr2 (see page 4968)

50.1.23 VarHlpr.VariantShl2 Function

Performs an **shl** (shift left) operation between two Variants (see page 4973).

Pascal

```
function VariantShl2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantShl2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantShl2 performs a bit-wise **shl** (shift left) operation between **V1** and **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantShl (see page 4966)

VariantShr (see page 4967)

VariantShr2 (see page 4968)

50.1.24 VarHlpr.VariantShr Function

Performs an **shr** (shift right) operation between two Variants (see page 4973).

Pascal

```
procedure VariantShr(const src: Variant; var dst: Variant);
```

C++

```
VariantShr(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantShr performs a bit-wise **shr** (shift right) operation between **src** and **dst** and returns the result as **dst**.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantShr2 (see page 4968)

VariantShl (see page 4966)

VariantShl2 (see page 4967)

50.1.25 VarHlpr.VariantShr2 Function

Performs an **shr** (shift right) operation between two Variants (see page 4973).

Pascal

```
function VariantShr2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantShr2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantShr2 performs a bit-wise **shr** (shift right) operation between **V1** and **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantShr (see page 4967)

VariantShl (see page 4966)

VariantShl2 (see page 4967)

50.1.26 VarHlpr.VariantSub Function

Subtracts two Variants (see page 4973).

Pascal

```
procedure VariantSub(const src: Variant; var dst: Variant);
```

C++

```
VariantSub(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantSub subtracts **src** from **dst** and returns the result as **dst**.

The input values must have compatible types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantSub2 (see page 4969)

VariantAdd (see page 4955)

VariantAdd2 (see page 4956)

50.1.27 VarHlpr.VariantSub2 Function

Subtracts two Variants (see page 4973).

Pascal

```
function VariantSub2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantSub2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantSub2 subtracts **V1** from **V2** and returns a new Variant (see page 3421) holding the result.

The input values must have compatible types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantSub (see page 4968)

VariantAdd (see page 4955)

VariantAdd2 (see page 4956)

50.1.28 VarHlpr.VariantToUnicodeString Function

Converts a Variant (see page 3421) to an Unicode string.

Pascal

```
procedure VariantToUnicodeString(const V: Variant; var Str: UnicodeString);
```

C++

```
VariantToUnicodeString(const Variant V, UnicodeString Str);
```

File

VarHlpr

Description

VariantToUnicodeString converts the parameter **V** to an Unicode string and places the result into **Str (see page 3676)**.

See Also

VariantFromUnicodeString (see page 4960)

VariantClear (see page 4958)

VariantCast (see page 4958)

50.1.29 VarHlpr.VariantXor Function

Performs a **xor** (exclusive or) operation between two Variants (see page 4973).

Pascal

```
procedure VariantXor(const src: Variant; var dst: Variant);
```

C++

```
VariantXor(const Variant src, Variant dst);
```

File

VarHlpr

Description

VariantXor performs a bit-wise **xor** (exclusive or) operation between **src** and **dst** and returns the result as **dst**.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantXor2 (see page 4970)

VariantOr (see page 4964)

VariantOr2 (see page 4965)

50.1.30 VarHlpr.VariantXor2 Function

Performs a **xor** (exclusive or) operation between two Variants (see page 4973).

Pascal

```
function VariantXor2(const V1: Variant; const V2: Variant): Variant;
```

C++

```
Variant VariantXor2(const Variant V1, const Variant V2);
```

File

VarHlpr

Description

VariantXor2 performs a bit-wise **xor** (exclusive or) operation between **V1** and **V2** and returns a new Variant (see page 3421) holding the result.

The input values must be convertible to numerical types; otherwise an EVariantTypeCastError exception will be raised.

See Also

VariantXor (see page 4970)

VariantOr (see page 4964)

VariantOr2 (see page 4965)

51 Variants Namespace

This is namespace Variants.

Topics

Name	Description
Classes (see page 4978)	The following table lists classes in this documentation.
Interfaces (see page 5022)	The following table lists interfaces in this documentation.
Functions (see page 5027)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5094)	The following table lists structs, records, enums in this documentation.
Types (see page 5097)	The following table lists types in this documentation.
Variables (see page 5100)	The following table lists variables in this documentation.

Classes

	Name	Description
	EVariantArrayCreateError (see page 4978)	EVariantArrayCreateError is the exception class for failure to create or resize a variant array.
	EVariantArrayLockedError (see page 4979)	EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.
	EVariantBadIndexError (see page 4980)	EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.
	EVariantBadVarTypeError (see page 4980)	EVariantBadVarTypeError is the exception class for variant type errors.
	EVariantDispatchError (see page 4981)	EVariantDispatchError is the exception class for failed dispatch attempts.
	EVariantInvalidArgError (see page 4981)	EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.
	EVariantInvalidNullOpError (see page 4982)	EVariantInvalidNullOpError is the exception class for invalid Null (see page 5056) variant operations.
	EVariantInvalidOpError (see page 4983)	EVariantInvalidOpError is the exception class for invalid variant operations.
	EVariantNotAnArrayError (see page 4983)	EVariantNotAnArrayError is the exception class inappropriate variant array operations.
	EVariantNotImplError (see page 4984)	EVariantNotImplError is the exception class for unimplemented variant operations.
	EVariantOutOfMemoryError (see page 4984)	EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.
	EVariantOverflowError (see page 4985)	EVariantOverflowError is the exception class for overflow in a variant operation.
	EVariantRangeCheckError (see page 4986)	EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.
	EVariantTypeCastError (see page 4986)	EVariantTypeCastError is the exception class for variant type cast errors.
	EVariantUnexpectedError (see page 4987)	EVariantUnexpectedError is the exception class for unexpected variant errors.

	TCustomVariantType (see page 4987)	TCustomVariantType is the base class for Delphi custom variant types.
	TInvokeableVariantType (see page 5014)	TInvokeableVariantType is the base class for custom System::Variant (see page 3421) types that implement custom Variants with properties and methods.

Functions

	Name	Description
	_DispInvoke (see page 5029)	_DispInvoke is used internally by the Delphi compiler.
	_OleVarFromInt (see page 5030)	_OleVarFromInt is used internally by the Delphi compiler.
	_OleVarFromInt64 (see page 5030)	_OleVarFromInt64 is used internally by the Delphi compiler.
	_OleVarFromLStr (see page 5031)	_OleVarFromLStr is used internally by the Delphi compiler.
	_OleVarFromPStr (see page 5031)	_OleVarFromPStr is used internally by the Delphi compiler.
	_OleVarFromUInt64 (see page 5031)	_OleVarFromUInt64 is used internally by the Delphi compiler.
	_OleVarFromUStr (see page 5032)	_OleVarFromUStr is used internally by the Delphi compiler.
	_OleVarFromVar (see page 5032)	_OleVarFromVar is used internally by the Delphi compiler.
	_VarAdd (see page 5032)	_VarAdd is used internally by the Delphi compiler.
	_VarAddRef (see page 5033)	_VarAddRef is used internally by the Delphi compiler.
	_VarAnd (see page 5033)	_VarAnd is used internally by the Delphi compiler.
	_VarArrayGet (see page 5034)	_VarArrayGet is used internally by the Delphi compiler.
	_VarArrayPut (see page 5034)	_VarArrayPut is used internally by the Delphi compiler.
	_VarArrayRedim (see page 5034)	_VarArrayRedim is used internally by the Delphi compiler.
	_VarCast (see page 5035)	_VarCast is used internally by the Delphi compiler.
	_VarCastOle (see page 5035)	_VarCastOle is used internally by the Delphi compiler.
	_VarClear (see page 5035)	_VarClear is used internally by the Delphi compiler.
	_VarClr (see page 5036)	_VarClr is used internally by the Delphi compiler.
	_VarCmpEQ (see page 5036)	_VarCmpEQ is used internally by the Delphi compiler.
	_VarCmpGE (see page 5037)	_VarCmpGE is used internally by the Delphi compiler.
	_VarCmpGT (see page 5037)	_VarCmpGT is used internally by the Delphi compiler.
	_VarCmpLE (see page 5037)	_VarCmpLE is used internally by the Delphi compiler.
	_VarCmpLT (see page 5038)	_VarCmpLT is used internally by the Delphi compiler.
	_VarCmpNE (see page 5038)	_VarCmpNE is used internally by the Delphi compiler.
	_VarCopy (see page 5038)	_VarCopy is used internally by the Delphi compiler.
	_VarCopyNoInd (see page 5039)	_VarCopyNoInd is used internally by the Delphi compiler.
	_VarDiv (see page 5039)	_VarDiv is used internally by the Delphi compiler.
	_VarFromBool (see page 5040)	_VarFromBool is used internally by the Delphi compiler.
	_VarFromCurr (see page 5040)	_VarFromCurr is used internally by the Delphi compiler.
	_VarFromDisp (see page 5040)	_VarFromDisp is used internally by the Delphi compiler.
	_VarFromDynArray (see page 5041)	_VarFromDynArray is used internally by the Delphi compiler.
	_VarFromInt (see page 5041)	_VarFromInt is used internally by the Delphi compiler.
	_VarFromInt64 (see page 5041)	_VarFromInt64 is used internally by the Delphi compiler.
	_VarFromIntf (see page 5042)	_VarFromIntf is used internally by the Delphi compiler.
	_VarFromLStr (see page 5042)	_VarFromLStr is used internally by the Delphi compiler.
	_VarFromPStr (see page 5043)	_VarFromPStr is used internally by the Delphi compiler.
	_VarFromReal (see page 5043)	_VarFromReal is used internally by the Delphi compiler.
	_VarFromTDateTime (see page 5043)	_VarFromTDateTime is used internally by the Delphi compiler.
	_VarFromUInt64 (see page 5044)	_VarFromUInt64 is used internally by the Delphi compiler.
	_VarFromUStr (see page 5044)	_VarFromUStr is used internally by the Delphi compiler.
	_VarFromWChar (see page 5044)	_VarFromWChar is used internally by the Delphi compiler.
	_VarFromWStr (see page 5045)	_VarFromWStr is used internally by the Delphi compiler.
	_VarMod (see page 5045)	_VarMod is used internally by the Delphi compiler.
	_VarMul (see page 5046)	_VarMul is used internally by the Delphi compiler.
	_VarNeg (see page 5046)	_VarNeg is used internally by the Delphi compiler.
	_VarNot (see page 5046)	_VarNot is used internally by the Delphi compiler.
	_VarOr (see page 5047)	_VarOr is used internally by the Delphi compiler.
	_VarRDiv (see page 5047)	_VarRDiv is used internally by the Delphi compiler.
	_VarShl (see page 5047)	_VarShl is used internally by the Delphi compiler.

	_VarShr (see page 5048)	_VarShr is used internally by the Delphi compiler.
	_VarSub (see page 5048)	_VarSub is used internally by the Delphi compiler.
	_VarToBool (see page 5049)	_VarToBool is used internally by the Delphi compiler.
	_VarToCurrency (see page 5049)	_VarToCurrency is used internally by the Delphi compiler.
	_VarToDisp (see page 5049)	_VarToDisp is used internally by the Delphi compiler.
	_VarToDynArray (see page 5050)	_VarToDynArray is used internally by the Delphi compiler.
	_VarToInt64 (see page 5050)	_VarToInt64 is used internally by the Delphi compiler.
	_VarToInteger (see page 5050)	_VarToInteger is used internally by the Delphi compiler.
	_VarToIntf (see page 5051)	_VarToIntf is used internally by the Delphi compiler.
	_VarToLStr (see page 5051)	_VarToLStr is used internally by the Delphi compiler.
	_VarToPStr (see page 5052)	_VarToPStr is used internally by the Delphi compiler.
	_VarToReal (see page 5052)	_VarToReal is used internally by the Delphi compiler.
	_VarToUInt64 (see page 5052)	_VarToUInt64 is used internally by the Delphi compiler.
	_VarToUStr (see page 5053)	_VarToUStr is used internally by the Delphi compiler.
	_VarToWStr (see page 5053)	_VarToWStr is used internally by the Delphi compiler.
	_VarXor (see page 5053)	_VarXor is used internally by the Delphi compiler.
	DynArrayFromVariant (see page 5054)	Creates a dynamic array from a System::Variant (see page 3421).
	DynArrayToVariant (see page 5054)	Creates a System::Variant (see page 3421) array from a dynamic array.
	FindCustomVariantType (see page 5055)	Retrieves the object that implements a custom System::Variant (see page 3421) type.
	FindCustomVariantType (see page 5055)	Retrieves the object that implements a custom System::Variant (see page 3421) type.
	FindVarData (see page 5055)	Returns pointer to variant's data.
	HandleConversionException (see page 5056)	Handles exceptions during variant type conversions.
	Null (see page 5056)	Returns a Null variant.
	Unassigned (see page 5058)	Returns an "empty" variant.
	VarArrayAsPSafeArray (see page 5059)	This is function Variants.VarArrayAsPSafeArray.
	VarArrayCreate (see page 5059)	Creates a variant array.
	VarArrayCreateError (see page 5061)	Indicates an array creation error.
	VarArrayDimCount (see page 5061)	Returns number of dimensions of a variant array.
	VarArrayGet (see page 5063)	Returns a System::Variant (see page 3421) that represents a single value from a multi-dimensional System::Variant (see page 3421) array.
	VarArrayHighBound (see page 5065)	Returns high bound for a dimension in a variant array.
	VarArrayLock (see page 5067)	Locks a variant array and returns a pointer to the data.
	VarArrayLowBound (see page 5067)	Returns the low bound of a dimension in a variant array.
	VarArrayOf (see page 5069)	Creates and fills a one-dimensional variant array.
	VarArrayPut (see page 5069)	Sets the value of a single cell in a multi-dimensional System::Variant (see page 3421) array.
	VarArrayRef (see page 5071)	Returns a reference to the specified variant array.
	VarArrayUnlock (see page 5072)	Unlocks a variant array.
	VarAsError (see page 5072)	Converts a HRESULT (see page 3754) into an Error (see page 3560) variant.
	VarAsType (see page 5073)	Converts a variant to specified type.
	VarCastError (see page 5073)	Raises an EVariantTypeCastError (see page 4986) exception.
	VarCastError (see page 5073)	Raises an EVariantTypeCastError (see page 4986) exception.
	VarCheckEmpty (see page 5074)	Raises an exception if a specified variant's value is Unassigned (see page 5058).
	VarCompareValue (see page 5074)	Returns the relationship between Variants.
	VarCopyNoInd (see page 5075)	Copies a System::Variant (see page 3421).
	VarEnsureRange (see page 5076)	Returns a System::Variant (see page 3421) with a value in a specified range.
	VarFromDateTime (see page 5076)	Returns a variant containing a specified data and time.
	VarInRange (see page 5077)	Indicates whether a System::Variant (see page 3421)'s value is in a specified range.
	VarInvalidNullOp (see page 5077)	Indicate variant operation on null.
	VarInvalidOp (see page 5078)	Indicate invalid variant operation.
	VarIsArray (see page 5078)	Indicates whether the specified variant is an array.

	VarIsArray (see page 5078)	Indicates whether the specified variant is an array.
	VarIsByRef (see page 5079)	Indicates whether the specified variant's value is by reference.
	VarIsClear (see page 5079)	Indicates whether the specified variant has an undefined value.
	VarIsCustom (see page 5080)	Indicates whether the specified variant is a custom variant.
	VarIsEmpty (see page 5080)	Indicates whether the specified variant is unassigned.
	VarIsEmptyParam (see page 5081)	Indicates whether the specified variant represents an unassigned optional parameter.
	VarIsError (see page 5082)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT (see page 3754).
	VarIsError (see page 5082)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT (see page 3754).
	VarIsFloat (see page 5082)	Indicates whether the specified variant represents a floating-point value.
	VarIsNull (see page 5083)	Indicates whether the specified variant is Null (see page 5056).
	VarIsNumeric (see page 5083)	Indicates whether the specified variant represents a numeric value.
	VarIsOrdinal (see page 5084)	Indicates whether the specified variant represents an ordinal value.
	VarIsStr (see page 5084)	Indicates whether the specified variant represents a string value.
	VarIsType (see page 5085)	Indicates whether the specified variant represents a specified type.
	VarIsType (see page 5085)	Indicates whether the specified variant represents a specified type.
	VarOverflowError (see page 5085)	Raises an EVariantOverflowError (see page 4985) exception.
	VarRangeCheckError (see page 5086)	Raises an EVariantRangeCheckError (see page 4986) exception.
	VarResultCheck (see page 5086)	Raises variant exception based on HRESULT (see page 3754) value.
	VarResultCheck (see page 5086)	Raises variant exception based on HRESULT (see page 3754) value.
	VarSameValue (see page 5087)	Indicates whether two Variants have equivalent values.
	VarSupports (see page 5087)	Indicates whether the System::Variant (see page 3421)'s value is an interface that supports a specified interface.
	VarSupports (see page 5087)	Indicates whether the System::Variant (see page 3421)'s value is an interface that supports a specified interface.
	VarToDateTime (see page 5088)	Converts a specified variant to a TDateTime (see page 3323) value.
	VarToStr (see page 5088)	Converts a variant's value to a string.
	VarToStrDef (see page 5089)	Converts a variant's value to a string.
	VarToWideStr (see page 5089)	Converts a variant's value to a WideString (see page 3467).
	VarToWideStrDef (see page 5090)	Converts a variant's value to a WideString (see page 3467).
	VarType (see page 5090)	Returns the type code of a specified variant.
	VarTypeAsText (see page 5092)	Returns variant type descriptive string.
	VarTypeIsValidArrayType (see page 5092)	Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.
	VarTypeIsValidElementType (see page 5093)	Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.

Interfaces

	Name	Description
	IVarInstanceReference (see page 5022)	IVarInstanceReference is the interface for extracting the instance that represents the data from a Variant (see page 3421) of the custom type.
	IVarInvokeable (see page 5023)	IVarInvokeable is the interface for custom Variant (see page 3421) types that implement dynamic properties and methods.

Structs, Records, Enums

	Name	Description
	TBooleanToStringRule (see page 5094)	TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 5100).
	TNullCompareRule (see page 5094)	TNullCompareRule enumerates possible rules for comparing variant nulls with other values.
	TVarCompareResult (see page 5095)	TVarCompareResult describes the results of comparing two Variants.
	TVariantRelationship (see page 5096)	TVariantRelationship describes the results of comparing two Variants.

Types

Name	Description
TAnyProc (see page 5097)	TAnyProc represents a pointer to a procedure that accepts a parameter of type TVarData (see page 3740).
TCustomVariantTypeClass (see page 5097)	TCustomVariantTypeClass defines the metaclass for TCustomVariantType (see page 4987).
TVarDataArray (see page 5098)	TVarDataArray is an array of TVarData (see page 3740) records.
TVarDispProc (see page 5098)	TVarDispProc defines a pointer to a procedure used as support for IDispatch (see page 3494)-based Automation.

Variables

Name	Description
BooleanToStringRule (see page 5100)	Specifies rule fixing up Boolean values converted to strings.
ChangeAnyProc (see page 5101)	Provides the support for changing the type of a Variant (see page 3421) from varAny (see page 3861) to a real Variant (see page 3421).
ClearAnyProc (see page 5101)	Provides the support for clearing a Variant (see page 3421) of type varAny (see page 3861).
EmptyParam (see page 5102)	Contains an OleVariant (see page 3274) that represents an unused optional parameter on a dual interface.
NullAsStringValue (see page 5102)	Specifies string value of Null (see page 5056) variants.
NullEqualityRule (see page 5103)	Specifies rule for Null (see page 5056) variant equality comparison.
NullMagnitudeRule (see page 5103)	Specifies rule for Null (see page 5056) variant magnitude comparison.
NullStrictConvert (see page 5104)	Specifies whether Null (see page 5056) conversion is an error.
OleVariantInt64AsDouble (see page 5105)	Controls the mode in which `Int64` values are stored in a OleVariant (see page 3274).
PackVarCreation (see page 5105)	Specifies whether space-efficient System::Variant (see page 3421) Types (see page 4649) are preferred.
RefAnyProc (see page 5106)	Provides the support for increasing the reference count of a Variant (see page 3421) of type varAny (see page 3861).
VarDispProc (see page 5106)	Provides the support for IDispatch (see page 3494)-based Automation.

51.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EVariantArrayCreateError (see page 4978)	EVariantArrayCreateError is the exception class for failure to create or resize a variant array.
	EVariantArrayLockedError (see page 4979)	EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.
	EVariantBadIndexError (see page 4980)	EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.
	EVariantBadVarTypeError (see page 4980)	EVariantBadVarTypeError is the exception class for variant type errors.
	EVariantDispatchError (see page 4981)	EVariantDispatchError is the exception class for failed dispatch attempts.
	EVariantInvalidArgError (see page 4981)	EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.
	EVariantInvalidNullOpError (see page 4982)	EVariantInvalidNullOpError is the exception class for invalid Null (see page 5056) variant operations.
	EVariantInvalidOpError (see page 4983)	EVariantInvalidOpError is the exception class for invalid variant operations.
	EVariantNotAnArrayError (see page 4983)	EVariantNotAnArrayError is the exception class inappropriate variant array operations.
	EVariantNotImplError (see page 4984)	EVariantNotImplError is the exception class for unimplemented variant operations.
	EVariantOutOfMemoryError (see page 4984)	EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.
	EVariantOverflowError (see page 4985)	EVariantOverflowError is the exception class for overflow in a variant operation.
	EVariantRangeCheckError (see page 4986)	EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.
	EVariantTypeCastError (see page 4986)	EVariantTypeCastError is the exception class for variant type cast errors.
	EVariantUnexpectedError (see page 4987)	EVariantUnexpectedError is the exception class for unexpected variant errors.
	TCustomVariantType (see page 4987)	TCustomVariantType is the base class for Delphi custom variant types.
	TInvokeableVariantType (see page 5014)	TInvokeableVariantType is the base class for custom System::Variant (see page 3421) types that implement custom Variants (see page 4973) with properties and methods.

51.1.1 EVariantArrayCreateError Class

EVariantArrayCreateError is the exception class for failure to create or resize a variant array.

Class Hierarchy

Pascal

```
EVariantArrayCreateError = class(EVariantError);
```

C++

```
class EVariantArrayCreateError : public EVariantError;
```

File

Variants

Description

EVariantArrayCreateError is raised when an attempt to create or resize a variant array fails. To raise this exception programmatically, call VarArrayCreateError (see page 5061)

See Also

VarArrayCreateError (see page 5061)

TVarData (see page 3740)

VarArrayCreate (see page 5059)

VarArrayOf (see page 5069)

VarArrayRedim (see page 3702)

TCustomVariantType (see page 4987)

51.1.2 EVariantArrayLockedError Class

EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.

Class Hierarchy

Pascal

```
EVariantArrayLockedError = class(EVariantError);
```

C++

```
class EVariantArrayLockedError : public EVariantError;
```

File

Variants

Description

EVariantArrayLockedError is raised when an operation on a variant array fails because the array is locked or fixed.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

VarArrayLock (see page 5067)

VarArrayUnlock (see page 5072)

VarArrayOf (see page 5069)

VarArrayRedim (see page 3702)

51.1.3 EVariantBadIndexError Class

EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.

Class Hierarchy

Pascal

```
EVariantBadIndexError = class(EVariantError);
```

C++

```
class EVariantBadIndexError : public EVariantError;
```

File

Variants

Description

EVariantBadIndexError is raised when an operation on a variant array fails because an index value is out of bounds.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

VarArrayCreate (see page 5059)

VarArrayHighBound (see page 5065)

VarArrayLowBound (see page 5067)

VarArrayOf (see page 5069)

VarArrayRedim (see page 3702)

TCustomVariantType (see page 4987)

51.1.4 EVariantBadVarTypeError Class

EVariantBadVarTypeError is the exception class for variant type errors.

Class Hierarchy

Pascal

```
EVariantBadVarTypeError = class(EVariantError);
```

C++

```
class EVariantBadVarTypeError : public EVariantError;
```

File

Variants

Description

EVariantBadVarTypeError is raised when a variant operation fails because of a value that isn't a valid variant type.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

TCustomVariantType (see page 4987)

51.1.5 EVariantDispatchError Class

EVariantDispatchError is the exception class for failed dispatch attempts.

Class Hierarchy

Pascal

```
EVariantDispatchError = class(EVariantError);
```

C++

```
class EVariantDispatchError : public EVariantError;
```

File

Variants

Description

EVariantDispatchError is raised when a variant type is unable to dispatch a method call. Do not directly instantiate EVariantDispatchError. Instead call the RaiseDispError method of TCustomVariant.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

TCustomVariantType (see page 4987)

51.1.6 EVariantInvalidArgError Class

EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.

Class Hierarchy

Pascal

```
EVariantInvalidArgError = class(EVariantError);
```

C++

```
class EVariantInvalidArgError : public EVariantError;
```

File

Variants

Description

EVariantInvalidArgError is raised when a variant operation fails because it was passed an inappropriate value.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

TCustomVariantType (see page 4987)

51.1.7 EVariantInvalidNullOpError Class

EVariantInvalidNullOpError is the exception class for invalid Null (see page 5056) variant operations.

Class Hierarchy

Pascal

```
EVariantInvalidNullOpError = class(EVariantInvalidOpError);
```

C++

```
class EVariantInvalidNullOpError : public EVariantInvalidOpError;
```

File

Variants

Description

EVariantInvalidNullOpError is raised when a variant operation fails because the operation is not valid for Null (see page 5056) variants. To raise this exception programmatically, call VarInvalidNullOp (see page 5077).

Note: Do not raise EVariantInvalidNullOpError unless NullEqualityRule (see page 5103) or NullMagnitudeRule (see page 5103) is ncrError, and a corresponding operation has been attempted.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

TCustomVariantType (see page 4987)

VarInvalidNullOp (see page 5077)

Null (see page 5056)

NullEqualityRule (see page 5103)

NullMagnitudeRule (see page 5103)

51.1.8 EVariantInvalidOpError Class

EVariantInvalidOpError is the exception class for invalid variant operations.

Class Hierarchy

Pascal

```
EVariantInvalidOpError = class(EVariantError);
```

C++

```
class EVariantInvalidOpError : public EVariantError;
```

File

Variants

Description

EVariantInvalidOpError is raised when a variant operation fails because the operands are incompatible with the specific operation. To raise this exception programmatically, call VarInvalidOp (see page 5078).

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

TCustomVariantType (see page 4987)

VarInvalidOp (see page 5078)

51.1.9 EVariantNotAnArrayError Class

EVariantNotAnArrayError is the exception class inappropriate variant array operations.

Class Hierarchy

Pascal

```
EVariantNotAnArrayError = class(EVariantError);
```

C++

```
class EVariantNotAnArrayError : public EVariantError;
```

File

Variants

Description

EVariantNotAnArrayError is raised when an array operation is attempted on a variant that does not contain an array.

See Also

VarArrayCreateError (see page 5061)

TVarData (see page 3740)

VarArrayCreate (see page 5059)

VarArrayOf (see page 5069)

VarArrayRedim (see page 3702)

TCustomVariantType (see page 4987)

51.1.10 EVariantNotImplError Class

EVariantNotImplError is the exception class for unimplemented variant operations.

Class Hierarchy

Pascal

```
EVariantNotImplError = class(EVariantError);
```

C++

```
class EVariantNotImplError : public EVariantError;
```

File

Variants

Description

EVariantNotImplError is raised when an operation is attempted on a variant type that does not implement that operation.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

TCustomVariantType (see page 4987)

51.1.11 EVariantOutOfMemoryError Class

EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.

Class Hierarchy

Pascal

```
EVariantOutOfMemoryError = class(EVariantError);
```

C++

```
class EVariantOutOfMemoryError : public EVariantError;
```

File

Variants

Description

EVariantOutOfMemoryError is raised when a variant operation fails because of a failure to allocate necessary memory.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarArrayCreate (see page 5059)

VarArrayOf (see page 5069)

VarArrayRedim (see page 3702)

VarToDateTime (see page 5088)

TCustomVariantType (see page 4987)

EOutOfMemory (see page 3942)

51.1.12 EVariantOverflowError Class

EVariantOverflowError is the exception class for overflow in a variant operation.

Class Hierarchy

Pascal

```
EVariantOverflowError = class(EVariantError);
```

C++

```
class EVariantOverflowError : public EVariantError;
```

File

Variants

Description

EVariantOverflowError is raised when a variant operation fails because the result was too large. To raise this exception programmatically, call VarOverflowError (see page 5085).

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

VarToDateTime (see page 5088)

TCustomVariantType (see page 4987)

VarOverflowError (see page 5085)

51.1.13 EVariantRangeCheckError Class

EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.

Class Hierarchy

Pascal

```
EVariantRangeCheckError = class(EVariantOverflowError);
```

C++

```
class EVariantRangeCheckError : public EVariantOverflowError;
```

File

Variants

Description

EVariantRangeCheckError is raised when a variant operation fails because the result is out-of-range for the destination variant type. To raise this exception programmatically, call VarRangeCheckError (see page 5086).

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

VarToDateTime (see page 5088)

TCustomVariantType (see page 4987)

VarRangeCheckError (see page 5086)

51.1.14 EVariantTypeCastError Class

EVariantTypeCastError is the exception class for variant type cast errors.

Class Hierarchy

Pascal

```
EVariantTypeCastError = class(EVariantError);
```

C++

```
class EVariantTypeCastError : public EVariantError;
```

File

Variants

Description

EVariantTypeCastError is raised when a variant operation fails because a value could not be cast to the destination variant type.

To raise this exception programmatically, call VarCastError (see page 5073).

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

VarAsType (see page 5073)

VarToDateTime (see page 5088)

TCustomVariantType (see page 4987)

VarOverflowError (see page 5085)

51.1.15 EVariantUnexpectedError Class

EVariantUnexpectedError is the exception class for unexpected variant errors.

Class Hierarchy

Pascal

```
EVariantUnexpectedError = class(EVariantError);
```

C++

```
class EVariantUnexpectedError : public EVariantError;
```

File

Variants

Description

EVariantUnexpectedError is raised when a variant operation generates an unexpected error.

See Also

TVarData (see page 3740)

System::TVariantManager (see page 3745)

TCustomVariantType (see page 4987)

51.1.16 TCustomVariantType Class

TCustomVariantType is the base class for Delphi custom variant types.

Class Hierarchy

Pascal

```
TCustomVariantType = class(TObject, IInterface);
```

C++

```
class TCustomVariantType : public TObject, public IInterface;
```

File

Variants

Description

Use TCustomVariantType to define new data types for Delphi Variants (see page 4973). TCustomVariantType descendants do not represent the Variants (see page 4973) themselves. Rather, they act as utility classes that the custom Variants (see page 4973) call on to perform their operations.

To create a System::Variant (see page 3421) type,

1.Map the storage of the System::Variant (see page 3421)'s data on to the TVarData (see page 3740) record.

2.Write (see page 3707) a method that creates instances of your custom System::Variant (see page 3421). This fills in the System::Variant (see page 3421)'s data as defined in step 1.

3.Declare a class that descends from TCustomVariantType.

4.Implement all required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically BinaryOp (see page 4994), UnaryOp (see page 5006), CompareOp (see page 4998) or Compare (see page 4997), Cast (see page 4995), CastTo (see page 4995), Clear (see page 4996), Copy (see page 4999), IsClear (see page 5000), LeftPromotion (see page 5000), and RightPromotion (see page 5004)).

5.In the initialization section of the unit that defines your TCustomVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the System::Variant (see page 3421)-handling system so that the new System::Variant (see page 3421) type is enabled.

6.In the finalization section of the unit that defines your TCustomVariantType descendant, free the instance of your class. This automatically unregisters the System::Variant (see page 3421) type.

Note: C++ can use Custom System::Variant (see page 3421) types, but TCustomVariantType descendants must be implemented in Delphi.

For an example, see the FMTBcd unit, which implements a custom System::Variant (see page 3421) type for binary-coded decimal.

Tip: To create a custom System::Variant (see page 3421) that allows users to call methods or procedures and to get or set property values, use TInvokeableVariantType (see page 5014) as a base class instead.

See Also

TInvokeableVariantType (see page 5014)

Creating a Class to Enable the Custom Variant Type

51.1.16.1 TCustomVariantType Members

The following tables list the members exposed by TCustomVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 4993)	Responds when the caller acquires a reference to this object's interface.
	_Release (see page 4993)	Responds when the caller releases a reference to this object's interface.
V	DispInvoke (see page 4999)	Invokes a method call when the System::Variant (see page 3421) supports such operations.

	LeftPromotion (see page 5000)	Indicates whether the left argument to a binary operation should be coerced to a different type.
	OlePromotion (see page 5001)	Indicates the type to which a System::Variant (see page 3421) value must be cast to make it Automation-compatible.
	QueryInterface (see page 5002)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 5002)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 5003)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 5003)	Generates a system error indicating an invalid operation.
	RightPromotion (see page 5004)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 5005)	Clears a TVarData (see page 3740) record by re-initializing it.
	SimplisticCopy (see page 5005)	Performs a simple block copy of one TVarData (see page 3740) record to another.
	VarDataCast (see page 5006)	Performs a cast from one System::Variant (see page 3421) type to another.
	VarDataCastTo (see page 5007)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 5007)	Performs a cast to a System::Variant (see page 3421) type of varOleStr (see page 3869).
	VarDataClear (see page 5008)	Clears the data from a built-in System::Variant (see page 3421) type.
	VarDataCopy (see page 5008)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataCopyNoInd (see page 5009)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataFromOleStr (see page 5009)	Creates a TVarData (see page 3740) record to represent a Unicode string.
	VarDataFromStr (see page 5010)	Creates a TVarData (see page 3740) record to represent a string.
	VarDataInit (see page 5010)	Initializes a TVarData (see page 3740) record.
	VarDataIsArray (see page 5010)	Indicates whether a TVarData (see page 3740) record represents the data from a System::Variant (see page 3421) array.
	VarDataIsByRef (see page 5011)	Indicates whether a TVarData (see page 3740) record stores its data indirectly.
	VarDataIsEmptyParam (see page 5011)	Indicates whether a TVarData (see page 3740) record represents an unassigned optional parameter.
	VarDataIsFloat (see page 5011)	Indicates whether a TVarData (see page 3740) record represents a floating-point value.
	VarDataIsNumeric (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a numeric value.
	VarDataIsOrdinal (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a ordinal value.
	VarDataIsStr (see page 5013)	Indicates whether a TVarData (see page 3740) record represents a string (normal or Unicode).
	VarDataToStr (see page 5013)	Returns a string that represents the value from a TVarData (see page 3740) record.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	BinaryOp (see page 4994)	Implements any binary operations of which the custom System::Variant (see page 3421) type is capable.
	Cast (see page 4995)	Converts the data from another System::Variant (see page 3421) type so that it represents this custom type's data format.
	CastTo (see page 4995)	Converts data in the format of this TCustomVariantType (see page 4987) to the format of another System::Variant (see page 3421) type.
	CastToOle (see page 4996)	Converts data in the format of this custom System::Variant (see page 3421) type to a format that can be used by COM Variants (see page 4973).
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.

	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 4996)	Sets the data for this custom System::Variant (see page 3421) type to a blank or unassigned value.
V	Compare (see page 4997)	Implements comparisons that involve the custom System::Variant (see page 3421) type.
V	CompareOp (see page 4998)	Implements any comparison operations of which the custom System::Variant (see page 3421) type is capable.
A	Copy (see page 4999)	Copies the data from a System::Variant (see page 3421) of this custom type.
	Create (see page 4990)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 4991)	Frees an instance of TCustomVariantType (see page 4987).
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
V	IsClear (see page 5000)	Indicates whether the data from a custom System::Variant (see page 3421) represents a blank or unassigned value.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
V	UnaryOp (see page 5006)	Implements any unary operations of which the custom System::Variant (see page 3421) type is capable.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	VarType (see page 5014)	Indicates the System::Variant (see page 3421) type code for the custom System::Variant (see page 3421) type.

51.1.16.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TCustomVariantType.Create () (see page 4991)	Creates an instance of TCustomVariantType (see page 4987).
	TCustomVariantType.Create (TVarType) (see page 4991)	Creates an instance of TCustomVariantType (see page 4987).

51.1.16.2.1 TCustomVariantType.Create Constructor ()

Creates an instance of TCustomVariantType (see page 4987).

Pascal

```
constructor Create; overload;
constructor Create(RequestedVarType: TVarType); overload;
```

C++

```
__fastcall TCustomVariantType();
__fastcall TCustomVariantType(TVarType RequestedVarType);
```

Description

Call Create in the initialization section of the unit that defines your TCustomVariantType (see page 4987) descendant to instantiate a single instance of the custom System::Variant (see page 3421) type. This single instance automatically registers itself with the System::Variant (see page 3421) system so that the custom System::Variant (see page 3421) type is enabled in the application.

The RequestedVarType parameter specifies a type code for the new custom System::Variant (see page 3421) type. It must be in the range from $010F to $0FFF.

When called with no parameters, the constructor generates a new type code for the custom System::Variant (see page 3421) type.

The TCustomVariantType (see page 4987) constructor raises an exception if there is a problem with the new System::Variant (see page 3421) type code. Such problems include

The RequestedVarType parameter specifies a type code that is already used by another System::Variant (see page 3421) type.

The RequestedVarType parameter specifies a type code that is not in the valid range for custom Variants (see page 4973).

There are too many custom Variants (see page 4973) already defined to allow another one.

See Also

VarType (see page 5014)

51.1.16.3 TCustomVariantType.Destroy Destructor

Frees an instance of TCustomVariantType (see page 4987).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomVariantType();
```

Description

To free a TCustomVariantType (see page 4987) instance, use the Free method instead. Free checks that the instance is not already nil before calling Destroy.

Free the single instance of a TCustomVariantType (see page 4987) descendant from the finalization section of the unit that implements the class.

System::TObject::Free (see page 3372)

51.1.16.4 TCustomVariantType Methods

The methods of the TCustomVariantType class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 4993)	Responds when the caller acquires a reference to this object's interface.
	_Release (see page 4993)	Responds when the caller releases a reference to this object's interface.
V	DispInvoke (see page 4999)	Invokes a method call when the System::Variant (see page 3421) supports such operations.
V	LeftPromotion (see page 5000)	Indicates whether the left argument to a binary operation should be coerced to a different type.
V	OlePromotion (see page 5001)	Indicates the type to which a System::Variant (see page 3421) value must be cast to make it Automation-compatible.
V	QueryInterface (see page 5002)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 5002)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 5003)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 5003)	Generates a system error indicating an invalid operation.
V	RightPromotion (see page 5004)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 5005)	Clears a TVarData (see page 3740) record by re-initializing it.
	SimplisticCopy (see page 5005)	Performs a simple block copy of one TVarData (see page 3740) record to another.
	VarDataCast (see page 5006)	Performs a cast from one System::Variant (see page 3421) type to another.
	VarDataCastTo (see page 5007)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 5007)	Performs a cast to a System::Variant (see page 3421) type of varOleStr (see page 3869).
	VarDataClear (see page 5008)	Clears the data from a built-in System::Variant (see page 3421) type.
	VarDataCopy (see page 5008)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataCopyNoInd (see page 5009)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataFromOleStr (see page 5009)	Creates a TVarData (see page 3740) record to represent a Unicode string.
	VarDataFromStr (see page 5010)	Creates a TVarData (see page 3740) record to represent a string.
	VarDataInit (see page 5010)	Initializes a TVarData (see page 3740) record.
	VarDataIsArray (see page 5010)	Indicates whether a TVarData (see page 3740) record represents the data from a System::Variant (see page 3421) array.
	VarDataIsByRef (see page 5011)	Indicates whether a TVarData (see page 3740) record stores its data indirectly.
	VarDataIsEmptyParam (see page 5011)	Indicates whether a TVarData (see page 3740) record represents an unassigned optional parameter.
	VarDataIsFloat (see page 5011)	Indicates whether a TVarData (see page 3740) record represents a floating-point value.
	VarDataIsNumeric (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a numeric value.
	VarDataIsOrdinal (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a ordinal value.
	VarDataIsStr (see page 5013)	Indicates whether a TVarData (see page 3740) record represents a string (normal or Unicode).
	VarDataToStr (see page 5013)	Returns a string that represents the value from a TVarData (see page 3740) record.

Public Methods

	Name	Description
V	BinaryOp (see page 4994)	Implements any binary operations of which the custom System::Variant (see page 3421) type is capable.

	Cast (see page 4995)	Converts the data from another System::Variant (see page 3421) type so that it represents this custom type's data format.
	CastTo (see page 4995)	Converts data in the format of this TCustomVariantType (see page 4987) to the format of another System::Variant (see page 3421) type.
	CastToOle (see page 4996)	Converts data in the format of this custom System::Variant (see page 3421) type to a format that can be used by COM Variants (see page 4973).
	Clear (see page 4996)	Sets the data for this custom System::Variant (see page 3421) type to a blank or unassigned value.
	Compare (see page 4997)	Implements comparisons that involve the custom System::Variant (see page 3421) type.
	CompareOp (see page 4998)	Implements any comparison operations of which the custom System::Variant (see page 3421) type is capable.
	Copy (see page 4999)	Copies the data from a System::Variant (see page 3421) of this custom type.
	IsClear (see page 5000)	Indicates whether the data from a custom System::Variant (see page 3421) represents a blank or unassigned value.
	UnaryOp (see page 5006)	Implements any unary operations of which the custom System::Variant (see page 3421) type is capable.

51.1.16.4.1 TCustomVariantType._AddRef Method

Responds when the caller acquires a reference to this object's interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

When an application uses an interface that is implemented by TCustomVariantType (see page 4987) or one of its descendants, it automatically calls __AddRef. Typically, interfaced objects use the __AddRef method to increment a reference count, which is then decremented when the application releases the interface. In this typical scenario, when the reference count drops to zero, the object frees itself.

TCustomVariantType (see page 4987) implements its own version of the IInterface (see page 3502) methods __AddRef and _Release (see page 4993) that avoid this typical behavior. An application should have only a single instance of TCustomVariantType (see page 4987), and that instance should not be auto-freed when it is not in use. Thus, TCustomVariantType (see page 4987) implements __AddRef so that it always returns –1.

See Also

_Release (see page 4993)

_AddRef (see page 3503)

51.1.16.4.2 TCustomVariantType._Release Method

Responds when the caller releases a reference to this object's interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

When an application releases an interface that is implemented by TCustomVariantType (see page 4987) or one of its descendants, it automatically calls __Release. Typically, interfaced objects use the __Release method to decrement a reference

count. When the reference count drops to zero, the object is automatically freed.

TCustomVariantType (see page 4987) implements its own version of the IInterface (see page 3502) methods _AddRef (see page 4993) and __Release that avoid this typical behavior. An application should have only a single instance of TCustomVariantType (see page 4987), and that instance should not be auto-freed when it is not in use. Thus, TCustomVariantType (see page 4987) implements __Release so that it always returns –1.

See Also

_AddRef (see page 4993)

_Release (see page 3503)

51.1.16.4.3 TCustomVariantType.BinaryOp Method

Implements any binary operations of which the custom System::Variant (see page 3421) type is capable.

Pascal

```
procedure BinaryOp(var Left: TVarData; const Right: TVarData; const Operator: TVarOp); virtual;
```

C++

```
virtual __fastcall BinaryOp(TVarData Left, const TVarData Right, const TVarOp Operator);
```

Description

Override BinaryOp to implement any binary operators the custom System::Variant (see page 3421) type supports.

Left is the value that appears to the left of the operator. BinaryOp changes this value to indicate the result of the operation.

Right is the value that appears to the right of the operator.

Operator identifies the operator that appears between Left and Right. It can be any of the following values:

Value	Operation
opAdd (see page 3850)	addition
opSubtract (see page 3858)	subtraction
opMultiply (see page 3855)	multiplication
opDivide (see page 3854)	floating-point division
opIntDivide (see page 3855)	integer division
opModulus (see page 3855)	remainder
opShiftLeft (see page 3857)	bitwise left shift
opShiftRight (see page 3858)	bitwise right shift
opAnd (see page 3850)	bitwise and
opOr (see page 3857)	bitwise or
opXor (see page 3859)	bitwise exclusive or

As implemented in TCustomVariantType (see page 4987), BinaryOp raises a system error indicating an invalid operation.

See Also

UnaryOp (see page 5006)

CompareOp (see page 4998)

LeftPromotion (see page 5000)

RightPromotion (see page 5004)

Implementing Binary Operations

51.1.16.4.4 TCustomVariantType.Cast Method

Converts the data from another System::Variant (see page 3421) type so that it represents this custom type's data format.

Pascal

```
procedure Cast(var Dest: TVarData; const Source: TVarData); virtual;
```

C++

```
virtual __fastcall Cast(TVarData Dest, const TVarData Source);
```

Description

Override Cast to enable other types of Variants (see page 4973) to be cast to this custom System::Variant (see page 3421) type.

Dest is a TVarData (see page 3740) record that returns the System::Variant (see page 3421)'s data stored in the format used by this custom System::Variant (see page 3421) type. The Cast method fills out this record from the information in Source.

Source is a TVarData (see page 3740) record that contains the data from another System::Variant (see page 3421) type. Check the VType field of Source to identify how it currently stores its data. Then use the other fields to fetch the data and convert it to the format used by this System::Variant (see page 3421) type.

As implemented in TCustomVariantType (see page 4987), Cast checks whether Source is another custom System::Variant (see page 3421) type. If so, it calls its CastTo (see page 4995) method, to convert it to this System::Variant (see page 3421) type. If not, it raises a system error indicating an invalid cast.

See Also

CastTo (see page 4995)

VarDataCast (see page 5006)

Enabling Casting

51.1.16.4.5 TCustomVariantType.CastTo Method

Converts data in the format of this TCustomVariantType (see page 4987) to the format of another System::Variant (see page 3421) type.

Pascal

```
procedure CastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType);
virtual;
```

C++

```
virtual __fastcall CastTo(TVarData Dest, const TVarData Source, const TVarType AVarType);
```

Description

Override CastTo to enable Variants (see page 4973) of this custom type to be cast to other System::Variant (see page 3421) types.

Dest is a TVarData (see page 3740) record that returns the System::Variant (see page 3421)'s data stored in the format identified by the AVarType parameter. The CastTo method fills out this record.

Source is the data from a System::Variant (see page 3421) of this custom System::Variant (see page 3421) type. CastTo

extracts the data from this record, converts it to the format expected by AVarType, and fills out Dest. If the VType field of source is not the same as the VarType (see page 5014) property, then CastTo creates a new instance of the associated System::Variant (see page 3421) data and casts it to the destination type.

AVarType is the type to which the data should be converted.

See Also

Cast (see page 4995)

VarType (see page 5014)

VarDataCastTo (see page 5007)

51.1.16.4.6 TCustomVariantType.CastToOle Method

Converts data in the format of this custom System::Variant (see page 3421) type to a format that can be used by COM Variants (see page 4973).

Pascal

```
procedure CastToOle(var Dest: TVarData; const Source: TVarData); virtual;
```

C++

```
virtual __fastcall CastToOle(TVarData Dest, const TVarData Source);
```

Description

Override CastToOle to change the way this custom type is converted for use in COM interface calls. CastToOle converts this custom System::Variant (see page 3421) type to the closest Automation-compatible System::Variant (see page 3421) type.

Dest is a TVarData (see page 3740) record that returns the System::Variant (see page 3421)'s data stored in an Automation-compatible format.

Source is a TVarData (see page 3740) record that represents the data from a System::Variant (see page 3421) of this custom type.

As implemented in TCustomVariantType (see page 4987), CastToOle calls the OlePromotion (see page 5001) method to determine the Automation-compatible type to which Source should be converted. It then calls the CastTo (see page 4995) method to perform the actual conversion.

See Also

CastTo (see page 4995)

OlePromotion (see page 5001)

VarDataCastToOleStr (see page 5007)

51.1.16.4.7 TCustomVariantType.Clear Method

Sets the data for this custom System::Variant (see page 3421) type to a blank or unassigned value.

Pascal

```
procedure Clear(var V: TVarData); virtual; abstract;
```

C++

```
virtual __fastcall Clear(TVarData V) = 0;
```

Description

Override Clear to implement the way this custom System::Variant (see page 3421) type represents a blank or unassigned

value.

V is a TVarData (see page 3740) record that represents the data from a System::Variant (see page 3421) of this custom type that needs to be cleared.

In TCustomVariantType (see page 4987), Clear is an abstract method. Descendant classes must override this method to provide an implementation. If the custom System::Variant (see page 3421) type stores its data in a manner that includes memory that needs to be freed, Clear should free that memory. Once any memory is freed, Clear can call the SimplisticClear (see page 5005) method, which re-initializes the TVarData (see page 3740) record, or set the VType field to varEmpty (see page 3865).

See Also

Unassigned (see page 5058)

IsClear (see page 5000)

SimplisticClear (see page 5005)

VarDataClear (see page 5008)

Copying and Clearing Custom Variants

51.1.16.4.8 TCustomVariantType.Compare Method

Implements comparisons that involve the custom System::Variant (see page 3421) type.

Pascal

```
procedure Compare(const Left: TVarData; const Right: TVarData; var Relationship:
TVarCompareResult); virtual;
```

C++

```
virtual __fastcall Compare(const TVarData Left, const TVarData Right, TVarCompareResult
Relationship);
```

Description

Override Compare to implement any comparison operators the custom System::Variant (see page 3421) type supports. Descendants can implement comparison operators by overriding either the Compare or the CompareOp (see page 4998) method.

Left is the value that appears to the left of the operator.

Right is the value that appears to the right of the operator.

Relationship returns a value indicating the relationship between Left and Right, as indicated in the following table:

Value	Operation
crLessThan	Left is less than Right.
crEqual	Left is equal to Right.
crGreaterThan	Left is greater than Right.

As implemented in TCustomVariantType (see page 4987), CompareOp (see page 4998) raises a system error indicating an invalid operation.

Tip: For custom Variants (see page 4973) that support a test of inequality, but not ordering, it makes more sense to override the CompareOp (see page 4998) method instead.

See Also

CompareOp (see page 4998)

CompareValue

Implementing Comparison Operations

51.1.16.4.9 TCustomVariantType.CompareOp Method

Implements any comparison operations of which the custom System::Variant (see page 3421) type is capable.

Pascal

```
function CompareOp(const Left: TVarData; const Right: TVarData; const Operator: TVarOp):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CompareOp(const TVarData Left, const TVarData Right, const TVarOp
Operator);
```

Description

Override CompareOp to implement any comparison operators the custom System::Variant (see page 3421) type supports. Descendants can implement comparison operators by overriding either the Compare (see page 4997) or the CompareOp method.

Left is the value that appears to the left of the operator.

Right is the value that appears to the right of the operator.

Operator identifies the operator that appears between Left and Right. It can be any of the following values:

Value	Operation
opCmpEQ (see page 3851)	equality comparison
opCmpNE (see page 3853)	inequality comparison
opCmpLT (see page 3853)	less than
opCmpLE (see page 3852)	less than or equal
opCmpGT (see page 3852)	greater than
opCmpGE (see page 3851)	greater than or equal

CompareOp returns true if the comparison is true as specified. It returns false if the specified comparison does not hold true.

As implemented in TCustomVariantType (see page 4987), CompareOp raises a system error indicating an invalid operation.

See Also

UnaryOp (see page 5006)

BinaryOp (see page 4994)

LeftPromotion (see page 5000)

RightPromotion (see page 5004)

Compare (see page 4997)

Implementing Comparison Operations

51.1.16.4.10 TCustomVariantType.Copy Method

Copies the data from a System::Variant (see page 3421) of this custom type.

Pascal

```
procedure Copy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean); virtual;
abstract;
```

C++

```
virtual __fastcall Copy(TVarData Dest, const TVarData Source, const Boolean Indirect) = 0;
```

Description

Override Copy to enable the custom System::Variant (see page 3421) type to be copied (assigned) to another System::Variant (see page 3421).

Dest is the TVarData (see page 3740) record from the System::Variant (see page 3421) whose value is to be a copy of the source System::Variant (see page 3421).

Source is the TVarData (see page 3740) record from a System::Variant (see page 3421) of this custom type that is to be copied to Dest.

Indirect indicates whether the copy is direct or indirect. When Indirect is true, the source TVarData (see page 3740) record contains an indirect reference to its data (the VarDataIsByRef (see page 5011) method should return true for Source). When making an indirect copy, it is not necessary to reallocate records or objects, because the System::Variant (see page 3421) does not "own" the data, it merely points to it. When making a direct copy, Copy must allocate new memory for any allocated records or objects, so that Dest can "own" its own copy of the data.

In TCustomVariantType (see page 4987), Copy is an abstract method. Descendant classes must override this method to provide an implementation.

See Also

VarDataCopy (see page 5008)

VarDataCopyNoInd (see page 5009)

SimplisticCopy (see page 5005)

VarDataIsByRef (see page 5011)

Copying and Clearing Custom Variants

51.1.16.4.11 TCustomVariantType.DispInvoke Method

Invokes a method call when the System::Variant (see page 3421) supports such operations.

Pascal

```
procedure DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); virtual;
```

C++

```
virtual __fastcall DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void *
Params);
```

Description

When the application tries to call a method, set a property, or read a property using a System::Variant (see page 3421) of the custom System::Variant (see page 3421) type, the system automatically generates a call to DispInvoke. TCustomVariantType (see page 4987) responds by generating a system error indicating an invalid dispatch attempt.

To create a custom System::Variant (see page 3421) type that allows applications to call methods or use properties, use TInvokeableVariantType (see page 5014) as a base class instead of TCustomVariantType (see page 4987). TInvokeableVariantType (see page 5014) introduces methods for executing method calls and implementing properties, and overrides the DispInvoke method so that it dispatches method calls to the appropriate methods.

Dest is a TVarData (see page 3740) record that receives the return value of any function calls.

Source is the TVarData (see page 3740) record that holds the data from the custom System::Variant (see page 3421) whose property or method was invoked.

CallDesc identifies the method that was called, including the type and number of its arguments.

Params points to an array of parameter values that were passed in the method call.

See Also

TInvokeableVariantType (see page 5014)

51.1.16.4.12 TCustomVariantType.IsClear Method

Indicates whether the data from a custom System::Variant (see page 3421) represents a blank or unassigned value.

Pascal

```
function IsClear(const V: TVarData): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsClear(const TVarData V);
```

Description

Override IsClear to identify when data from a System::Variant (see page 3421) of the custom System::Variant (see page 3421) type represents a blank or unassigned value. The global VarIsClear (see page 5079) method calls IsClear when given a custom System::Variant (see page 3421) of this type.

As Implemented in TCustomVariantType (see page 4987), IsClear always returns false. Override this method to return true for invalid values or special values set by the Clear (see page 4996) method.

See Also

Clear (see page 4996)

VarIsClear (see page 5079)

Copying and Clearing Custom Variants

51.1.16.4.13 TCustomVariantType.LeftPromotion Method

Indicates whether the left argument to a binary operation should be coerced to a different type.

Pascal

```
function LeftPromotion(const V: TVarData; const Operator: TVarOp; out RequiredVarType:
TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean LeftPromotion(const TVarData V, const TVarOp Operator, TVarType
RequiredVarType);
```

Description

Override LeftPromotion to indicate when the left argument for a binary or comparison operation should be implicitly cast to another type before performing the operation. LeftPromotion is called when the right-hand System::Variant (see page 3421) in

a binary or comparison operation is of this System::Variant (see page 3421) type and

The left-hand argument is a built-in System::Variant (see page 3421) type.

The left-hand argument is a custom System::Variant (see page 3421) type that does not indicate any problem with this System::Variant (see page 3421) type for the right-hand argument.

V is the TVarData (see page 3740) record for the left-hand argument of the operation.

Operator indicates the type of operation. It can be any of the operators in the following table:

Value	Operation
opAdd (see page 3850)	addition
opSubtract (see page 3858)	subtraction
opMultiply (see page 3855)	multiplication
opDivide (see page 3854)	floating-point division
opIntDivide (see page 3855)	integer division
opModulus (see page 3855)	remainder
opShiftLeft (see page 3857)	left shift
opShiftRight (see page 3858)	right shift
opAnd (see page 3850)	bitwise and
opOr (see page 3857)	bitwise or
opXor (see page 3859)	bitwise exclusive or
opCompare (see page 3854)	any comparison operation

RequiredVarType returns the System::Variant (see page 3421) type code for the type to which the left-hand argument should be cast before performing the operation. If the operation can proceed with the left-hand argument left as-is, RequiredVarType returns the VType field of V.

LeftPromotion returns true if the TCustomVariantType (see page 4987) descendant can perform the operation (using the BinaryOp (see page 4994), CompareOp (see page 4998), or Compare (see page 4997) method) assuming the left-hand argument can be cast to RequiredVarType. It returns false if the TCustomVariantType (see page 4987) descendant can't perform the operation.

As implemented in TCustomVariantType (see page 4987), LeftPromotion returns the VarType (see page 5014) property as RequiredVarType, and returns true.

See Also

BinaryOp (see page 4994)

CompareOp (see page 4998)

Compare (see page 4997)

VarType (see page 5014)

RightPromotion (see page 5004)

Implementing Binary Operations

51.1.16.4.14 TCustomVariantType.OlePromotion Method

Indicates the type to which a System::Variant (see page 3421) value must be cast to make it Automation-compatible.

Pascal

```
function OlePromotion(const V: TVarData; out RequiredVarType: TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean OlePromotion(const TVarData V, TVarType RequiredVarType);
```

Description

Override OlePromotion to indicate when a System::Variant (see page 3421) of this custom System::Variant (see page 3421) type must be cast to another type before it can be auto-marshaled using an Automation interface.

V is the TVarData (see page 3740) record for the custom System::Variant (see page 3421) that the application wants to marshal.

RequiredVarType returns the type to which V must be cast before it is Automation-compatible.

OlePromotion returns true if V can be cast to an Automation-compatible type, false if there is no type to which V can be cast.

As implemented in TCustomVariantType (see page 4987), OlePromotion sets RequiredVarType to varOleStr (see page 3869) and returns true if V does not already represent a Unicode string.

See Also

CastToOle (see page 4996)

51.1.16.4.15 TCustomVariantType.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the TCustomVariantType (see page 4987) object supports the interface specified by IID. If so, QueryInterface

increments the reference count.

sets the Obj parameter so that it points to an instance of the specified interface.

returns 0 to indicate success.

If the object does not support the interface, QueryInterface returns a nonzero error code such as E_NoInterface.

See Also

_AddRef (see page 4993)

_Release (see page 4993)

51.1.16.4.16 TCustomVariantType.RaiseCastError Method

Generates a system error that indicates an invalid cast.

Pascal

```
procedure RaiseCastError;
```

C++

```
__fastcall RaiseCastError();
```

Description

Call RaiseCastError from the implementation of a TCustomVariantType (see page 4987) descendant when an operation fails because a System::Variant (see page 3421) value could not be cast to a necessary type.

See Also

Cast (see page 4995)

CastTo (see page 4995)

51.1.16.4.17 TCustomVariantType.RaiseDispError Method

Generates a system error indicating an invalid dispatch attempt.

Pascal

```
procedure RaiseDispError;
```

C++

```
__fastcall RaiseDispError();
```

Description

Call RaiseDispError from the implementation of a TCustomVariantType (see page 4987) descendant when an operation fails because the variant can't execute a method call. This raises EVariantDispatchError (see page 4981).

See Also

DispInvoke (see page 4999)

EVariantDispatchError (see page 4981)

51.1.16.4.18 TCustomVariantType.RaiseInvalidOp Method

Generates a system error indicating an invalid operation.

Pascal

```
procedure RaiseInvalidOp;
```

C++

```
__fastcall RaiseInvalidOp();
```

Description

Call RaiseInvalidOp from the implementation of a TCustomVariantType (see page 4987) descendant when it can't perform an operation.

See Also

BinaryOp (see page 4994)

UnaryOp (see page 5006)

CompareOp (see page 4998)

Compare (see page 4997)

51.1.16.4.19 TCustomVariantType.RightPromotion Method

Indicates whether the right argument to a binary operation should be coerced to a different type.

Pascal

```
function RightPromotion(const V: TVarData; const Operator: TVarOp; out RequiredVarType:
TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean RightPromotion(const TVarData V, const TVarOp Operator, TVarType
RequiredVarType);
```

Description

Override RightPromotion to indicate when the right-hand argument for a binary or comparison operation should be implicitly cast to another type before performing the operation. RightPromotion is called when the right-hand System::Variant (see page 3421) in a binary or comparison operation is of this System::Variant (see page 3421) type.

Note: In operations that involve two custom Variants (see page 4973), the left-hand argument's RightPromotion method is called first. The right-hand argument's LeftPromotion (see page 5000) method is then called only if the left-hand argument's RightPromotion method returns false.

V is the TVarData (see page 3740) record for the left-hand argument of the operation.

Operator indicates the type of operation. It can be any of the operators in the following table:

Value	Operation
opAdd (see page 3850)	addition
opSubtract (see page 3858)	subtraction
opMultiply (see page 3855)	multiplication
opDivide (see page 3854)	floating-point division
opIntDivide (see page 3855)	integer division
opModulus (see page 3855)	remainder
opShiftRight (see page 3858)	right shift
opShiftRight (see page 3858)	right shift
opAnd (see page 3850)	bitwise and
opOr (see page 3857)	bitwise or
opXor (see page 3859)	bitwise exclusive or
opCompare (see page 3854)	any comparison operation

RequiredVarType returns the System::Variant (see page 3421) type code for the type to which the right-hand argument should be cast before performing the operation. If the operation can proceed with the right-hand argument left as-is, RequiredVarType returns the VType field of V.

RightPromotion returns true if the TCustomVariantType (see page 4987) descendant can perform the operation (using the BinaryOp (see page 4994), CompareOp (see page 4998), or Compare (see page 4997) method) assuming the right-hand argument can be cast to RequiredVarType. It returns false if the TCustomVariantType (see page 4987) descendant can't perform the operation.

As implemented in TCustomVariantType (see page 4987), RightPromotion returns the VarType (see page 5014) property as RequiredVarType, and returns true.

See Also

BinaryOp (see page 4994)

CompareOp (see page 4998)

Compare (see page 4997)

VarType (see page 5014)

LeftPromotion (see page 5000)

Implementing Binary Operations

51.1.16.4.20 TCustomVariantType.SimplisticClear Method

Clears a TVarData (see page 3740) record by re-initializing it.

Pascal

```
procedure SimplisticClear(var V: TVarData);
```

C++

```
__fastcall SimplisticClear(TVarData V);
```

Description

Call SimplisticClear from the implementation of a TCustomVariantType (see page 4987) descendant to clear the TVarData (see page 3740) record of a System::Variant (see page 3421) of the custom type. This method should only be called if the TVarData (see page 3740) record does not contain any members that must be freed.

SimplisticClear simply calls the VarDataInit (see page 5010) method, which reinitializes the TVarData (see page 3740) record passed as V.

See Also

Clear (see page 4996)

VarDataClear (see page 5008)

VarDataInit (see page 5010)

51.1.16.4.21 TCustomVariantType.SimplisticCopy Method

Performs a simple block copy of one TVarData (see page 3740) record to another.

Pascal

```
procedure SimplisticCopy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean =
False);
```

C++

```
__fastcall SimplisticCopy(TVarData Dest, const TVarData Source, const Boolean Indirect =
False);
```

Description

Call SimplisticCopy from the implementation of a TCustomVariantType (see page 4987) descendant to block copy one TVarData (see page 3740) record to another.

Dest is the TVarData (see page 3740) record that receives the copy.

Source is the TVarData (see page 3740) record to copy.

Indirect indicates whether Source represents the data (false) or merely a reference to the data (true).

See Also

Copy (see page 4999)

VarDataCopy (see page 5008)

VarDataCopyNoInd (see page 5009)

Copying and Clearing Custom Variants

51.1.16.4.22 TCustomVariantType.UnaryOp Method

Implements any unary operations of which the custom System::Variant (see page 3421) type is capable.

Pascal

```
procedure UnaryOp(var Right: TVarData; const Operator: TVarOp); virtual;
```

C++

```
virtual __fastcall UnaryOp(TVarData Right, const TVarOp Operator);
```

Description

Override UnaryOp to implement any unary operators the custom System::Variant (see page 3421) type supports.

Right is the value that appears to the right of the operator. UnaryOp changes this value to indicate the result of the operation.

Operator identifies the operator that appears before Right. It can be any of the following values:

Value	Operation
opNegate (see page 3856)	unary minus
opNot (see page 3856)	logical negation

As implemented in TCustomVariantType (see page 4987), UnaryOp raises a system error indicating an invalid operation.

See Also

BinaryOp (see page 4994)

CompareOp (see page 4998)

Implementing Unary Operations

51.1.16.4.23 TCustomVariantType.VarDataCast Method

Performs a cast from one System::Variant (see page 3421) type to another.

Pascal

```
procedure VarDataCast(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCast(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCast from the implementation of a TCustomVariantType (see page 4987) descendant to perform casts on the data from another System::Variant (see page 3421) type to the type specified by the VarType (see page 5014) property. Do not use VarDataCast as the entire implementation of the Cast (see page 4995) method, as this will lead to a circular reference.

Dest returns the result of the cast.

Source is the TVarData (see page 3740) record of another System::Variant (see page 3421) type that is to be converted.

See Also

Cast (see page 4995)

CastTo (see page 4995)

VarDataCastTo (see page 5007)

VarType (see page 5014)

51.1.16.4.24 VarDataCastTo Method

This is the overview for the VarDataCastTo method overload.

Overload List

	Name	Description
	TCustomVariantType.VarDataCastTo (TVarData, TVarData, TVarType) (see page 5007)	Performs a cast from one System::Variant (see page 3421) type to another.
	TCustomVariantType.VarDataCastTo (TVarData, TVarType) (see page 5007)	Performs a cast from one System::Variant (see page 3421) type to another.

51.1.16.4.24.1 TCustomVariantType.VarDataCastTo Method (TVarData, TVarData, TVarType)

Performs a cast from one System::Variant (see page 3421) type to another.

Pascal

```
procedure VarDataCastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType);
overload;
procedure VarDataCastTo(var Dest: TVarData; const AVarType: TVarType); overload;
```

C++

```
__fastcall VarDataCastTo(TVarData Dest, const TVarData Source, const TVarType AVarType);
__fastcall VarDataCastTo(TVarData Dest, const TVarType AVarType);
```

Description

Call VarDataCastTo from the implementation of a TCustomVariantType (see page 4987) descendant to perform casts on the data from one System::Variant (see page 3421) type to another. Do not use VarDataCastTo as the entire implementation of the CastTo (see page 4995) method, as this will lead to a circular reference.

Dest returns the result of the cast. If VarDataCastTo is called with no Source parameter, it also provides the source data to be cast.

Source is the TVarData (see page 3740) record to be cast.

VarType (see page 5014) is the type code of the System::Variant (see page 3421) type to which the data should be cast.

See Also

CastTo (see page 4995)

51.1.16.4.25 TCustomVariantType.VarDataCastToOleStr Method

Performs a cast to a System::Variant (see page 3421) type of varOleStr (see page 3869).

Pascal

```
procedure VarDataCastToOleStr(var Dest: TVarData);
```

C++

```
__fastcall VarDataCastToOleStr(TVarData Dest);
```

Description

Call VarDataCastToOleStr from the implementation of a TCustomVariantType (see page 4987) descendant to perform casts to a TVarData (see page 3740) record with System::Variant (see page 3421) type code of varOleStr (see page 3869) (Unicode string).

Dest is the TVarData (see page 3740) record of a System::Variant (see page 3421), and returns the result of the cast.

See Also

VarDataFromOleStr (see page 5009)

VarDataToStr (see page 5013)

51.1.16.4.26 TCustomVariantType.VarDataClear Method

Clears the data from a built-in System::Variant (see page 3421) type.

Pascal

```
procedure VarDataClear(var Dest: TVarData);
```

C++

```
__fastcall VarDataClear(TVarData Dest);
```

Description

Call VarDataClear from the implementation of a TCustomVariantType (see page 4987) descendant to clear the data in the TVarData (see page 3740) record of a System::Variant (see page 3421). Do not use VarDataClear as the entire implementation of the Clear (see page 4996) method, as this will lead to a circular reference.

Dest is the TVarData (see page 3740) record of a System::Variant (see page 3421) type, and returns the result after clearing the data.

See Also

SimplisticClear (see page 5005)

Clear (see page 4996)

51.1.16.4.27 TCustomVariantType.VarDataCopy Method

Copies the data from one built-in System::Variant (see page 3421) type to another.

Pascal

```
procedure VarDataCopy(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCopy(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCopy from the implementation of a TCustomVariantType (see page 4987) descendant to clear the data from a destination System::Variant (see page 3421) and then copy the TVarData (see page 3740) record from another System::Variant (see page 3421). VarDataCopy can handle data that is stored indirectly (when the VType field includes

varByRef (see page 3862)). Do not use VarDataCopy as the entire implementation of the Copy (see page 4999) method, as this will lead to a circular reference.

Dest is the TVarData (see page 3740) record that receives the copy.

Source is the TVarData (see page 3740) record to be copied.

See Also

SimplisticCopy (see page 5005)

VarDataCopyNoInd (see page 5009)

Copy (see page 4999)

51.1.16.4.28 TCustomVariantType.VarDataCopyNoInd Method

Copies the data from one built-in System::Variant (see page 3421) type to another.

Pascal

```
procedure VarDataCopyNoInd(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCopyNoInd(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCopyNoInd from the implementation of a TCustomVariantType (see page 4987) descendant to clear the data from a destination System::Variant (see page 3421) and then copy the TVarData (see page 3740) record from another System::Variant (see page 3421). Unlike the VarDataCopy (see page 5008) method, it can't handle data that is stored indirectly (when the VType field includes varByRef (see page 3862)). However, it is often more efficient than VarDataCopy (see page 5008).

Dest is the TVarData (see page 3740) record that receives the copy.

Source is the TVarData (see page 3740) record to be copied.

See Also

VarDataCopy (see page 5008)

Copy (see page 4999)

51.1.16.4.29 TCustomVariantType.VarDataFromOleStr Method

Creates a TVarData (see page 3740) record to represent a Unicode string.

Pascal

```
procedure VarDataFromOleStr(var V: TVarData; const Value: WideString);
```

C++

```
__fastcall VarDataFromOleStr(TVarData V, const BSTR Value);
```

Description

Call VarDataCopy (see page 5008) from the implementation of a TCustomVariantType (see page 4987) descendant to fill out a TVarData (see page 3740) record so that it represents a specified Unicode string.

V is the TVarData (see page 3740) record to be filled out.

Value is a Unicode string that becomes the value of V.

See Also

VarDataCastToOleStr (see page 5007)

VarDataFromStr (see page 5010)

51.1.16.4.30 TCustomVariantType.VarDataFromStr Method

Creates a TVarData (see page 3740) record to represent a string.

Pascal

```
procedure VarDataFromStr(var V: TVarData; const Value: string);
```

C++

```
__fastcall VarDataFromStr(TVarData V, const UnicodeString Value);
```

Description

Call VarDataCopy (see page 5008) from the implementation of a TCustomVariantType (see page 4987) descendant to fill out a TVarData (see page 3740) record so that it represents a specified string.

V is the TVarData (see page 3740) record to be filled out.

Value is a string that becomes the value of V.

See Also

VarDataFromOleStr (see page 5009)

VarDataIsStr (see page 5013)

VarDataToStr (see page 5013)

51.1.16.4.31 TCustomVariantType.VarDataInit Method

Initializes a TVarData (see page 3740) record.

Pascal

```
procedure VarDataInit(var Dest: TVarData);
```

C++

```
__fastcall VarDataInit(TVarData Dest);
```

Description

Call VarDataInit from the implementation of a TCustomVariantType (see page 4987) descendant to initialize a newly-allocated TVarData (see page 3740) record.

See Also

VarDataClear (see page 5008)

51.1.16.4.32 TCustomVariantType.VarDataIsArray Method

Indicates whether a TVarData (see page 3740) record represents the data from a System::Variant (see page 3421) array.

Pascal

```
function VarDataIsArray(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsArray(const TVarData V);
```

Description

VarDataIsArray returns true if the VType field of V contains the varArray (see page 3861) bit.

See Also

VarDataIsByRef (see page 5011)

VarType (see page 5090)

51.1.16.4.33 TCustomVariantType.VarDataIsByRef Method

Indicates whether a TVarData (see page 3740) record stores its data indirectly.

Pascal

```
function VarDataIsByRef(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsByRef(const TVarData V);
```

Description

VarDataIsArray (see page 5010) returns true if the VType field of V contains the varByRef (see page 3862) bit.

See Also

VarDataIsArray (see page 5010)

VarType (see page 5090)

51.1.16.4.34 TCustomVariantType.VarDataIsEmptyParam Method

Indicates whether a TVarData (see page 3740) record represents an unassigned optional parameter.

Pascal

```
function VarDataIsEmptyParam(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsEmptyParam(const TVarData V);
```

Description

VarDataIsEmptyParam returns true if the given TVarData (see page 3740) record represents an unassigned optional parameter.

See Also

VarDataIsArray (see page 5010)

VarType (see page 5090)

51.1.16.4.35 TCustomVariantType.VarDataIsFloat Method

Indicates whether a TVarData (see page 3740) record represents a floating-point value.

Pascal

```
function VarDataIsFloat(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsFloat(const TVarData V);
```

Description

VarDataIsFloat returns true if the given TVarData (see page 3740) record comes from a built-in System::Variant (see page 3421) type that represents a floating-point value (Single, Double, or Currency (see page 3235)). VarDataIsFloat does not return true for data from Custom System::Variant (see page 3421) types.

See Also

VarDataIsNumeric (see page 5012)

VarType (see page 5090)

VarDataIsOrdinal (see page 5012)

VarDataIsStr (see page 5013)

51.1.16.4.36 TCustomVariantType.VarDataIsNumeric Method

Indicates whether a TVarData (see page 3740) record represents a numeric value.

Pascal

```
function VarDataIsNumeric(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsNumeric(const TVarData V);
```

Description

VarDataIsNumeric returns true if the given TVarData (see page 3740) record represents a numeric value of some sort. This can be either a floating-point value or an ordinal value. VarDataIsNumeric does not return true for data from Custom System::Variant (see page 3421) types.

See Also

VarDataIsFloat (see page 5011)

VarType (see page 5090)

VarDataIsOrdinal (see page 5012)

VarDataIsStr (see page 5013)

51.1.16.4.37 TCustomVariantType.VarDataIsOrdinal Method

Indicates whether a TVarData (see page 3740) record represents a ordinal value.

Pascal

```
function VarDataIsOrdinal(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsOrdinal(const TVarData V);
```

Description

VarDataIsOrdinal returns true if the given TVarData (see page 3740) record comes from a built-in System::Variant (see page 3421) type that represents a ordinal value (such as an integer or Boolean type). VarDataIsOrdinal does not return true for data from Custom System::Variant (see page 3421) types.

See Also

VarDataIsNumeric (see page 5012)

VarType (see page 5090)

VarDataIsFloat (see page 5011)

VarDataIsStr (see page 5013)

51.1.16.4.38 TCustomVariantType.VarDataIsStr Method

Indicates whether a TVarData (see page 3740) record represents a string (normal or Unicode).

Pascal

```
function VarDataIsStr(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsStr(const TVarData V);
```

Description

VarDataIsStr returns true if the given TVarData (see page 3740) record has a VType field of varString (see page 3871) or varOleStr (see page 3869).

See Also

VarDataIsNumeric (see page 5012)

VarType (see page 5090)

VarDataIsFloat (see page 5011)

51.1.16.4.39 TCustomVariantType.VarDataToStr Method

Returns a string that represents the value from a TVarData (see page 3740) record.

Pascal

```
function VarDataToStr(const V: TVarData): string;
```

C++

```
__fastcall UnicodeString VarDataToStr(const TVarData V);
```

Description

Call VarDataToStr from the implementation of a TCustomVariantType (see page 4987) descendant to extract a string that represents the value of a System::Variant (see page 3421).

V is the TVarData (see page 3740) record that represents the value of the System::Variant (see page 3421).

See Also

VarDataCastToOleStr (see page 5007)

VarDataFromStr (see page 5010)

51.1.16.5 TCustomVariantType Properties

The properties of the TCustomVariantType class are listed here.

Public Properties

	Name	Description
	VarType (see page 5014)	Indicates the System::Variant (see page 3421) type code for the custom System::Variant (see page 3421) type.

51.1.16.5.1 TCustomVariantType.VarType Property

Indicates the System::Variant (see page 3421) type code for the custom System::Variant (see page 3421) type.

Pascal

```
property VarType: TVarType;
```

C++

```
__property TVarType VarType;
```

Description

The VarType property provides read-only access to the type code that identifies a custom System::Variant (see page 3421) data type.

The value of VarType is set in the constructor. This can be an automatically generated value, or it can be a value explicitly passed to the constructor. Note that if the VarType is automatically-generated, it may not remain the same for every application that uses the custom System::Variant (see page 3421) type: its value will depend on the other custom Variants (see page 4973) also used in the application.

VarType (see page 5090)

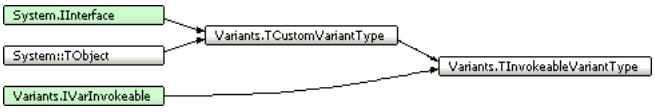
FindCustomVariantType (see page 5055)

Enabling Casting

51.1.17 TInvokeableVariantType Class

TInvokeableVariantType is the base class for custom System::Variant (see page 3421) types that implement custom Variants (see page 4973) with properties and methods.

Class Hierarchy



Pascal

```
TInvokeableVariantType = class(TCustomVariantType, IVarInvokeable);
```

C++

```
class TInvokeableVariantType : public TCustomVariantType, public IVarInvokeable;
```

File

Variants

Description

Use TInvokeableVariantType to define new data types for Delphi Variants (see page 4973) with properties and methods. TInvokeableVariantType descendants do not represent the Variants (see page 4973) themselves. Rather, they act as utility classes that the custom Variants (see page 4973) call on to perform their operations.

Note: Do not define TInvokeableVariantType descendants in C++. The logic for custom System::Variant (see page 3421) types must be defined in Delphi code.

To create a System::Variant (see page 3421) type that supports properties and methods,

1. Map the storage of the System::Variant (see page 3421)'s data on to the TVarData (see page 3740) record.
2. Write (see page 3707) a method that creates instances of your custom System::Variant (see page 3421). This fills in the System::Variant (see page 3421)'s data as defined in step 1.
3. Declare a class that descends from TInvokeableVariantType.
4. Implement all required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically DoFunction (see page 5018), DoProcedure (see page 5019), GetProperty (see page 5020), SetProperty (see page 5021), BinaryOp (see page 4994), UnaryOp (see page 5006), CompareOp (see page 4998) or Compare (see page 4997), Cast (see page 4995), CastTo (see page 4995), Clear (see page 4996), Copy (see page 4999), IsClear (see page 5000), LeftPromotion (see page 5000), and RightPromotion (see page 5004)).
5. In the initialization section of the unit that defines your TInvokeableVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the System::Variant (see page 3421)-handling system so that the new System::Variant (see page 3421) type is enabled.
6. In the finalization section of the unit that defines your TInvokeableVariantType descendant, free the instance of your class. This automatically unregisters the System::Variant (see page 3421) type.

For an example, see the VarConv (see page 4947) unit, which implements a custom System::Variant (see page 3421) type for measurements.

Tip: If the custom System::Variant (see page 3421) type uses an object instance to store its data, you can automatically implement the published properties of that object by deriving your custom System::Variant (see page 3421) type from TPublishableVariantType instead.

See Also

TPublishableVariantType (see page 4694)

TVarData (see page 3740)

Supporting Properties and Methods in Custom Variants

51.1.17.1 TInvokeableVariantType Members

The following tables list the members exposed by TInvokeableVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 4993)	Responds when the caller acquires a reference to this object's interface.
	_Release (see page 4993)	Responds when the caller releases a reference to this object's interface.
	DispInvoke (see page 5018)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 5014) method.
	FixupIdent (see page 5020)	Fixes up dispatch identifier.
	LeftPromotion (see page 5000)	Indicates whether the left argument to a binary operation should be coerced to a different type.

	OlePromotion (see page 5001)	Indicates the type to which a System::Variant (see page 3421) value must be cast to make it Automation-compatible.
	QueryInterface (see page 5002)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 5002)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 5003)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 5003)	Generates a system error indicating an invalid operation.
	RightPromotion (see page 5004)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 5005)	Clears a TVarData (see page 3740) record by re-initializing it.
	SimplisticCopy (see page 5005)	Performs a simple block copy of one TVarData (see page 3740) record to another.
	VarDataCast (see page 5006)	Performs a cast from one System::Variant (see page 3421) type to another.
	VarDataCastTo (see page 5007)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 5007)	Performs a cast to a System::Variant (see page 3421) type of varOleStr (see page 3869).
	VarDataClear (see page 5008)	Clears the data from a built-in System::Variant (see page 3421) type.
	VarDataCopy (see page 5008)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataCopyNoInd (see page 5009)	Copies the data from one built-in System::Variant (see page 3421) type to another.
	VarDataFromOleStr (see page 5009)	Creates a TVarData (see page 3740) record to represent a Unicode string.
	VarDataFromStr (see page 5010)	Creates a TVarData (see page 3740) record to represent a string.
	VarDataInit (see page 5010)	Initializes a TVarData (see page 3740) record.
	VarDataIsArray (see page 5010)	Indicates whether a TVarData (see page 3740) record represents the data from a System::Variant (see page 3421) array.
	VarDataIsByRef (see page 5011)	Indicates whether a TVarData (see page 3740) record stores its data indirectly.
	VarDataIsEmptyParam (see page 5011)	Indicates whether a TVarData (see page 3740) record represents an unassigned optional parameter.
	VarDataIsFloat (see page 5011)	Indicates whether a TVarData (see page 3740) record represents a floating-point value.
	VarDataIsNumeric (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a numeric value.
	VarDataIsOrdinal (see page 5012)	Indicates whether a TVarData (see page 3740) record represents a ordinal value.
	VarDataIsStr (see page 5013)	Indicates whether a TVarData (see page 3740) record represents a string (normal or Unicode).
	VarDataToStr (see page 5013)	Returns a string that represents the value from a TVarData (see page 3740) record.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	BinaryOp (see page 4994)	Implements any binary operations of which the custom System::Variant (see page 3421) type is capable.
	Cast (see page 4995)	Converts the data from another System::Variant (see page 3421) type so that it represents this custom type's data format.
	CastTo (see page 4995)	Converts data in the format of this TCustomVariantType (see page 4987) to the format of another System::Variant (see page 3421) type.
	CastToOle (see page 4996)	Converts data in the format of this custom System::Variant (see page 3421) type to a format that can be used by COM Variants (see page 4973).
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.

	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 4996)	Sets the data for this custom System::Variant (see page 3421) type to a blank or unassigned value.
V	Compare (see page 4997)	Implements comparisons that involve the custom System::Variant (see page 3421) type.
V	CompareOp (see page 4998)	Implements any comparison operations of which the custom System::Variant (see page 3421) type is capable.
A	Copy (see page 4999)	Copies the data from a System::Variant (see page 3421) of this custom type.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 4990)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Destroy (see page 4991)	Frees an instance of TCustomVariantType (see page 4987).
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	DoFunction (see page 5018)	Implements all methods that return values.
V	DoProcedure (see page 5019)	Implements all methods that do not return values.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetProperty (see page 5020)	Returns the value for any property this System::Variant (see page 3421) type supports.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
V	IsClear (see page 5000)	Indicates whether the data from a custom System::Variant (see page 3421) represents a blank or unassigned value.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	SetProperty (see page 5021)	Sets the value for any property this System::Variant (see page 3421) type supports.
V	ToString (see page 3380)	Returns a string containing the class name.
V	UnaryOp (see page 5006)	Implements any unary operations of which the custom System::Variant (see page 3421) type is capable.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	VarType (see page 5014)	Indicates the System::Variant (see page 3421) type code for the custom System::Variant (see page 3421) type.

51.1.17.2 TInvokeableVariantType Methods

The methods of the TInvokeableVariantType class are listed here.

Protected Methods

	Name	Description
	DispInvoke (see page 5018)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 5014) method.
	FixupIdent (see page 5020)	Fixes up dispatch identifier.

Public Methods

	Name	Description
	DoFunction (see page 5018)	Implements all methods that return values.
	DoProcedure (see page 5019)	Implements all methods that do not return values.
	GetProperty (see page 5020)	Returns the value for any property this System::Variant (see page 3421) type supports.
	SetProperty (see page 5021)	Sets the value for any property this System::Variant (see page 3421) type supports.

51.1.17.2.1 TInvokeableVariantType.DispInvoke Method

Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 5014) method.

Pascal

```
procedure DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); override;
```

C++

```
virtual __fastcall DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void *
Params);
```

Description

When the application tries to call a method, set a property, or read a property using a System::Variant (see page 3421) of the custom System::Variant (see page 3421) type, the system automatically generates a call to DispInvoke. TInvokeableVariantType (see page 5014) responds by generating a call to the GetProperty (see page 5020), SetProperty (see page 5021), DoProcedure (see page 5019), or DoFunction (see page 5018) method, as appropriate.

Dest is a TVarData (see page 3740) record that receives the return value of any function calls.

Source is the TVarData (see page 3740) record that holds the data from the custom System::Variant (see page 3421) whose property or method was invoked.

CallDesc identifies the method that was called, including the type and number of its arguments.

Params points to an array of parameter values that were passed in the method call.

See Also

GetProperty (see page 5020)

SetProperty (see page 5021)

DoProcedure (see page 5019)

DoFunction (see page 5018)

51.1.17.2.2 TInvokeableVariantType.DoFunction Method

Implements all methods that return values.

Pascal

```
function DoFunction(var Dest: TVarData; const V: TVarData; const Name: string; const
```

```
Arguments: TVarDataArray): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoFunction(TVarData Dest, const TVarData V, const UnicodeString
Name, const TVarDataArray Arguments);
```

Description

Override DoFunction to provide the implementation for method calls that return values. When the application invokes a System::Variant (see page 3421) member function (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++) a call is automatically generated to DoFunction.

Dest is a TVarData (see page 3740) record that receives the value that the function returns.

V is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to call the function.

Name is the name of the function.

Arguments is a dynamic array of TVarData (see page 3740) records, where each one represents the value of an argument passed to the function.

DoFunction returns true if it executes the method call, false if it does not implement the specified function.

As implemented in TInvokeableVariant, DoFunction always returns false, because it does not implement any function calls.

See Also

GetProperty (see page 5020)

DoProcedure (see page 5019)

SetProperty (see page 5021)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.1.17.2.3 TInvokeableVariantType.DoProcedure Method

Implements all methods that do not return values.

Pascal

```
function DoProcedure(const V: TVarData; const Name: string; const Arguments: TVarDataArray):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoProcedure(const TVarData V, const UnicodeString Name, const
TVarDataArray Arguments);
```

Description

Override DoProcedure to provide the implementation for methods calls that do not return values. When the application invokes a System::Variant (see page 3421) member procedure (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++) a call is automatically generated to DoProcedure that allows the TInvokeableVariant descendant to implement the call.

V is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to call the procedure.

Name is the name of the procedure.

Arguments is a dynamic array of TVarData (see page 3740) records, where each one represents the value of an argument passed to the procedure.

DoProcedure returns true if it executes the procedure call, false if it does not implement the specified procedure.

As implemented in TInvokeableVariant, DoProcedure always returns false, because it does not implement any procedure calls.

See Also

GetProperty (see page 5020)

DoFunction (see page 5018)

SetProperty (see page 5021)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.1.17.2.4 TInvokeableVariantType.FixupIdent Method

Fixes up dispatch identifier.

Pascal

```
function FixupIdent(const AText: string): string; virtual;
```

C++

```
virtual __fastcall UnicodeString FixupIdent(const UnicodeString AText);
```

Description

FixupIdent is called internally to determine the final fixup for the dispatch identifier. As defined in TInvokeableVariantType (see page 5014), this fixup consists of converting the identifier to all upper case.

51.1.17.2.5 TInvokeableVariantType.GetProperty Method

Returns the value for any property this System::Variant (see page 3421) type supports.

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
virtual;
```

C++

```
virtual __fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const UnicodeString
Name);
```

Description

Override GetProperty to provide the read implementations for properties of instances of the System::Variant (see page 3421). When the application reads a System::Variant (see page 3421) property (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++) a call is automatically generated to GetProperty that allows the TInvokeableVariant descendant to implement the call.

Dest is a TVarData (see page 3740) record that receives the property value.

V is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance whose property is being read.

Name is the name of the property.

GetProperty returns true if it returns a property value, false if it does not implement the specified property.

As implemented in TInvokeableVariant, GetProperty always returns false, because it does not implement any properties.

See Also

DoFunction (see page 5018)

SetProperty (see page 5021)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.1.17.2.6 TInvokeableVariantType.SetProperty Method

Sets the value for any property this System::Variant (see page 3421) type supports.

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
virtual;
```

C++

```
virtual __fastcall Boolean SetProperty(const TVarData V, const UnicodeString Name, const
TVarData Value);
```

Description

Override SetProperty to provide the write implementation for the properties of instances of the invokeable System::Variant (see page 3421) type. When the application writes to a System::Variant (see page 3421) property (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++) a call is automatically generated to SetProperty that allows the TInvokeableVariant descendant to implement the call.

Name is the name of the property.

Value is a TVarData (see page 3740) record that contains the new property value.

GetProperty (see page 5020) returns true if it sets a property value, false if it does not implement the specified property or if the specified property is read-only.

As implemented in TInvokeableVariant, GetProperty (see page 5020) always returns false, because it does not implement any properties.

See Also

DoFunction (see page 5018)

51.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IVarInstanceReference (see page 5022)	IVarInstanceReference is the interface for extracting the instance that represents the data from a Variant (see page 3421) of the custom type.
	IVarInvokeable (see page 5023)	IVarInvokeable is the interface for custom Variant (see page 3421) types that implement dynamic properties and methods.

51.2.1 IVarInstanceReference Interface

IVarInstanceReference is the interface for extracting the instance that represents the data from a Variant (see page 3421) of the custom type.

Class Hierarchy

Pascal

```
IVarInstanceReference = interface;
```

C++

```
__interface IVarInstanceReference;
```

File

Variants

Description

Implement IVarInstanceReference in the proxy classes that manage a custom Variant (see page 3421) data type. IVarInstanceReference exposes a single method that must be implemented, called GetInstance (see page 5023).

See Also

TPublishableVariantType (see page 4694)

Creating a Class to Enable the Custom Variant Type

51.2.1.1 IVarInstanceReference Members

The following tables list the members exposed by IVarInstanceReference.

Public Methods

	Name	Description
	GetInstance (see page 5023)	Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.

51.2.1.2 IVarInstanceReference Methods

The methods of the IVarInstanceReference class are listed here.

Public Methods

	Name	Description
	GetInstance (see page 5023)	Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.

51.2.1.2.1 IVarInstanceReference.GetInstance Method

Returns the object instance that represents the data from a Variant (see page 3421) of the custom type.

Pascal

```
function GetInstance(const V: TVarData): TObject;
```

C++

```
__fastcall TObject * GetInstance(const TVarData V);
```

Description

Implement GetInstance to return the object that represents the data from a Variant (see page 3421) of the custom Type.

The V parameter is the data from a Variant (see page 3421) of the custom type. This data must include a reference to an object that represents the Variant (see page 3421)'s data and is returned by GetInstance.

See Also

TPublishableVariantType (see page 4694)

GetInstance (see page 4698)

Supporting Properties and Methods in Custom Variants

51.2.2 IVarInvokeable Interface

IVarInvokeable is the interface for custom Variant (see page 3421) types that implement dynamic properties and methods.

Class Hierarchy

Pascal

```
IVarInvokeable = interface;
```

C++

```
__interface IVarInvokeable;
```

File

Variants

Description

Implement IVarInvokeable in the proxy classes that manage a custom Variant (see page 3421) data type. IVarInvokeable exposes four functions, which need to be implemented. Each of these functions are called whenever a function, method, or a property is called on the custom Variant (see page 3421) managed by the proxy class implementing IVarInvokeable.

See Also

TInvokeableVariantType (see page 5014)

TVarData (see page 3740)

Supporting Properties and Methods in Custom Variants

51.2.2.1 IVarInvokeable Members

The following tables list the members exposed by IVarInvokeable.

Public Methods

	Name	Description
	DoFunction (see page 5024)	Implements all the methods that return values.
	DoProcedure (see page 5025)	Implements all methods that do not return values.
	GetProperty (see page 5025)	Returns the value for any property supported by a custom System::Variant (see page 3421) type.
	SetProperty (see page 5026)	Sets the value for any property supported by a custom System::Variant (see page 3421) type.

51.2.2.2 IVarInvokeable Methods

The methods of the IVarInvokeable class are listed here.

Public Methods

	Name	Description
	DoFunction (see page 5024)	Implements all the methods that return values.
	DoProcedure (see page 5025)	Implements all methods that do not return values.
	GetProperty (see page 5025)	Returns the value for any property supported by a custom System::Variant (see page 3421) type.
	SetProperty (see page 5026)	Sets the value for any property supported by a custom System::Variant (see page 3421) type.

51.2.2.2.1 IVarInvokeable.DoFunction Method

Implements all the methods that return values.

Pascal

```
function DoFunction(var Dest: TVarData; const V: TVarData; const Name: string; const
Arguments: TVarDataArray): Boolean;
```

C++

```
__fastcall Boolean DoFunction(TVarData Dest, const TVarData V, const UnicodeString Name, const
TVarDataArray Arguments);
```

Description

Implement DoFunction to provide the implementation for method calls that return values. When the application invokes a System::Variant (see page 3421) member function (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++), a call is automatically generated to DoFunction.

`Dest` is a TVarData (see page 3740) record that receives the value returned by the function. V is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to call the function. `Name` is the name of the function being called. `Arguments` is a dynamic array of TVarData (see page 3740) records, where each one represents the value of an argument passed to the function.

DoFunction returns **True** if it executes the method call, or **False** if it does not implement the specified function.

See Also

DoFunction (see page 5018)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.2.2.2.2 IVarInvokeable.DoProcedure Method

Implements all methods that do not return values.

Pascal

```
function DoProcedure(const V: TVarData; const Name: string; const Arguments: TVarDataArray):
Boolean;
```

C++

```
__fastcall Boolean DoProcedure(const TVarData V, const UnicodeString Name, const TVarDataArray
Arguments);
```

Description

Implement DoProcedure to provide the implementation for method calls that do not return values. When the application invokes a System::Variant (see page 3421) member function (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++), a call is automatically generated to DoProcedure.

`V` is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to call the function. `Name` is the name of the function being called. `Arguments` is a dynamic array of TVarData (see page 3740) records, where each record represents the value of an argument passed to the function.

DoProcedure returns **True** if it executes the method call, or **False** if it does not implement the specified procedure.

See Also

DoProcedure (see page 5019)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.2.2.2.3 IVarInvokeable.GetProperty Method

Returns the value for any property supported by a custom System::Variant (see page 3421) type.

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
```

C++

```
__fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const UnicodeString Name);
```

Description

Implement GetProperty to provide the implementation for reading properties. When the application tries to read a property of a System::Variant (see page 3421) (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++), a call is automatically generated to GetProperty.

`Dest` is a TVarData (see page 3740) record that receives the value of the read property. `V` is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to access the property. `Name` is the name of the property being read.

GetProperty returns **True** if it handles the property, **False** if it does not implement the specified property.

See Also

GetProperty (see page 5020)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.2.2.2.4 IVarInvokeable.SetProperty Method

Sets the value for any property supported by a custom System::Variant (see page 3421) type.

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
```

C++

```
__fastcall Boolean SetProperty(const TVarData V, const UnicodeString Name, const TVarData
Value);
```

Description

Implement SetProperty to provide the implementation for setting properties. When the application tries to set a property of a System::Variant (see page 3421) (Delphi) or calls the System::Variant (see page 3421)'s Exec method (C++), a call is automatically generated to SetProperty.

`Value` is a TVarData (see page 3740) record that is the value assigned to the property. `V` is the TVarData (see page 3740) record from the System::Variant (see page 3421) instance that was used to access the property. `Name` is the name of the property being set.

SetProperty returns **True** if it handles the property, **False** if it does not implement the specified property.

SetProperty (see page 5021)

System::Variant::Exec

Supporting Properties and Methods in Custom Variants

51.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	_DispInvoke (see page 5029)	_DispInvoke is used internally by the Delphi compiler.
	_OleVarFromInt (see page 5030)	_OleVarFromInt is used internally by the Delphi compiler.
	_OleVarFromInt64 (see page 5030)	_OleVarFromInt64 is used internally by the Delphi compiler.
	_OleVarFromLStr (see page 5031)	_OleVarFromLStr is used internally by the Delphi compiler.
	_OleVarFromPStr (see page 5031)	_OleVarFromPStr is used internally by the Delphi compiler.
	_OleVarFromUInt64 (see page 5031)	_OleVarFromUInt64 is used internally by the Delphi compiler.
	_OleVarFromUStr (see page 5032)	_OleVarFromUStr is used internally by the Delphi compiler.
	_OleVarFromVar (see page 5032)	_OleVarFromVar is used internally by the Delphi compiler.
	_VarAdd (see page 5032)	_VarAdd is used internally by the Delphi compiler.
	_VarAddRef (see page 5033)	_VarAddRef is used internally by the Delphi compiler.
	_VarAnd (see page 5033)	_VarAnd is used internally by the Delphi compiler.
	_VarArrayGet (see page 5034)	_VarArrayGet is used internally by the Delphi compiler.
	_VarArrayPut (see page 5034)	_VarArrayPut is used internally by the Delphi compiler.
	_VarArrayRedim (see page 5034)	_VarArrayRedim is used internally by the Delphi compiler.
	_VarCast (see page 5035)	_VarCast is used internally by the Delphi compiler.
	_VarCastOle (see page 5035)	_VarCastOle is used internally by the Delphi compiler.
	_VarClear (see page 5035)	_VarClear is used internally by the Delphi compiler.
	_VarClr (see page 5036)	_VarClr is used internally by the Delphi compiler.
	_VarCmpEQ (see page 5036)	_VarCmpEQ is used internally by the Delphi compiler.
	_VarCmpGE (see page 5037)	_VarCmpGE is used internally by the Delphi compiler.
	_VarCmpGT (see page 5037)	_VarCmpGT is used internally by the Delphi compiler.
	_VarCmpLE (see page 5037)	_VarCmpLE is used internally by the Delphi compiler.
	_VarCmpLT (see page 5038)	_VarCmpLT is used internally by the Delphi compiler.
	_VarCmpNE (see page 5038)	_VarCmpNE is used internally by the Delphi compiler.
	_VarCopy (see page 5038)	_VarCopy is used internally by the Delphi compiler.
	_VarCopyNoInd (see page 5039)	_VarCopyNoInd is used internally by the Delphi compiler.
	_VarDiv (see page 5039)	_VarDiv is used internally by the Delphi compiler.
	_VarFromBool (see page 5040)	_VarFromBool is used internally by the Delphi compiler.
	_VarFromCurr (see page 5040)	_VarFromCurr is used internally by the Delphi compiler.
	_VarFromDisp (see page 5040)	_VarFromDisp is used internally by the Delphi compiler.
	_VarFromDynArray (see page 5041)	_VarFromDynArray is used internally by the Delphi compiler.
	_VarFromInt (see page 5041)	_VarFromInt is used internally by the Delphi compiler.
	_VarFromInt64 (see page 5041)	_VarFromInt64 is used internally by the Delphi compiler.
	_VarFromIntf (see page 5042)	_VarFromIntf is used internally by the Delphi compiler.
	_VarFromLStr (see page 5042)	_VarFromLStr is used internally by the Delphi compiler.
	_VarFromPStr (see page 5043)	_VarFromPStr is used internally by the Delphi compiler.
	_VarFromReal (see page 5043)	_VarFromReal is used internally by the Delphi compiler.
	_VarFromTDateTime (see page 5043)	_VarFromTDateTime is used internally by the Delphi compiler.
	_VarFromUInt64 (see page 5044)	_VarFromUInt64 is used internally by the Delphi compiler.
	_VarFromUStr (see page 5044)	_VarFromUStr is used internally by the Delphi compiler.
	_VarFromWChar (see page 5044)	_VarFromWChar is used internally by the Delphi compiler.
	_VarFromWStr (see page 5045)	_VarFromWStr is used internally by the Delphi compiler.
	_VarMod (see page 5045)	_VarMod is used internally by the Delphi compiler.
	_VarMul (see page 5046)	_VarMul is used internally by the Delphi compiler.

	_VarNeg (see page 5046)	_VarNeg is used internally by the Delphi compiler.
	_VarNot (see page 5046)	_VarNot is used internally by the Delphi compiler.
	_VarOr (see page 5047)	_VarOr is used internally by the Delphi compiler.
	_VarRDiv (see page 5047)	_VarRDiv is used internally by the Delphi compiler.
	_VarShl (see page 5047)	_VarShl is used internally by the Delphi compiler.
	_VarShr (see page 5048)	_VarShr is used internally by the Delphi compiler.
	_VarSub (see page 5048)	_VarSub is used internally by the Delphi compiler.
	_VarToBool (see page 5049)	_VarToBool is used internally by the Delphi compiler.
	_VarToCurrency (see page 5049)	_VarToCurrency is used internally by the Delphi compiler.
	_VarToDisp (see page 5049)	_VarToDisp is used internally by the Delphi compiler.
	_VarToDynArray (see page 5050)	_VarToDynArray is used internally by the Delphi compiler.
	_VarToInt64 (see page 5050)	_VarToInt64 is used internally by the Delphi compiler.
	_VarToInteger (see page 5050)	_VarToInteger is used internally by the Delphi compiler.
	_VarToIntf (see page 5051)	_VarToIntf is used internally by the Delphi compiler.
	_VarToLStr (see page 5051)	_VarToLStr is used internally by the Delphi compiler.
	_VarToPStr (see page 5052)	_VarToPStr is used internally by the Delphi compiler.
	_VarToReal (see page 5052)	_VarToReal is used internally by the Delphi compiler.
	_VarToUInt64 (see page 5052)	_VarToUInt64 is used internally by the Delphi compiler.
	_VarToUStr (see page 5053)	_VarToUStr is used internally by the Delphi compiler.
	_VarToWStr (see page 5053)	_VarToWStr is used internally by the Delphi compiler.
	_VarXor (see page 5053)	_VarXor is used internally by the Delphi compiler.
	DynArrayFromVariant (see page 5054)	Creates a dynamic array from a System::Variant (see page 3421).
	DynArrayToVariant (see page 5054)	Creates a System::Variant (see page 3421) array from a dynamic array.
	FindCustomVariantType (see page 5055)	Retrieves the object that implements a custom System::Variant (see page 3421) type.
	FindCustomVariantType (see page 5055)	Retrieves the object that implements a custom System::Variant (see page 3421) type.
	FindVarData (see page 5055)	Returns pointer to variant's data.
	HandleConversionException (see page 5056)	Handles exceptions during variant type conversions.
	Null (see page 5056)	Returns a Null variant.
	Unassigned (see page 5058)	Returns an "empty" variant.
	VarArrayAsPSafeArray (see page 5059)	This is function Variants.VarArrayAsPSafeArray.
	VarArrayCreate (see page 5059)	Creates a variant array.
	VarArrayCreateError (see page 5061)	Indicates an array creation error.
	VarArrayDimCount (see page 5061)	Returns number of dimensions of a variant array.
	VarArrayGet (see page 5063)	Returns a System::Variant (see page 3421) that represents a single value from a multi-dimensional System::Variant (see page 3421) array.
	VarArrayHighBound (see page 5065)	Returns high bound for a dimension in a variant array.
	VarArrayLock (see page 5067)	Locks a variant array and returns a pointer to the data.
	VarArrayLowBound (see page 5067)	Returns the low bound of a dimension in a variant array.
	VarArrayOf (see page 5069)	Creates and fills a one-dimensional variant array.
	VarArrayPut (see page 5069)	Sets the value of a single cell in a multi-dimensional System::Variant (see page 3421) array.
	VarArrayRef (see page 5071)	Returns a reference to the specified variant array.
	VarArrayUnlock (see page 5072)	Unlocks a variant array.
	VarAsError (see page 5072)	Converts a HRESULT (see page 3754) into an Error (see page 3560) variant.
	VarAsType (see page 5073)	Converts a variant to specified type.
	VarCastError (see page 5073)	Raises an EVariantTypeCastError (see page 4986) exception.
	VarCastError (see page 5073)	Raises an EVariantTypeCastError (see page 4986) exception.
	VarCheckEmpty (see page 5074)	Raises an exception if a specified variant's value is Unassigned (see page 5058).
	VarCompareValue (see page 5074)	Returns the relationship between Variants (see page 4973).
	VarCopyNoInd (see page 5075)	Copies a System::Variant (see page 3421).
	VarEnsureRange (see page 5076)	Returns a System::Variant (see page 3421) with a value in a specified range.
	VarFromDateTime (see page 5076)	Returns a variant containing a specified data and time.

	VarInRange (see page 5077)	Indicates whether a System::Variant (see page 3421)'s value is in a specified range.
	VarInvalidNullOp (see page 5077)	Indicate variant operation on null.
	VarInvalidOp (see page 5078)	Indicate invalid variant operation.
	VarIsArray (see page 5078)	Indicates whether the specified variant is an array.
	VarIsArray (see page 5078)	Indicates whether the specified variant is an array.
	VarIsByRef (see page 5079)	Indicates whether the specified variant's value is by reference.
	VarIsClear (see page 5079)	Indicates whether the specified variant has an undefined value.
	VarIsCustom (see page 5080)	Indicates whether the specified variant is a custom variant.
	VarIsEmpty (see page 5080)	Indicates whether the specified variant is unassigned.
	VarIsEmptyParam (see page 5081)	Indicates whether the specified variant represents an unassigned optional parameter.
	VarIsError (see page 5082)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT (see page 3754).
	VarIsError (see page 5082)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT (see page 3754).
	VarIsFloat (see page 5082)	Indicates whether the specified variant represents a floating-point value.
	VarIsNull (see page 5083)	Indicates whether the specified variant is Null (see page 5056).
	VarIsNumeric (see page 5083)	Indicates whether the specified variant represents a numeric value.
	VarIsOrdinal (see page 5084)	Indicates whether the specified variant represents an ordinal value.
	VarIsStr (see page 5084)	Indicates whether the specified variant represents a string value.
	VarIsType (see page 5085)	Indicates whether the specified variant represents a specified type.
	VarIsType (see page 5085)	Indicates whether the specified variant represents a specified type.
	VarOverflowError (see page 5085)	Raises an EVariantOverflowError (see page 4985) exception.
	VarRangeCheckError (see page 5086)	Raises an EVariantRangeCheckError (see page 4986) exception.
	VarResultCheck (see page 5086)	Raises variant exception based on HRESULT (see page 3754) value.
	VarResultCheck (see page 5086)	Raises variant exception based on HRESULT (see page 3754) value.
	VarSameValue (see page 5087)	Indicates whether two Variants (see page 4973) have equivalent values.
	VarSupports (see page 5087)	Indicates whether the System::Variant (see page 3421)'s value is an interface that supports a specified interface.
	VarSupports (see page 5087)	Indicates whether the System::Variant (see page 3421)'s value is an interface that supports a specified interface.
	VarToDateTime (see page 5088)	Converts a specified variant to a TDateTime (see page 3323) value.
	VarToStr (see page 5088)	Converts a variant's value to a string.
	VarToStrDef (see page 5089)	Converts a variant's value to a string.
	VarToWideStr (see page 5089)	Converts a variant's value to a WideString (see page 3467).
	VarToWideStrDef (see page 5090)	Converts a variant's value to a WideString (see page 3467).
	VarType (see page 5090)	Returns the type code of a specified variant.
	VarTypeAsText (see page 5092)	Returns variant type descriptive string.
	VarTypeIsValidArrayType (see page 5092)	Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.
	VarTypeIsValidElementType (see page 5093)	Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.

51.3.1 Variants._DispInvoke Function

_DispInvoke is used internally by the Delphi compiler.

Pascal

```
procedure _DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); cdecl;
```

C++

```
__cdecl _DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void * Params);
```

File

Variants

Description

Do not call _DispInvoke directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _DispInvoke is not publicly available to Delphi applications.

51.3.2 Variants._OleVarFromInt Function

_OleVarFromInt is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromInt(var V: TVarData; const Value: Integer; const Range: ShortInt);
```

C++

```
_OleVarFromInt(TVarData V, const int Value, const ShortInt Range);
```

File

Variants

Description

Do not call _OleVarFromInt directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromInt is not publicly available to Delphi applications.

51.3.3 Variants._OleVarFromInt64 Function

_OleVarFromInt64 is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromInt64(var V: TVarData; const Value: Int64);
```

C++

```
_OleVarFromInt64(TVarData V, const Int64 Value);
```

File

Variants

Description

Do not call _OleVarFromInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromInt64 is not publicly available to Delphi applications.

51.3.4 Variants._OleVarFromLStr Function

_OleVarFromLStr is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromLStr(var V: TVarData; const Value: AnsiString);
```

C++

```
_OleVarFromLStr(TVarData V, const AnsiString Value);
```

File

Variants

Description

Do not call _OleVarFromLStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromLStr is not publicly available to Delphi applications.

51.3.5 Variants._OleVarFromPStr Function

_OleVarFromPStr is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromPStr(var V: TVarData; const Value: ShortString);
```

C++

```
_OleVarFromPStr(TVarData V, const ShortString Value);
```

File

Variants

Description

Do not call _OleVarFromPStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromPStr is not publicly available to Delphi applications.

51.3.6 Variants._OleVarFromUInt64 Function

_OleVarFromUInt64 is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromUInt64(var V: TVarData; const Value: UInt64);
```

C++

```
_OleVarFromUInt64(TVarData V, const UInt64 Value);
```

File

Variants

Description

Do not call _OleVarFromUInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromUInt64 is not publicly available to Delphi applications.

51.3.7 Variants._OleVarFromUStr Function

_OleVarFromUStr is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromUStr(var V: TVarData; const Value: UnicodeString);
```

C++

```
_OleVarFromUStr(TVarData V, const UnicodeString Value);
```

File

Variants

Description

Do not call _OleVarFromUStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromUStr is not publicly available to Delphi applications.

51.3.8 Variants._OleVarFromVar Function

_OleVarFromVar is used internally by the Delphi compiler.

Pascal

```
procedure _OleVarFromVar(var Dest: TVarData; const Source: TVarData);
```

C++

```
_OleVarFromVar(TVarData Dest, const TVarData Source);
```

File

Variants

Description

Do not call _OleVarFromVar directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _OleVarFromVar is not publicly available to Delphi applications.

51.3.9 Variants._VarAdd Function

_VarAdd is used internally by the Delphi compiler.

Pascal

```
procedure _VarAdd(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarAdd(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarAdd directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarAdd is not publicly available to Delphi applications.

51.3.10 Variants._VarAddRef Function

_VarAddRef is used internally by the Delphi compiler.

Pascal

```
procedure _VarAddRef(var V: TVarData);
```

C++

```
_VarAddRef(TVarData V);
```

File

Variants

Description

Do not call _VarAddRef directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarAddRef is not publicly available to Delphi applications.

51.3.11 Variants._VarAnd Function

_VarAnd is used internally by the Delphi compiler.

Pascal

```
procedure _VarAnd(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarAnd(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarAnd directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarAnd is not publicly available to Delphi applications.

51.3.12 Variants._VarArrayGet Function

_VarArrayGet is used internally by the Delphi compiler.

Pascal

```
function _VarArrayGet(var A: TVarData; IndexCount: Integer; const Indices:
TVarArrayCoorArray): TVarData; cdecl;
```

C++

```
__cdecl TVarData _VarArrayGet(TVarData A, int IndexCount, const TVarArrayCoorArray Indices);
```

File

Variants

Description

Do not call _VarArrayGet directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarArrayGet is not publicly available to Delphi applications.

51.3.13 Variants._VarArrayPut Function

_VarArrayPut is used internally by the Delphi compiler.

Pascal

```
procedure _VarArrayPut(var A: TVarData; const Value: TVarData; IndexCount: Integer; const
Indices: TVarArrayCoorArray); cdecl;
```

C++

```
__cdecl _VarArrayPut(TVarData A, const TVarData Value, int IndexCount, const
TVarArrayCoorArray Indices);
```

File

Variants

Description

Do not call _VarArrayPut directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarArrayPut is not publicly available to Delphi applications.

51.3.14 Variants._VarArrayRedim Function

_VarArrayRedim is used internally by the Delphi compiler.

Pascal

```
procedure _VarArrayRedim(var A: TVarData; HighBound: Integer);
```

C++

```
_VarArrayRedim(TVarData A, int HighBound);
```

File

Variants

Description

Do not call _VarArrayRedim directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarArrayRedim is not publicly available to Delphi applications.

51.3.15 Variants._VarCast Function

_VarCast is used internally by the Delphi compiler.

Pascal

```
procedure _VarCast(var Dest: TVarData; const Source: TVarData; AVarType: Integer);
```

C++

```
_VarCast(TVarData Dest, const TVarData Source, int AVarType);
```

File

Variants

Description

Do not call _VarCast directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCast is not publicly available to Delphi applications.

51.3.16 Variants._VarCastOle Function

_VarCastOle is used internally by the Delphi compiler.

Pascal

```
procedure _VarCastOle(var Dest: TVarData; const Source: TVarData; AVarType: Integer);
```

C++

```
_VarCastOle(TVarData Dest, const TVarData Source, int AVarType);
```

File

Variants

Description

Do not call _VarCastOle directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCastOle is not publicly available to Delphi applications.

51.3.17 Variants._VarClear Function

_VarClear is used internally by the Delphi compiler.

Pascal

```
procedure _VarClear(var V: TVarData);
```

C++

```
_VarClear(TVarData V);
```

File

Variants

Description

Do not call _VarClear directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarClear is not publicly available to Delphi applications.

51.3.18 Variants._VarClr Function

_VarClr is used internally by the Delphi compiler.

Pascal

```
procedure _VarClr(var V: TVarData);
```

C++

```
_VarClr(TVarData V);
```

File

Variants

Description

Do not call _VarClr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarClr is not publicly available to Delphi applications.

51.3.19 Variants._VarCmpEQ Function

_VarCmpEQ is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpEQ(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpEQ(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpEQ directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpEQ is not publicly available to Delphi applications.

51.3.20 Variants._VarCmpGE Function

_VarCmpGE is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpGE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpGE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpGE directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpGE is not publicly available to Delphi applications.

51.3.21 Variants._VarCmpGT Function

_VarCmpGT is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpGT(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpGT(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpGT directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpGT is not publicly available to Delphi applications.

51.3.22 Variants._VarCmpLE Function

_VarCmpLE is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpLE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpLE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpLE directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpLE is not publicly available to Delphi applications.

51.3.23 Variants._VarCmpLT Function

_VarCmpLT is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpLT(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpLT(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpLT directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpLT is not publicly available to Delphi applications.

51.3.24 Variants._VarCmpNE Function

_VarCmpNE is used internally by the Delphi compiler.

Pascal

```
procedure _VarCmpNE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpNE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarCmpNE directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCmpNE is not publicly available to Delphi applications.

51.3.25 Variants._VarCopy Function

_VarCopy is used internally by the Delphi compiler.

Pascal

```
procedure _VarCopy(var Dest: TVarData; const Source: TVarData);
```

C++

```
_VarCopy(TVarData Dest, const TVarData Source);
```

File

Variants

Description

Do not call _VarCopy directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCopy is not publicly available to Delphi applications.

51.3.26 Variants._VarCopyNoInd Function

_VarCopyNoInd is used internally by the Delphi compiler.

Pascal

```
procedure _VarCopyNoInd(var Dest: TVarData; const Source: TVarData);
```

C++

```
_VarCopyNoInd(TVarData Dest, const TVarData Source);
```

File

Variants

Description

Do not call _VarCopyNoInd directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarCopyNoInd is not publicly available to Delphi applications.

51.3.27 Variants._VarDiv Function

_VarDiv is used internally by the Delphi compiler.

Pascal

```
procedure _VarDiv(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarDiv(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarDiv directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarDiv is not publicly available to Delphi applications.

51.3.28 Variants._VarFromBool Function

_VarFromBool is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromBool(var V: TVarData; const Value: Boolean);
```

C++

```
_VarFromBool(TVarData V, const Boolean Value);
```

File

Variants

Description

Do not call _VarFromBool directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromBool is not publicly available to Delphi applications.

51.3.29 Variants._VarFromCurr Function

_VarFromCurr is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromCurr;
```

C++

```
_VarFromCurr();
```

File

Variants

Description

Do not call _VarFromCurr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromCurr is not publicly available to Delphi applications.

51.3.30 Variants._VarFromDisp Function

_VarFromDisp is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromDisp(var V: TVarData; const Value: IDispatch);
```

C++

```
_VarFromDisp(TVarData V, const IDispatch Value);
```

File

Variants

Description

Do not call _VarFromDisp directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromDisp is not publicly available to Delphi applications.

51.3.31 Variants._VarFromDynArray Function

_VarFromDynArray is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromDynArray(var V: TVarData; const DynArray: Pointer; TypeInfo: Pointer);
```

C++

```
_VarFromDynArray(TVarData V, const void * DynArray, void * TypeInfo);
```

File

Variants

Description

Do not call _VarFromDynArray directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromDynArray is not publicly available to Delphi applications.

51.3.32 Variants._VarFromInt Function

_VarFromInt is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromInt(var V: TVarData; const Value: Integer; const Range: ShortInt);
```

C++

```
_VarFromInt(TVarData V, const int Value, const ShortInt Range);
```

File

Variants

Description

Do not call _VarFromInt directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromInt is not publicly available to Delphi applications.

51.3.33 Variants._VarFromInt64 Function

_VarFromInt64 is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromInt64(var V: TVarData; const Value: Int64);
```

C++

```
_VarFromInt64(TVarData V, const Int64 Value);
```

File

Variants

Description

Do not call _VarFromInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromInt64 is not publicly available to Delphi applications.

51.3.34 Variants._VarFromIntf Function

_VarFromIntf is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromIntf(var V: TVarData; const Value: IInterface);
```

C++

```
_VarFromIntf(TVarData V, const IInterface Value);
```

File

Variants

Description

Do not call _VarFromIntf directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromIntf is not publicly available to Delphi applications.

51.3.35 Variants._VarFromLStr Function

_VarFromLStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromLStr(var V: TVarData; const Value: AnsiString);
```

C++

```
_VarFromLStr(TVarData V, const AnsiString Value);
```

File

Variants

Description

Do not call _VarFromLStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromLStr is not publicly available to Delphi applications.

51.3.36 Variants._VarFromPStr Function

_VarFromPStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromPStr(var V: TVarData; const Value: ShortString);
```

C++

```
_VarFromPStr(TVarData V, const ShortString Value);
```

File

Variants

Description

Do not call _VarFromPStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromPStr is not publicly available to Delphi applications.

51.3.37 Variants._VarFromReal Function

_VarFromReal is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromReal;
```

C++

```
_VarFromReal();
```

File

Variants

Description

Do not call _VarFromReal directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromReal is not publicly available to Delphi applications.

51.3.38 Variants._VarFromTDateTime Function

_VarFromTDateTime is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromTDateTime;
```

C++

```
_VarFromTDateTime();
```

File

Variants

Description

Do not call _VarFromTDateTime directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromTDateTime is not publicly available to Delphi applications.

51.3.39 Variants._VarFromUInt64 Function

_VarFromUInt64 is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromUInt64(var V: TVarData; const Value: UInt64);
```

C++

```
_VarFromUInt64(TVarData V, const UInt64 Value);
```

File

Variants

Description

Do not call _VarFromUInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromUInt64 is not publicly available to Delphi applications.

51.3.40 Variants._VarFromUStr Function

_VarFromUStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromUStr(var V: TVarData; const Value: UnicodeString);
```

C++

```
_VarFromUStr(TVarData V, const UnicodeString Value);
```

File

Variants

Description

Do not call _VarFromUStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromUStr is not publicly available to Delphi applications.

51.3.41 Variants._VarFromWChar Function

_VarFromWChar is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromWChar(var V: TVarData; const Value: WideChar);
```

C++

```
_VarFromWChar(TVarData V, const WideChar Value);
```

File

Variants

Description

Do not call _VarFromWChar directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromWChar is not publicly available to Delphi applications.

51.3.42 Variants._VarFromWStr Function

_VarFromWStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarFromWStr(var V: TVarData; const Value: WideString);
```

C++

```
_VarFromWStr(TVarData V, const BSTR Value);
```

File

Variants

Description

Do not call _VarFromWStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarFromWStr is not publicly available to Delphi applications.

51.3.43 Variants._VarMod Function

_VarMod is used internally by the Delphi compiler.

Pascal

```
procedure _VarMod(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarMod(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarMod directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarMod is not publicly available to Delphi applications.

51.3.44 Variants._VarMul Function

_VarMul is used internally by the Delphi compiler.

Pascal

```
procedure _VarMul(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarMul(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarMul directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarMul is not publicly available to Delphi applications.

51.3.45 Variants._VarNeg Function

_VarNeg is used internally by the Delphi compiler.

Pascal

```
procedure _VarNeg(var Dest: TVarData);
```

C++

```
_VarNeg(TVarData Dest);
```

File

Variants

Description

Do not call _VarNeg directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarNeg is not publicly available to Delphi applications.

51.3.46 Variants._VarNot Function

_VarNot is used internally by the Delphi compiler.

Pascal

```
procedure _VarNot(var Dest: TVarData);
```

C++

```
_VarNot(TVarData Dest);
```

File

Variants

Description

Do not call _VarNot directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarNot is not publicly available to Delphi applications.

51.3.47 Variants._VarOr Function

_VarOr is used internally by the Delphi compiler.

Pascal

```
procedure _VarOr(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarOr(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarOr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarOr is not publicly available to Delphi applications.

51.3.48 Variants._VarRDiv Function

_VarRDiv is used internally by the Delphi compiler.

Pascal

```
procedure _VarRDiv(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarRDiv(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarRDiv directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarRDiv is not publicly available to Delphi applications.

51.3.49 Variants._VarShl Function

_VarShl is used internally by the Delphi compiler.

Pascal

```
procedure _VarShl(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarShl(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarShl directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarShl is not publicly available to Delphi applications.

51.3.50 Variants._VarShr Function

_VarShr is used internally by the Delphi compiler.

Pascal

```
procedure _VarShr(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarShr(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarShr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarShr is not publicly available to Delphi applications.

51.3.51 Variants._VarSub Function

_VarSub is used internally by the Delphi compiler.

Pascal

```
procedure _VarSub(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarSub(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarSub directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarSub is not publicly available to Delphi applications.

51.3.52 Variants._VarToBool Function

_VarToBool is used internally by the Delphi compiler.

Pascal

```
function _VarToBool(const V: TVarData): LongBool;
```

C++

```
LongBool _VarToBool(const TVarData V);
```

File

Variants

Description

Do not call _VarToBool directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToBool is not publicly available to Delphi applications.

51.3.53 Variants._VarToCurrency Function

_VarToCurrency is used internally by the Delphi compiler.

Pascal

```
function _VarToCurrency(const V: TVarData): Currency;
```

C++

```
Currency _VarToCurrency(const TVarData V);
```

File

Variants

Description

Do not call _VarToCurrency directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToCurrency is not publicly available to Delphi applications.

51.3.54 Variants._VarToDisp Function

_VarToDisp is used internally by the Delphi compiler.

Pascal

```
procedure _VarToDisp(var Dispatch: IDispatch; const V: TVarData);
```

C++

```
_VarToDisp(IDispatch Dispatch, const TVarData V);
```

File

Variants

Description

Do not call _VarToDisp directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToDisp is not publicly available to Delphi applications.

51.3.55 Variants._VarToDynArray Function

_VarToDynArray is used internally by the Delphi compiler.

Pascal

```
procedure _VarToDynArray(var DynArray: Pointer; const V: TVarData; TypeInfo: Pointer);
```

C++

```
_VarToDynArray(void * DynArray, const TVarData V, void * TypeInfo);
```

File

Variants

Description

Do not call _VarToDynArray directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToDynArray is not publicly available to Delphi applications.

51.3.56 Variants._VarToInt64 Function

_VarToInt64 is used internally by the Delphi compiler.

Pascal

```
function _VarToInt64(const V: TVarData): Int64;
```

C++

```
Int64 _VarToInt64(const TVarData V);
```

File

Variants

Description

Do not call _VarToInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToInt64 is not publicly available to Delphi applications.

51.3.57 Variants._VarToInteger Function

_VarToInteger is used internally by the Delphi compiler.

Pascal

```
function _VarToInteger(const V: TVarData): Integer;
```

C++

```
int _VarToInteger(const TVarData V);
```

File

Variants

Description

Do not call _VarToInteger directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToInteger is not publicly available to Delphi applications.

51.3.58 Variants._VarToIntf Function

_VarToIntf is used internally by the Delphi compiler.

Pascal

```
procedure _VarToIntf(var Intf: IInterface; const V: TVarData);
```

C++

```
_VarToIntf(IInterface Intf, const TVarData V);
```

File

Variants

Description

Do not call _VarToIntf directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToIntf is not publicly available to Delphi applications.

51.3.59 Variants._VarToLStr Function

_VarToLStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarToLStr(var S: AnsiString; const V: TVarData);
```

C++

```
_VarToLStr(AnsiString S, const TVarData V);
```

File

Variants

Description

Do not call _VarToLStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToLStr is not publicly available to Delphi applications.

51.3.60 Variants._VarToPStr Function

_VarToPStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarToPStr(var S; const V: TVarData);
```

C++

```
_VarToPStr( S, const TVarData V);
```

File

Variants

Description

Do not call _VarToPStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToPStr is not publicly available to Delphi applications.

51.3.61 Variants._VarToReal Function

_VarToReal is used internally by the Delphi compiler.

Pascal

```
function _VarToReal(const V: TVarData): Extended;
```

C++

```
Extended _VarToReal(const TVarData V);
```

File

Variants

Description

Do not call _VarToReal directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToReal is not publicly available to Delphi applications.

51.3.62 Variants._VarToUInt64 Function

_VarToUInt64 is used internally by the Delphi compiler.

Pascal

```
function _VarToUInt64(const V: TVarData): UInt64;
```

C++

```
UInt64 _VarToUInt64(const TVarData V);
```

File

Variants

Description

Do not call _VarToUInt64 directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToUInt64 is not publicly available to Delphi applications.

51.3.63 Variants._VarToUStr Function

_VarToUStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarToUStr(var S: UnicodeString; const V: TVarData);
```

C++

```
_VarToUStr(UnicodeString S, const TVarData V);
```

File

Variants

Description

Do not call _VarToUStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToUStr is not publicly available to Delphi applications.

51.3.64 Variants._VarToWStr Function

_VarToWStr is used internally by the Delphi compiler.

Pascal

```
procedure _VarToWStr(var S: WideString; const V: TVarData);
```

C++

```
_VarToWStr(BSTR S, const TVarData V);
```

File

Variants

Description

Do not call _VarToWStr directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarToWStr is not publicly available to Delphi applications.

51.3.65 Variants._VarXor Function

_VarXor is used internally by the Delphi compiler.

Pascal

```
procedure _VarXor(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarXor(TVarData Left, const TVarData Right);
```

File

Variants

Description

Do not call _VarXor directly. The Delphi compiler automatically inserts calls to this function whenever appropriate.

Note: _VarXor is not publicly available to Delphi applications.

51.3.66 Variants.DynArrayFromVariant Function

Creates a dynamic array from a System::Variant (see page 3421).

Pascal

```
procedure DynArrayFromVariant(var DynArray: Pointer; const V: Variant; TypeInfo: Pointer);
```

C++

```
DynArrayFromVariant(void * DynArray, const Variant V, void * TypeInfo);
```

File

Variants

Description

Call DynArrayFromVariant to copy the contents of a variant (V) to an existing dynamic array variable (DynArray).

DynArray is a dynamic array variable whose value is assigned from the System::Variant (see page 3421).

V is the System::Variant (see page 3421) to copy. Its value must be an array.

TypeInfo points to the runtime type information that identifies the type of array elements. You can obtain this pointer using the TypeInfo function (Delphi) or the __delphirtti function (C++).

See Also

DynArrayToVariant (see page 5054)

51.3.67 Variants.DynArrayToVariant Function

Creates a System::Variant (see page 3421) array from a dynamic array.

Pascal

```
procedure DynArrayToVariant(var V: Variant; const DynArray: Pointer; TypeInfo: Pointer);
```

C++

```
DynArrayToVariant(Variant V, const void * DynArray, void * TypeInfo);
```

File

Variants

Description

Call DynArrayToVariant to assign the contents of a dynamic array as the value of a System::Variant (see page 3421) variable.

V is the System::Variant (see page 3421) whose value is assigned by DynArrayToVariant.

DynArray is a dynamic array to copy.

TypeInfo points to the runtime type information that identifies the type of array elements. You can obtain this pointer using the TypeInfo function (Delphi) or the __delphirtti function (C++).

See Also

DynArrayFromVariant (see page 5054)

51.3.68 Variants.FindCustomVariantType Function

Retrieves the object that implements a custom System::Variant (see page 3421) type.

Pascal

```
function FindCustomVariantType(const AVarType: TVarType; out CustomVariantType:
TCustomVariantType): Boolean; overload;
function FindCustomVariantType(const TypeName: string; out CustomVariantType:
TCustomVariantType): Boolean; overload;
```

C++

```
Boolean FindCustomVariantType(const TVarType AVarType, TCustomVariantType CustomVariantType);
Boolean FindCustomVariantType(const UnicodeString TypeName, TCustomVariantType
CustomVariantType);
```

File

Variants

Description

Use FindCustomVariantType to obtain a reference to the object that implements a custom System::Variant (see page 3421) type.

TypeName is the name of the TCustomVariantType (see page 4987) descendant class you want to retrieve.

AVarType is the type code of System::Variant (see page 3421) whose implementation class you want to retrieve. If you have an instance of a System::Variant (see page 3421) whose value is a custom System::Variant (see page 3421) Type, you can obtain a value for this parameter using the VarType (see page 5090) function.

CustomVariantType returns an instance of the TCustomVariantType (see page 4987) descendant that implements the indicated custom System::Variant (see page 3421) type.

See Also

VarType (see page 5090)

VarIsCustom (see page 5080)

51.3.69 Variants.FindVarData Function

Returns pointer to variant's data.

Pascal

```
function FindVarData(const V: Variant): PVarData;
```

C++

```
PVarData FindVarData(const Variant V);
```

File

Variants

Description

FindVarData returns a pointer to the System::Variant (see page 3421) data contained referenced by a System::Variant (see page 3421). If the System::Variant (see page 3421) contains another System::Variant (see page 3421), FindVarData follows the chain of references until it finds the actual data.

See Also

VarType (see page 5090)

51.3.70 Variants.HandleConversionException Function

Handles exceptions during variant type conversions.

Pascal

```
procedure HandleConversionException(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
HandleConversionException(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

HandleConversionException handles exceptions resulting from attempts to convert between variant types. Code that implements such conversions should call HandleConversionException when a conversion throws an exception.

ASourceType and ADestType indicate the variant types of the source and destination. HandleConversionException uses these to format an appropriate error string. If the current exception corresponds to a variant exception, HandleConversionException raises that exception. Otherwise, HandleConversionException simply re-raises the original exception.

See Also

VarResultCheck (see page 5086)

EVariantError (see page 3948)

51.3.71 Variants.Null Function

Returns a Null variant.

Pascal

```
function Null: Variant;
```

C++

```
Variant Null();
```

File

Variants

Description

Use Null to obtain a Null variant that can indicate unknown or missing data. Null Variants (see page 4973) can be assigned to variant variables in an application that must contain a null value. Assigning Null to a variant variable does not cause an error, and Null can be returned from any function with a variant return value.

Assigning Null to a variable of any type other than System::Variant (see page 3421) causes either a compile-time error or raises an EVariantTypeMismatch exception. For example, in the following code the assignment of v, the Null variant, to variant q is successful; whereas the conversion of variant v, which is now Null, to the integer return type of the Test function, raises an exception.

function Test(v: System::Variant (see page 3421)): Integer;

```
var
  q: Variant;
  msg: string;
begin
  q := v; { this is ok, since q is a variant }
  if VarIsNull(q) then
    msg := 'q is a null variant'
  else
    msg := 'q is not a null variant';
  ShowMessage(msg);

  Result := v; { this raises an exception!!!}
```

end;

procedure TForm1.Button1Click(Sender: TObject (see page 3354));

```
begin
  Test(Null);
```

end;

int Test(Variant (see page 3421) v)

```
{
  Variant q = v; // this is ok, since q is a variant
  AnsiString msg;
  if (VarIsNull(q))
    msg = "q is a null variant";
  else
    msg = "q is not a null variant";
  ShowMessage(msg);

   return v; // this throws an exception!!!
```

}

void __fastcall TForm1::Button1Click(TObject (see page 3354) *Sender)

{

```
  Test(Null());
```

}

Except for comparisons, which always result in Boolean values, expressions involving Null variants always result in Null variants.

Note: The Null variant returned by the Null function is different from the nil constant in Delphi code and the NULL macro in C++ code. Neither nil nor NULL is a variant. The nil constant is an object reference that does not refer to any actual object. The NULL macro is a pointer that does not refer to any actual object or value.

See Also

Unassigned (see page 5058)

VarIsNull (see page 5083)

VarType (see page 5090)

NullEqualityRule (see page 5103)

NullMagnitudeRule (see page 5103)

51.3.72 Variants.Unassigned Function

Returns an "empty" variant.

Pascal

```
function Unassigned: Variant;
```

C++

```
Variant Unassigned();
```

File

Variants

Description

A variant variable can be "empty", meaning it has not yet been assigned to. The Unassigned function returns an empty variant, which can be assigned to a variant variable to restore the variable to its initial state.

Use the VarIsEmpty (see page 5080) function to test whether a variant is empty. When used on an empty variant, the VarType (see page 5090) standard function returns varEmpty (see page 3865).

If an empty variant is cast to another type (for example, by assigning to a non-variant variable or calling VarAsType (see page 5073)) the following conversions occur:

Destination	Conversion result
Numeric type	Zero
String type	Empty string
Boolean	False.

Note: Unassigned is useful with variants referencing OLE Automation Objects that you want to keep "alive" until another value is assigned to the variant.

There's corresponding functionality under Linux. Should document when time permits.

See Also

Null (see page 5056)

VarIsEmpty (see page 5080)

VarType (see page 5090)

VarAsType (see page 5073)

51.3.73 Variants.VarArrayAsPSafeArray Function

Pascal

```
function VarArrayAsPSafeArray(const A: Variant): PVarArray;
```

C++

```
PVarArray VarArrayAsPSafeArray(const Variant A);
```

File

Variants

Description

This is function Variants.VarArrayAsPSafeArray.

51.3.74 Variants.VarArrayCreate Function

Creates a variant array.

Pascal

```
function VarArrayCreate(const Bounds: array of Integer; AVarType: TVarType): Variant;
```

C++

```
Variant VarArrayCreate(const array of Integer Bounds, TVarType AVarType);
```

File

Variants

Description

VarArrayCreate creates a variant array with the bounds given by Bounds (see page 4651) and the element type given by VarType (see page 5090).

The Bounds (see page 4651) parameter must contain an even number of values, where each pair of values specifies the upper and lower bounds of one dimension of the array.

Note: The Bounds_size parameter is the index of the last value in the Bounds (see page 4651) array. This is one less than the total number of values. Thus, Bounds_size must always be an odd number.

The element type of the array, given by the VarType (see page 5090) parameter, is a variant type code. This must be one of the constants defined in the System (see page 3159) unit. It cannot include the varArray (see page 3861) or varByRef (see page 3862) bits. The element type cannot be varString (see page 3871) or a custom System::Variant (see page 3421) type. To create a variant array of strings use the varOleStr (see page 3869) type code. If the element type is varVariant (see page 3873), the elements of the array are themselves variants and can in turn contain variant arrays.

If VarArrayCreate is unable to create the array, an EVariantArrayCreateError (see page 4978) is raised.

Note: :Variant (see page 3421) arrays with an element type of varByte (see page 3863) are the preferred method of passing binary data between OLE Automation controllers and servers. Such arrays are subject to no translation of their data, and can be efficiently accessed using the VarArrayLock (see page 5067) and VarArrayUnlock (see page 5072) routines.

There's corresponding functionality under Linux. Should document when time permits.

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
```

```
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      VarArrayPut(Arr, I, [I]);
    end;

    { Now read the elements of the array }
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      if VarArrayGet(Arr, [I]) <> I then
        MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
    end;

    { Clear the variant array }
    VarClear(Arr);
  end;
```

VarArrayUnlock (see page 5072)

EVariantArrayCreateError (see page 4978)

51.3.75 Variants.VarArrayCreateError Function

Indicates an array creation error.

Pascal

```
procedure VarArrayCreateError;
```

C++

```
VarArrayCreateError();
```

File

Variants

See Also

EVariantArrayCreateError (see page 4978)

51.3.76 Variants.VarArrayDimCount Function

Returns number of dimensions of a variant array.

Pascal

```
function VarArrayDimCount(const A: Variant): Integer;
```

C++

```
int VarArrayDimCount(const Variant A);
```

File

Variants

Description

VarArrayDimCount returns the number of dimensions of the given variant. The resulting value is zero if the given variant is not a variant array.

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);
```

```
    { Increase the length of the variant array }
    VarArrayRedim(Arr, 49);

    MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
        mtInformation, [mbOK], 0);

    { Traverse the array from lower to higher bounds }
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      VarArrayPut(Arr, I, [I]);
    end;

    { Now read the elements of the array }
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      if VarArrayGet(Arr, [I]) <> I then
        MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
    end;

    { Clear the variant array }
    VarClear(Arr);
  end;
```

VarArrayLowBound (see page 5067)

51.3.77 Variants.VarArrayGet Function

Returns a System::Variant (see page 3421) that represents a single value from a multi-dimensional System::Variant (see page 3421) array.

Pascal

```
function VarArrayGet(const A: Variant; const Indices: array of Integer): Variant;
```

C++

```
Variant VarArrayGet(const Variant A, const array of Integer Indices);
```

File

Variants

Description

Use VarArrayGet to obtain the value of a single cell from a multi-dimensional System::Variant (see page 3421) array.

A is the System::Variant (see page 3421) array that contains the desired value.

Indices is an array of index values, one for each dimension of the array.

Note: Indices_Size is the index of the last value in Indices (one less than the number of dimensions in the array).

If the values specified by Indices are out of bounds, VarArrayGet raises an EVariantBadIndexError (see page 4980).

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    VarArrayPut(Arr, I, [I]);
  end;

  { Now read the elements of the array }
```

```
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      if VarArrayGet(Arr, [I]) <> I then
        MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
    end;

    { Clear the variant array }
    VarClear(Arr);
  end;
```

See Also

VarArrayPut (see page 5069)

EVariantBadIndexError (see page 4980)

51.3.78 Variants.VarArrayHighBound Function

Returns high bound for a dimension in a variant array.

Pascal

```
function VarArrayHighBound(const A: Variant; Dim: Integer): Integer;
```

C++

```
int VarArrayHighBound(const Variant A, int Dim);
```

File

Variants

Description

VarArrayHighBound returns the high bound of the given dimension in the given variant array. The Dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An exception is raised if the variant given by A is not an array (EVariantInvalidArgError (see page 4981)), or if the dimension specified by Dim does not exist (EVariantBadIndexError (see page 4980)).

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
```

```
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    VarArrayPut(Arr, I, [I]);
  end;

  { Now read the elements of the array }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    if VarArrayGet(Arr, [I]) <> I then
      MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
  end;

  { Clear the variant array }
  VarClear(Arr);
end;
```

EVariantInvalidArgError (see page 4981)

EVariantBadIndexError (see page 4980)

51.3.79 Variants.VarArrayLock Function

Locks a variant array and returns a pointer to the data.

Pascal

```
function VarArrayLock(const A: Variant): Pointer;
```

C++

```
void * VarArrayLock(const Variant A);
```

File

Variants

Description

VarArrayLock locks the given variant array and returns a pointer to the data stored in the array. While locked, a variant array can not be resized and any calls to VarArrayRedim (see page 3702) will fail. Once locked, a variant array must later be unlocked using VarArrayUnlock (see page 5072). An EVariantInvalidArgError (see page 4981) exception is raise if the variant given by A is not an array.

The pointer returned by VarArrayLock points to an array of elements in which the leftmost dimension increases first. In other words, the dimensions of the returned array pointer are reversed from the dimensions of the variant array.

Once it is verified that a variant array has the correct bounds and dimensions, VarArrayLock can be used to gain direct access to the array data, which results in improved performance.

See Also

VarArrayUnlock (see page 5072)

VarArrayRedim (see page 3702)

51.3.80 Variants.VarArrayLowBound Function

Returns the low bound of a dimension in a variant array.

Pascal

```
function VarArrayLowBound(const A: Variant; Dim: Integer): Integer;
```

C++

```
int VarArrayLowBound(const Variant A, int Dim);
```

File

Variants

Description

VarArrayLowBound returns the low bound of the given dimension in the given variant array. The Dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An exception is raised if the variant given by A is not an array (EVariantInvalidArgError (see page 4981)), or if the dimension specified by Dim does not exist (EVariantBadIndexError (see page 4980))..

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    VarArrayPut(Arr, I, [I]);
```

```
    end;

    { Now read the elements of the array }
    for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
    begin
      { Put the element I at index I}
      if VarArrayGet(Arr, [I]) <> I then
        MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
    end;

    { Clear the variant array }
    VarClear(Arr);
  end;
```

See Also

EVariantBadIndexError (see page 4980)

51.3.81 Variants.VarArrayOf Function

Creates and fills a one-dimensional variant array.

Pascal

```
function VarArrayOf(const Values: array of Variant): Variant;
```

C++

```
Variant VarArrayOf(const array of Variant Values);
```

File

Variants

Description

VarArrayOf returns a one-dimensional variant array with the elements given by the Values parameter

Values is an array of System::Variant (see page 3421) values to convert into a System::Variant (see page 3421) array.

Note: Values_Size indicates the index of the last value in the Values array (one less than the number of values).

The low bound of the returned array is zero, the high bound is the number of values given by the Values parameter less one (Values_Size), and the element type is System::Variant (see page 3421).

See Also

VarArrayCreate (see page 5059)

51.3.82 Variants.VarArrayPut Function

Sets the value of a single cell in a multi-dimensional System::Variant (see page 3421) array.

Pascal

```
procedure VarArrayPut(var A: Variant; const Value: Variant; const Indices: array of Integer);
```

C++

```
VarArrayPut(Variant A, const Variant Value, const array of Integer Indices);
```

File

Variants

Description

Use VarArrayPut to set the value of a single cell in a multi-dimensional System::Variant (see page 3421) array.

A is the System::Variant (see page 3421) array that contains the cell to set.

Value is the value to assign to the specified cell.

Indices is an array of index values, one for each dimension of the array.

Note: Indices_Size is the index of the last value in Indices (one less than the number of dimensions in the array).

If the values specified by Indices are out of bounds, VarArrayPut raises an EVariantBadIndexError (see page 4980).

C++ Examples:

```
/*
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    Variant array;
    int bounds[2] = {0, 9};

    /*
    Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer
    */
    array = VarArrayCreate(bounds, 1, varInteger);

    // Increase the length of the variant array
    VarArrayRedim(array, 49);

    MessageDlg(String("Variant array has ") + IntToStr(VarArrayDimCount(array)) +
        " dimensions", mtInformation, TMsgDlgButtons() << mbOK, 0);

    // Traverse the array from lower to higher bounds
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        VarArrayPut(array, i, &i, 0);
    }

    // Now read the elements of the array
    for (int i = VarArrayLowBound(array, 1); i <= VarArrayHighBound(array, 1); i++)
    {
        // Put the element I at index I
        if (VarArrayGet(array, &i, 0) != i)
            MessageDlg("Error! Invalid element found at current position!",
                mtError, TMsgDlgButtons() << mbOK, 0);
    }

    // Clear the variant array
    VarClear(array);
}
```

Delphi Examples:

```
{
This example demonstrates the use of variant arrays. In this
example a variant array is created, modified, populated and then freed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Arr: Variant;
  I: Integer;
begin
  { Create a variant array of 10 elements, starting at 0
    and ending at 9. The array contains elements of type integer }
  Arr := VarArrayCreate([0, 9], varInteger);

  { Increase the length of the variant array }
  VarArrayRedim(Arr, 49);

  MessageDlg('Variant array has ' + IntToStr(VarArrayDimCount(Arr)) + ' dimensions',
      mtInformation, [mbOK], 0);

  { Traverse the array from lower to higher bounds }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    VarArrayPut(Arr, I, [I]);
  end;

  { Now read the elements of the array }
  for I := VarArrayLowBound(Arr, 1) to VarArrayHighBound(Arr, 1) do
  begin
    { Put the element I at index I}
    if VarArrayGet(Arr, [I]) <> I then
      MessageDlg('Error! Invalid element found at current position!', mtError, [mbOK], 0);
  end;

  { Clear the variant array }
  VarClear(Arr);
end;
```

See Also

VarArrayGet (see page 5063)

EVariantBadIndexError (see page 4980)

51.3.83 Variants.VarArrayRef Function

Returns a reference to the specified variant array.

Pascal

```
function VarArrayRef(const A: Variant): Variant;
```

C++

```
Variant VarArrayRef(const Variant A);
```

File

Variants

Description

Use VarArrayRef to reference a variant array when a referenced variant array is expected in an API call. VarArrayRef creates a

new variant array of the same type as A, but with an extra level of indirection if A does not include the varByRef (see page 3862) type bit. The returned variant includes the varByRef (see page 3862) type bit.

If A is not an array, VarArrayRef raises an EVariantInvalidArgError (see page 4981) exception.

See Also

VarArrayCreate (see page 5059)

TVarType (see page 3801)

VarCopyNoInd (see page 5075)

EVariantInvalidArgError (see page 4981)

51.3.84 Variants.VarArrayUnlock Function

Unlocks a variant array.

Pascal

```
procedure VarArrayUnlock(const A: Variant);
```

C++

```
VarArrayUnlock(const Variant A);
```

File

Variants

Description

VarArrayUnlock unlocks a variant array that was previously locked by VarArrayLock (see page 5067). If the variant given by A is not an array, VarArrayUnlock raises an EVariantInvalidArtgError exception.

See Also

VarArrayLock (see page 5067)

51.3.85 Variants.VarAsError Function

Converts a HRESULT (see page 3754) into an Error (see page 3560) variant.

Pascal

```
function VarAsError(AResult: HRESULT): Variant;
```

C++

```
Variant VarAsError(HRESULT AResult);
```

File

Variants

Description

VarAsError converts an HRESULT (see page 3754) result code into an equivalent variant of type varError (see page 3866).

See Also

VarType (see page 5090)

51.3.86 Variants.VarAsType Function

Converts a variant to specified type.

Pascal

```
function VarAsType(const V: Variant; AVarType: TVarType): Variant;
```

C++

```
Variant VarAsType(const Variant V, TVarType AVarType);
```

File

Variants

Description

VarAsType converts a variant to a specified type and returns a new System::Variant (see page 3421) that has the specified type.

V is the System::Variant (see page 3421) to convert.

VarType (see page 5090) is a variant type code that indicates the type to which V should be converted. This can be one of the constants defined in the System (see page 3159) unit, or it can be the type code for a custom variant type. It cannot include the varArray (see page 3861) or varByRef (see page 3862) bits.

VarAsType raises an exception if the variant cannot be converted to the given type. This will be EVariantError (see page 3948) or one of its descendants, such as EVariantOverflowError (see page 4985) or EVariantTypeCastError (see page 4986).

See Also

VarType (see page 5090)

51.3.87 Variants.VarCastError Function

Raises an EVariantTypeCastError (see page 4986) exception.

Pascal

```
procedure VarCastError; overload;
procedure VarCastError(const ASourceType: TVarType; const ADestType: TVarType); overload;
```

C++

```
VarCastError();
VarCastError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarCastError to indicate that a variant operation has failed due to cast error. VarCastError raises EVariantTypeCastError (see page 4986). If no arguments are specified, the error string is a general error message. If ASourceType and ADestType are

specified, the error string incorporates the names of the specified System::Variant (see page 3421) Types (see page 4649).

See Also

EVariantTypeCastError (see page 4986)

TVarData (see page 3740)

VarType (see page 5090)

51.3.88 Variants.VarCheckEmpty Function

Raises an exception if a specified variant's value is Unassigned (see page 5058).

Pascal

```
procedure VarCheckEmpty(const V: Variant);
```

C++

```
VarCheckEmpty(const Variant V);
```

File

Variants

Description

Call VarCheckEmpty when your code requires that a System::Variant (see page 3421) have a value, and you want to raise an exception if it doesn't. VarCheckEmpty checks whether the System::Variant (see page 3421) specified by V has a value of Unassigned (see page 5058). If so, it raises an EVariantTypeMismatchError exception.

To check whether the System::Variant (see page 3421) is Unassigned (see page 5058) without raising an exception, use the VarIsEmpty (see page 5080) function instead. To check whether the System::Variant (see page 3421)'s value is undefined, use the VarIsClear (see page 5079) function instead.

Note: Do not confuse an Unassigned (see page 5058) variant with a System::Variant (see page 3421) whose value is Null (see page 5056). A Null (see page 5056) variant is still assigned, but has the value Null (see page 5056). Unlike unassigned variants, Null (see page 5056) variants can be used in expressions and can be converted to other types of variants.

See Also

VarIsEmpty (see page 5080)

Unassigned (see page 5058)

VarType (see page 5090)

VarIsNull (see page 5083)

VarIsClear (see page 5079)

EVariantTypeCastError (see page 4986)

51.3.89 Variants.VarCompareValue Function

Returns the relationship between Variants (see page 4973).

Pascal

```
function VarCompareValue(const A: Variant; const B: Variant): TVariantRelationship;
```

C++

```
TVariantRelationship VarCompareValue(const Variant A, const Variant B);
```

File

Variants

Description

Call VarCompareValue to determine the relationship between two Variants (see page 4973).

A and B are the values to compare.

VarCompareValue returns a value that indicates whether A and B are equal (vrEqual), whether one is greater than the other (vrLessThan or vrGreaterThan), or whether the two values can't be ordered relative to each other (vrNotEqual).

See Also

VarSameValue (see page 5087)

CompareValue

51.3.90 Variants.VarCopyNoInd Function

Copies a System::Variant (see page 3421).

Pascal

```
procedure VarCopyNoInd(var Dest: Variant; const Source: Variant);
```

C++

```
VarCopyNoInd(Variant Dest, const Variant Source);
```

File

Variants

Description

VarCopyNoInd copies the variant given by Source into the variant given by Dest. Calling VarCopyNoInd in C++ or Delphi code is equivalent to a simple variant assignment in Delphi code.

Dest can be a System::Variant (see page 3421) or an OleVariant (see page 3274), and it must be possible to assign a value to it.

Source is defined as a System::Variant (see page 3421), but an OleVariant (see page 3274) is also allowed because it is a compatible type. However, Source can't have a VarType (see page 5090) that includes the varByRef (see page 3862) bit.

The following table lists the expected behavior when using System::Variant (see page 3421) and OleVariant (see page 3274) types as parameters:

Dest	Source	Behavior
Variant (see page 3421)	OleVariant (see page 3274)	Works as expected.
Variant (see page 3421)	Variant (see page 3421)	Works as expected.

OleVariant (see page 3274)	OleVariant (see page 3274)	Works as expected.
OleVariant (see page 3274)	Variant (see page 3421)	Source should be implicitly cast to an OleVariant (see page 3274).

51.3.91 Variants.VarEnsureRange Function

Returns a System::Variant (see page 3421) with a value in a specified range.

Pascal

```
function VarEnsureRange(const AValue: Variant; const AMin: Variant; const AMax: Variant): Variant;
```

C++

```
Variant VarEnsureRange(const Variant AValue, const Variant AMin, const Variant AMax);
```

File

Variants

Description

VarEnsureRange returns a System::Variant (see page 3421) whose value is guaranteed to be within a specified range.

AValue is a System::Variant (see page 3421) with the value you want as long as it is in range. If AValue is in range, VarEnsureRange returns AValue.

AMin is a System::Variant (see page 3421) with the minimum acceptable value. If AValue is less than AMin, VarEnsureRange returns AMin.

AMax is a System::Variant (see page 3421) with the maximum acceptable value. If AValue is greater than AMax, VarEnsureRange returns AMax.

See Also

VarInRange (see page 5077)

51.3.92 Variants.VarFromDateTime Function

Returns a variant containing a specified data and time.

Pascal

```
function VarFromDateTime(const DateTime: TDateTime): Variant;
```

C++

```
Variant VarFromDateTime(const TDateTime DateTime);
```

File

Variants

Description

VarFromDateTime returns a System::Variant (see page 3421) that represents the date and time of the given TDateTime (see page 3323) value, DateTime. The type code of the resulting variant is varDate (see page 3864).

See Also

VarToDateTime (see page 5088)

VarType (see page 5090)

51.3.93 Variants.VarInRange Function

Indicates whether a System::Variant (see page 3421)'s value is in a specified range.

Pascal

```
function VarInRange(const AValue: Variant; const AMin: Variant; const AMax: Variant): Boolean;
```

C++

```
Boolean VarInRange(const Variant AValue, const Variant AMin, const Variant AMax);
```

File

Variants

Description

VarInRange checks whether a System::Variant (see page 3421) has a value in a specified range.

AValue is a System::Variant (see page 3421) to check.

AMin is a System::Variant (see page 3421) with the minimum acceptable value.

AMax is a System::Variant (see page 3421) with the maximum acceptable value.

VarInRange returns true if AValue is greater than or equal to AMin and less than or equal to AMax. Otherwise, it returns false.

See Also

VarEnsureRange (see page 5076)

51.3.94 Variants.VarInvalidNullOp Function

Indicate variant operation on null.

Pascal

```
procedure VarInvalidNullOp;
```

C++

```
VarInvalidNullOp();
```

File

Variants

See Also

EVariantInvalidOpError (see page 4983)

51.3.95 Variants.VarInvalidOp Function

Indicate invalid variant operation.

Pascal

```
procedure VarInvalidOp;
```

C++

```
VarInvalidOp();
```

File

Variants

See Also

EVariantInvalidOpError (see page 4983)

51.3.96 Variants.VarIsArray Function

Indicates whether the specified variant is an array.

Pascal

```
function VarIsArray(const A: Variant): Boolean; overload;
function VarIsArray(const A: Variant; AResolveByRef: Boolean): Boolean; overload;
```

C++

```
Boolean VarIsArray(const Variant A);
Boolean VarIsArray(const Variant A, Boolean AResolveByRef);
```

File

Variants

Description

VarIsArray returns true if the given variant is an array. Otherwise, the function result is false.

A is the System::Variant (see page 3421) to check.

AResolveByRef indicates how VarIsArray should handle the case when A is a reference to a System::Variant (see page 3421) (when the VarType (see page 5090) of A is varByRef (see page 3862) or varVariant (see page 3873)).When AResolveByRef is true, VarIsArray checks whether A is an array or A points to an array. When AResolveByRef is false, VarIsArray returns false when A has a VarType (see page 5090) of varByRef (see page 3862) or varVariant (see page 3873).

See Also

VarArrayCreate (see page 5059)

VarType (see page 5090)

VarIsType (see page 5085)

51.3.97 Variants.VarIsByRef Function

Indicates whether the specified variant's value is by reference.

Pascal

```
function VarIsByRef(const V: Variant): Boolean;
```

C++

```
Boolean VarIsByRef(const Variant V);
```

File

Variants

Description

VarIsByRef returns true if the given variant's type code includes the includes the varByRef (see page 3862) bit. Otherwise, the function result is false.

See Also

VarType (see page 5090)

VarIsType (see page 5085)

51.3.98 Variants.VarIsClear Function

Indicates whether the specified variant has an undefined value.

Pascal

```
function VarIsClear(const V: Variant): Boolean;
```

C++

```
Boolean VarIsClear(const Variant V);
```

File

Variants

Description

VarIsClear returns true if the given variant's value is undefined. The value can be undefined for any of several reasons:

The System::Variant (see page 3421) may have had its value set to Unassigned (see page 5058).

The System::Variant (see page 3421)'s value may be an interface type that has been set to nil (Delphi) or NULL (C++).

The System::Variant (see page 3421) may be a custom variant that returns true from its IsClear method.

In all other cases, the function result is false.

Note: Do not confuse an unassigned variant with a Null (see page 5056) variant. A Null (see page 5056) variant is still assigned, but has the value Null (see page 5056). Unlike unassigned variants, Null (see page 5056) variants can be used in expressions and can be converted to other types of variants.

See Also

Unassigned (see page 5058)

VarType (see page 5090)

VarCheckEmpty (see page 5074)

VarIsNull (see page 5083)

VarIsEmpty (see page 5080)

VarIsType (see page 5085)

TCustomVariantType (see page 4987)

51.3.99 Variants.VarIsCustom Function

Indicates whether the specified variant is a custom variant.

Pascal

```
function VarIsCustom(const V: Variant): Boolean;
```

C++

```
Boolean VarIsCustom(const Variant V);
```

File

Variants

Description

VarIsCustom returns true if the given variant represents a custom variant type. Otherwise, the function result is false.

See Also

VarType (see page 5090)

FindCustomVariantType (see page 5055)

VarIsType (see page 5085)

51.3.100 Variants.VarIsEmpty Function

Indicates whether the specified variant is unassigned.

Pascal

```
function VarIsEmpty(const V: Variant): Boolean;
```

C++

```
Boolean VarIsEmpty(const Variant V);
```

File

Variants

Description

VarIsEmpty returns true if the given variant contains the value Unassigned (see page 5058). If the variant contains any other value, the function result is false.

Note: VarIsEmpty does not indicate when a System::Variant (see page 3421) that represents an interface has had the

interface pointer cleared or when a custom System::Variant (see page 3421) is clear. If either of these situations may exist, use the VarIsClear (see page 5079) method instead.

Note: Do not confuse an unassigned variant with a Null (see page 5056) variant. A Null (see page 5056) variant is still assigned, but has the value Null (see page 5056). Unlike unassigned variants, Null (see page 5056) variants can be used in expressions and can be converted to other types of variants.

See Also

Unassigned (see page 5058)

VarType (see page 5090)

VarCheckEmpty (see page 5074)

VarIsNull (see page 5083)

VarIsClear (see page 5079)

VarIsEmptyParam (see page 5081)

VarIsType (see page 5085)

51.3.101 Variants.VarIsEmptyParam Function

Indicates whether the specified variant represents an unassigned optional parameter.

Pascal

```
function VarIsEmptyParam(const V: Variant): Boolean;
```

C++

```
Boolean VarIsEmptyParam(const Variant V);
```

File

Variants

Description

VarIsEmptyParam returns true if the given variant represents an unassigned optional parameter. If the variant contains any other value, the function result is false.

See Also

VarIsClear (see page 5079)

VarIsEmpty (see page 5080)

VarIsNull (see page 5083)

EmptyParam (see page 5102)

VarIsType (see page 5085)

51.3.102 Variants.VarIsError Function

Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT (see page 3754).

Pascal

```
function VarIsError(const V: Variant; out AResult: HRESULT): Boolean; overload;
function VarIsError(const V: Variant): Boolean; overload;
```

C++

```
Boolean VarIsError(const Variant V, HRESULT AResult);
Boolean VarIsError(const Variant V);
```

File

Variants

Description

VarIsError returns true if the given variant is an Error (see page 3560) variant (type varError (see page 3866)). If AResult is specified, it is set to the corresponding result code.

See Also

VarType (see page 5090)

VarIsType (see page 5085)

51.3.103 Variants.VarIsFloat Function

Indicates whether the specified variant represents a floating-point value.

Pascal

```
function VarIsFloat(const V: Variant): Boolean;
```

C++

```
Boolean VarIsFloat(const Variant V);
```

File

Variants

Description

VarIsFloat returns true if the given variant represents a floating-point value (In Delphi: Single, Double, or Currency (see page 3235); In C++: float, double, or Currency (see page 3235)). If the variant contains any other type of value, the function result is false.

See Also

VarIsOrdinal (see page 5084)

VarIsNumeric (see page 5083)

VarIsStr (see page 5084)

VarType (see page 5090)

VarIsType (see page 5085)

51.3.104 Variants.VarIsNull Function

Indicates whether the specified variant is Null (see page 5056).

Pascal

```
function VarIsNull(const V: Variant): Boolean;
```

C++

```
Boolean VarIsNull(const Variant V);
```

File

Variants

Description

VarIsNull returns true if the given variant contains the value Null (see page 5056). If the variant contains any other value, the function result is false.

Note: Do not confuse a Null (see page 5056) variant with an unassigned variant. A Null (see page 5056) variant is still assigned, but has the value Null (see page 5056). Unlike unassigned variants, Null (see page 5056) variants can be used in expressions and can be converted to other types of variants.

See Also

Null (see page 5056)

VarType (see page 5090)

VarIsEmpty (see page 5080)

VarIsClear (see page 5079)

VarIsEmptyParam (see page 5081)

VarIsType (see page 5085)

51.3.105 Variants.VarIsNumeric Function

Indicates whether the specified variant represents a numeric value.

Pascal

```
function VarIsNumeric(const V: Variant): Boolean;
```

C++

```
Boolean VarIsNumeric(const Variant V);
```

File

Variants

Description

VarIsNumeric returns true if the given variant's type code indicates a numeric value of some sort. This can be either a floating-point value or an ordinal value. If the variant contains any other type of value, the function result is false.

See Also

VarIsOrdinal (see page 5084)

VarIsFloat (see page 5082)

VarIsStr (see page 5084)

VarType (see page 5090)

VarIsType (see page 5085)

51.3.106 Variants.VarIsOrdinal Function

Indicates whether the specified variant represents an ordinal value.

Pascal

```
function VarIsOrdinal(const V: Variant): Boolean;
```

C++

```
Boolean VarIsOrdinal(const Variant V);
```

File

Variants

Description

VarIsOrdinal returns true if the given variant represents an ordinal value (such as an integer or boolean type). If the variant contains any other type of value, the function result is false.

See Also

VarIsNumeric (see page 5083)

VarIsFloat (see page 5082)

VarIsStr (see page 5084)

VarType (see page 5090)

VarIsType (see page 5085)

51.3.107 Variants.VarIsStr Function

Indicates whether the specified variant represents a string value.

Pascal

```
function VarIsStr(const V: Variant): Boolean;
```

C++

```
Boolean VarIsStr(const Variant V);
```

File

Variants

Description

VarIsStr returns true if the given variant's type code is varString (see page 3871) or varOleStr (see page 3869). If the variant contains any other type of value, the function result is false.

See Also

VarIsNumeric (see page 5083)

VarIsFloat (see page 5082)

VarIsOrdinal (see page 5084)

VarType (see page 5090)

VarIsType (see page 5085)

51.3.108 Variants.VarIsType Function

Indicates whether the specified variant represents a specified type.

Pascal

```
function VarIsType(const V: Variant; AVarType: TVarType): Boolean; overload;
function VarIsType(const V: Variant; const AVarTypes: array of TVarType): Boolean; overload;
```

C++

```
Boolean VarIsType(const Variant V, TVarType AVarType);
Boolean VarIsType(const Variant V, const array of TVarType AVarTypes);
```

File

Variants

Description

VarIsType checks whether the type code for the System::Variant (see page 3421) specified by V matches the specified type code or one of the type codes in the specified array.

V is the System::Variant (see page 3421) to check.

AVarType is the type code against which to check V.

AVarTypes is an array of valid type codes against which to check V.

AVarTypes_size is the index of the last entry in AVarTypes (one less than the number of entries).

VarIsType returns true if the given variant's type code matches the supplied type code or codes, false otherwise.

See Also

VarType (see page 5090)

51.3.109 Variants.VarOverflowError Function

Raises an EVariantOverflowError (see page 4985) exception.

Pascal

```
procedure VarOverflowError(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
VarOverflowError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarOverflowError to indicate that a variant operation has failed due to numeric overflow. ASourceType and ADestType should contain the variant type codes for the source and destination variant types. VarOverflowError uses this information to compose an error string and raise EVariantOverflowError (see page 4985).

See Also

EVariantOverflowError (see page 4985)

TVarType (see page 3801)

51.3.110 Variants.VarRangeCheckError Function

Raises an EVariantRangeCheckError (see page 4986) exception.

Pascal

```
procedure VarRangeCheckError(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
VarRangeCheckError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarRangeCheckError to indicate that a variant operation has failed because the result is not in the allowed range for the destination variant type. ASourceType and ADestType are the variant types of the source and destination.

See Also

EVariantRangeCheckError (see page 4986)

51.3.111 Variants.VarResultCheck Function

Raises variant exception based on HRESULT (see page 3754) value.

Pascal

```
procedure VarResultCheck(AResult: HRESULT); overload;
procedure VarResultCheck(AResult: HRESULT; ASourceType: TVarType; ADestType: TVarType);
overload;
```

C++

```
VarResultCheck(HRESULT AResult);
VarResultCheck(HRESULT AResult, TVarType ASourceType, TVarType ADestType);
```

File

Variants

Description

VarResultCheck examines the HRESULT (see page 3754) value returned by many variant routines. If AResult is S_OK (see page 3860), VarResultCheck does nothing. Otherwise, VarResultCheck attempts to map AResult to a variant exception and raise that exception. If VarResultCheck is unable to map AResult to a specific variant Exception (see page 3949), it raises EVariantError (see page 3948).

Specify ASourceType and ADestType when the operation involves conversion between two variant types.

See Also

EVariantError (see page 3948)

51.3.112 Variants.VarSameValue Function

Indicates whether two Variants (see page 4973) have equivalent values.

Pascal

```
function VarSameValue(const A: Variant; const B: Variant): Boolean;
```

C++

```
Boolean VarSameValue(const Variant A, const Variant B);
```

File

Variants

Description

VarSameValue returns true when A has the same value as B, false if the two values are not equivalent.

If A and B can't be compared, VarSameValue raises an exception.

See Also

VarCompareValue (see page 5074)

SameValue

51.3.113 Variants.VarSupports Function

Indicates whether the System::Variant (see page 3421)'s value is an interface that supports a specified interface.

Pascal

```
function VarSupports(const V: Variant; const IID: TGUID; out Intf): Boolean; overload;
function VarSupports(const V: Variant; const IID: TGUID): Boolean; overload;
```

C++

```
Boolean VarSupports(const Variant V, const TGUID IID,  Intf);
Boolean VarSupports(const Variant V, const TGUID IID);
```

File

Variants

Description

VarSupports returns the lower twelve bits of a variant type code. These indicate the type of the variant. For a list of possible variant type codes, see VarType (see page 5090).

Call VarSupports to determine whether the System::Variant (see page 3421) represents an interface that supports the interface identified by the IID parameter. If V supports the interface, VarSupports returns the interface as the Intf parameter (if using the first syntax) and returns true (both versions). If the interface specified by IID is not supported, VarSupports returns false.

Unlike calling the QueryInterface method of the interface, VarSupports handles the case when the System::Variant (see page 3421)'s value is nil (Delphi) or NULL (C++).

See Also

Supports (see page 4294)

51.3.114 Variants.VarToDateTime Function

Converts a specified variant to a TDateTime (see page 3323) value.

Pascal

```
function VarToDateTime(const V: Variant): TDateTime;
```

C++

```
TDateTime VarToDateTime(const Variant V);
```

File

Variants

Description

VarToDateTime converts the given variant to a TDateTime (see page 3323) value. VarToDateTime raises an exception if the conversion fails.

See Also

VarFromDateTime (see page 5076)

51.3.115 Variants.VarToStr Function

Converts a variant's value to a string.

Pascal

```
function VarToStr(const V: Variant): string;
```

C++

```
UnicodeString VarToStr(const Variant V);
```

File

Variants

Description

VarToStr converts the data in the variant V to a string and returns the result. If the variant has a null value, VarToStr returns an empty string.

See Also

VarToStrDef (see page 5089)

VarToWideStr (see page 5089)

VarToWideStrDef (see page 5090)

51.3.116 Variants.VarToStrDef Function

Converts a variant's value to a string.

Pascal

```
function VarToStrDef(const V: Variant; const ADefault: string): string;
```

C++

```
UnicodeString VarToStrDef(const Variant V, const UnicodeString ADefault);
```

File

Variants

Description

VarToStrDef converts the data in the variant V to a string and returns the result. If the variant has a null value, VarToStrDef returns ADefault.

See Also

VarToStr (see page 5088)

VarToWideStr (see page 5089)

VarToWideStrDef (see page 5090)

51.3.117 Variants.VarToWideStr Function

Converts a variant's value to a WideString (see page 3467).

Pascal

```
function VarToWideStr(const V: Variant): WideString;
```

C++

```
BSTR VarToWideStr(const Variant V);
```

File

Variants

Description

VarToWideStr converts the data in the variant V to a WideString (see page 3467) and returns the result. If the variant has a

null value, VarToWideStr returns an empty string.

See Also

VarToStrDef (see page 5089)

VarToStr (see page 5088)

VarToWideStrDef (see page 5090)

51.3.118 Variants.VarToWideStrDef Function

Converts a variant's value to a WideString (see page 3467).

Pascal

```
function VarToWideStrDef(const V: Variant; const ADefault: WideString): WideString;
```

C++

```
BSTR VarToWideStrDef(const Variant V, const BSTR ADefault);
```

File

Variants

Description

VarToWideStrDef converts the data in the variant V to a WideString (see page 3467) and returns the result. If the variant has a null value, VarToWideStrDef returns ADefault.

See Also

VarToStr (see page 5088)

VarToWideStr (see page 5089)

VarToStrDef (see page 5089)

51.3.119 Variants.VarType Function

Returns the type code of a specified variant.

Pascal

```
function VarType(const V: Variant): TVarType;
```

C++

```
TVarType VarType(const Variant V);
```

File

Variants

Description

VarType returns the type code of the given variant. The resulting value is either the type code for a custom Variant (see page 3421) type, or it is constructed from the constants declared in the System (see page 3159) unit.

The lower twelve bits of a variant type code (the bits defined by the varTypeMask (see page 3872) bit mask) define the type of the variant. The varArray (see page 3861) bit is set if the variant is an array of the given type. The varByRef (see page

3862) bit is set if the variant is a reference to a value of the given type as opposed to an actual value.

The following table describes the meaning of each of the variant type codes defined in the System (see page 3159) unit:

VarType	Contents of variant
varEmpty (see page 3865)	The variant is Unassigned (see page 5058).
varNull (see page 3868)	The variant is Null (see page 5056).
varSmallint (see page 3870)	16-bit signed integer (type Smallint in Delphi, short in C++).
varInteger (see page 3867)	32-bit signed integer (type Integer in Delphi, int in C++).
varSingle (see page 3870)	Single-precision floating-point value (type Single in Delphi, float in C++).
varDouble (see page 3865)	Double-precision floating-point value (type double).
varCurrency (see page 3863)	Currency (see page 3235) floating-point value (type Currency (see page 3235)).
varDate (see page 3864)	Date (see page 4087) and time value (type TDateTime (see page 3323)).
varOleStr (see page 3869)	Reference to a dynamically allocated UNICODE string.
varDispatch (see page 3864)	Reference to an Automation object (an IDispatch (see page 3494) interface pointer).
varError (see page 3866)	Operating system error code.
varBoolean (see page 3862)	16-bit boolean (type WordBool).
varVariant (see page 3873)	A variant.
varUnknown (see page 3873)	Reference to an unknown object (an IInterface (see page 3502) or IUnknown (see page 3756) interface pointer).
varShortInt (see page 3869)	8-bit signed integer (type ShortInt in Delphi or signed char in C++)
varByte (see page 3863)	A Byte
varWord (see page 3874)	unsigned 16-bit value (Word)
varLongWord (see page 3868)	unsigned 32-bit value (type LongWord in Delphi or unsigned long in C++)
varInt64 (see page 3867)	64-bit signed integer (Int64 in Delphi or __int64 in C++)
varStrArg (see page 3871)	COM-compatible string.
varString (see page 3871)	Reference to a dynamically allocated string (not COM compatible).

The value returned by VarType corresponds to the VType field of a TVarData (see page 3740) record.

The type of a variant can be changed using VarAsType (see page 5073).

See Also

TVarData (see page 3740)

VarAsType (see page 5073)

VarTypeToDataType

VarTypeAsText (see page 5092)

51.3.120 Variants.VarTypeAsText Function

Returns variant type descriptive string.

Pascal

```
function VarTypeAsText(const AType: TVarType): string;
```

C++

```
UnicodeString VarTypeAsText(const TVarType AType);
```

File

Variants

Description

VarTypeAsText returns a short string that names the variant type indicated by AType.

See Also

TVarData (see page 3740)

VarAsType (see page 5073)

VarTypeToDataType

VarType (see page 5090)

51.3.121 Variants.VarTypeIsValidArrayType Function

Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.

Pascal

```
function VarTypeIsValidArrayType(const AVarType: TVarType): Boolean;
```

C++

```
Boolean VarTypeIsValidArrayType(const TVarType AVarType);
```

File

Variants

Description

VarTypeIsValidArrayType indicates whether AVarType is the type code for a System::Variant (see page 3421) type that can

represent the elements of a System::Variant (see page 3421) array. This function is only intended for use with built-in System::Variant (see page 3421) types. It returns false for custom System::Variant (see page 3421) types, although they can be used for the elements of System::Variant (see page 3421) arrays.

See Also

VarArrayCreate (see page 5059)

VarTypeIsValidElementType (see page 5093)

51.3.122 Variants.VarTypeIsValidElementType Function

Indicates whether a System::Variant (see page 3421) type code represents a type that can be used for the elements in a System::Variant (see page 3421) array.

Pascal

```
function VarTypeIsValidElementType(const AVarType: TVarType): Boolean;
```

C++

```
Boolean VarTypeIsValidElementType(const TVarType AVarType);
```

File

Variants

Description

VarTypeIsValidElementType indicates whether AVarType is the type code for a System::Variant (see page 3421) type that can represent the elements of a System::Variant (see page 3421) array. Unlike the VarTypeIsValidArrayType (see page 5092) function, this function returns true for custom System::Variant (see page 3421) types.

See Also

VarArrayCreate (see page 5059)

VarTypeIsValidArrayType (see page 5092)

51.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBooleanToStringRule (see page 5094)	TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 5100).
	TNullCompareRule (see page 5094)	TNullCompareRule enumerates possible rules for comparing variant nulls with other values.
	TVarCompareResult (see page 5095)	TVarCompareResult describes the results of comparing two Variants (see page 4973).
	TVariantRelationship (see page 5096)	TVariantRelationship describes the results of comparing two Variants (see page 4973).

51.4.1 Variants.TBooleanToStringRule Enumeration

TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 5100).

Pascal

```
TBooleanToStringRule = (
  bsrAsIs,
  bsrLower,
  bsrUpper
);
```

C++

```
enum TBooleanToStringRule {
  bsrAsIs,
  bsrLower,
  bsrUpper
};
```

File

Variants

Description

TBooleanToStringRule enumerates the values that can be assigned to the global variables NullEqualityRule (see page 5103) and NullMagnitudeRule (see page 5103).

51.4.2 Variants.TNullCompareRule Enumeration

TNullCompareRule enumerates possible rules for comparing variant nulls with other values.

Pascal

```
TNullCompareRule = (
  ncrError,
  ncrStrict,
  ncrLoose
```

```
);
```

C++

```
enum TNullCompareRule {
  ncrError,
  ncrStrict,
  ncrLoose
};
```

File

Variants

Description

TNullCompareRule enumerates the values that can be assigned to the global variables NullEqualityRule (see page 5103) and NullMagnitudeRule (see page 5103).

51.4.3 Variants.TVarCompareResult Enumeration

TVarCompareResult describes the results of comparing two Variants (see page 4973).

Pascal

```
TVarCompareResult = (
  crLessThan,
  crEqual,
  crGreaterThan
);
```

C++

```
enum TVarCompareResult {
  crLessThan,
  crEqual,
  crGreaterThan
};
```

File

Variants

Description

TVarCompareResult describes the result of the comparison between two System::Variant (see page 3421) values. The following table lists the possible values and their meaning.

Value	Meaning
crEqual	A is equivalent to B. Note that two NULL Variants (see page 4973) are considered equal and two empty Variants (see page 4973) are considered equal, but a NULL System::Variant (see page 3421) does not equal an empty System::Variant (see page 3421).
crLessThan	A is less than B.
crGreaterThan	A is greater than B.

See Also

Compare (see page 4997)

51.4.4 Variants.TVariantRelationship Enumeration

TVariantRelationship describes the results of comparing two Variants (see page 4973).

Pascal

```
TVariantRelationship = (
  vrEqual,
  vrLessThan,
  vrGreaterThan,
  vrNotEqual
);
```

C++

```
enum TVariantRelationship {
  vrEqual,
  vrLessThan,
  vrGreaterThan,
  vrNotEqual
};
```

File

Variants

Description

TVariantRelationship describes the relationship between two System::Variant (see page 3421) values. The following table lists the possible values:

Value	Meaning
vrEqual	A is equivalent to B. Note that two NULL Variants (see page 4973) are considered equal, and two empty Variants (see page 4973) are considered equal, but a NULL System::Variant (see page 3421) does not equal an empty System::Variant (see page 3421).
vrLessThan	A is less than B.
vrGreaterThan	A is larger than B.
vrNotEqual	A and B are not equal, but the values are such that they can't be ordered relative to each other. For example, this describes the relationship when either A or B is empty or NULL, and the other one is not.

See Also

VarCompareValue (see page 5074)

51.5 Types

The following table lists types in this documentation.

Types

Name	Description
TAnyProc (see page 5097)	TAnyProc represents a pointer to a procedure that accepts a parameter of type TVarData (see page 3740).
TCustomVariantTypeClass (see page 5097)	TCustomVariantTypeClass defines the metaclass for TCustomVariantType (see page 4987).
TVarDataArray (see page 5098)	TVarDataArray is an array of TVarData (see page 3740) records.
TVarDispProc (see page 5098)	TVarDispProc defines a pointer to a procedure used as support for IDispatch (see page 3494)-based Automation.

51.5.1 Variants.TAnyProc Type

TAnyProc represents a pointer to a procedure that accepts a parameter of type TVarData (see page 3740).

Pascal

```
TAnyProc = procedure (var V: TVarData);
```

C++

```
(var V: TVarData) ( TAnyProc)();
```

File

Variants

Description

Declare variables of type TAnyProc to accept any procedure that has a single parameter of type TVarData (see page 3740). TAnyProc is primarily used in the Variants (see page 4973) unit to support custom processing for Variants (see page 4973) of type varAny (see page 3861).

See Also

ChangeAnyProc (see page 5101)

ClearAnyProc (see page 5101)

RefAnyProc (see page 5106)

51.5.2 Variants.TCustomVariantTypeClass Type

TCustomVariantTypeClass defines the metaclass for TCustomVariantType (see page 4987).

Pascal

```
TCustomVariantTypeClass = class of TCustomVariantType;
```

C++

```
TCustomVariantType TCustomVariantTypeClass;
```

File

Variants

Description

TCustomVariantTypeClass is the metaclass for TCustomVariantType (see page 4987). Its value is the class reference for TCustomVariantType (see page 4987) or for one of its descendants.

See Also

TCustomVariantType (see page 4987)

Class References

51.5.3 Variants.TVarDataArray Type

TVarDataArray is an array of TVarData (see page 3740) records.

Pascal

```
TVarDataArray = array of TVarData;
```

C++

```
array of TVarData TVarDataArray;
```

File

Variants

Description

TVarDataArray represents a dynamic array of TVarData (see page 3740) records. TVarDataArray is primarily used by methods like DoProcedure and DoFunction of the TInvokeableVariantType (see page 5014) class in order to pass a list of parameters to the dynamically invoked methods in a Variant (see page 3421) variable.

See Also

TVarData (see page 3740)

DoProcedure (see page 5019)

DoFunction (see page 5018)

51.5.4 Variants.TVarDispProc Type

TVarDispProc defines a pointer to a procedure used as support for IDispatch (see page 3494)-based Automation.

Pascal

```
TVarDispProc = procedure (Dest: PVariant; const Source: Variant; CallDesc: PCallDesc; Params:
Pointer);
```

C++

```
(Dest: PVariant; const Source: Variant; CallDesc: PCallDesc; Params: Pointer) (
```

```
TVarDispProc)();
```

File

Variants

Description

In Delphi, TVarDispProc is a pointer to a routine that is called to execute methods (or access properties) of an interface that is assigned to a System::Variant (see page 3421). TVarDispProc is used in the Variants (see page 4973) unit to control how Variants (see page 4973) execute methods when a value of the Variants (see page 4973) is an interface.

See Also

VarDispProc (see page 5106)

EVariantDispatchError (see page 4981)

51.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
BooleanToStringRule (see page 5100)	Specifies rule fixing up Boolean values converted to strings.
ChangeAnyProc (see page 5101)	Provides the support for changing the type of a Variant (see page 3421) from varAny (see page 3861) to a real Variant (see page 3421).
ClearAnyProc (see page 5101)	Provides the support for clearing a Variant (see page 3421) of type varAny (see page 3861).
EmptyParam (see page 5102)	Contains an OleVariant (see page 3274) that represents an unused optional parameter on a dual interface.
NullAsStringValue (see page 5102)	Specifies string value of Null (see page 5056) variants.
NullEqualityRule (see page 5103)	Specifies rule for Null (see page 5056) variant equality comparison.
NullMagnitudeRule (see page 5103)	Specifies rule for Null (see page 5056) variant magnitude comparison.
NullStrictConvert (see page 5104)	Specifies whether Null (see page 5056) conversion is an error.
OleVariantInt64AsDouble (see page 5105)	Controls the mode in which `Int64` values are stored in a OleVariant (see page 3274).
PackVarCreation (see page 5105)	Specifies whether space-efficient System::Variant (see page 3421) Types (see page 4649) are preferred.
RefAnyProc (see page 5106)	Provides the support for increasing the reference count of a Variant (see page 3421) of type varAny (see page 3861).
VarDispProc (see page 5106)	Provides the support for IDispatch (see page 3494)-based Automation.

51.6.1 Variants.BooleanToStringRule Variable

Specifies rule fixing up Boolean values converted to strings.

Pascal

```
BooleanToStringRule: TBooleanToStringRule = bsrAsIs;
```

C++

```
TBooleanToStringRule BooleanToStringRule = bsrAsIs;
```

File

Variants

Description

BooleanToStringRule determines the rule for fixing up the string generated by a conversion from Boolean to string.

Constant	Meaning
bsrAsIs	(Default.) The value obtained from the locale is left as is.
bsrUpper	The string is converted to all upper case.
bsrLower	The string is converted to all lower case.

51.6.2 Variants.ChangeAnyProc Variable

Provides the support for changing the type of a Variant (see page 3421) from varAny (see page 3861) to a real Variant (see page 3421).

Pascal

```
ChangeAnyProc: TAnyProc;
```

C++

```
TAnyProc ChangeAnyProc;
```

File

Variants

Description

Use ChangeAnyProc to change a Variant (see page 3421) of the varAny (see page 3861) type to a real Variant (see page 3421).

Assign a custom TAnyProc (see page 5097) to ChangeAnyProc in order to control how the varAny (see page 3861) Variants (see page 4973) are being transformed to real Variants (see page 4973).

See Also

TAnyProc (see page 5097)

ClearAnyProc (see page 5101)

RefAnyProc (see page 5106)

51.6.3 Variants.ClearAnyProc Variable

Provides the support for clearing a Variant (see page 3421) of type varAny (see page 3861).

Pascal

```
ClearAnyProc: TAnyProc;
```

C++

```
TAnyProc ClearAnyProc;
```

File

Variants

Description

Use ClearAnyProc to clear a Variant (see page 3421) of type varAny (see page 3861). Clearing a varAny (see page 3861) Variant (see page 3421) usually implies clearing the real value of the Variant (see page 3421).

Assign a custom TAnyProc (see page 5097) to ClearAnyProc in order to control how the varAny (see page 3861) variants are being cleared.

See Also

TAnyProc (see page 5097)

ChangeAnyProc (see page 5101)

RefAnyProc (see page 5106)

51.6.4 Variants.EmptyParam Variable

Contains an OleVariant (see page 3274) that represents an unused optional parameter on a dual interface.

Pascal

```
EmptyParam: OleVariant;
```

C++

```
OleVariant EmptyParam;
```

File

Variants

Description

EmptyParam can be used for Variants (see page 4973) that represent optional parameters whose value is unassigned. This is useful when the code that marshals method calls requires a fixed number of parameters, even if some of them are optional.

When marshaling interface calls that include optional parameters, COM requires a value for those parameters even when they are not used. EmptyParam returns an OleVariant (see page 3274) you can pass as that value to indicate that the parameter is not used.

Marshaling interfaces also exist under Linux, but we can't spare the resources to document them right now.

See Also

VarIsEmptyParam (see page 5081)

51.6.5 Variants.NullAsStringValue Variable

Specifies string value of Null (see page 5056) variants.

Pascal

```
NullAsStringValue: string = '';
```

C++

```
UnicodeString NullAsStringValue = '';
```

File

Variants

Description

NullAsStringValue specifies the string that is the result of a conversion from a Null (see page 5056) variant to a string type. By default, NullAsStringValue is the empty string.

NullAsStringValue is only used when the NullStrictConvert (see page 5104) global variable is set to false.

See Also

NullStrictConvert (see page 5104)

Null (see page 5056)

51.6.6 Variants.NullEqualityRule Variable

Specifies rule for Null (see page 5056) variant equality comparison.

Pascal

```
NullEqualityRule: TNullCompareRule = ncrLoose;
```

C++

```
TNullCompareRule NullEqualityRule = ncrLoose;
```

File

Variants

Description

NullEqualityRule determines the rule for handling equality comparisons (equals or not-equals) when one of the values compared is a variant containing a null value. NullEqualityRule can have the following values:

Constant	Meaning
ncrLoose	(Default.) A variant containing a null is treated as a unique value that is only equal to another variant containing a null.
ncrStrict	An equality comparison of a variant containing a null is always false, regardless of the other value.
ncrError	An equality comparison raises an EVariantInvalidNullOpError (see page 4982) if either value is a variant containing a null.

See Also

Null (see page 5056)

NullMagnitudeRule (see page 5103)

NullStrictConvert (see page 5104)

EVariantInvalidNullOpError (see page 4982)

51.6.7 Variants.NullMagnitudeRule Variable

Specifies rule for Null (see page 5056) variant magnitude comparison.

Pascal

```
NullMagnitudeRule: TNullCompareRule = ncrLoose;
```

C++

```
TNullCompareRule NullMagnitudeRule = ncrLoose;
```

File

Variants

Description

NullMagnitudeRule determines the rule for handling magnitude comparisons (one value is greater than, greater than or equals,

less than, or less than or equals to another) when one of the values compared is a variant containing a null value. NullMagnitudeRule can have the following values:

Constant	Meaning
ncrLoose	(Default.) A variant containing a null is treated as a unique value that is less than any other value, but equal to another variant containing a null.
ncrStrict	A magnitude comparison of a variant containing a null is always false, regardless of the other value.
ncrError	A magnitude comparison raises an EVariantInvalidNullOpError (see page 4982) if either value is a variant containing a null.

See Also

Null (see page 5056)

NullStrictConvert (see page 5104)

EVariantInvalidNullOpError (see page 4982)

51.6.8 Variants.NullStrictConvert Variable

Specifies whether Null (see page 5056) conversion is an error.

Pascal

```
NullStrictConvert: Boolean = True;
```

C++

```
Boolean NullStrictConvert = True;
```

File

Variants

Description

NullStrictConvert determines the outcome of attempts to convert Null (see page 5056) variants to other types. If NullStrictConvert is true (default), attempting to convert a Null (see page 5056) variant raises a EVariantTypeCastError (see page 4986), unless the conversion is to a custom variant that defines a conversion from Null (see page 5056). If NullStrictConvert is false, then conversion from Null (see page 5056) follows the following rules:

Destination	Conversion result
Numeric type	Zero
String type	Value of NullAsStringValue (see page 5102) global variable. (Default: empty string.)
Boolean	False.

See Also

TVarData (see page 3740)

VarType (see page 5090)

NullAsStringValue (see page 5102)

EVariantTypeCastError (see page 4986)

51.6.9 Variants.OleVariantInt64AsDouble Variable

Controls the mode in which `Int64` values are stored in a OleVariant (see page 3274).

Pascal

```
OleVariantInt64AsDouble: Boolean = False;
```

C++

```
Boolean OleVariantInt64AsDouble = False;
```

File

Variants

Description

Use OleVariantInt64AsDouble to set or check whether the `Int64` values are stored in a OleVariant (see page 3274) as `Double` values. If the value of OleVariantInt64AsDouble is **True**, then `Int64` values are stored as `Double` values and the type of the OleVariant (see page 3274) is varDouble (see page 3865). Otherwise, the `Int64` values are stored directly and the type of the OleVariant (see page 3274) is varInt64 (see page 3867).

Note: This flag is useful only on Windows 9x/2000 platforms, on which OleVariants cannot store an `Int64` value.

See Also

BooleanToStringRule (see page 5100)

PackVarCreation (see page 5105)

51.6.10 Variants.PackVarCreation Variable

Specifies whether space-efficient System::Variant (see page 3421) Types (see page 4649) are preferred.

Pascal

```
PackVarCreation: Boolean = True;
```

C++

```
Boolean PackVarCreation = True;
```

File

Variants

Description

PackVarCreation controls the way System::Variant (see page 3421) Types (see page 4649) are chosen for newly-created Variants (see page 4973). If PackVarCreation is true (default), a new System::Variant (see page 3421) has the smallest possible System::Variant (see page 3421) Type. If PackVarCreation is false, a new System::Variant (see page 3421) has the System::Variant (see page 3421) Type that minimizes execution time.

See Also

TVarData (see page 3740)

VarType (see page 5090)

51.6.11 Variants.RefAnyProc Variable

Provides the support for increasing the reference count of a Variant (see page 3421) of type varAny (see page 3861).

Pascal

```
RefAnyProc: TAnyProc;
```

C++

```
TAnyProc RefAnyProc;
```

File

Variants

Description

Use RefAnyProc to increase the reference count of a Variant (see page 3421) of type varAny (see page 3861).

Assign a custom TAnyProc (see page 5097) to RefAnyProc in order to control the referencing of the varAny (see page 3861) Variants (see page 4973).

See Also

TAnyProc (see page 5097)

ChangeAnyProc (see page 5101)

ClearAnyProc (see page 5101)

51.6.12 Variants.VarDispProc Variable

Provides the support for IDispatch (see page 3494)-based Automation.

Pascal

```
VarDispProc: TVarDispProc;
```

C++

```
TVarDispProc VarDispProc;
```

File

Variants

Description

In Delphi, VarDispProc points to a routine that is called to execute methods (or access properties) of an interface that is assigned to a System::Variant (see page 3421). The Variants (see page 4973) unit assigns a procedure that generates error 222 or raises an EVariantDispatchError (see page 4981) exception. The ComObj unit reassigns this variable to a procedure that generates the appropriate COM IDispatch (see page 3494) calls.

To control how Variants (see page 4973) execute methods when they have a value that is an interface, assign your own procedure to VarDispProc.

See Also

EVariantDispatchError (see page 4981)

52 VarUtils Namespace

This is namespace VarUtils.

Topics

Name	Description
Classes (see page 5110)	The following table lists classes in this documentation.
Functions (see page 5115)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5132)	The following table lists structs, records, enums in this documentation.
Variables (see page 5133)	The following table lists variables in this documentation.
Constants (see page 5149)	The following table lists constants in this documentation.

Classes

	Name	Description
	ESafeArrayBoundsError (see page 5110)	ESafeArrayBoundsError is the exception class for errors that occur because a variant array index is out of bounds.
	ESafeArrayCreateError (see page 5110)	ESafeArrayCreateError is the exception class for failing to create a variant array.
	ESafeArrayError (see page 5111)	ESafeArrayError is the exception class for errors involving variant arrays.
	ESafeArrayLockedError (see page 5114)	ESafeArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.

Constants

Name	Description
ARR_DISPATCH (see page 5150)	Used to test whether the variant array contains IDispatch (see page 3494) elements.
ARR_FIXEDSIZE (see page 5150)	Used to test whether the variant array is of fixed size.
ARR_NONE (see page 5151)	Specifies that a variant array has no flags set.
ARR_OLESTR (see page 5151)	Used to test whether the variant array contains BSTR elements.
ARR_UNKNOWN (see page 5152)	Used to test whether the variant array contains IUnknown (see page 3756) elements.
ARR_VARIANT (see page 5152)	Used to test whether the variant array contains `Variant (see page 3421)` elements.
CMaxArrayVarType (see page 5153)	CMaxArrayVarType gives the upper bound of the CVarTypeToElementInfo (see page 5154) array.
CMinArrayVarType (see page 5153)	CMinArrayVarType gives the lower bound of the CVarTypeToElementInfo (see page 5154) array.
CVarTypeToElementInfo (see page 5154)	This constant is internally used by the SafeArrayCreate (see page 5118) function.

GenericOperations (see page 5155)	Specifies whether the implementation for the variant operation routines is cross-platform.
GenericSafeArrays (see page 5155)	Specifies whether the implementation for the safe array routines is cross-platform.
GenericSafeArrayUsesLibC (see page 5156)	Specifies whether the implementation for the safe array routines uses the `Libc` unit.
GenericVariants (see page 5156)	Specifies whether the implementation for the variant support routines is cross-platform.
GenericVarUtils (see page 5157)	Specifies whether the implementation for the variant-manipulating routines is cross-platform.
VAR_ARRAYISLOCKED (see page 5157)	Specifies that the given array is locked.
VAR_BADINDEX (see page 5158)	Indicates that the given index is out of range.
VAR_BADVARTYPE (see page 5158)	Specifies that the variant type of the input parameter is invalid.
VAR_CMP_EQ (see page 5158)	VAR_CMP_EQ specifies that the variants are equal, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_GT (see page 5159)	VAR_CMP_GT specifies that the first variant is greater than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_LT (see page 5159)	VAR_CMP_LT specifies that the first variant is lower than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_NULL (see page 5160)	VAR_CMP_NULL specifies that either one of the variants is `nil`, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_EXCEPTION (see page 5160)	Specifies that the application raised an exception.
VAR_INVALIDARG (see page 5161)	Specifies that either one of the arguments is invalid.
VAR_LOCALE_USER_DEFAULT (see page 5161)	Specifies the default locale for the user or process.
VAR_NOTIMPL (see page 5161)	Specifies that the operation is not implemented.
VAR_OK (see page 5162)	Specifies that a variant operation was successful.
VAR_OUTOFMEMORY (see page 5162)	Specifies that there is not enough memory to complete the operation.
VAR_OVERFLOW (see page 5163)	Specifies that a variant operation caused an overflow.
VAR_PARAMNOTFOUND (see page 5163)	Indicates that there is no correspondence between the parameter DISPIDs and a parameter of the method.
VAR_TYPEMISMATCH (see page 5163)	Specifies that the argument cannot be cast to the specified type.
VAR_UNEXPECTED (see page 5164)	Indicates that an unexpected error occurred.

Functions

	Name	Description
	SafeArrayAccessData (see page 5115)	Returns a pointer to the actual safe array data and locks the safe array.
	SafeArrayAllocData (see page 5116)	Allocates the actual data of the given safe array.
	SafeArrayAllocDescriptor (see page 5116)	Allocates a descriptor for the safe array.
	SafeArrayCheck (see page 5117)	Checks whether the given parameter is a safe array operation error code.
	SafeArrayCopy (see page 5117)	Copies a safe array to another.
	SafeArrayCopyData (see page 5118)	Copies the data from a safe array to another.
	SafeArrayCreate (see page 5118)	Creates a safe array.
	SafeArrayDestroy (see page 5119)	Destroys a safe array.
	SafeArrayDestroyData (see page 5120)	Destroys the actual data of the given safe array.
	SafeArrayDestroyDescriptor (see page 5120)	Destroys the descriptor of the given safe array.
	SafeArrayError (see page 5120)	Raises an event corresponding to the given safe array operation error code.
	SafeArrayGetDim (see page 5121)	Returns the number of dimension of the given safe array.
	SafeArrayGetElement (see page 5121)	Returns the element at the specified position in the given safe array.
	SafeArrayGetElemSize (see page 5122)	Returns the size in bytes of an element in the given safe array.
	SafeArrayGetLBound (see page 5122)	Returns the lower bound for the given dimension of a safe array.
	SafeArrayGetUBound (see page 5123)	Returns the upper bound for the given dimension of a safe array.
	SafeArrayLock (see page 5123)	Locks a safe array.
	SafeArrayPtrOfIndex (see page 5124)	Returns a pointer to the element at the specified position in the given safe array.
	SafeArrayPutElement (see page 5125)	Sets the element at the specified position in the given safe array.
	SafeArrayRedim (see page 5125)	Changes the bound information for the last dimension of a safe array.
	SafeArrayUnaccessData (see page 5126)	Unlocks a safe array previously locked using the SafeArrayAccessData (see page 5115) routine.
	SafeArrayUnlock (see page 5127)	Unlocks a safe array.

	VarExceptionToResult (see page 5127)	Converts an Exception (see page 3949) type argument to an HRESULT (see page 3754) type.
	VariantChangeType (see page 5128)	Converts a variant from one type to another.
	VariantClear (see page 5128)	Clears a variant.
	VariantCopy (see page 5129)	Clears the destination variant and makes a copy of the source variant.
	VariantCopyInd (see page 5130)	Clears the destination variant and makes a copy of the source variant, including the case when the source is of varByRef (see page 3862) type.
	VariantInit (see page 5130)	Initializes a variant.

Structs, Records, Enums

	Name	Description
	TVarTypeToElementInfo (see page 5132)	This is an internal record type used in declaring the CVarTypeToElementInfo (see page 5154) constant array.

Variables

Name	Description
VarAdd (see page 5133)	VarAdd is a function type variable that specifies the function making the addition operation between two variants.
VarAnd (see page 5134)	VarAnd is a function type variable that specifies the function making the bitwise **and** operation between two variants.
VarBoolFromStr (see page 5134)	VarBoolFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a boolean value.
VarBstrFromBool (see page 5135)	VarBstrFromBool is used to specify the function that makes the conversion from a boolean value to a WideString (see page 3467).
VarBstrFromCy (see page 5136)	VarBstrFromCy is used to specify the function that makes the conversion from a currency value to a WideString (see page 3467).
VarBstrFromDate (see page 5137)	VarBstrFromDate is used to specify the function that makes the conversion from a date value to a WideString (see page 3467).
VarCmp (see page 5138)	VarCmp is a variable used to specify the function that compares two variants.
VarCyFromStr (see page 5139)	VarCyFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a currency value.
VarDateFromStr (see page 5139)	VarDateFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a date value.
VarDiv (see page 5140)	VarDiv is a function type variable that specifies the function making the division operation between two variants.
VarI4FromStr (see page 5141)	VarI4FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a four bytes integer value.
VariantChangeTypeEx (see page 5142)	VariantChangeTypeEx stores the function that converts a variant from one type to another, using locale-specific information.
VarIDiv (see page 5142)	VarIDiv is a function type variable that specifies the function making the division operation between two variants, after converting the variants to integers.
VarMod (see page 5143)	VarMod is a function type variable that specifies the function that calculates the remainder on division of two variants.
VarMul (see page 5143)	VarMul is a function type variable that specifies the function making the multiplication operation between two variants.
VarNeg (see page 5144)	VarNeg is a function type variable that specifies the function that inverts the sign of a variant.
VarNot (see page 5144)	VarNot is a function type variable that specifies the function that performs a **not** operation on a variant.
VarOr (see page 5145)	VarOr is a function type variable that specifies the function doing the bitwise **or** operation between two variants.
VarR4FromStr (see page 5145)	VarR4FromStr is used to specify the function that does the conversion from a WideString (see page 3467) to a four bytes floating-point value.
VarR8FromStr (see page 5146)	VarR8FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a eight bytes floating-point value.
VarSub (see page 5147)	VarSub is a function type variable that specifies the function making the subtraction operation between two variants.
VarXor (see page 5147)	VarXor is a function type variable that specifies the function making the bitwise **xor** (exclusive or) operation between two variants.

52.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ESafeArrayBoundsError (see page 5110)	ESafeArrayBoundsError is the exception class for errors that occur because a variant array index is out of bounds.
	ESafeArrayCreateError (see page 5110)	ESafeArrayCreateError is the exception class for failing to create a variant array.
	ESafeArrayError (see page 5111)	ESafeArrayError is the exception class for errors involving variant arrays.
	ESafeArrayLockedError (see page 5114)	ESafeArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.

52.1.1 ESafeArrayBoundsError Class

ESafeArrayBoundsError is the exception class for errors that occur because a variant array index is out of bounds.

Class Hierarchy

Pascal

```
ESafeArrayBoundsError = class(ESafeArrayError);
```

C++

```
class ESafeArrayBoundsError : public ESafeArrayError;
```

File

VarUtils

Description

ESafeArrayBoundsError is raised when an operation on a variant array fails because an index value is out of bounds.

To raise this exception programmatically, call SafeArrayError (see page 5120) with the argument `VAR_BADINDEX` (see page 5158).

See Also

SafeArrayGetElement (see page 5121)

SafeArrayError (see page 5120)

ESafeArrayError (see page 5111)

52.1.2 ESafeArrayCreateError Class

ESafeArrayCreateError is the exception class for failing to create a variant array.

Class Hierarchy

Pascal

```
ESafeArrayCreateError = class(ESafeArrayError);
```

C++

```
class ESafeArrayCreateError : public ESafeArrayError;
```

File

VarUtils

Description

ESafeArrayCreateError is raised when an attempt to create a variant array fails.

See Also

SafeArrayCreate (see page 5118)

ESafeArrayError (see page 5111)

52.1.3 ESafeArrayError Class

ESafeArrayError is the exception class for errors involving variant arrays.

Class Hierarchy

Pascal

```
ESafeArrayError = class(Exception);
```

C++

```
class ESafeArrayError : public Exception;
```

File

VarUtils

Description

ESafeArrayError is raised when a variant array operation fails.

ESafeArrayError has a number of descendant classes that provide more specific information about the error, namely ESafeArrayBoundsError (see page 5110), ESafeArrayCreateError (see page 5110), and ESafeArrayLockedError (see page 5114).

See Also

ESafeArrayBoundsError (see page 5110)

ESafeArrayCreateError (see page 5110)

ESafeArrayLockedError (see page 5114)

52.1.3.1 ESafeArrayError Members

The following tables list the members exposed by ESafeArrayError.

Protected Methods

	Name	Description
	GetStackTrace (see page 3962)	This is GetStackTrace, a member of class Exception.
	RaisingException (see page 3962)	This is RaisingException, a member of class Exception.
	SetInnerException (see page 3962)	This is SetInnerException, a member of class Exception.
	SetStackInfo (see page 3963)	This is SetStackInfo, a member of class Exception.

Public Fields

	Name	Description
	CleanUpStackInfoProc (see page 3961)	This is CleanUpStackInfoProc, a member of class Exception.
	GetExceptionStackInfoProc (see page 3961)	This is GetExceptionStackInfoProc, a member of class Exception.
	GetStackInfoStringProc (see page 3961)	This is GetStackInfoStringProc, a member of class Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 3355)	Constructs an object and initializes its data before the object is first used.
	Create (see page 3952)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 3954)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 3955)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 3955)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateHResult (see page 5113)	This is CreateHResult, a member of class ESafeArrayError.
	CreateRes (see page 3956)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 3957)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 3958)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 3959)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	Destroy (see page 3356)	Disposes of an object instance.
	Destroy (see page 3960)	Disposes of an object instance.
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetBaseException (see page 3962)	This is GetBaseException, a member of class Exception.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RaiseOuterException (see page 3962)	This is RaiseOuterException, a member of class Exception.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	ThrowOuterException (see page 3963)	This is ThrowOuterException, a member of class Exception.
V	ToString (see page 3380)	Returns a string containing the class name.
V	ToString (see page 3963)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	BaseException (see page 3964)	This is BaseException, a member of class Exception.
	ErrorCode (see page 5113)	This is ErrorCode, a member of class ESafeArrayError.
	HelpContext (see page 3964)	Indicates the context ID number for context-sensitive online help associated with the exception.
R	InnerException (see page 3965)	This is InnerException, a member of class Exception.
	Message (see page 3965)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	StackInfo (see page 3966)	This is StackInfo, a member of class Exception.
R	StackTrace (see page 3966)	This is StackTrace, a member of class Exception.

52.1.3.2 ESafeArrayError.CreateHResult Constructor

Pascal

```
constructor CreateHResult(AResult: HRESULT; const AMessage: string = '');
```

C++

```
__fastcall ESafeArrayError(HRESULT AResult, const UnicodeString AMessage = '');
```

Description

This is CreateHResult, a member of class ESafeArrayError.

52.1.3.3 ESafeArrayError Properties

The properties of the ESafeArrayError class are listed here.

Public Properties

	Name	Description
	ErrorCode (see page 5113)	This is ErrorCode, a member of class ESafeArrayError.

52.1.3.3.1 ESafeArrayError.ErrorCode Property

Pascal

```
property ErrorCode: HRESULT;
```

C++

```
__property HRESULT ErrorCode;
```

Description

This is ErrorCode, a member of class ESafeArrayError.

52.1.4 ESafeArrayLockedError Class

ESafeArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.

Class Hierarchy

Pascal

```
ESafeArrayLockedError = class(ESafeArrayError);
```

C++

```
class ESafeArrayLockedError : public ESafeArrayError;
```

File

VarUtils

Description

ESafeArrayLockedError is raised when an operation on a variant array fails because the array is locked or fixed.

To raise this exception programmatically, call SafeArrayError (see page 5120) with the argument VAR_ARRAYISLOCKED (see page 5157).

See Also

SafeArrayLock (see page 5123)

SafeArrayUnlock (see page 5127)

SafeArrayError (see page 5120)

ESafeArrayError (see page 5111)

52.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	SafeArrayAccessData (see page 5115)	Returns a pointer to the actual safe array data and locks the safe array.
	SafeArrayAllocData (see page 5116)	Allocates the actual data of the given safe array.
	SafeArrayAllocDescriptor (see page 5116)	Allocates a descriptor for the safe array.
	SafeArrayCheck (see page 5117)	Checks whether the given parameter is a safe array operation error code.
	SafeArrayCopy (see page 5117)	Copies a safe array to another.
	SafeArrayCopyData (see page 5118)	Copies the data from a safe array to another.
	SafeArrayCreate (see page 5118)	Creates a safe array.
	SafeArrayDestroy (see page 5119)	Destroys a safe array.
	SafeArrayDestroyData (see page 5120)	Destroys the actual data of the given safe array.
	SafeArrayDestroyDescriptor (see page 5120)	Destroys the descriptor of the given safe array.
	SafeArrayError (see page 5120)	Raises an event corresponding to the given safe array operation error code.
	SafeArrayGetDim (see page 5121)	Returns the number of dimension of the given safe array.
	SafeArrayGetElement (see page 5121)	Returns the element at the specified position in the given safe array.
	SafeArrayGetElemSize (see page 5122)	Returns the size in bytes of an element in the given safe array.
	SafeArrayGetLBound (see page 5122)	Returns the lower bound for the given dimension of a safe array.
	SafeArrayGetUBound (see page 5123)	Returns the upper bound for the given dimension of a safe array.
	SafeArrayLock (see page 5123)	Locks a safe array.
	SafeArrayPtrOfIndex (see page 5124)	Returns a pointer to the element at the specified position in the given safe array.
	SafeArrayPutElement (see page 5125)	Sets the element at the specified position in the given safe array.
	SafeArrayRedim (see page 5125)	Changes the bound information for the last dimension of a safe array.
	SafeArrayUnaccessData (see page 5126)	Unlocks a safe array previously locked using the SafeArrayAccessData (see page 5115) routine.
	SafeArrayUnlock (see page 5127)	Unlocks a safe array.
	VarExceptionToResult (see page 5127)	Converts an Exception (see page 3949) type argument to an HRESULT (see page 3754) type.
	VariantChangeType (see page 5128)	Converts a variant from one type to another.
	VariantClear (see page 5128)	Clears a variant.
	VariantCopy (see page 5129)	Clears the destination variant and makes a copy of the source variant.
	VariantCopyInd (see page 5130)	Clears the destination variant and makes a copy of the source variant, including the case when the source is of varByRef (see page 3862) type.
	VariantInit (see page 5130)	Initializes a variant.

52.2.1 VarUtils.SafeArrayAccessData Function

Returns a pointer to the actual safe array data and locks the safe array.

Pascal

```
function SafeArrayAccessData(VarArray: PVarArray; out Data: Pointer): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayAccessData(PVarArray VarArray, void * Data);
```

File

VarUtils

Description

Use SafeArrayAccessData to obtain a pointer to the actual safe array data and also to lock the safe array.

See Also

SafeArrayUnaccessData (see page 5126)

52.2.2 VarUtils.SafeArrayAllocData Function

Allocates the actual data of the given safe array.

Pascal

```
function SafeArrayAllocData(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayAllocData(PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayAllocData allocates the actual data for the given safe array. It is used internally by the SafeArrayCreate (see page 5118) and SafeArrayCopy (see page 5117) routines. We recommend you not to use it directly when writing your application.

See Also

SafeArrayCreate (see page 5118)

SafeArrayCopy (see page 5117)

52.2.3 VarUtils.SafeArrayAllocDescriptor Function

Allocates a descriptor for the safe array.

Pascal

```
function SafeArrayAllocDescriptor(DimCount: Integer; out VarArray: PVarArray): HRESULT;
stdcall;
```

C++

```
__stdcall HRESULT SafeArrayAllocDescriptor(int DimCount, PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayAllocDescriptor allocates a descriptor for the given safe array. It is used internally by the SafeArrayCreate (see page 5118) and SafeArrayCopy (see page 5117) routines. We recommend you not to use it directly when writing your application.

See Also

SafeArrayCreate (see page 5118)

SafeArrayCopy (see page 5117)

52.2.4 VarUtils.SafeArrayCheck Function

Checks whether the given parameter is a safe array operation error code.

Pascal

```
procedure SafeArrayCheck(AResult: HRESULT);
```

C++

```
SafeArrayCheck(HRESULT AResult);
```

File

VarUtils

Description

Use SafeArrayCheck to check whether the parameter given through `AResult` is one of the possible safe array operation error codes.

See Also

SafeArrayError (see page 5120)

52.2.5 VarUtils.SafeArrayCopy Function

Copies a safe array to another.

Pascal

```
function SafeArrayCopy(SourceArray: PVarArray; out TargetArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayCopy(PVarArray SourceArray, PVarArray TargetArray);
```

File

VarUtils

Description

Use SafeArrayCopy to create a copy of the safe array given through `SourceArray` to the safe array stored in `TargetArray`.

In order to copy the safe array, SafeArrayCopy first checks if the source array is valid. SafeArrayCopy then locks the source array, allocates memory for the descriptor and for the actual data of the target array, and copies over the data from the source array to the target array. Finally, the source array is unlocked.

If SafeArrayCopy managed to copy the source array, then `TargetArray` contains the copied array. If SafeArrayCopy did not manage to copy over the safe array, it simply sets the `TargetArray` parameter to **nil**.

See Also

SafeArrayCreate (see page 5118)

SafeArrayCopyData (see page 5118)

52.2.6 VarUtils.SafeArrayCopyData Function

Copies the data from a safe array to another.

Pascal

```
function SafeArrayCopyData(SourceArray: PVarArray; TargetArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayCopyData(PVarArray SourceArray, PVarArray TargetArray);
```

File

VarUtils

Description

Use SafeArrayCopyData to copy over the data from the safe array given through `SourceArray` to the safe array stored in `TargetArray`.

In order to copy the data from the safe array, SafeArrayCopyData first checks if the source array is valid and also establishes that the source and target arrays are compatible. SafeArrayCopyData then locks the source array, clears up the data in the target array, and copies over the data from the source array. Finally, the source array is unlocked.

If SafeArrayCopyData managed to copy over the data from the source array, then `TargetArray` contains the copied data. If the two arrays are incompatible, SafeArrayCopyData returns a VAR_INVALIDARG (see page 5161) value. Otherwise, it returns VAR_OK (see page 5162)

See Also

SafeArrayCreate (see page 5118)

SafeArrayCopy (see page 5117)

52.2.7 VarUtils.SafeArrayCreate Function

Creates a safe array.

Pascal

```
function SafeArrayCreate(VarType: Integer; DimCount: Integer; const Bounds:
TVarArrayBoundArray): PVarArray; stdcall;
```

C++

```
__stdcall PVarArray SafeArrayCreate(int VarType, int DimCount, const TVarArrayBoundArray
Bounds);
```

File

VarUtils

Description

Use SafeArrayCreate to create a safe array with the given parameters.

The `VarType` parameter gives the type of each element in the safe array. Use the `var...` constants (varInteger (see page

3867), varBoolean (see page 3862), varDate (see page 3864), varCurrency (see page 3863) and so on) in the `System` (see page 3159) unit to specify the elements' variant type.

The `DimCount` parameter gives the safe array's number of dimensions. `DimCount` also represents the number of elements in the `Bounds` (see page 4651) constant array.

`Bounds` (see page 4651) is a constant TVarArrayBoundArray (see page 3798) type giving the bound information of the safe array, in all its dimensions.

In order to create the safe array, SafeArrayCreate first checks whether the element type is valid, then allocates memory for the safe array descriptor using the SafeArrayAllocDescriptor (see page 5116) function. Finally, it attempts to allocate memory for the actual data of the safe array, using SafeArrayAllocData (see page 5116). If this is not successful, then it destroys the previously allocated descriptor using the SafeArrayDestroyDescriptor (see page 5120) routine.

If SafeArrayCreate managed to create the safe array, then it returns a pointer to the array as a PVarArray (see page 3779) type variable. In the case when SafeArrayCreate did not manage to create the safe array, it simply returns **nil**.

To destroy a safe array, use the SafeArrayDestroy (see page 5119) function.

See Also

SafeArrayDestroy (see page 5119)

SafeArrayAllocData (see page 5116)

SafeArrayAllocDescriptor (see page 5116)

SafeArrayDestroyDescriptor (see page 5120)

TVarArrayBoundArray (see page 3798)

52.2.8 VarUtils.SafeArrayDestroy Function

Destroys a safe array.

Pascal

```
function SafeArrayDestroy(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayDestroy(PVarArray VarArray);
```

File

VarUtils

Description

Use SafeArrayDestroy to destroy safe array given through `VarArray`.

SafeArrayDestroy first checks whether the given safe array is locked or **nil**. If this is the case, then SafeArrayDestroy returns VAR_ARRAYISLOCKED (see page 5157) or VAR_INVALIDARG (see page 5161), correspondingly.

If the safe array is valid, then SafeArrayDestroy removes the actual data from memory using a call to SafeArrayDestroyData (see page 5120) and also destroys the associated safe array descriptor with a call to SafeArrayDestroyDescriptor (see page 5120). If SafeArrayDestroy manages to destroy the safe array, it returns a VAR_OK (see page 5162) result.

See Also

SafeArrayCreate (see page 5118)

SafeArrayDestroyData (see page 5120)

SafeArrayDestroyDescriptor (see page 5120)

52.2.9 VarUtils.SafeArrayDestroyData Function

Destroys the actual data of the given safe array.

Pascal

```
function SafeArrayDestroyData(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayDestroyData(PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayDestroyData destroys the actual data of the given safe array. It is used internally by the SafeDestroy routine. We recommend you not to use it directly when writing your application.

See Also

SafeArrayDestroy (see page 5119)

52.2.10 VarUtils.SafeArrayDestroyDescriptor Function

Destroys the descriptor of the given safe array.

Pascal

```
function SafeArrayDestroyDescriptor(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayDestroyDescriptor(PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayDestroyDescriptor destroys the descriptor of the given safe array. It is used internally by the SafeDestroy routine. We recommend you not to use it directly when writing your application.

See Also

SafeArrayDestroy (see page 5119)

52.2.11 VarUtils.SafeArrayError Function

Raises an event corresponding to the given safe array operation error code.

Pascal

```
procedure SafeArrayError(AResult: HRESULT);
```

C++

```
SafeArrayError(HRESULT AResult);
```

File

VarUtils

Description

Use SafeArrayError to programatically raise an event corresponding to the safe array operation error code given through the `AResult` parameter.

See Also

SafeArrayCheck (see page 5117)

52.2.12 VarUtils.SafeArrayGetDim Function

Returns the number of dimension of the given safe array.

Pascal

```
function SafeArrayGetDim(VarArray: PVarArray): Integer; stdcall;
```

C++

```
__stdcall int SafeArrayGetDim(PVarArray VarArray);
```

File

VarUtils

Description

Use SafeArrayGetDim to obtain the number of dimensions of the safe array referenced through the `VarArray` parameter.

See Also

SafeArrayGetLBound (see page 5122)

SafeArrayGetUBound (see page 5123)

SafeArrayGetElemSize (see page 5122)

52.2.13 VarUtils.SafeArrayGetElement Function

Returns the element at the specified position in the given safe array.

Pascal

```
function SafeArrayGetElement(VarArray: PVarArray; Indices: PVarArrayCoorArray; Data: Pointer):
HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayGetElement(PVarArray VarArray, PVarArrayCoorArray Indices, void *
Data);
```

File

VarUtils

Description

Use SafeArrayGetElement to obtain the element found at the position specified through the `Indices` parameter, in the safe array given through `VarArray`.

If retrieving the element is successful, SafeArrayGetElement stores the element in the `Data` parameter.

Note: SafeArrayGetElement also locks and unlocks the safe array before and after retrieving the element, using the SafeArrayLock (see page 5123) and SafeArrayUnlock (see page 5127) routines.

See Also

SafeArrayPutElement (see page 5125)

SafeArrayLock (see page 5123)

SafeArrayUnlock (see page 5127)

52.2.14 VarUtils.SafeArrayGetElemSize Function

Returns the size in bytes of an element in the given safe array.

Pascal

```
function SafeArrayGetElemSize(VarArray: PVarArray): LongWord; stdcall;
```

C++

```
__stdcall LongWord SafeArrayGetElemSize(PVarArray VarArray);
```

File

VarUtils

Description

Use SafeArrayGetElemSize to obtain the size in bytes of an element in the safe array referenced through the `VarArray` parameter.

See Also

SafeArrayGetLBound (see page 5122)

SafeArrayGetUBound (see page 5123)

SafeArrayGetDim (see page 5121)

52.2.15 VarUtils.SafeArrayGetLBound Function

Returns the lower bound for the given dimension of a safe array.

Pascal

```
function SafeArrayGetLBound(VarArray: PVarArray; Dim: Integer; out LBound: Integer): HRESULT;
stdcall;
```

C++

```
__stdcall HRESULT SafeArrayGetLBound(PVarArray VarArray, int Dim, int LBound);
```

File

VarUtils

Description

Use SafeArrayGetLBound to obtain the lower bound for the dimension given through `Dim` of the safe array referenced by `VarArray`.

See Also

SafeArrayGetUBound (see page 5123)

SafeArrayGetDim (see page 5121)

SafeArrayGetElemSize (see page 5122)

52.2.16 VarUtils.SafeArrayGetUBound Function

Returns the upper bound for the given dimension of a safe array.

Pascal

```
function SafeArrayGetUBound(VarArray: PVarArray; Dim: Integer; out UBound: Integer): HRESULT;
stdcall;
```

C++

```
__stdcall HRESULT SafeArrayGetUBound(PVarArray VarArray, int Dim, int UBound);
```

File

VarUtils

Description

Use SafeArrayGetUBound to obtain the upper bound for the dimension given through `Dim` of the safe array referenced by `VarArray`.

See Also

SafeArrayGetLBound (see page 5122)

SafeArrayGetDim (see page 5121)

SafeArrayGetElemSize (see page 5122)

52.2.17 VarUtils.SafeArrayLock Function

Locks a safe array.

Pascal

```
function SafeArrayLock(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayLock(PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayLock locks the safe array given through the `VarArray` parameter. `VarArray` is a pointer to the safe array.

The possible return values of SafeArrayLock are listed in the following table, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_INVALIDARG (see page 5161)	The given argument is `nil`.
VAR_ARRAYISLOCKED (see page 5157)	The array given through `VarArray` is locked.

While locked, a safe array cannot be resized and any calls to SafeArrayRedim (see page 5125) fail. Once locked, a safe array must later be unlocked using SafeArrayUnlock (see page 5127).

If the locking operation succeeded, `VarArray` points to an array of elements in which the leftmost dimension increases first. In other words, the dimensions of the returned array pointer are reversed from the dimensions of the safe array.

Tip: Once SafeArrayLock verifies that the safe array has the correct bounds and dimensions, SafeArrayLock can be used to gain direct access to the array data, which results in improved performance.

See Also

SafeArrayUnlock (see page 5127)

SafeArrayRedim (see page 5125)

52.2.18 VarUtils.SafeArrayPtrOfIndex Function

Returns a pointer to the element at the specified position in the given safe array.

Pascal

```
function SafeArrayPtrOfIndex(VarArray: PVarArray; Indices: PVarArrayCoorArray; var Address:
Pointer): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayPtrOfIndex(PVarArray VarArray, PVarArrayCoorArray Indices, void *
Address);
```

File

VarUtils

Description

Use SafeArrayPtrOfIndex to obtain a pointer to the element found at the position specified through the `Indices` parameter, in the safe array given through `VarArray`.

If retrieving the pointer to the element is successful, SafeArrayPtrOfIndex stores the element in the `Address` parameter.

See Also

SafeArrayGetElement (see page 5121)

SafeArrayPutElement (see page 5125)

52.2.19 VarUtils.SafeArrayPutElement Function

Sets the element at the specified position in the given safe array.

Pascal

```
function SafeArrayPutElement(VarArray: PVarArray; Indices: PVarArrayCoorArray; const Data:
Pointer): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayPutElement(PVarArray VarArray, PVarArrayCoorArray Indices, const
void * Data);
```

File

VarUtils

Description

Use SafeArrayPutElement to change the value of the element found at the position specified through the `Indices` parameter, in the safe array given through `VarArray`. The new value is stored in the `Data` parameter.

Note: SafeArrayPutElement also locks and unlocks the safe array before and after setting the element, using the SafeArrayLock (see page 5123) and SafeArrayUnlock (see page 5127) routines.

See Also

SafeArrayGetElement (see page 5121)

SafeArrayLock (see page 5123)

SafeArrayUnlock (see page 5127)

52.2.20 VarUtils.SafeArrayRedim Function

Changes the bound information for the last dimension of a safe array.

Pascal

```
function SafeArrayRedim(VarArray: PVarArray; const NewBound: TVarArrayBound): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayRedim(PVarArray VarArray, const TVarArrayBound NewBound);
```

File

VarUtils

Description

SafeArrayRedim resizes the safe array given through the `VarArray` parameter, by changing the bound information for the last dimension of the array, according to the `NewBound` parameter. `VarArray` is a pointer to the safe array.

The possible return values of SafeArrayRedim are listed in the following table, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_INVALIDARG (see page 5161)	The given argument is `nil`.
VAR_ARRAYISLOCKED (see page 5157)	The array given through `VarArray` is locked.
VAR_EXCEPTION (see page 5160)	The application raised an exception.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the operation.

After the resizing operation took place, the existing elements of the array are preserved and the new elements are set to zero or empty.

Note: A safe array cannot be resized while it is locked.

See Also

SafeArrayLock (see page 5123)

SafeArrayUnlock (see page 5127)

52.2.21 VarUtils.SafeArrayUnaccessData Function

Unlocks a safe array previously locked using the SafeArrayAccessData (see page 5115) routine.

Pascal

```
function SafeArrayUnaccessData(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayUnaccessData(PVarArray VarArray);
```

File

VarUtils

Description

Use SafeArrayUnaccessData to unlock a safe array that was previously locked with a call to SafeArrayAccessData (see page 5115).

Calling SafeArrayUnaccessData is equivalent to making a call to SafeArrayUnlock (see page 5127) with the same safe array as parameter.

See Also

SafeArrayAccessData (see page 5115)

SafeArrayUnlock (see page 5127)

52.2.22 VarUtils.SafeArrayUnlock Function

Unlocks a safe array.

Pascal

```
function SafeArrayUnlock(VarArray: PVarArray): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT SafeArrayUnlock(PVarArray VarArray);
```

File

VarUtils

Description

SafeArrayUnlock unlocks the safe array given through the `VarArray` parameter. `VarArray` is a pointer to the safe array.

The possible return values of SafeArrayUnlock are listed in the table below, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_INVALIDARG (see page 5161)	The given argument is `nil`.
VAR_ARRAYISLOCKED (see page 5157)	The array given through `VarArray` is locked.

If the unlocking operation succeeded, `VarArray` points to the unlocked safe array.

The safe array referenced by `VarArray` is assumed to have been locked using the SafeArrayLock (see page 5123) function.

See Also

SafeArrayLock (see page 5123)

52.2.23 VarUtils.VarExceptionToResult Function

Converts an Exception (see page 3949) type argument to an HRESULT (see page 3754) type.

Pascal

```
function VarExceptionToResult(const E: Exception): HRESULT;
```

C++

```
HRESULT VarExceptionToResult(const Exception E);
```

File

VarUtils

Description

VarExceptionToResult is an internal routine that converts the value given through E from an Exception (see page 3949) type to an HRESULT (see page 3754) type.

52.2.24 VarUtils.VariantChangeType Function

Converts a variant from one type to another.

Pascal

```
function VariantChangeType(var Dest: TVarData; const Source: TVarData; wFlags: Word; VarType:
Word): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT VariantChangeType(TVarData Dest, const TVarData Source, Word wFlags, Word
VarType);
```

File

VarUtils

Description

Use VariantChangeType to convert the variant given in `Source` to the variant stored in `Dest` of type `VarType`, using the parameter `wFlags`, which specifies the conversion flags.

VariantChangeType returns the result of the conversion operation, which can be one of the following.

Value	Meaning
`VAR_OK` (see page 5162)	The conversion was successful.
`VAR_BADVARTYPE` (see page 5158)	The variant type of the input parameter is not valid.
`VAR_OVERFLOW` (see page 5163)	The data stored in the output parameter does not fit in the destination type.
`VAR_TYPEMISMATCH` (see page 5163)	The argument cannot be cast to the specified type.
`VAR_INVALIDARG` (see page 5161)	Either one of the arguments is invalid.
`VAR_OUTOFMEMORY` (see page 5162)	There is not enough memory to complete the conversion.

Note: To do the conversion using locale-specific information, use the function referenced by the VariantChangeTypeEx (see page 5142) variable.

See Also

VariantChangeTypeEx (see page 5142)

52.2.25 VarUtils.VariantClear Function

Clears a variant.

Pascal

```
function VariantClear(var V: TVarData): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT VariantClear(TVarData V);
```

File

VarUtils

Description

VariantClear first clears the variant given through V and then it reinitializes it, using a call to VariantInit (see page 5130).

The possible return values of VariantClear are given in the following table, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_UNEXPECTED (see page 5164)	An unexpected error occurred.

See Also

VariantInit (see page 5130)

52.2.26 VarUtils.VariantCopy Function

Clears the destination variant and makes a copy of the source variant.

Pascal

```
function VariantCopy(var Dest: TVarData; const Source: TVarData): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT VariantCopy(TVarData Dest, const TVarData Source);
```

File

VarUtils

Description

Use VariantCopy to copy the source variant given through `Source` to the destination variant denoted by `Dest`, after clearing up `Dest` using a call to VariantClear (see page 5128).

The possible return values of VariantCopy are given in the following table, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the operation.
VAR_UNEXPECTED (see page 5164)	An unexpected error occurred.
VAR_EXCEPTION (see page 5160)	The application raised an exception.

See Also

VariantCopyInd (see page 5130)

52.2.27 VarUtils.VariantCopyInd Function

Clears the destination variant and makes a copy of the source variant, including the case when the source is of varByRef (see page 3862) type.

Pascal

```
function VariantCopyInd(var Dest: TVarData; const Source: TVarData): HRESULT; stdcall;
```

C++

```
__stdcall HRESULT VariantCopyInd(TVarData Dest, const TVarData Source);
```

File

VarUtils

Description

Use VariantCopyInd to copy the source variant given through `Source` to the destination variant denoted by `Dest`, after clearing up `Dest` using a call to VariantClear (see page 5128).

In the case when the source is of varByRef (see page 3862) type, VariantCopyInd performs the indirection and copies the correct information.

The possible return values of VariantCopyInd are given in the following table, together with their meaning.

Value	Meaning
VAR_OK (see page 5162)	The operation was completed successfully.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the operation.
VAR_UNEXPECTED (see page 5164)	An unexpected error occurred.
VAR_EXCEPTION (see page 5160)	The application raised an exception.

See Also

VariantCopy (see page 5129)

52.2.28 VarUtils.VariantInit Function

Initializes a variant.

Pascal

```
procedure VariantInit(var V: TVarData); stdcall;
```

C++

```
__stdcall VariantInit(TVarData V);
```

File

VarUtils

Description

Use the VariantInit procedure to initialize the variant given through the V parameter.

VariantInit sets the VType field of V to varEmpty (see page 3865) and sets all its bytes to zero.

See Also

VariantClear (see page 5128)

52.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TVarTypeToElementInfo (see page 5132)	This is an internal record type used in declaring the CVarTypeToElementInfo (see page 5154) constant array.

52.3.1 VarUtils.TVarTypeToElementInfo Record

This is an internal record type used in declaring the CVarTypeToElementInfo (see page 5154) constant array.

Pascal

```
TVarTypeToElementInfo = record
  ValidBase: Boolean;
  ValidElement: Boolean;
  Size: Integer;
  Flags: Word;
end;
```

C++

```
struct TVarTypeToElementInfo {
  Boolean ValidBase;
  Boolean ValidElement;
  int Size;
  Word Flags;
};
```

File

VarUtils

Description

TVarTypeToElementInfo is an internal record type that specifies the elements' type in the CVarTypeToElementInfo (see page 5154) constant array. We recommend you not to use it directly when writing your application.

See Also

CVarTypeToElementInfo (see page 5154)

52.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
VarAdd (see page 5133)	VarAdd is a function type variable that specifies the function making the addition operation between two variants.
VarAnd (see page 5134)	VarAnd is a function type variable that specifies the function making the bitwise **and** operation between two variants.
VarBoolFromStr (see page 5134)	VarBoolFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a boolean value.
VarBstrFromBool (see page 5135)	VarBstrFromBool is used to specify the function that makes the conversion from a boolean value to a WideString (see page 3467).
VarBstrFromCy (see page 5136)	VarBstrFromCy is used to specify the function that makes the conversion from a currency value to a WideString (see page 3467).
VarBstrFromDate (see page 5137)	VarBstrFromDate is used to specify the function that makes the conversion from a date value to a WideString (see page 3467).
VarCmp (see page 5138)	VarCmp is a variable used to specify the function that compares two variants.
VarCyFromStr (see page 5139)	VarCyFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a currency value.
VarDateFromStr (see page 5139)	VarDateFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a date value.
VarDiv (see page 5140)	VarDiv is a function type variable that specifies the function making the division operation between two variants.
VarI4FromStr (see page 5141)	VarI4FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a four bytes integer value.
VariantChangeTypeEx (see page 5142)	VariantChangeTypeEx stores the function that converts a variant from one type to another, using locale-specific information.
VarIDiv (see page 5142)	VarIDiv is a function type variable that specifies the function making the division operation between two variants, after converting the variants to integers.
VarMod (see page 5143)	VarMod is a function type variable that specifies the function that calculates the remainder on division of two variants.
VarMul (see page 5143)	VarMul is a function type variable that specifies the function making the multiplication operation between two variants.
VarNeg (see page 5144)	VarNeg is a function type variable that specifies the function that inverts the sign of a variant.
VarNot (see page 5144)	VarNot is a function type variable that specifies the function that performs a **not** operation on a variant.
VarOr (see page 5145)	VarOr is a function type variable that specifies the function doing the bitwise **or** operation between two variants.
VarR4FromStr (see page 5145)	VarR4FromStr is used to specify the function that does the conversion from a WideString (see page 3467) to a four bytes floating-point value.
VarR8FromStr (see page 5146)	VarR8FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a eight bytes floating-point value.
VarSub (see page 5147)	VarSub is a function type variable that specifies the function making the subtraction operation between two variants.
VarXor (see page 5147)	VarXor is a function type variable that specifies the function making the bitwise **xor** (exclusive or) operation between two variants.

52.4.1 VarUtils.VarAdd Variable

VarAdd is a function type variable that specifies the function making the addition operation between two variants.

Pascal

```
VarAdd: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarAdd;
```

File

VarUtils

Description

Use VarAdd to specify the function that makes the addition operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantAdd (see page 4955)

52.4.2 VarUtils.VarAnd Variable

VarAnd is a function type variable that specifies the function making the bitwise **and** operation between two variants.

Pascal

```
VarAnd: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarAnd;
```

File

VarUtils

Description

Use VarAnd to specify the function that does the bitwise **and** operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantAnd (see page 4956)

52.4.3 VarUtils.VarBoolFromStr Variable

VarBoolFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a boolean value.

Pascal

```
VarBoolFromStr: function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out
boolOut: WordBool): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out boolOut: WordBool):
HRESULT VarBoolFromStr;
```

File

VarUtils

Description

Use VarBoolFromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the boolean value stored in `boolOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarBoolFromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a boolean value to a WideString (see page 3467), use the function referenced by VarBstrFromBool (see page 5135).

See Also

VarBstrFromBool (see page 5135)

52.4.4 VarUtils.VarBstrFromBool Variable

VarBstrFromBool is used to specify the function that makes the conversion from a boolean value to a WideString (see page 3467).

Pascal

```
VarBstrFromBool: function(boolIn: WordBool; LCID: Integer; dwFlags: Longint; out bstrOut:
WideString): HRESULT;
```

C++

```
function(boolIn: WordBool; LCID: Integer; dwFlags: Longint; out bstrOut: WideString): HRESULT
VarBstrFromBool;
```

File

VarUtils

Description

Use VarBstrFromBool to specify the function that makes the conversion from the boolean value given through `boolIn` to the WideString (see page 3467) stored in `bstrOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarBstrFromBool returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a WideString (see page 3467) to a boolean value, use the function referenced by VarBoolFromStr (see page 5134).

See Also

VarBoolFromStr (see page 5134)

52.4.5 VarUtils.VarBstrFromCy Variable

VarBstrFromCy is used to specify the function that makes the conversion from a currency value to a WideString (see page 3467).

Pascal

```
VarBstrFromCy: function(cyIn: Currency; LCID: Integer; dwFlags: Longint; out bstrOut:
WideString): HRESULT;
```

C++

```
function(cyIn: Currency; LCID: Integer; dwFlags: Longint; out bstrOut: WideString): HRESULT
VarBstrFromCy;
```

File

VarUtils

Description

Use VarBstrFromCy to specify the function that makes the conversion from the currency value given through `cyIn` to the WideString (see page 3467) stored in `bstrOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarBstrFromCy returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a WideString (see page 3467) to a currency value, use the function referenced by VarCyFromStr (see page 5139).

See Also

VarCyFromStr (see page 5139)

52.4.6 VarUtils.VarBstrFromDate Variable

VarBstrFromDate is used to specify the function that makes the conversion from a date value to a WideString (see page 3467).

Pascal

```
VarBstrFromDate: function(dateIn: TDateTime; LCID: Integer; dwFlags: Longint; out bstrOut:
WideString): HRESULT;
```

C++

```
function(dateIn: TDateTime; LCID: Integer; dwFlags: Longint; out bstrOut: WideString): HRESULT
VarBstrFromDate;
```

File

VarUtils

Description

Use VarBstrFromDate to specify the function that makes the conversion from the date value given through `dateIn` to the WideString (see page 3467) stored in `bstrOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarBstrFromDate returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.

VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a WideString (see page 3467) to a date value, use the function referenced by VarDateFromStr (see page 5139).

See Also

VarDateFromStr (see page 5139)

52.4.7 VarUtils.VarCmp Variable

VarCmp is a variable used to specify the function that compares two variants.

Pascal

```
VarCmp: function(const Left, Right: TVarData; LCID: Integer; Flags: LongWord): HRESULT;
```

C++

```
function(const Left, Right: TVarData; LCID: Integer; Flags: LongWord): HRESULT VarCmp;
```

File

VarUtils

Description

Use VarCmp to specify the function that compares two variants, given through the `Left` and `Right` parameters. The `LCID` parameter is a locale identifier and `Flags` specifies the flags used in the comparison.

VarCmp returns the result of the comparison, which can be one of the following.

Result	Meaning
`VAR_CMP_LT` (see page 5159)	`Left` is less than `Right`
`VAR_CMP_EQ` (see page 5158)	`Left` is equal to `Right`
`VAR_CMP_GT` (see page 5159)	`Left` is greater than `Right`
`VAR_CMP_NULL` (see page 5160)	Either one of `Left` or `Right` is `nil`.

See Also

VAR_CMP_LT (see page 5159)

VAR_CMP_EQ (see page 5158)

VAR_CMP_GT (see page 5159)

VAR_CMP_NULL (see page 5160)

52.4.8 VarUtils.VarCyFromStr Variable

VarCyFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a currency value.

Pascal

```
VarCyFromStr: function(const strIn: WideString; LCID: DWORD; dwFlags: Longint; out cyOut:
Currency): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: DWORD; dwFlags: Longint; out cyOut: Currency): HRESULT
VarCyFromStr;
```

File

VarUtils

Description

Use VarCyFromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the currency value stored in `cyOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarCyFromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a currency value to a WideString (see page 3467), use the function referenced by VarBstrFromCy (see page 5136).

See Also

VarBstrFromCy (see page 5136)

52.4.9 VarUtils.VarDateFromStr Variable

VarDateFromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a date value.

Pascal

```
VarDateFromStr: function(const strIn: WideString; LCID: DWORD; dwFlags: Longint; out dateOut:
TDateTime): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: DWORD; dwFlags: Longint; out dateOut: TDateTime):
HRESULT VarDateFromStr;
```

File

VarUtils

Description

Use VarDateFromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the date value stored in `dateOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarDateFromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

To make the inverse conversion, from a date value to a WideString (see page 3467), use the function referenced by VarBstrFromDate (see page 5137).

See Also

VarBstrFromDate (see page 5137)

52.4.10 VarUtils.VarDiv Variable

VarDiv is a function type variable that specifies the function making the division operation between two variants.

Pascal

```
VarDiv: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarDiv;
```

File

VarUtils

Description

Use VarDiv to specify the function that makes the division operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils (see page 5107)` unit.

See Also

VariantDiv (see page 4959)

52.4.11 VarUtils.VarI4FromStr Variable

VarI4FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a four bytes integer value.

Pascal

```
VarI4FromStr: function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out lOut:
Longint): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out lOut: Longint): HRESULT
VarI4FromStr;
```

File

VarUtils

Description

Use VarI4FromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the four bytes integer value stored in `lOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarI4FromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

See Also

VarR4FromStr (see page 5145)

VarR8FromStr (see page 5146)

52.4.12 VarUtils.VariantChangeTypeEx Variable

VariantChangeTypeEx stores the function that converts a variant from one type to another, using locale-specific information.

Pascal

```
VariantChangeTypeEx: function(var Dest: TVarData; const Source: TVarData; LCID: Integer;
wFlags: Word; VarType: Word): HRESULT;
```

C++

```
function(var Dest: TVarData; const Source: TVarData; LCID: Integer; wFlags: Word; VarType:
Word): HRESULT VariantChangeTypeEx;
```

File

VarUtils

Description

Use VariantChangeTypeEx to specify the function that converts the variant given in `Source` to the variant stored in `Dest` of type `VarType`, using the locale-specific information given through `LCID` and the parameter `wFlags` specifying the conversion flags.

The function stored in VariantChangeTypeEx returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

Note: To make the conversion without using locale-specific information, use the VariantChangeType (see page 5128) function.

See Also

VariantChangeType (see page 5128)

52.4.13 VarUtils.VarIDiv Variable

VarIDiv is a function type variable that specifies the function making the division operation between two variants, after converting the variants to integers.

Pascal

```
VarIDiv: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarIDiv;
```

File

VarUtils

Description

Use VarIDiv to specify the function that makes the division operation between the two variants given through the `Left` and `Right` parameters, after converting the variants to integers. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VarDiv (see page 5140)

VariantDiv (see page 4959)

52.4.14 VarUtils.VarMod Variable

VarMod is a function type variable that specifies the function that calculates the remainder on division of two variants.

Pascal

```
VarMod: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarMod;
```

File

VarUtils

Description

Use VarMod to specify the function that calculates the remainder on the division of the two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantMod (see page 4962)

52.4.15 VarUtils.VarMul Variable

VarMul is a function type variable that specifies the function making the multiplication operation between two variants.

Pascal

```
VarMul: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarMul;
```

File

VarUtils

Description

Use VarMul to specify the function that makes the multiplication operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantMul (see page 4963)

52.4.16 VarUtils.VarNeg Variable

VarNeg is a function type variable that specifies the function that inverts the sign of a variant.

Pascal

```
VarNeg: function(const Source: TVarData; var Dest: TVarData): HRESULT;
```

C++

```
function(const Source: TVarData; var Dest: TVarData): HRESULT VarNeg;
```

File

VarUtils

Description

Use VarNeg to specify the function that inverts the sign of the variant given through the `Source` parameter. The result is stored in the `Dest` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantNeg (see page 4964)

52.4.17 VarUtils.VarNot Variable

VarNot is a function type variable that specifies the function that performs a **not** operation on a variant.

Pascal

```
VarNot: function(const Source: TVarData; var Dest: TVarData): HRESULT;
```

C++

```
function(const Source: TVarData; var Dest: TVarData): HRESULT VarNot;
```

File

VarUtils

Description

Use VarNot to specify the function that performs a **not** operation on the variant given through the `Source` parameter. The result is stored in the `Dest` parameter.

The function specified through VarNot returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantNeg (see page 4964)

52.4.18 VarUtils.VarOr Variable

VarOr is a function type variable that specifies the function doing the bitwise **or** operation between two variants.

Pascal

```
VarOr: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarOr;
```

File

VarUtils

Description

Use VarOr to specify the function that does the bitwise **or** operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantOr (see page 4964)

52.4.19 VarUtils.VarR4FromStr Variable

VarR4FromStr is used to specify the function that does the conversion from a WideString (see page 3467) to a four bytes floating-point value.

Pascal

```
VarR4FromStr: function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out fltOut:
Single): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out fltOut: Single):
HRESULT VarR4FromStr;
```

File

VarUtils

Description

Use VarR4FromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the four bytes floating-point value stored in `fltOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarR4FromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

See Also

VarR8FromStr (see page 5146)

52.4.20 VarUtils.VarR8FromStr Variable

VarR8FromStr is used to specify the function that makes the conversion from a WideString (see page 3467) to a eight bytes floating-point value.

Pascal

```
VarR8FromStr: function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out dblOut:
Double): HRESULT;
```

C++

```
function(const strIn: WideString; LCID: Integer; dwFlags: Longint; out dblOut: Double):
HRESULT VarR8FromStr;
```

File

VarUtils

Description

Use VarR8FromStr to specify the function that makes the conversion from the WideString (see page 3467) given through `strIn` to the eight bytes floating-point value stored in `dblOut`. The `LCID` parameter is a locale identifier and `dwFlags` specifies the flags used in the conversion.

The function stored in VarR8FromStr returns the result of the conversion operation, which can be one of the following.

Value	Meaning
VAR_OK (see page 5162)	The conversion was successful.
VAR_BADVARTYPE (see page 5158)	The variant type of the input parameter is not valid.
VAR_OVERFLOW (see page 5163)	The data stored in the output parameter does not fit in the destination type.
VAR_TYPEMISMATCH (see page 5163)	The argument cannot be cast to the specified type.
VAR_INVALIDARG (see page 5161)	Either one of the arguments is invalid.
VAR_OUTOFMEMORY (see page 5162)	There is not enough memory to complete the conversion.

See Also

VarR4FromStr (see page 5145)

52.4.21 VarUtils.VarSub Variable

VarSub is a function type variable that specifies the function making the subtraction operation between two variants.

Pascal

```
VarSub: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarSub;
```

File

VarUtils

Description

Use VarSub to specify the function that makes the subtraction operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantSub (see page 4968)

52.4.22 VarUtils.VarXor Variable

VarXor is a function type variable that specifies the function making the bitwise **xor** (exclusive or) operation between two variants.

Pascal

```
VarXor: function(const Left, Right: TVarData; var AResult: TVarData): HRESULT;
```

C++

```
function(const Left, Right: TVarData; var AResult: TVarData): HRESULT VarXor;
```

File

VarUtils

Description

Use VarXor to specify the function that makes the bitswise **xor** (exclusive or) operation between two variants given through the `Left` and `Right` parameters. The result is stored in the `AResult` parameter.

The function specified through VarNot (see page 5144) returns a value of type HRESULT (see page 3754). For a list of possible return values, see the VAR_ constants in the `VarUtils` (see page 5107) unit.

See Also

VariantXor (see page 4970)

52.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
ARR_DISPATCH (see page 5150)	Used to test whether the variant array contains IDispatch (see page 3494) elements.
ARR_FIXEDSIZE (see page 5150)	Used to test whether the variant array is of fixed size.
ARR_NONE (see page 5151)	Specifies that a variant array has no flags set.
ARR_OLESTR (see page 5151)	Used to test whether the variant array contains BSTR elements.
ARR_UNKNOWN (see page 5152)	Used to test whether the variant array contains IUnknown (see page 3756) elements.
ARR_VARIANT (see page 5152)	Used to test whether the variant array contains `Variant (see page 3421)` elements.
CMaxArrayVarType (see page 5153)	CMaxArrayVarType gives the upper bound of the CVarTypeToElementInfo (see page 5154) array.
CMinArrayVarType (see page 5153)	CMinArrayVarType gives the lower bound of the CVarTypeToElementInfo (see page 5154) array.
CVarTypeToElementInfo (see page 5154)	This constant is internally used by the SafeArrayCreate (see page 5118) function.
GenericOperations (see page 5155)	Specifies whether the implementation for the variant operation routines is cross-platform.
GenericSafeArrays (see page 5155)	Specifies whether the implementation for the safe array routines is cross-platform.
GenericSafeArrayUsesLibC (see page 5156)	Specifies whether the implementation for the safe array routines uses the `Libc` unit.
GenericVariants (see page 5156)	Specifies whether the implementation for the variant support routines is cross-platform.
GenericVarUtils (see page 5157)	Specifies whether the implementation for the variant-manipulating routines is cross-platform.
VAR_ARRAYISLOCKED (see page 5157)	Specifies that the given array is locked.
VAR_BADINDEX (see page 5158)	Indicates that the given index is out of range.
VAR_BADVARTYPE (see page 5158)	Specifies that the variant type of the input parameter is invalid.
VAR_CMP_EQ (see page 5158)	VAR_CMP_EQ specifies that the variants are equal, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_GT (see page 5159)	VAR_CMP_GT specifies that the first variant is greater than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_LT (see page 5159)	VAR_CMP_LT specifies that the first variant is lower than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_CMP_NULL (see page 5160)	VAR_CMP_NULL specifies that either one of the variants is `nil`, after a call to the function referenced by the VarCmp (see page 5138) variable.
VAR_EXCEPTION (see page 5160)	Specifies that the application raised an exception.
VAR_INVALIDARG (see page 5161)	Specifies that either one of the arguments is invalid.
VAR_LOCALE_USER_DEFAULT (see page 5161)	Specifies the default locale for the user or process.
VAR_NOTIMPL (see page 5161)	Specifies that the operation is not implemented.
VAR_OK (see page 5162)	Specifies that a variant operation was successful.
VAR_OUTOFMEMORY (see page 5162)	Specifies that there is not enough memory to complete the operation.
VAR_OVERFLOW (see page 5163)	Specifies that a variant operation caused an overflow.
VAR_PARAMNOTFOUND (see page 5163)	Indicates that there is no correspondence between the parameter DISPIDs and a parameter of the method.
VAR_TYPEMISMATCH (see page 5163)	Specifies that the argument cannot be cast to the specified type.
VAR_UNEXPECTED (see page 5164)	Indicates that an unexpected error occurred.

52.5.1 VarUtils.ARR_DISPATCH Constant

Used to test whether the variant array contains IDispatch (see page 3494) elements.

Pascal

```
ARR_DISPATCH = $0400;
```

C++

```
ARR_DISPATCH = 0x0400;
```

File

VarUtils

Description

Do a bitwise **and** operation between the `Flags` field of a TVarArray (see page 3739) variable and the ARR_DISPATCH constant to test whether the variant array contains IDispatch (see page 3494) elements. If the result is nonzero, then the elements of the variant array are of IDispatch (see page 3494) type. Otherwise, the elements are of a different type.

See Also

ARR_FIXEDSIZE (see page 5150)

ARR_NONE (see page 5151)

ARR_OLESTR (see page 5151)

ARR_UNKNOWN (see page 5152)

ARR_VARIANT (see page 5152)

52.5.2 VarUtils.ARR_FIXEDSIZE Constant

Used to test whether the variant array is of fixed size.

Pascal

```
ARR_FIXEDSIZE = $0010;
```

C++

```
ARR_FIXEDSIZE = 0x0010;
```

File

VarUtils

Description

Do a bitwise **and** operation between the `Flags` field of a TVarArray (see page 3739) variable and the ARR_FIXEDSIZE constant to test whether the variant array is of fixed size. If the result is nonzero, then the array is of fixed size. Otherwise, the array can be resized or reallocated.

See Also

ARR_DISPATCH (see page 5150)

ARR_NONE (see page 5151)

ARR_OLESTR (see page 5151)

ARR_UNKNOWN (see page 5152)

ARR_VARIANT (see page 5152)

52.5.3 VarUtils.ARR_NONE Constant

Specifies that a variant array has no flags set.

Pascal

```
ARR_NONE = $0000;
```

C++

```
ARR_NONE = 0x0000;
```

File

VarUtils

Description

Assign the ARR_NONE value to the `Flags` field of a TVarArray (see page 3739) variable to specify that the variant array variable has no flags set.

See Also

ARR_DISPATCH (see page 5150)

ARR_FIXEDSIZE (see page 5150)

ARR_OLESTR (see page 5151)

ARR_UNKNOWN (see page 5152)

ARR_VARIANT (see page 5152)

52.5.4 VarUtils.ARR_OLESTR Constant

Used to test whether the variant array contains BSTR elements.

Pascal

```
ARR_OLESTR = $0100;
```

C++

```
ARR_OLESTR = 0x0100;
```

File

VarUtils

Description

Do a bitwise **and** operation between the `Flags` field of a TVarArray (see page 3739) variable and the ARR_OLESTR constant to test whether the variant array contains BSTR elements. If the result is nonzero, then the elements of the variant array are of BSTR type. Otherwise, the elements are of a different type.

See Also

ARR_DISPATCH (see page 5150)

ARR_FIXEDSIZE (see page 5150)

ARR_NONE (see page 5151)

ARR_UNKNOWN (see page 5152)

ARR_VARIANT (see page 5152)

52.5.5 VarUtils.ARR_UNKNOWN Constant

Used to test whether the variant array contains IUnknown (see page 3756) elements.

Pascal

```
ARR_UNKNOWN = $0200;
```

C++

```
ARR_UNKNOWN = 0x0200;
```

File

VarUtils

Description

Do a bitwise **and** operation between the `Flags` field of a TVarArray (see page 3739) variable and the ARR_UNKNOWN constant to test whether the variant array contains IUnknown (see page 3756) elements. If the result is nonzero, then the elements of the variant array are of IUnknown (see page 3756) type. Otherwise, the elements are of a different type.

See Also

ARR_DISPATCH (see page 5150)

ARR_FIXEDSIZE (see page 5150)

ARR_NONE (see page 5151)

ARR_OLESTR (see page 5151)

ARR_VARIANT (see page 5152)

52.5.6 VarUtils.ARR_VARIANT Constant

Used to test whether the variant array contains `Variant (see page 3421)` elements.

Pascal

```
ARR_VARIANT = $0800;
```

C++

```
ARR_VARIANT = 0x0800;
```

File

VarUtils

Description

Do a bitwise **and** operation between the `Flags` field of a TVarArray (see page 3739) variable and the ARR_VARIANT constant to test whether the variant array contains `Variant (see page 3421)` elements. If the result is nonzero, then the elements of the variant array are of `Variant (see page 3421)` type. Otherwise, the elements are of a different type.

See Also

ARR_DISPATCH (see page 5150)

ARR_FIXEDSIZE (see page 5150)

ARR_NONE (see page 5151)

ARR_OLESTR (see page 5151)

ARR_UNKNOWN (see page 5152)

52.5.7 VarUtils.CMaxArrayVarType Constant

CMaxArrayVarType gives the upper bound of the CVarTypeToElementInfo (see page 5154) array.

Pascal

```
CMaxArrayVarType = varUInt64;
```

C++

```
CMaxArrayVarType = varUInt64;
```

File

VarUtils

Description

CMaxArrayVarType is a constant that specifies the upper bound of the CVarTypeToElementInfo (see page 5154) array.

CMaxArrayVarType is equal to the varUInt64 (see page 3872) constant.

See Also

CVarTypeToElementInfo (see page 5154)

52.5.8 VarUtils.CMinArrayVarType Constant

CMinArrayVarType gives the lower bound of the CVarTypeToElementInfo (see page 5154) array.

Pascal

```
CMinArrayVarType = varEmpty;
```

C++

```
CMinArrayVarType = varEmpty;
```

File

VarUtils

Description

CMinArrayVarType is a constant that specifies the lower bound of the CVarTypeToElementInfo (see page 5154) array.

CMinArrayVarType is equal to the varEmpty (see page 3865) constant.

See Also

CVarTypeToElementInfo (see page 5154)

52.5.9 VarUtils.CVarTypeToElementInfo Constant

This constant is internally used by the SafeArrayCreate (see page 5118) function.

Pascal

```
CVarTypeToElementInfo: array [CMinArrayVarType..CMaxArrayVarType] of TVarTypeToElementInfo = (
(ValidBase: False; ValidElement: True; Size: 0; Flags: ARR_NONE), (ValidBase: False;
ValidElement: True; Size: 0; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 2;
Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase:
True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase: True; ValidElement: True;
Size: 8; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 8; Flags: ARR_NONE),
(ValidBase: True; ValidElement: True; Size: 8; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 4; Flags: ARR_OLESTR), (ValidBase: True; ValidElement: True; Size:
4; Flags: ARR_DISPATCH), (ValidBase: True; ValidElement: True; Size: 4; Flags: ARR_NONE),
(ValidBase: True; ValidElement: True; Size: 2; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 16; Flags: ARR_VARIANT), (ValidBase: True; ValidElement: True; Size:
4; Flags: ARR_UNKNOWN), (ValidBase: False; ValidElement: False; Size: 14; Flags: ARR_NONE),
(ValidBase: False; ValidElement: False; Size: 0; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 1; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 1;
Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 2; Flags: ARR_NONE), (ValidBase:
True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase: False; ValidElement: True;
Size: 8; Flags: ARR_NONE), (ValidBase: False; ValidElement: False; Size: 8; Flags: ARR_NONE));
```

C++

```
array [CMinArrayVarType..CMaxArrayVarType] of TVarTypeToElementInfo CVarTypeToElementInfo = (
(ValidBase: False; ValidElement: True; Size: 0; Flags: ARR_NONE), (ValidBase: False;
ValidElement: True; Size: 0; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 2;
Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase:
True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase: True; ValidElement: True;
Size: 8; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 8; Flags: ARR_NONE),
(ValidBase: True; ValidElement: True; Size: 8; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 4; Flags: ARR_OLESTR), (ValidBase: True; ValidElement: True; Size:
4; Flags: ARR_DISPATCH), (ValidBase: True; ValidElement: True; Size: 4; Flags: ARR_NONE),
(ValidBase: True; ValidElement: True; Size: 2; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 16; Flags: ARR_VARIANT), (ValidBase: True; ValidElement: True; Size:
4; Flags: ARR_UNKNOWN), (ValidBase: False; ValidElement: False; Size: 14; Flags: ARR_NONE),
(ValidBase: False; ValidElement: False; Size: 0; Flags: ARR_NONE), (ValidBase: True;
ValidElement: True; Size: 1; Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 1;
Flags: ARR_NONE), (ValidBase: True; ValidElement: True; Size: 2; Flags: ARR_NONE), (ValidBase:
True; ValidElement: True; Size: 4; Flags: ARR_NONE), (ValidBase: False; ValidElement: True;
Size: 8; Flags: ARR_NONE), (ValidBase: False; ValidElement: False; Size: 8; Flags: ARR_NONE));
```

File

VarUtils

Description

CVarTypeToElementInfo is an constant array used internally in the implementation of the SafeArrayCreate (see page 5118) function. We recommend you not to use it directly when writing your application.

See Also

SafeArrayCreate (see page 5118)

CMinArrayVarType (see page 5153)

CMaxArrayVarType (see page 5153)

52.5.10 VarUtils.GenericOperations Constant

Specifies whether the implementation for the variant operation routines is cross-platform.

Pascal

```
GenericOperations = GenericVariants;
```

C++

```
GenericOperations = GenericVariants;
```

File

VarUtils

Description

GenericOperations is a constant that specifies whether the implementation for the variant operation routines is cross-platform. The operation routines refer to the binary and unary operations on variants, as well as the conversion routines.

GenericOperations has the same value with GenericVariants (see page 5156).

See Also

GenericVarUtils (see page 5157)

GenericVariants (see page 5156)

GenericSafeArrays (see page 5155)

GenericSafeArrayUsesLibC (see page 5156)

52.5.11 VarUtils.GenericSafeArrays Constant

Specifies whether the implementation for the safe array routines is cross-platform.

Pascal

```
GenericSafeArrays = GenericVarUtils;
```

C++

```
GenericSafeArrays = GenericVarUtils;
```

File

VarUtils

Description

GenericSafeArrays is a constant that specifies whether the implementation for the safe array routines is cross-platform.

GenericSafeArrays has the same value with GenericVarUtils (see page 5157).

See Also

GenericVarUtils (see page 5157)

GenericVariants (see page 5156)

GenericOperations (see page 5155)

GenericSafeArrayUsesLibC (see page 5156)

52.5.12 VarUtils.GenericSafeArrayUsesLibC Constant

Specifies whether the implementation for the safe array routines uses the `Libc` unit.

Pascal

```
GenericSafeArrayUsesLibC = FALSE;
```

C++

```
GenericSafeArrayUsesLibC = FALSE;
```

File

VarUtils

Description

GenericSafeArrayUsesLibC is a constant that specifies whether the implementation for the safe array routines uses the `Libc` unit.

See Also

GenericVarUtils (see page 5157)

GenericVariants (see page 5156)

GenericSafeArrays (see page 5155)

GenericOperations (see page 5155)

52.5.13 VarUtils.GenericVariants Constant

Specifies whether the implementation for the variant support routines is cross-platform.

Pascal

```
GenericVariants = GenericVarUtils;
```

C++

```
GenericVariants = GenericVarUtils;
```

File

VarUtils

Description

GenericVariants is a constant that specifies whether the implementation for the variant support routines is cross-platform. Support routines refer to initializing, copying, changing the type of a variant, and other similar routines.

GenericVariants has the same value with GenericVarUtils (see page 5157).

See Also

GenericVarUtils (see page 5157)

GenericSafeArrays (see page 5155)

GenericOperations (see page 5155)

GenericSafeArrayUsesLibC (see page 5156)

52.5.14 VarUtils.GenericVarUtils Constant

Specifies whether the implementation for the variant-manipulating routines is cross-platform.

Pascal

```
GenericVarUtils = False;
```

C++

```
GenericVarUtils = False;
```

File

VarUtils

Description

GenericVarUtils is a constant that specifies whether the implementation for the variant-manipulating routines is cross-platform.

See Also

GenericVariants (see page 5156)

GenericSafeArrays (see page 5155)

GenericOperations (see page 5155)

GenericSafeArrayUsesLibC (see page 5156)

52.5.15 VarUtils.VAR_ARRAYISLOCKED Constant

Specifies that the given array is locked.

Pascal

```
VAR_ARRAYISLOCKED = HRESULT($8002000D);
```

C++

```
VAR_ARRAYISLOCKED = HRESULT($8002000D);
```

File

VarUtils

Description

VAR_ARRAYISLOCKED is a possible return value of the variant-manipulating functions, specifying that the given variant array is locked.

52.5.16 VarUtils.VAR_BADINDEX Constant

Indicates that the given index is out of range.

Pascal

```
VAR_BADINDEX = HRESULT($8002000B);
```

C++

```
VAR_BADINDEX = HRESULT($8002000B);
```

File

VarUtils

Description

VAR_BADINDEX is a possible return value of the variant-manipulating functions, specifying that the given index is out of range.

52.5.17 VarUtils.VAR_BADVARTYPE Constant

Specifies that the variant type of the input parameter is invalid.

Pascal

```
VAR_BADVARTYPE = HRESULT($80020008);
```

C++

```
VAR_BADVARTYPE = HRESULT($80020008);
```

File

VarUtils

Description

VAR_BADVARTYPE is used to specify that the variant type of a routine's input parameter is invalid.

52.5.18 VarUtils.VAR_CMP_EQ Constant

VAR_CMP_EQ specifies that the variants are equal, after a call to the function referenced by the VarCmp (see page 5138) variable.

Pascal

```
VAR_CMP_EQ = 1;
```

C++

```
VAR_CMP_EQ = 1;
```

File

VarUtils

Description

VAR_CMP_EQ is one of the possible return values of the function referenced by the VarCmp (see page 5138) variable.

VAR_CMP_EQ specifies that the two variants are equal, after making the comparison.

See Also

VarCmp (see page 5138)

VAR_CMP_LT (see page 5159)

VAR_CMP_GT (see page 5159)

VAR_CMP_NULL (see page 5160)

52.5.19 VarUtils.VAR_CMP_GT Constant

VAR_CMP_GT specifies that the first variant is greater than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.

Pascal

```
VAR_CMP_GT = 2;
```

C++

```
VAR_CMP_GT = 2;
```

File

VarUtils

Description

VAR_CMP_GT is one of the possible return values of the function referenced by the VarCmp (see page 5138) variable.

VAR_CMP_GT specifies that the first variant is greater than the second, after making the comparison.

See Also

VarCmp (see page 5138)

VAR_CMP_EQ (see page 5158)

VAR_CMP_LT (see page 5159)

VAR_CMP_NULL (see page 5160)

52.5.20 VarUtils.VAR_CMP_LT Constant

VAR_CMP_LT specifies that the first variant is lower than the second, after a call to the function referenced by the VarCmp (see page 5138) variable.

Pascal

```
VAR_CMP_LT = 0;
```

C++

```
VAR_CMP_LT = 0;
```

File

VarUtils

Description

VAR_CMP_LT is one of the possible return values of the function referenced by the VarCmp (see page 5138) variable.

VAR_CMP_LT specifies that the first variant is lower than the second, after making the comparison.

See Also

VarCmp (see page 5138)

VAR_CMP_EQ (see page 5158)

VAR_CMP_GT (see page 5159)

VAR_CMP_NULL (see page 5160)

52.5.21 VarUtils.VAR_CMP_NULL Constant

VAR_CMP_NULL specifies that either one of the variants is `nil`, after a call to the function referenced by the VarCmp (see page 5138) variable.

Pascal

```
VAR_CMP_NULL = 3;
```

C++

```
VAR_CMP_NULL = 3;
```

File

VarUtils

Description

VAR_CMP_NULL is one of the possible return values of the function referenced by the VarCmp (see page 5138) variable.

VAR_CMP_NULL specifies that either one of the variants is `nil`, after making the comparison.

See Also

VarCmp (see page 5138)

VAR_CMP_LT (see page 5159)

VAR_CMP_EQ (see page 5158)

VAR_CMP_GT (see page 5159)

52.5.22 VarUtils.VAR_EXCEPTION Constant

Specifies that the application raised an exception.

Pascal

```
VAR_EXCEPTION = HRESULT($80020009);
```

C++

```
VAR_EXCEPTION = HRESULT($80020009);
```

File

VarUtils

Description

VAR_EXCEPTION is a possible return value of the variant-manipulating functions, specifying that the application raised an exception during the execution of the function.

52.5.23 VarUtils.VAR_INVALIDARG Constant

Specifies that either one of the arguments is invalid.

Pascal

```
VAR_INVALIDARG = HRESULT($80070057);
```

C++

```
VAR_INVALIDARG = HRESULT($80070057);
```

File

VarUtils

Description

VAR_INVALIDARG is a possible return value of the variant-manipulating functions, specifying that either one of the given arguments is invalid.

52.5.24 VarUtils.VAR_LOCALE_USER_DEFAULT Constant

Specifies the default locale for the user or process.

Pascal

```
VAR_LOCALE_USER_DEFAULT = $400;
```

C++

```
VAR_LOCALE_USER_DEFAULT = 0x400;
```

File

VarUtils

Description

VAR_LOCALE_USER_DEFAULT gives the default locale for the user or process.

52.5.25 VarUtils.VAR_NOTIMPL Constant

Specifies that the operation is not implemented.

Pascal

```
VAR_NOTIMPL = HRESULT($80004001);
```

C++

```
VAR_NOTIMPL = HRESULT($80004001);
```

File

VarUtils

Description

VAR_NOTIMPL is a possible return value of the variant-manipulating functions, specifying that the operation is not implemented.

52.5.26 VarUtils.VAR_OK Constant

Specifies that a variant operation was successful.

Pascal

```
VAR_OK = HRESULT($00000000);
```

C++

```
VAR_OK = HRESULT($00000000);
```

File

VarUtils

Description

VAR_OK is a possible return value of the variant-manipulating functions, specifying that the operation was successfully completed.

52.5.27 VarUtils.VAR_OUTOFMEMORY Constant

Specifies that there is not enough memory to complete the operation.

Pascal

```
VAR_OUTOFMEMORY = HRESULT($8007000E);
```

C++

```
VAR_OUTOFMEMORY = HRESULT($8007000E);
```

File

VarUtils

Description

VAR_OUTOFMEMORY is a possible return value of the variant-manipulating functions, specifying that there is not enough memory to complete the operation.

52.5.28 VarUtils.VAR_OVERFLOW Constant

Specifies that a variant operation caused an overflow.

Pascal

```
VAR_OVERFLOW = HRESULT($8002000A);
```

C++

```
VAR_OVERFLOW = HRESULT($8002000A);
```

File

VarUtils

Description

VAR_OVERFLOW is a possible return value of the variant-manipulating functions, specifying that the data stored in the output parameter does not fit in the destination type.

52.5.29 VarUtils.VAR_PARAMNOTFOUND Constant

Indicates that there is no correspondence between the parameter DISPIDs and a parameter of the method.

Pascal

```
VAR_PARAMNOTFOUND = HRESULT($80020004);
```

C++

```
VAR_PARAMNOTFOUND = HRESULT($80020004);
```

File

VarUtils

Description

VAR_PARAMNOTFOUND indicates that there is no correspondence between the parameter DISPIDs and a parameter of the method.

52.5.30 VarUtils.VAR_TYPEMISMATCH Constant

Specifies that the argument cannot be cast to the specified type.

Pascal

```
VAR_TYPEMISMATCH = HRESULT($80020005);
```

C++

```
VAR_TYPEMISMATCH = HRESULT($80020005);
```

File

VarUtils

Description

VAR_TYPEMISMATCH is a possible return value of the variant-manipulating functions, specifying that the given argument cannot be cast to the specified type.

52.5.31 VarUtils.VAR_UNEXPECTED Constant

Indicates that an unexpected error occurred.

Pascal

```
VAR_UNEXPECTED = HRESULT($8000FFFF);
```

C++

```
VAR_UNEXPECTED = HRESULT($8000FFFF);
```

File

VarUtils

Description

VAR_ARRAYISLOCKED (see page 5157) is a possible return value of the variant-manipulating functions, specifying that an unexpected error occurred during the execution of the operation.

53 VCLCom Namespace

This is namespace VCLCom.

Topics

Name	Description
Classes (see page 5166)	The following table lists classes in this documentation.

Classes

	Name	Description
	TComponentFactory (see page 5166)	TComponentFactory is the class factory for creating instances of components that support interfaces.

53.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TComponentFactory (see page 5166)	TComponentFactory is the class factory for creating instances of components that support interfaces.

53.1.1 TComponentFactory Class

TComponentFactory is the class factory for creating instances of components that support interfaces.

Class Hierarchy

Pascal

```
TComponentFactory = class(TAutoObjectFactory, IClassFactory);
```

C++

```
class TComponentFactory : public TAutoObjectFactory, public IClassFactory;
```

File

VCLCom

Description

TComponentFactory creates instances of component classes that implement interfaces. TComponentFactory supports the IClassFactory interface and inherits support for the IClassFactory2 interface.

Note: These components are actually created as contained objects of an automation object (aggregate).

53.1.1.1 TComponentFactory Members

The following tables list the members exposed by TComponentFactory.

Protected Methods

	Name	Description
	CreateInstance (see page 5168)	This is CreateInstance, a member of class TComponentFactory.

Public Methods

	Name	Description
	Create (see page 5167)	Instantiates an instance of a TComponentFactory (see page 5166) object.
	CreateComObject (see page 5167)	Instantiates a TComObject object.
	UpdateRegistry (see page 5168)	Registers the typed COM object class.

53.1.1.2 TComponentFactory.Create Constructor

Instantiates an instance of a TComponentFactory (see page 5166) object.

Pascal

```
constructor Create(ComServer: TComServerObject; ComponentClass: TComponentClass; const
ClassID: TGUID; Instancing: TClassInstancing; ThreadingModel: TThreadingModel = tmSingle);
```

C++

```
__fastcall TComponentFactory(TComServerObject ComServer, TComponentClass ComponentClass, const
TGUID ClassID, TClassInstancing Instancing, TThreadingModel ThreadingModel = tmSingle);
```

Description

Create allocates memory for a TComponentFactory (see page 5166) object, and calls the inherited Create, passing its parameters in the same order. The ComponentClass parameter is passed cast as a TAutoClass and passed to the AutoClass parameter.

53.1.1.3 TComponentFactory Methods

The methods of the TComponentFactory class are listed here.

Protected Methods

	Name	Description
	CreateInstance (see page 5168)	This is CreateInstance, a member of class TComponentFactory.

Public Methods

	Name	Description
	CreateComObject (see page 5167)	Instantiates a TComObject object.
	UpdateRegistry (see page 5168)	Registers the typed COM object class.

53.1.1.3.1 TComponentFactory.CreateComObject Method

Instantiates a TComObject object.

Pascal

```
function CreateComObject(const Controller: IUnknown): TComObject; override;
```

C++

```
virtual __fastcall TComObject CreateComObject(const IUnknown Controller);
```

Description

CreateComObject is the method that instantiates the class type for which TComObjectFactory is the class factory. CreateComObject calls the CreateFromFactory constructor of the TComObject class to create a COM object. CreateComObject passes itself as the Factory parameter to CreateFromFactory.

CreateComClass creates a COM object based upon the value of the ComClass property. ComClass is the class identifier (CLSID) used by other applications to identify the COM class for which they request an object instance.

See Also

ComClass

CreateFromFactory

TComObject

53.1.1.3.2 TComponentFactory.CreateInstance Method

Pascal

```
function CreateInstance(const UnkOuter: IUnknown; const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CreateInstance(const IUnknown UnkOuter, const TGUID IID,  Obj);
```

Description

This is CreateInstance, a member of class TComponentFactory.

53.1.1.3.3 TComponentFactory.UpdateRegistry Method

Registers the typed COM object class.

Pascal

```
procedure UpdateRegistry(Register: Boolean); override;
```

C++

```
virtual __fastcall UpdateRegistry(Boolean Register);
```

Description

UpdateRegistry is called for EXEs when the EXE is run, and for DLLs or EXEs when the routines are called to specifically register or unregister the server.

Constants (see page 5931)	The following table lists constants in this documentation.

Classes

	Name	Description
	EAdapterException (see page 5177)	EAdapterException is raised by WebSnap adapter objects.
	EAdapterFieldException (see page 5178)	EAdapterFieldException is an exception class for errors by adapters using fields.
	TAbstractFieldValuesAdapter (see page 5180)	TAbstractFieldValuesAdapter is the base class for adapters that have a single default field.
	TAdapter (see page 5190)	TAdapter defines a scriptable interface to event handlers that return data items or execute commands in your application.
	TAdapterAction (see page 5201)	TAdapterAction is a generic adapter action that relies on event handlers.
	TAdapterActions (see page 5209)	TAdapterActions manages the list of actions that belong to an adapter.
	TAdapterApplicationField (see page 5214)	TAdapterApplicationField is a base class for adapter field components that are children of a TApplicationAdapter (see page 5439) component.
	TAdapterApplicationTitleField (see page 5218)	TAdapterApplicationTitleField is an adapter field used to access the application title.
	TAdapterBooleanField (see page 5223)	TAdapterBooleanField is an event handler based adapter field that works with a Boolean value.
	TAdapterDefaultActions (see page 5231)	TAdapterDefaultActions manages the list of actions that belong to an adapter that supports a default set of actions.
	TAdapterDefaultFields (see page 5237)	TAdapterDefaultFields manages the list of fields that belong to an adapter that supports a default set of fields.
	TAdapterEndUserDisplayNameField (see page 5244)	TAdapterEndUserDisplayNameField is an adapter field used to access the end-user's name.
	TAdapterEndUserField (see page 5248)	TAdapterEndUserField is a base class for adapter field components that are children of an end-user adapter component.
	TAdapterEndUserLoggedInField (see page 5252)	TAdapterEndUserLoggedInField is an adapter field used to access the end-user logged in flag.

	TAdapterError (see page 5256)	TAdapterError is the implementation of IAdapterError (see page 992).
	TAdapterErrorsList (see page 5259)	TAdapterErrorsList keeps track of errors that an adapter encounters.
	TAdapterField (see page 5267)	TAdapterField is an event handler based adapter field that provides a single value.
	TAdapterFields (see page 5276)	TAdapterFields manages the list of fields that belong to an adapter.
	TAdapterFileField (see page 5281)	TAdapterFileField is an event handler based adapter field that can accept uploaded files.
	TAdapterGotoPageAction (see page 5291)	TAdapterGotoPageAction is an adapter action that supports commands to go to a page of a TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterHiddenField (see page 5299)	This is class WebAdapt.TAdapterHiddenField.
	TAdapterHiddenFieldsList (see page 5301)	TAdapterHiddenFieldsList maintains a collection of name/value pairs that an adapter includes as hidden fields in an HTML form.
	TAdapterImageField (see page 5308)	TAdapterImageField is an event handler based adapter field that can provide the URL of an image file and also accept an uploaded image file.
	TAdapterLoginField (see page 5320)	TAdaperLoginField is a base class for adapter field components that are children of a TLoginFormAdapter (see page 5824) component.
	TAdapterMemoField (see page 5323)	TAdapterMemoField is an event handler based adapter field that supports a multi-line text value.
	TAdapterMultiValueField (see page 5332)	TAdapterMultiValueField is an event handler based adapter field that provides zero or more values.
	TAdapterNamedDisplayField (see page 5343)	The AdapterNamedDisplayField is a base class for adapter fields.
	TAdapterNamedField (see page 5351)	TAdapterNamedField is a based class for adapter field components.
	TAdapterNextPageAction (see page 5370)	TAdapterNextPageAction implements the next page command for TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterNextPageField (see page 5379)	The TAdapterNextPageField navigates to the next page of data.
	TAdapterObjectErrorsList (see page 5387)	This is class WebAdapt.TAdapterObjectErrorsList.
	TAdapterPasswordField (see page 5391)	TAdapterPasswordField is an adapter field used to access the password entered by the end-user.
	TAdapterPrevPageAction (see page 5396)	TAdapterPrevPageAction implements the previous page command for TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterSubComponent (see page 5406)	TAdapterSubComponent is the base class for objects that represent a collection of actions or fields that belong to an adapter.
	TAdapterUpdateField (see page 5419)	TAdapterUpdateField is a base class for adapter field components that support data entry into an HTML form.
	TAdapterUserNameField (see page 5433)	TAdapterUserNameField is an adapter field used to access the user name entered by the end-user.
	TApplicationAdapter (see page 5439)	TApplicationAdapter is a container for field and action components that are available through the Application script variable.
	TBaseAdapterAction (see page 5447)	TBaseAdapterAction is a based class for adapter action components.
	TBaseAdapterErrorsList (see page 5479)	TBaseAdapterErrorsList is the base class for adapter error object managers.
	TBaseAdapterMultiValueField (see page 5488)	TBaseAdapterMultiValueField is a base class for adapter fields that have zero or more values.
	TBaseEndUserAdapter (see page 5497)	TBaseEndUserAdapter contains user information.
	TBaseValuesListAdapter (see page 5517)	TBaseValuesListAdapter is a base class for adapters that provide a list of name/value pairs.
	TBaseValuesListField (see page 5527)	TBaseValuesListField is a base class for adapter field components that are children of a values list adapter component.
	TCustomAdapter (see page 5531)	TCustomAdapter is a base class for adapter components.
	TCustomAdapterAction (see page 5579)	TCustomAdapterAction is a base class for adapter actions.
	TCustomAdapterBooleanField (see page 5589)	TCustomAdapterBooleanField is a base class for adapter fields that provide a single Boolean value.
	TCustomAdapterField (see page 5597)	TCustomAdapterField is a base class for adapter fields that provide a single value.
	TCustomAdapterFileField (see page 5604)	TCustomAdapterFileField is a base class for adapter fields that can have associated files.
	TCustomAdapterGotoPageAction (see page 5614)	TCustomAdapterGotoPageAction is an adapter action that supports commands to go to a page of a TDefaultFieldsPagedAdapter (see page 5747).
	TCustomAdapterImageField (see page 5623)	TCustomAdapterImageField is a base class for adapter fields that have an associated image file.
	TCustomAdapterMemoField (see page 5638)	TCustomAdapterMemoField is a base class for adapter fields that have a multi-line text value.

	TCustomAdapterMultiValueField (see page 5646)	TCustomAdapterMultiValueField is a base class for adapter fields that have one or more values.
	TCustomAdapterPageAction (see page 5656)	TCustomPagedAdapterAction (see page 5722) is a base class for adapter actions that execute the next or previous page commands.
	TCustomApplicationAdapter (see page 5663)	TCustomApplicationAdapter is a base class for components that implement the server-side script Application object.
	TCustomApplicationAdapterAction (see page 5671)	TCustomApplicationAdapterAction is a base class for adapter actions that work with descendants of TCustomApplicationAdapter (see page 5663).
	TCustomEndUserAdapter (see page 5676)	TCustomEndUserAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TCustomEndUserAdapterAction (see page 5687)	TCustomEndUserAdapterAction is a base class for adapter actions that work with descendants of TCustomEndUserAdapter (see page 5676).
	TCustomEndUserSessionAdapter (see page 5692)	TCustomEndUserSessionAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TCustomLoginFormAdapter (see page 5701)	TCustomLoginFormAdapter is the base class for adapters that manage the fields and actions of a login form.
	TCustomLoginFormAdapterAction (see page 5717)	TCustomEndUserAdapterAction (see page 5687) is a base class for adapter actions that work with descendants of TCustomLoginFormAdapter (see page 5701).
	TCustomPagedAdapter (see page 5721)	TCustomPagedAdapter is a base class for adapters that support paging.
	TCustomPagedAdapterAction (see page 5722)	TCustomPagedAdapterAction is a base class for adapter actions that work with descendants of TDefaultFieldsPagedAdapter (see page 5747).
	TCustomStringsValuesList (see page 5728)	TCustomStringsValuesList is a base class for a values list that defines it's name/value pairs using a string list.
	TDefaultFieldsAdapter (see page 5738)	TDefaultFieldsAdapter is a base class for adapters that automatically adds default fields and/or actions.
	TDefaultFieldsPagedAdapter (see page 5747)	TDefaultFieldsPagedAdapter is a base class for adapters that support paging.
	TEndUserAdapter (see page 5764)	TEndUserAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TEndUserAdapterLoginFormAction (see page 5776)	TEndUserAdapterLoginFormAction is an adapter action that displays a login form when executed.
	TEndUserAdapterLogoutAction (see page 5784)	TEndUserAdapterLogoutAction is an adapter action that logs the end-user out.
	TEndUserSessionAdapter (see page 5792)	TEndUserSessionAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TFieldValuesAdapter (see page 5803)	TFieldValuesAdapter is an adapter that includes a single field value.
	TFieldValuesValueField (see page 5813)	TFieldValuesValueField is a adapter field child of TFieldValuesAdapter (see page 5803).
	TImplementedAdapterAction (see page 5818)	TImplementedAdapterAction is a base class for adapter actions.
	TLogicalPageList (see page 5819)	This is class WebAdapt.TLogicalPageList.
	TLoginFormAdapter (see page 5824)	TLoginFormAdapter contains the adapter fields and adapter actions used to generate a login form.
	TLoginFormAdapterLoginAction (see page 5835)	TLoginFormAdapterLoginAction executes the login command of a login form generated with TLoginFormAdapter (see page 5824).
	TPagedAdapter (see page 5844)	TPagedAdapter divides a large amount of data into several pages, each page displaying a portion of the data records.
	TStringsValuesList (see page 5857)	TStringsValuesList is an adapter component that provides a list of name/value pairs defined by items in a TStrings property.
	TUpdateFileList (see page 5864)	TUpdateFileList is a container for uploaded files.
	TValuesListNameField (see page 5866)	TValuesListNameField is an adapter field used to access the Name of the current list item of a values list adapter.
	TValuesListValueField (see page 5869)	TValuesListValueField is an adapter field used to access the Value (see page 5369) of the current list item of a values list adapter.

Constants

Name	Description
sActionRequestLong (see page 5931)	This is constant WebAdapt.sActionRequestLong.
sCurrentPage (see page 5931)	This is constant WebAdapt.sCurrentPage.
sGotoPageAction (see page 5932)	This is constant WebAdapt.sGotoPageAction.
sImageRequest (see page 5932)	This is constant WebAdapt.sImageRequest.
sLoginPassword (see page 5932)	This is constant WebAdapt.sLoginPassword.
sLoginUserName (see page 5933)	This is constant WebAdapt.sLoginUserName.

sNextPageAction (see page 5933)	This is constant WebAdapt.sNextPageAction.
sPrevPageAction (see page 5933)	This is constant WebAdapt.sPrevPageAction.

Functions

	Name	Description
	AddDefaultActions (see page 5897)	This is function WebAdapt.AddDefaultActions.
	AddDefaultFields (see page 5897)	This is function WebAdapt.AddDefaultFields.
	FindAdapterAction (see page 5898)	This is function WebAdapt.FindAdapterAction.
	FindAdapterField (see page 5898)	This is function WebAdapt.FindAdapterField.
	FindAdapterInParent (see page 5898)	This is function WebAdapt.FindAdapterInParent.
	MakeAdapterRequestIdentifier (see page 5899)	This is function WebAdapt.MakeAdapterRequestIdentifier.
	MakeValidAdapterFieldName (see page 5899)	This is function WebAdapt.MakeValidAdapterFieldName.
	RaiseFileUploadNotSupported (see page 5899)	This is function WebAdapt.RaiseFileUploadNotSupported.
	RaiseMultipleFilesException (see page 5900)	This is function WebAdapt.RaiseMultipleFilesException.
	RaiseMultipleValuesException (see page 5900)	This is function WebAdapt.RaiseMultipleValuesException.

Interfaces

	Name	Description
	IAdapterEditor (see page 5874)	This is class WebAdapt.IAdapterEditor.
	IAdapterNotifyAdapterChange (see page 5875)	This is class WebAdapt.IAdapterNotifyAdapterChange.
	ICheckOrigValue (see page 5876)	This is class WebAdapt.ICheckOrigValue.
	ICheckValueChange (see page 5877)	This is class WebAdapt.ICheckValueChange.
	IClearAdapterValues (see page 5878)	This is class WebAdapt.IClearAdapterValues.
	ICreateActionRequestContext (see page 5879)	This is class WebAdapt.ICreateActionRequestContext.
	IEchoActionFieldValue (see page 5880)	This is class WebAdapt.IEchoActionFieldValue.
	IEchoAdapterFieldValues (see page 5882)	This is class WebAdapt.IEchoAdapterFieldValues.
	IExecuteValue (see page 5883)	IExecuteValue is the interface for executing an adapter's fields with values passed in an HTTP request.
	IFullyQualifyInputNames (see page 5885)	This is class WebAdapt.IFullyQualifyInputNames.
	IGetAdapterErrorsList (see page 5886)	This is class WebAdapt.IGetAdapterErrorsList.
	IGetAdapterModeNames (see page 5887)	This is class WebAdapt.IGetAdapterModeNames.
	IGetRecordKeys (see page 5888)	This is class WebAdapt.IGetRecordKeys.
	IIdentifyAdapter (see page 5889)	This is class WebAdapt.IIdentifyAdapter.
	ISetSubComponents (see page 5889)	This is class WebAdapt.ISetSubComponents.
	ISetWebFieldValue (see page 5890)	This is class WebAdapt.ISetWebFieldValue.
	IUpdateValue (see page 5891)	This is class WebAdapt.IUpdateValue.
	IValidateValue (see page 5892)	This is class WebAdapt.IValidateValue.
	IWebActionsSubcomponent (see page 5893)	This is class WebAdapt.IWebActionsSubcomponent.
	IWebFieldsSubcomponent (see page 5893)	This is class WebAdapt.IWebFieldsSubcomponent.
	IWebGetFieldPrevValue (see page 5894)	This is class WebAdapt.IWebGetFieldPrevValue.

Structs, Records, Enums

	Name	Description
	TAdapterHiddenFieldOption (see page 5901)	TAdapterHiddenFieldOptions (see page 5919) identifies the types of hidden fields an adapter adds to generated HTML forms.
	TIteratorMethod (see page 5902)	TIteratorMethod identifies a record of data to which an adapter should navigate.

Types

Name	Description
IActionFieldValue (see page 5904)	This is type WebAdapt.IActionFieldValue.
IActionRequest (see page 5905)	This is type WebAdapt.IActionRequest.
TAbstractWebRequestFile (see page 5905)	This is type WebAdapt.TAbstractWebRequestFile.
TActionExecuteEvent (see page 5905)	TActionExecuteEvent is the type for event handlers on adapter action objects that are called when the action executes.
TActionExecuteHandledEvent (see page 5906)	TActionExecuteHandledEvent is the type for event handlers on adapter action objects that can handle the execution of the action.

TActionGetEnabledEvent (see page 5906)	TActionGetEnabledEvent is the type for event handlers on adapter action objects that are called when the action executes.
TActionGetParamsEvent (see page 5907)	TActionGetParamsEvent is the type for event handlers that supply the parameters for an adapter action.
TActionRequestFieldsEvent (see page 5907)	TActionRequestFieldsEvent is the type for event handlers on adapter action objects that are called after the adapter performs some operation on its fields in response to an HTTP request.
TActionRequestFieldsHandledEvent (see page 5908)	TActionRequestFieldsHandledEvent is the type for event handlers on adapter action objects that are called when the adapter performs some operation on its fields in response to an HTTP request.
TAdapterActionExecuteEvent (see page 5909)	TAdapterActionExecuteEvent is the type for event handlers on adapter objects that are called after one of its actions executes.
TAdapterActionExecuteHandledEvent (see page 5909)	TAdapterActionExecuteHandledEvent is the type for event handlers on adapter objects that are called when one of its actions executes.
TAdapterActionGetParamsEvent (see page 5910)	TAdapterActionGetParamsEvent is the type for event handlers that supply the parameters needed to execute an adapter action.
TAdapterActionsClass (see page 5911)	TAdapterActionsClass defines the metaclass for TAdapterActions (see page 5209).
TAdapterFieldBooleanValueEvent (see page 5911)	TAdapterFieldBooleanValueEvent is the type for event handlers that respond when a boolean value is assigned to an adapter field.
TAdapterFieldFileEvent (see page 5912)	TAdapterFieldFileEvent is the type for event handlers that perform some action on an uploaded file.
TAdapterFieldFileListEvent (see page 5912)	TAdapterFieldFileListEvent is the type for event handlers that perform some action on a set of uploaded files.
TAdapterFieldGetBooleanEvent (see page 5913)	TAdapterFieldGetBooleanEvent is the type for event handlers that provide a boolean value associated with an adapter field.
TAdapterFieldGetMultiValueEvent (see page 5913)	TAdapterFieldGetMultiValueEvent is the type for event handlers that supply a set of values for an adapter field.
TAdapterFieldGetMultiValueStringEvent (see page 5914)	TAdapterFieldGetMultiValueStringEvent is the type for event handlers that supply a set of string values for an adapter field.
TAdapterFieldGetStringEvent (see page 5914)	TAdapterFieldGetStringEvent is the type for event handlers that provide a string associated with an adapter field.
TAdapterFieldGetValueCountEvent (see page 5915)	TAdapterFieldGetValueCountEvent is the type for event handlers that indicate the number of values associated with an adapter field.
TAdapterFieldGetValueEvent (see page 5915)	TAdapterFieldGetValueEvent is the type for event handlers that provide the value associated with an adapter field.
TAdapterFieldHasValueEvent (see page 5916)	TAdapterFieldHasValueEvent is the type for event handlers that indicate whether a value is assigned to an adapter field.
TAdapterFieldsClass (see page 5916)	This is type WebAdapt.TAdapterFieldsClass.
TAdapterFieldStringEvent (see page 5917)	TAdapterFieldStringEvent is the type for event handlers that respond when a string value is assigned to an adapter field.
TAdapterFieldStringsEvent (see page 5917)	TAdapterFieldStringsEvent is the type for event handlers that respond when a set of string values is assigned to an adapter field.
TAdapterFieldValidateValueEvent (see page 5918)	TAdapterFieldValidateValueEvent is the type for event handlers that validate a value for an adapter field.
TAdapterFieldValueEvent (see page 5918)	TAdapterFieldValueEvent is the type for event handlers that respond when an adapter field's value changes.
TAdapterHiddenFieldOptions (see page 5919)	This is type WebAdapt.TAdapterHiddenFieldOptions.
TEndUserGetNameEvent (see page 5919)	TEndUserGetNameEvent is the type for event handlers that supply the name of the current end user.
TEndUserGetUserIDEvent (see page 5920)	TEndUserGetUserIDEvent is the type for event handlers that supply the user ID of the current end user.
TEndUserHandledEvent (see page 5920)	TEndUserHandledEvent is the type for event handlers that can optionally handle a task for an end user adapter.
TEndUserIsLoggedInEvent (see page 5921)	TEndUserIsLoggedInEvent is the type for event handlers that indicate whether the current end user has logged in.
TEndUserRightsEvent (see page 5921)	TEndUserRightsEvent is the type for event handlers that check whether a user has rights to perform a specific operation.
TEndUserUserIDEvent (see page 5922)	TEndUserUserIDEvent is the type for event handlers that log in a user given the user ID.
TGetEOFEvent (see page 5922)	TGetEOFEvent is the type for event handlers on adapters that indicate when to stop iterating over values.
TGetRecordCountEvent (see page 5923)	TGetRecordCountEvent is the type for event handlers that indicate how many values an adapter has.

TGetRecordEvent (see page 5923)	TGetRecordEvent is the type for event handlers on adapters that position the adapter on one of multiple values.
TGetRecordIndexEvent (see page 5924)	TGetRecordIndexEvent is the type for event handlers that indicate which of multiple values an adapter is positioned on.
THandledEvent (see page 5924)	This is type WebAdapt.THandledEvent.
TImageFieldGetHREFEvent (see page 5925)	TImageFieldGetHREFEvent is the type for event handlers that supply an URL that can be used to access an image field associated with an adapter field..
TImageFieldGetImageEvent (see page 5925)	TImageFieldGetImageEvent is the type for event handlers that supply a stream from which to read an image.
TImageFieldGetParamsEvent (see page 5926)	TImageFieldGetParamsEvent is the type for event handlers that supply a set of parameters to identify the value of an image field.
TIterateRecordsEvent (see page 5926)	TIterateRecordsEvent is the type for event handlers that navigate the records of an adapter.
TLoginUserIDEvent (see page 5927)	TLoginUserIDEvent is the type for event handlers that respond after a user logs in.
TObjectList (see page 5928)	This is type WebAdapt.TObjectList.
TValidateAdapterFieldEvent (see page 5928)	TValidateAdapterFieldEvent is the type for event handlers that validate the values supplied for adapter fields.
TWebFormGetPageNameEvent (see page 5928)	TWebFormGetPageNameEvent is the type for event handlers that supply labels for the controls that navigate to Web pages.

Variables

Name	Description
NotifyPossibleHTMLChange (see page 5930)	This is variable WebAdapt.NotifyPossibleHTMLChange.

54.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EAdapterException (see page 5177)	EAdapterException is raised by WebSnap adapter objects.
	EAdapterFieldException (see page 5178)	EAdapterFieldException is an exception class for errors by adapters using fields.
	TAbstractFieldValuesAdapter (see page 5180)	TAbstractFieldValuesAdapter is the base class for adapters that have a single default field.
	TAdapter (see page 5190)	TAdapter defines a scriptable interface to event handlers that return data items or execute commands in your application.
	TAdapterAction (see page 5201)	TAdapterAction is a generic adapter action that relies on event handlers.
	TAdapterActions (see page 5209)	TAdapterActions manages the list of actions that belong to an adapter.
	TAdapterApplicationField (see page 5214)	TAdapterApplicationField is a base class for adapter field components that are children of a TApplicationAdapter (see page 5439) component.
	TAdapterApplicationTitleField (see page 5218)	TAdapterApplicationTitleField is an adapter field used to access the application title.
	TAdapterBooleanField (see page 5223)	TAdapterBooleanField is an event handler based adapter field that works with a Boolean value.
	TAdapterDefaultActions (see page 5231)	TAdapterDefaultActions manages the list of actions that belong to an adapter that supports a default set of actions.
	TAdapterDefaultFields (see page 5237)	TAdapterDefaultFields manages the list of fields that belong to an adapter that supports a default set of fields.
	TAdapterEndUserDisplayNameField (see page 5244)	TAdapterEndUserDisplayNameField is an adapter field used to access the end-user's name.
	TAdapterEndUserField (see page 5248)	TAdapterEndUserField is a base class for adapter field components that are children of an end-user adapter component.
	TAdapterEndUserLoggedInField (see page 5252)	TAdapterEndUserLoggedInField is an adapter field used to access the end-user logged in flag.
	TAdapterError (see page 5256)	TAdapterError is the implementation of IAdapterError (see page 992).
	TAdapterErrorsList (see page 5259)	TAdapterErrorsList keeps track of errors that an adapter encounters.
	TAdapterField (see page 5267)	TAdapterField is an event handler based adapter field that provides a single value.
	TAdapterFields (see page 5276)	TAdapterFields manages the list of fields that belong to an adapter.
	TAdapterFileField (see page 5281)	TAdapterFileField is an event handler based adapter field that can accept uploaded files.
	TAdapterGotoPageAction (see page 5291)	TAdapterGotoPageAction is an adapter action that supports commands to go to a page of a TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterHiddenField (see page 5299)	This is class WebAdapt.TAdapterHiddenField.
	TAdapterHiddenFieldsList (see page 5301)	TAdapterHiddenFieldsList maintains a collection of name/value pairs that an adapter includes as hidden fields in an HTML form.
	TAdapterImageField (see page 5308)	TAdapterImageField is an event handler based adapter field that can provide the URL of an image file and also accept an uploaded image file.
	TAdapterLoginField (see page 5320)	TAdaperLoginField is a base class for adapter field components that are children of a TLoginFormAdapter (see page 5824) component.
	TAdapterMemoField (see page 5323)	TAdapterMemoField is an event handler based adapter field that supports a multi-line text value.
	TAdapterMultiValueField (see page 5332)	TAdapterMultiValueField is an event handler based adapter field that provides zero or more values.
	TAdapterNamedDisplayField (see page 5343)	The AdapterNamedDisplayField is a base class for adapter fields.
	TAdapterNamedField (see page 5351)	TAdapterNamedField is a based class for adapter field components.
	TAdapterNextPageAction (see page 5370)	TAdapterNextPageAction implements the next page command for TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterNextPageField (see page 5379)	The TAdapterNextPageField navigates to the next page of data.
	TAdapterObjectErrorsList (see page 5387)	This is class WebAdapt.TAdapterObjectErrorsList.

	TAdapterPasswordField (see page 5391)	TAdapterPasswordField is an adapter field used to access the password entered by the end-user.
	TAdapterPrevPageAction (see page 5396)	TAdapterPrevPageAction implements the previous page command for TDefaultFieldsPagedAdapter (see page 5747).
	TAdapterSubComponent (see page 5406)	TAdapterSubComponent is the base class for objects that represent a collection of actions or fields that belong to an adapter.
	TAdapterUpdateField (see page 5419)	TAdapterUpdateField is a base class for adapter field components that support data entry into an HTML form.
	TAdapterUserNameField (see page 5433)	TAdapterUserNameField is an adapter field used to access the user name entered by the end-user.
	TApplicationAdapter (see page 5439)	TApplicationAdapter is a container for field and action components that are available through the Application script variable.
	TBaseAdapterAction (see page 5447)	TBaseAdapterAction is a based class for adapter action components.
	TBaseAdapterErrorsList (see page 5479)	TBaseAdapterErrorsList is the base class for adapter error object managers.
	TBaseAdapterMultiValueField (see page 5488)	TBaseAdapterMultiValueField is a base class for adapter fields that have zero or more values.
	TBaseEndUserAdapter (see page 5497)	TBaseEndUserAdapter contains user information.
	TBaseValuesListAdapter (see page 5517)	TBaseValuesListAdapter is a base class for adapters that provide a list of name/value pairs.
	TBaseValuesListField (see page 5527)	TBaseValuesListField is a base class for adapter field components that are children of a values list adapter component.
	TCustomAdapter (see page 5531)	TCustomAdapter is a base class for adapter components.
	TCustomAdapterAction (see page 5579)	TCustomAdapterAction is a base class for adapter actions.
	TCustomAdapterBooleanField (see page 5589)	TCustomAdapterBooleanField is a base class for adapter fields that provide a single Boolean value.
	TCustomAdapterField (see page 5597)	TCustomAdapterField is a base class for adapter fields that provide a single value.
	TCustomAdapterFileField (see page 5604)	TCustomAdapterFileField is a base class for adapter fields that can have associated files.
	TCustomAdapterGotoPageAction (see page 5614)	TCustomAdapterGotoPageAction is an adapter action that supports commands to go to a page of a TDefaultFieldsPagedAdapter (see page 5747).
	TCustomAdapterImageField (see page 5623)	TCustomAdapterImageField is a base class for adapter fields that have an associated image file.
	TCustomAdapterMemoField (see page 5638)	TCustomAdapterMemoField is a base class for adapter fields that have a multi-line text value.
	TCustomAdapterMultiValueField (see page 5646)	TCustomAdapterMultiValueField is a base class for adapter fields that have one or more values.
	TCustomAdapterPageAction (see page 5656)	TCustomPagedAdapterAction (see page 5722) is a base class for adapter actions that execute the next or previous page commands.
	TCustomApplicationAdapter (see page 5663)	TCustomApplicationAdapter is a base class for components that implement the server-side script Application object.
	TCustomApplicationAdapterAction (see page 5671)	TCustomApplicationAdapterAction is a base class for adapter actions that work with descendants of TCustomApplicationAdapter (see page 5663).
	TCustomEndUserAdapter (see page 5676)	TCustomEndUserAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TCustomEndUserAdapterAction (see page 5687)	TCustomEndUserAdapterAction is a base class for adapter actions that work with descendants of TCustomEndUserAdapter (see page 5676).
	TCustomEndUserSessionAdapter (see page 5692)	TCustomEndUserSessionAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TCustomLoginFormAdapter (see page 5701)	TCustomLoginFormAdapter is the base class for adapters that manage the fields and actions of a login form.
	TCustomLoginFormAdapterAction (see page 5717)	TCustomEndUserAdapterAction (see page 5687) is a base class for adapter actions that work with descendants of TCustomLoginFormAdapter (see page 5701).
	TCustomPagedAdapter (see page 5721)	TCustomPagedAdapter is a base class for adapters that support paging.
	TCustomPagedAdapterAction (see page 5722)	TCustomPagedAdapterAction is a base class for adapter actions that work with descendants of TDefaultFieldsPagedAdapter (see page 5747).
	TCustomStringsValuesList (see page 5728)	TCustomStringsValuesList is a base class for a values list that defines it's name/value pairs using a string list.
	TDefaultFieldsAdapter (see page 5738)	TDefaultFieldsAdapter is a base class for adapters that automatically adds default fields and/or actions.
	TDefaultFieldsPagedAdapter (see page 5747)	TDefaultFieldsPagedAdapter is a base class for adapters that support paging.

	TEndUserAdapter (see page 5764)	TEndUserAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TEndUserAdapterLoginFormAction (see page 5776)	TEndUserAdapterLoginFormAction is an adapter action that displays a login form when executed.
	TEndUserAdapterLogoutAction (see page 5784)	TEndUserAdapterLogoutAction is an adapter action that logs the end-user out.
	TEndUserSessionAdapter (see page 5792)	TEndUserSessionAdapter provides information about the current end user such as the user name, user ID, and whether the user is logged in.
	TFieldValuesAdapter (see page 5803)	TFieldValuesAdapter is an adapter that includes a single field value.
	TFieldValuesValueField (see page 5813)	TFieldValuesValueField is a adapter field child of TFieldValuesAdapter (see page 5803).
	TImplementedAdapterAction (see page 5818)	TImplementedAdapterAction is a base class for adapter actions.
	TLogicalPageList (see page 5819)	This is class WebAdapt.TLogicalPageList.
	TLoginFormAdapter (see page 5824)	TLoginFormAdapter contains the adapter fields and adapter actions used to generate a login form.
	TLoginFormAdapterLoginAction (see page 5835)	TLoginFormAdapterLoginAction executes the login command of a login form generated with TLoginFormAdapter (see page 5824).
	TPagedAdapter (see page 5844)	TPagedAdapter divides a large amount of data into several pages, each page displaying a portion of the data records.
	TStringsValuesList (see page 5857)	TStringsValuesList is an adapter component that provides a list of name/value pairs defined by items in a TStrings property.
	TUpdateFileList (see page 5864)	TUpdateFileList is a container for uploaded files.
	TValuesListNameField (see page 5866)	TValuesListNameField is an adapter field used to access the Name of the current list item of a values list adapter.
	TValuesListValueField (see page 5869)	TValuesListValueField is an adapter field used to access the Value (see page 5369) of the current list item of a values list adapter.

54.1.1 EAdapterException Class

EAdapterException is raised by WebSnap adapter objects.

Class Hierarchy

Pascal

```
EAdapterException = class(EWebBrokerException);
```

C++

```
class EAdapterException : public EWebBrokerException;
```

File

WebAdapt

Description

EAdapterException is raised when a WebSnap adapter object encounters an error. EAdapterException provides an ID (see page 5178) property to record application-defined errors.

54.1.1.1 EAdapterException Members

The following tables list the members exposed by EAdapterException.

Public Methods

	Name	Description
	CreateID (see page 5178)	Create exception object with error ID (see page 5178).

Public Properties

	Name	Description
	ID (see page 5178)	Application error ID.

54.1.1.2 EAdapterException.CreateID Constructor

Create exception object with error ID (see page 5178).

Pascal

```
constructor CreateID(const AMsg: string; AID: Integer; Reserved: Integer = 0);
```

C++

```
__fastcall EAdapterException(const UnicodeString AMsg, int AID, int Reserved = 0);
```

Description

CreateID creates an EAdapterException (see page 5177) object in the usual way, and also assigns AID to the ID (see page 5178) property.

Reserved is not implemented.

54.1.1.3 EAdapterException Properties

The properties of the EAdapterException class are listed here.

Public Properties

	Name	Description
	ID (see page 5178)	Application error ID.

54.1.1.3.1 EAdapterException.ID Property

Application error ID.

Pascal

```
property ID: Integer;
```

C++

```
__property int ID;
```

Description

The ID property returns an application-defined value relating to the error. To specify an ID value, create an EAdapterException (see page 5177) object using the CreateID (see page 5178) constructor (Delphi) or the constructor syntax that includes an ID as a parameter (C++). For exceptions raised by built-in WebSnap adapters, ID is always 0.

See Also

CreateID (see page 5178)

54.1.2 EAdapterFieldException Class

EAdapterFieldException is an exception class for errors by adapters using fields.

Class Hierarchy

Pascal

```
EAdapterFieldException = class(EAdapterException);
```

C++

```
class EAdapterFieldException : public EAdapterException;
```

File

WebAdapt

Description

EAdapterFieldException is raised when an adapter encounters an error using a field.

54.1.2.1 EAdapterFieldException Members

The following tables list the members exposed by EAdapterFieldException.

Public Methods

	Name	Description
	Create (see page 5179)	Create an EAdapterFieldException (see page 5178) instance.
	CreateID (see page 5178)	Create exception object with error ID (see page 5178).

Public Properties

	Name	Description
	FieldName (see page 5180)	FieldName contains the name of the field associated with the error.
	ID (see page 5178)	Application error ID.

54.1.2.2 EAdapterFieldException.Create Constructor

Create an EAdapterFieldException (see page 5178) instance.

Pascal

```
constructor Create(const AMsg: string; const AFieldName: string; AID: Integer = 0);
```

C++

```
__fastcall EAdapterFieldException(const UnicodeString AMsg, const UnicodeString AFieldName,
int AID = 0);
```

Description

Create instantiates an instance of EAdapterFieldException (see page 5178).

AMsg is the string containing the runtime error message to display in the exception dialog box. AMsg can be a hard-coded string, or can be a function call that returns a string.

AFieldName and AID are assigned to the FieldName (see page 5180) and ID (see page 5178) properties.

See Also

FieldName (see page 5180)

ID (see page 5178)

54.1.2.3 EAdapterFieldException Properties

The properties of the EAdapterFieldException class are listed here.

Public Properties

	Name	Description
	FieldName (see page 5180)	FieldName contains the name of the field associated with the error.

54.1.2.3.1 EAdapterFieldException.FieldName Property

FieldName contains the name of the field associated with the error.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;
```

Description

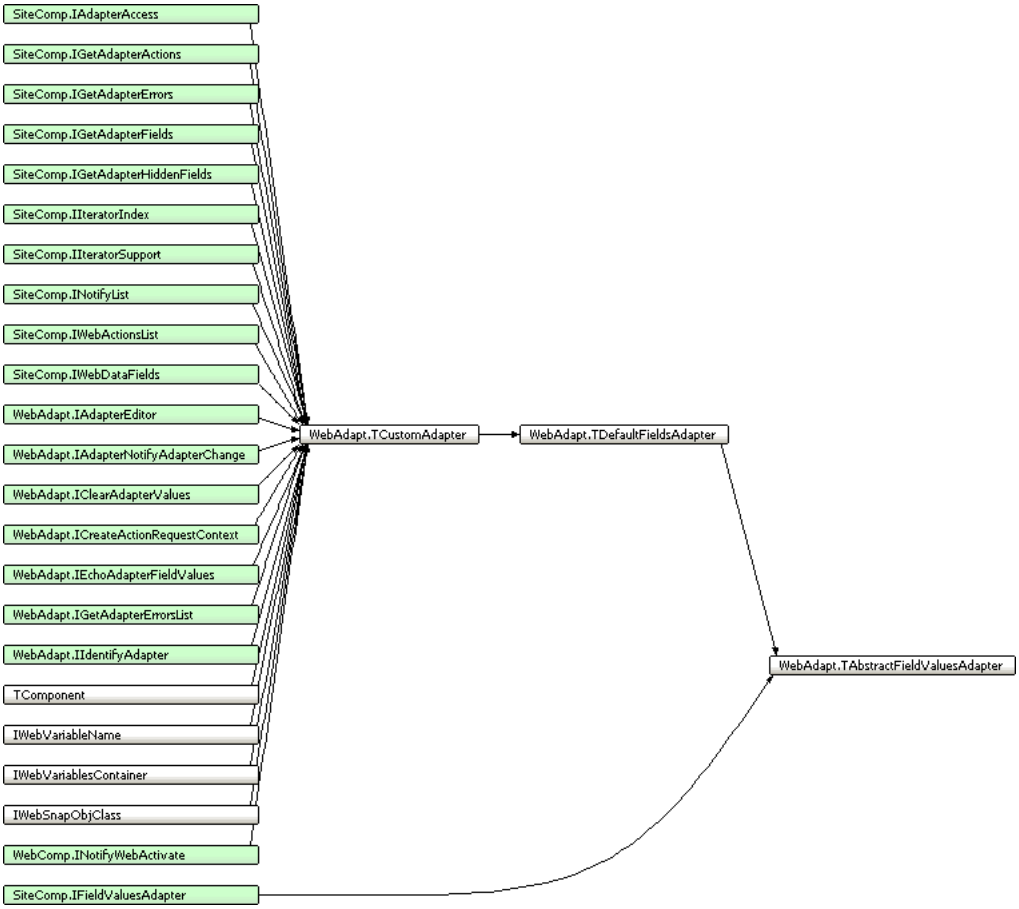
```
__property AnsiString FieldName = {read=FFieldName, write=FFieldName};
property FieldName: string;
```

FieldName contains the name of the field associated with the error.

54.1.3 TAbstractFieldValuesAdapter Class

TAbstractFieldValuesAdapter is the base class for adapters that have a single default field.

Class Hierarchy



Pascal

```
TAbstractFieldValuesAdapter = class(TDefaultFieldsAdapter, IFieldValuesAdapter);
```

C++

```
class TAbstractFieldValuesAdapter : public TDefaultFieldsAdapter, public IFieldValuesAdapter;
```

File

WebAdapt

Description

Derive from TAbstractFieldValuesAdapter to define adapter components that automatically include a single adapter field called ‘ValueField'.

Do not use TAbstractFieldValuesAdpter directly. It includes many abstract or, in C++ parlance, pure virtual methods, which must be implemented by a descendant class such as TFieldValuesAdapter (see page 5803).

See Also

TFieldValuesAdapter (see page 5803)

54.1.3.1 TAbstractFieldValuesAdapter Members

The following tables list the members exposed by TAbstractFieldValuesAdapter.

Protected Methods

	Name	Description
	AddAdapterModeHiddenField (see page 5538)	Defines a hidden field that passes the adapter's mode value in the HTTP request when an HTML form is submitted.
	AddDefaultActions (see page 5743)	Adds default action components to this adapter.
	AddDefaultFields (see page 5744)	Adds default field components to this adapter.
	AddOrigValueHiddenFields (see page 5539)	Defines hidden field(s) that pass the original values of adapter fields in the HTTP request when an HTML form is submitted.
	AddRecordKeysHiddenFields (see page 5539)	Defines hidden field(s) that pass key values in the HTTP request when an HTML form is submitted.
	CanAddActionClass (see page 5539)	Indicates whether a type of adapter action can be added to this adapter.
	CanAddFieldClass (see page 5540)	Indicates whether a type of adapter field can be added to this adapter.
	CheckModifyAccess (see page 5540)	Checks end-user rights to modify the adapter's field values.
	ClearAdapterValues (see page 5540)	Clears adapter state information.
	ClearErrors (see page 5541)	Clears the content of the adapter's Errors (see page 5573) property.
	CreateActionRequestContext (see page 5541)	Creates an object that describes the adapter action parameters and adapter field values.
	CreateErrorsList (see page 5542)	Creates the object used to manage errors associated with this adapter.
	DefaultWebComponentsChange (see page 5744)	Notifies other components of changes to the list of default actions or fields.
	EncodeActionParams (see page 5542)	Writes name/value pairs that represent adapter state.
	EndIterator (see page 5542)	Implements IIteratorSupport (see page 1054)'s EndIterator method to support iterating over the data records of the adapter.
	ExtractRequestParams (see page 5543)	Reads name/value pairs from the HTTP request.
	FindAction (see page 5543)	Returns an action component with a matching action name.
	FindField (see page 5543)	Returns an adapter field component with a matching field name.
	FindNamedAction (see page 5544)	Finds an action with a matching variable name.
	FindNamedField (see page 5544)	Finds an adapter field with a matching variable name.
	FindNamedVariable (see page 5544)	Finds a field or action with a matching variable name.
	FindVariable (see page 5545)	Finds an adapter action or adapter field with the given variable name.
	FindVariableContainer (see page 5545)	Finds an adapter action or adapter field that is a container for other scriptable objects.
	GetActionsClass (see page 5545)	Specifies the class to create as a container for adapter actions components.
	GetActionsClass (see page 5744)	Specifies the class to create as a container for adapter actions components.
	GetActionsList (see page 5546)	Provides a list of action types that can be added to this adapter.
	GetAdapterActions (see page 5546)	Returns the adapter actions container object.
	GetAdapterErrors (see page 5546)	Returns the adapter's errors object.
	GetAdapterErrorsList (see page 5547)	<insert text here>
	GetAdapterFields (see page 5547)	Returns the adapter fields container object.
	GetAdapterHiddenFields (see page 5547)	Returns a list of hidden fields that hold adapter state information.
	GetAdapterHiddenRecordFields (see page 5548)	Returns a list of hidden fields that associate HTML form fields and adapter field.
	GetChildren (see page 5548)	Provides the interface for a method that adapters use to return their child components.
	GetDataClass (see page 5548)	Specifies the class to create as a container for adapter fields components.
	GetDataClass (see page 5745)	Specifies the class to create as a container for adapter field components.
	GetEchoActionFieldValues (see page 5549)	Returns the value of the echo flag.
	GetField (see page 5186)	Returns the object that represents the single field of this adapter.
	GetFieldsList (see page 5549)	Provides a list of field types that can be added to this adapter.
	GetHiddenFieldOptions (see page 5549)	Indicates the types of hidden fields that this adapter requires in a submitted HTML form.
	GetIteratorIndex (see page 5550)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method to support iterating over the data records of the adapter.

A	GetValueFieldClass (see page 5186)	Returns the class of the single adapter field this adapter includes.
	GetValueIndex (see page 5187)	Returns an index that identifies the current adapter field value.
	GetVariable (see page 5550)	Returns an action or field.
	GetVariableCount (see page 5550)	Returns the total count of actions and fields.
	GetVariableName (see page 5551)	Gets the name used to reference this adapter with server-side script.
	GetVisibleActions (see page 5551)	Returns a list of this adapter's action components.
	GetVisibleFields (see page 5551)	Returns a list of this adapter's field components.
V	GetWebSnapObjClass (see page 5552)	Returns the class type for this adapter field.
	HasExecuteAccess (see page 5552)	Checks the end-user's right to execute this adapter's actions.
	HasModifyAccess (see page 5552)	Checks the end-user's right to modify this adapter's fields.
	HasViewAccess (see page 5553)	Checks the end-user's right to view this adapter's fields.
V	ImplCanAddActionClass (see page 5553)	Indicates whether a type of adapter action can be added to this adapter.
V	ImplCanAddFieldClass (see page 5187)	Provides the underlying implementation for the CanAddFieldClass (see page 5540) method.
V	ImplClearAdapterValues (see page 5554)	Clears adapter state information.
V	ImplEndIterator (see page 5188)	Provides the underlying implementation for the EndIterator (see page 5542) method.
V	ImplFindVariable (see page 5554)	Finds an adapter action or adapter field child with a matching variable name.
V	ImplFindVariableContainer (see page 5555)	Finds an adapter action or adapter field that is a container for other scriptable objects.
V	ImplGetActionsList (see page 5555)	Provides a list of action types that can be added to this adapter.
V	ImplGetEchoActionFieldValues (see page 5555)	Returns the value of the echo flag.
A	ImplGetField (see page 5188)	Provides the underlying implementation for the GetField (see page 5186) method.
V	ImplGetFieldsList (see page 5188)	Provides the underlying implementation for the GetFieldsList (see page 5549) method.
V	ImplGetIteratorIndex (see page 5556)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5550) method to support iterating over the data records of the adapter.
A	ImplGetValueIndex (see page 5189)	Provides the underlying implementation for the GetValueIndex (see page 5187) method.
V	ImplGetVariable (see page 5556)	Returns an action or field.
V	ImplGetVariableCount (see page 5557)	Returns the total count of actions and fields.
V	ImplGetVariableName (see page 5557)	Gets the name used to reference this adapter with server-side script.
V	ImplGetVisibleActions (see page 5557)	Returns a list of this adapter's action components.
V	ImplGetVisibleActions (see page 5745)	Returns a list of this adapter's action components.
V	ImplGetVisibleFields (see page 5558)	Returns a list of this adapter's field components.
V	ImplGetVisibleFields (see page 5745)	Returns a list of this adapter's field components.
V	ImplHasExecuteAccess (see page 5558)	Checks the end-user's right to execute this adapter's actions.
V	ImplHasModifyAccess (see page 5558)	Checks the end-user's right to modify this adapter's fields.
V	ImplHasViewAccess (see page 5559)	Checks the end-user's right to view this adapter's fields.
V	ImplInIterator (see page 5559)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5562) to support iterating over the data records of the adapter.
V	ImplNextIteration (see page 5189)	Provides the underlying implementation for the NextIteration (see page 5564) method.
V	ImplNotifyActivate (see page 5560)	Called when the web module is activated.
V	ImplNotifyDeactivate (see page 5560)	Called when the web module is deactivated.
V	ImplSetActions (see page 5561)	Initializes the Actions (see page 5572) property.
V	ImplSetActions (see page 5746)	Initializes the Actions (see page 5746) property.
V	ImplSetData (see page 5561)	Initializes the Data (see page 5572) property.
V	ImplSetData (see page 5746)	Initializes the Data (see page 5747) property.
V	ImplSetEchoActionFieldValues (see page 5561)	Sets the echo flag for this adapter's fields.
V	ImplStartIterator (see page 5190)	Provides the underlying implementation for the StartIterator (see page 5567) method.
	InIterator (see page 5562)	Implements IIteratorIndex (see page 1052)'s InIterator method to support iterating over the data records of the adapter.
	IsActionInUse (see page 5563)	Indicates whether a particular action has been added to the adapter.
	IsFieldInUse (see page 5563)	Indicates whether a particular field has been added to the adapter.
	ListHiddenFields (see page 5563)	Specifies the HTML form hidden fields needed by the adapter.

	ListHiddenRecordFields (see page 5564)	Specifies the HTML form hidden fields needed by the adapter.
	NextIteration (see page 5564)	Implements IIteratorSupport (see page 1054)'s NextIteration method to support iterating over the data records of the adapter.
V	Notification (see page 5565)	Clears references to deleted components.
	NotifyActivate (see page 5565)	Called when the web module is activated.
	NotifyAdapterChange (see page 5565)	Notifies components that the adapter has changed in some way.
	NotifyDeactivate (see page 5566)	Called when the web module is deactivated.
	SetActions (see page 5566)	Initializes the Actions (see page 5572) property.
V	SetData (see page 5566)	Initializes the Data (see page 5572) property.
	SetEchoActionFieldValues (see page 5567)	Sets the echo flag for this adapter's fields.
	StartIterator (see page 5567)	Implements IIteratorSupport (see page 1054)'s StartIterator method to support iterating over the records of the adapter.
V	UpdateFieldsExecuteValues (see page 5567)	Executes the adapter's fields with values passed in the HTTP request.
V	UpdateFieldsGetAnyChanges (see page 5568)	Determines whether the values in the HTTP request change any adapter fields.
V	UpdateFieldsUpdateValues (see page 5568)	Updates the adapter's fields with values passed in the HTTP request.
V	UpdateFieldsValidateValues (see page 5569)	Validate the adapter's field values passed in the HTTP request.
V	UpdateRecordsGetAnyChanges (see page 5570)	Determines whether values passed in the HTTP request will change any adapter fields.
V	UpdateRecordsUpdateValues (see page 5570)	Updates adapter fields with values passed in the HTTP request.
V	UpdateRecordsValidateValues (see page 5571)	Validate the adapter's field values passed in the HTTP request.
	WebComponentsChange (see page 5571)	WebComponentsChange is called when the list of adapter fields or adapter actions changes.

Protected Properties

	Name	Description
R	NotifyList (see page 5574)	Keeps track of components that are to be notified when the adapter is changed.
R	VisibleActions (see page 5575)	Returns a list of this adapter's action components.
R	VisibleFields (see page 5575)	Returns a list of this adapter's field components.

Public Events

	Name	Description
	OnAfterExecuteAction (see page 5576)	Occurs after an adapter action has executed.
	OnAfterGetActionResponse (see page 5576)	Occurs after the adapter action response is generated.
	OnAfterUpdateFields (see page 5576)	Occurs after values in the HTTP request are used to update adapter fields.
	OnAfterValidateFields (see page 5577)	Occurs after values in the HTTP request are validated by the adapter's fields.
	OnBeforeExecuteAction (see page 5577)	Occurs before an adapter action is executed.
	OnBeforeGetActionResponse (see page 5578)	Occurs before the adapter action response is generated.
	OnBeforeUpdateFields (see page 5578)	Occurs before values in the HTTP request are used to update adapter fields.
	OnBeforeValidateFields (see page 5578)	Occurs before values in the HTTP request are validated by the adapter's fields.
	OnGetActionParams (see page 5579)	Supplies name/value pairs needed to execute an adapter action.
	OnIterateRecords (see page 5579)	Occurs when the adapter needs to iterate over its data records.

Public Methods

	Name	Description
	AddNotify (see page 1059)	Registers an interest in change notifications.
	CanAddActionClass (see page 5875)	This is CanAddActionClass, a member of class IAdapterEditor.
	CanAddFieldClass (see page 5875)	This is CanAddFieldClass, a member of class IAdapterEditor.
	ClearAdapterValues (see page 5879)	This is ClearAdapterValues, a member of class IClearAdapterValues.
V	Create (see page 5536)	Constructor for TCustomAdapter (see page 5531).
	CreateActionRequestContext (see page 5880)	This is CreateActionRequestContext, a member of class ICreateActionRequestContext.
V	Destroy (see page 5536)	Destructor for TCustomAdapter (see page 5531).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	FindAction (see page 1077)	This is FindAction, a member of class IWebActionsList.
	FindField (see page 1082)	This is FindField, a member of class IWebDataFields.
	GetActionsList (see page 1077)	This is GetActionsList, a member of class IWebActionsList.

	GetAdapterActions (see page 1018)	This is GetAdapterActions, a member of class IGetAdapterActions.
	GetAdapterErrors (see page 1020)	This is GetAdapterErrors, a member of class IGetAdapterErrors.
	GetAdapterErrorsList (see page 5886)	This is GetAdapterErrorsList, a member of class IGetAdapterErrorsList.
	GetAdapterFields (see page 1021)	This is GetAdapterFields, a member of class IGetAdapterFields.
	GetAdapterHiddenFields (see page 1022)	This is GetAdapterHiddenFields, a member of class IGetAdapterHiddenFields.
	GetAdapterHiddenRecordFields (see page 1022)	This is GetAdapterHiddenRecordFields, a member of class IGetAdapterHiddenFields.
	GetEchoActionFieldValues (see page 5883)	This is GetEchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	GetFieldsList (see page 1082)	This is GetFieldsList, a member of class IWebDataFields.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
	GetVisibleActions (see page 1077)	This is GetVisibleActions, a member of class IWebActionsList.
	GetVisibleFields (see page 1083)	This is GetVisibleFields, a member of class IWebDataFields.
	HasExecuteAccess (see page 982)	This is HasExecuteAccess, a member of class IAdapterAccess.
	HasModifyAccess (see page 982)	This is HasModifyAccess, a member of class IAdapterAccess.
	HasViewAccess (see page 982)	This is HasViewAccess, a member of class IAdapterAccess.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.
	IsActionInUse (see page 1078)	This is IsActionInUse, a member of class IWebActionsList.
	IsFieldInUse (see page 1083)	This is IsFieldInUse, a member of class IWebDataFields.
	NextIteration (see page 1056)	Advances to the objects next item.
	NotifyActivate (see page 6089)	This is NotifyActivate, a member of class INotifyWebActivate.
	NotifyAdapterChange (see page 5876)	This is NotifyAdapterChange, a member of class IAdapterNotifyAdapterChange.
	NotifyDeactivate (see page 6089)	This is NotifyDeactivate, a member of class INotifyWebActivate.
	RemoveNotify (see page 1059)	Unregisters interest in change notifications.
	SetEchoActionFieldValues (see page 5883)	This is SetEchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
V	UpdateRecords (see page 5569)	Updates the adapter's fields with the field values passed in an HTTP request.

Public Properties

	Name	Description
R	Actions (see page 5572)	Actions is the container for adapter actions components.
R	Actions (see page 5746)	Container for adapter actions components.
R	Data (see page 5572)	Data is the container for adapter field components.
R	Data (see page 5747)	Container for adapter field components.
	EchoActionFieldValues (see page 5883)	This is EchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	EchoActionFieldValues (see page 5572)	Modifies the adapter's echo flag.
R	Errors (see page 5573)	Returns an object used to track errors on behalf of this adapter.
	ExecuteAccess (see page 5573)	Defines the rights required to execute this adapter's action.
R	IteratorIndex (see page 1054)	Indicates the index of the current item.
	ModifyAccess (see page 5574)	Identifies the rights required to update this adapter's fields.
	ViewAccess (see page 5574)	Identifies the rights required to view this adapter's fields.
R	VisibleActions (see page 1078)	This is VisibleActions, a member of class IWebActionsList.
R	VisibleFields (see page 1083)	This is VisibleFields, a member of class IWebDataFields.

54.1.3.2 TAbstractFieldValuesAdapter Methods

The methods of the TAbstractFieldValuesAdapter class are listed here.

Protected Methods

	Name	Description
	GetField (see page 5186)	Returns the object that represents the single field of this adapter.
A	GetValueFieldClass (see page 5186)	Returns the class of the single adapter field this adapter includes.
	GetValueIndex (see page 5187)	Returns an index that identifies the current adapter field value.
V	ImplCanAddFieldClass (see page 5187)	Provides the underlying implementation for the CanAddFieldClass (see page 5540) method.

	ImplEndIterator (see page 5188)	Provides the underlying implementation for the EndIterator (see page 5542) method.
	ImplGetField (see page 5188)	Provides the underlying implementation for the GetField (see page 5186) method.
	ImplGetFieldsList (see page 5188)	Provides the underlying implementation for the GetFieldsList (see page 5549) method.
	ImplGetValueIndex (see page 5189)	Provides the underlying implementation for the GetValueIndex (see page 5187) method.
	ImplNextIteration (see page 5189)	Provides the underlying implementation for the NextIteration (see page 5564) method.
	ImplStartIterator (see page 5190)	Provides the underlying implementation for the StartIterator (see page 5567) method.

54.1.3.2.1 TAbstractFieldValuesAdapter.GetField Method

Returns the object that represents the single field of this adapter.

Pascal

```
function GetField: TObject;
```

C++

```
__fastcall TObject * GetField();
```

Description

Call GetField to access the single field for this adapter. GetField returns an adapter field that is an instance of the class that the GetValueFieldClass (see page 5186) method returns.

GetField calls the abstract or, in C++ terminology, pure virtual ImplGetField (see page 5188) method to obtain the adapter field instance it returns. Descendant classes override ImplGetField (see page 5188) to provide the underlying implementation for GetField.

See Also

ImplGetField (see page 5188)

GetValueFieldClass (see page 5186)

54.1.3.2.2 TAbstractFieldValuesAdapter.GetValueFieldClass Method

Returns the class of the single adapter field this adapter includes.

Pascal

```
function GetValueFieldClass: TComponentClass; virtual; abstract;
```

C++

```
virtual __fastcall TComponentClass GetValueFieldClass() = 0;
```

Description

GetValueFieldClass returns the class reference for the type of the single adapter field that the GetField (see page 5186) method returns. The return value must be a descendant of TComponent and is typically a descendant of TAdapterNamedField (see page 5351).

In TAbstractFieldValuesAdapter (see page 5180), GetValueFieldClass is abstract or, in C++ terminology, pure virtual. Descendant classes must override this method to indicate the type of field this adapter includes.

See Also

GetField (see page 5186)

TAdapterNamedField (see page 5351)

54.1.3.2.3 TAbstractFieldValuesAdapter.GetValueIndex Method

Returns an index that identifies the current adapter field value.

Pascal

```
function GetValueIndex: Integer;
```

C++

```
__fastcall int GetValueIndex();
```

Description

Although this adapter only includes a single adapter field, that field may have several values (for example, if it represents a column in a table). When the field has several values, GetValueIndex is the index of the current value. This index may be the same as the value that the GetIteratorIndex (see page 5550) method returns if the application is using the adapter's iteration support. However, TAbstractFieldValuesAdapter (see page 5180) introduces GetValueIndex as a separate method for descendants that support multiple values that change using some other mechanism.

GetValueIndex calls the abstract or, in C++ terminology, pure virtual ImplGetValueIndex (see page 5189) method to obtain the index of the current value. Descendant classes override ImplGetValueIndex (see page 5189) to provide the underlying implementation for GetValueIndex.

See Also

ImplGetValueIndex (see page 5189)

GetIteratorIndex (see page 5550)

54.1.3.2.4 TAbstractFieldValuesAdapter.ImplCanAddFieldClass Method

Provides the underlying implementation for the CanAddFieldClass (see page 5540) method.

Pascal

```
function ImplCanAddFieldClass(AParent: TComponent; AClass: TClass): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplCanAddFieldClass(TComponent * AParent, TClass AClass);
```

Description

The CanAddFieldClass (see page 5540) method calls ImplCanAddFieldClass to determine whether this adapter can include a field that is an instance of a specified class. This allows the adapter editor to indicate the available fields at design time.

AParent is an instance of this adapter class to which the field is to be added.

AClass is the class of the object that represents the adapter field.

ImplCanAddFieldClass returns true if AClass is the same as (or a descendant of) the class that the GetValueFieldClass (see page 5186) method returns, indicating that this is the only child field this adapter supports. It returns false for any other class.

See Also

CanAddFieldClass (see page 5540)

GetValueFieldClass (see page 5186)

54.1.3.2.5 TAbstractFieldValuesAdapter.ImplEndIterator Method

Provides the underlying implementation for the EndIterator (see page 5542) method.

Pascal

```
procedure ImplEndIterator(OwnerData: Pointer); override;
```

C++

```
virtual __fastcall ImplEndIterator(void * OwnerData);
```

Description

The EndIterator (see page 5542) method calls ImplEndIterator to stop the process of iterating through the adapter's field's possible values.

OwnerData is a pointer to adapter-specific data that can affect the way it iterates over field values. Each adapter can interpret this value in its own way.

ImplEndIterator raises an exception, because this method should never be called at the TAbstractFieldValuesAdapter (see page 5180) level: The TAbstractFieldValuesAdapter (see page 5180) ImplStartIterator (see page 5190) method returns false, indicating that this adapter does not support iteration.

Descendant classes that implement support for iterating over field values override this method to end that iteration process.

See Also

EndIterator (see page 5542)

ImplStartIterator (see page 5190)

ImplNextIteration (see page 5189)

54.1.3.2.6 TAbstractFieldValuesAdapter.ImplGetField Method

Provides the underlying implementation for the GetField (see page 5186) method.

Pascal

```
function ImplGetField: TObject; virtual; abstract;
```

C++

```
virtual __fastcall TObject * ImplGetField() = 0;
```

Description

The GetField (see page 5186) method calls ImplGetField to obtain the object that represents this adapter's single field. Unlike the GetField (see page 5186) method, ImplGetField is virtual, so that descendant classes can override it to provide a class-specific mechanism for obtaining the adapter field object.

In TAbstractFieldValuesAdapter (see page 5180), ImplGetField is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the GetField (see page 5186) method.

See Also

GetField (see page 5186)

54.1.3.2.7 TAbstractFieldValuesAdapter.ImplGetFieldsList Method

Provides the underlying implementation for the GetFieldsList (see page 5549) method.

Pascal

```
procedure ImplGetFieldsList(AList: TStrings); override;
```

C++

```
virtual __fastcall ImplGetFieldsList(TStrings AList);
```

Description

The GetFieldsList (see page 5549) method calls ImplGetFieldsList to fill a string list with a list of all fields that the adapter includes. Each entry in the list is the name of one of the adapter's field, and has an associated object that is the class of the object that represents that adapter field. GetFieldsList (see page 5549) is part of the design-time support for editing adapters.

AList is an existing string list to fill with entries for all of the fields this adapter can include.

In TAbstractFieldValuesAdapter (see page 5180), ImplGetFieldsList clears AList and inserts a single entry for a field named 'ValueField'. It associates the class that the GetValueFieldClass (see page 5186) method returns with this field name.

See Also

GetValueFieldClass (see page 5186)

GetFieldsList (see page 5549)

54.1.3.2.8 TAbstractFieldValuesAdapter.ImplGetValueIndex Method

Provides the underlying implementation for the GetValueIndex (see page 5187) method.

Pascal

```
function ImplGetValueIndex: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int ImplGetValueIndex() = 0;
```

Description

The GetValueIndex (see page 5187) method calls ImplGetValueIndex to obtain the index of current value of this adapter's single field. Unlike the GetValueIndex (see page 5187) method, ImplGetValueIndex is virtual, so that descendant classes can override it to provide a class-specific mechanism for obtaining this index.

In TAbstractFieldValuesAdapter (see page 5180), ImplGetValueIndex is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the GetValueIndex (see page 5187) method.

See Also

GetValueIndex (see page 5187)

54.1.3.2.9 TAbstractFieldValuesAdapter.ImplNextIteration Method

Provides the underlying implementation for the NextIteration (see page 5564) method.

Pascal

```
function ImplNextIteration(var OwnerData: Pointer): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplNextIteration(void * OwnerData);
```

Description

The NextIteration (see page 5564) method calls ImplNextIteration when iterating over field values to determine whether there

is another field value after the current one and if so, to change the current value to the next one.

OwnerData is a pointer to adapter-specific data that can affect the way it iterates over field values. On entry, this value is typically the same as the value returned by the last call to NextIteration (see page 5564) or to StartIterator (see page 5567).

In TAbstractFieldValuesAdapter (see page 5180), ImplNextIteration always returns false, because TAbstractFieldValuesAdapter (see page 5180) does not implement support for iteration. Descendant classes that support iterating over field values override this method to check whether their is a next value and if so, move to it.

See Also

NextIteration (see page 5564)

ImplStartIterator (see page 5190)

ImplEndIterator (see page 5188)

54.1.3.2.10 TAbstractFieldValuesAdapter.ImplStartIterator Method

Provides the underlying implementation for the StartIterator (see page 5567) method.

Pascal

```
function ImplStartIterator(var OwnerData: Pointer): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplStartIterator(void * OwnerData);
```

Description

The StartIterator (see page 5567) method calls ImplStartIterator to start the process of iterating through the adapter's field's possible values. The return value indicates whether the adapter's field has any values over which to iterate.

OwnerData is a pointer to adapter-specific data that can affect the way it iterates over field values. Each adapter can interpret this value in its own way. Depending on the adapter, it may be supplied by the caller, or created by the ImplStartIterator method.

In TAbstractFieldValuesAdapter (see page 5180), ImplNextIteration (see page 5189) always returns false, because TAbstractFieldValuesAdapter (see page 5180) does not implement support for obtaining any field values. Descendant classes that override this method to check whether they can move to the first value in the field's set of values. If so, they move to the first value and return true. Otherwise they return false.

See Also

StartIterator (see page 5567)

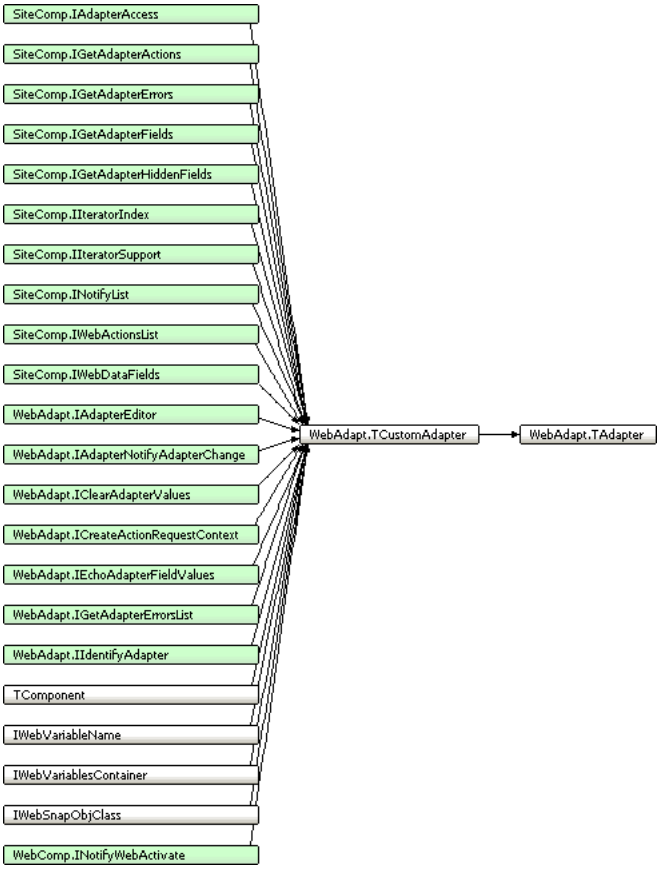
ImplEndIterator (see page 5188)

ImplNextIteration (see page 5189)

54.1.4 TAdapter Class

TAdapter defines a scriptable interface to event handlers that return data items or execute commands in your application.

Class Hierarchy



Pascal

```
TAdapter = class(TCustomAdapter);
```

C++

```
class TAdapter : public TCustomAdapter;
```

File

WebAdapt

Description

Use TAdapter to define a custom interface to application logic. Adapters contain field components and action components that represent data items and commands, respectively. Server-side script statements access the value of Adapter fields and the parameters of Adapter actions in order to build HTML forms and tables. Server-side script can be written by hand or automatically generated by the TAdapterPageProducer component. When an HTML form containing Adapter commands is submitted, the TAdapterDispatcher may automatically call an Adapter action component to execute the command. When an HTTP request for an adapter image field is received the TAdapterDispatcher may automatically call an Adapter field to retrieve the image.

For each field component added to TAdapter, you must implement an event handler to retrieve the data. For each action component added to TAdapter, you must implement an event handler to execute the command. Other adapter components, such as TDataSetAdapter and TLoginFormAdapter (see page 5824), have built in fields and actions that do not require events.

54.1.4.1 TAdapter Members

The following tables list the members exposed by TAdapter.

Protected Methods

	Name	Description
	AddAdapterModeHiddenField (see page 5538)	Defines a hidden field that passes the adapter's mode value in the HTTP request when an HTML form is submitted.
	AddOrigValueHiddenFields (see page 5539)	Defines hidden field(s) that pass the original values of adapter fields in the HTTP request when an HTML form is submitted.
	AddRecordKeysHiddenFields (see page 5539)	Defines hidden field(s) that pass key values in the HTTP request when an HTML form is submitted.
	CanAddActionClass (see page 5539)	Indicates whether a type of adapter action can be added to this adapter.
	CanAddFieldClass (see page 5540)	Indicates whether a type of adapter field can be added to this adapter.
	CheckModifyAccess (see page 5540)	Checks end-user rights to modify the adapter's field values.
	ClearAdapterValues (see page 5540)	Clears adapter state information.
	ClearErrors (see page 5541)	Clears the content of the adapter's Errors (see page 5573) property.
	CreateActionRequestContext (see page 5541)	Creates an object that describes the adapter action parameters and adapter field values.
	CreateErrorsList (see page 5542)	Creates the object used to manage errors associated with this adapter.
	EncodeActionParams (see page 5542)	Writes name/value pairs that represent adapter state.
	EndIterator (see page 5542)	Implements IIteratorSupport (see page 1054)'s EndIterator method to support iterating over the data records of the adapter.
	ExtractRequestParams (see page 5543)	Reads name/value pairs from the HTTP request.
	FindAction (see page 5543)	Returns an action component with a matching action name.
	FindField (see page 5543)	Returns an adapter field component with a matching field name.
	FindNamedAction (see page 5544)	Finds an action with a matching variable name.
	FindNamedField (see page 5544)	Finds an adapter field with a matching variable name.
	FindNamedVariable (see page 5544)	Finds a field or action with a matching variable name.
	FindVariable (see page 5545)	Finds an adapter action or adapter field with the given variable name.
	FindVariableContainer (see page 5545)	Finds an adapter action or adapter field that is a container for other scriptable objects.
	GetActionsClass (see page 5545)	Specifies the class to create as a container for adapter actions components.
	GetActionsList (see page 5546)	Provides a list of action types that can be added to this adapter.
	GetAdapterActions (see page 5546)	Returns the adapter actions container object.
	GetAdapterErrors (see page 5546)	Returns the adapter's errors object.
	GetAdapterErrorsList (see page 5547)	<insert text here>
	GetAdapterFields (see page 5547)	Returns the adapter fields container object.
	GetAdapterHiddenFields (see page 5547)	Returns a list of hidden fields that hold adapter state information.
	GetAdapterHiddenRecordFields (see page 5548)	Returns a list of hidden fields that associate HTML form fields and adapter field.
	GetChildren (see page 5548)	Provides the interface for a method that adapters use to return their child components.
	GetDataClass (see page 5548)	Specifies the class to create as a container for adapter fields components.
	GetEchoActionFieldValues (see page 5549)	Returns the value of the echo flag.
	GetFieldsList (see page 5549)	Provides a list of field types that can be added to this adapter.
	GetHiddenFieldOptions (see page 5549)	Indicates the types of hidden fields that this adapter requires in a submitted HTML form.
	GetIteratorIndex (see page 5550)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method to support iterating over the data records of the adapter.
	GetVariable (see page 5550)	Returns an action or field.
	GetVariableCount (see page 5550)	Returns the total count of actions and fields.
	GetVariableName (see page 5551)	Gets the name used to reference this adapter with server-side script.
	GetVisibleActions (see page 5551)	Returns a list of this adapter's action components.
	GetVisibleFields (see page 5551)	Returns a list of this adapter's field components.
	GetWebSnapObjClass (see page 5552)	Returns the class type for this adapter field.

	HasExecuteAccess (see page 5552)	Checks the end-user's right to execute this adapter's actions.
	HasModifyAccess (see page 5552)	Checks the end-user's right to modify this adapter's fields.
	HasViewAccess (see page 5553)	Checks the end-user's right to view this adapter's fields.
V	ImplCanAddActionClass (see page 5553)	Indicates whether a type of adapter action can be added to this adapter.
V	ImplCanAddFieldClass (see page 5553)	Indicates whether a type of adapter field can be added to this adapter.
V	ImplClearAdapterValues (see page 5554)	Clears adapter state information.
V	ImplEndIterator (see page 5554)	Implements IIteratorSupport (see page 1054)'s EndIterator (see page 5542) method to support iterating over the data records of the adapter.
V	ImplFindVariable (see page 5554)	Finds an adapter action or adapter field child with a matching variable name.
V	ImplFindVariableContainer (see page 5555)	Finds an adapter action or adapter field that is a container for other scriptable objects.
V	ImplGetActionsList (see page 5555)	Provides a list of action types that can be added to this adapter.
V	ImplGetEchoActionFieldValues (see page 5555)	Returns the value of the echo flag.
V	ImplGetFieldsList (see page 5556)	Provides a list of field types that can be added to this adapter.
V	ImplGetIteratorIndex (see page 5556)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5550) method to support iterating over the data records of the adapter.
V	ImplGetVariable (see page 5556)	Returns an action or field.
V	ImplGetVariableCount (see page 5557)	Returns the total count of actions and fields.
V	ImplGetVariableName (see page 5557)	Gets the name used to reference this adapter with server-side script.
V	ImplGetVisibleActions (see page 5557)	Returns a list of this adapter's action components.
V	ImplGetVisibleFields (see page 5558)	Returns a list of this adapter's field components.
V	ImplHasExecuteAccess (see page 5558)	Checks the end-user's right to execute this adapter's actions.
V	ImplHasModifyAccess (see page 5558)	Checks the end-user's right to modify this adapter's fields.
V	ImplHasViewAccess (see page 5559)	Checks the end-user's right to view this adapter's fields.
V	ImplInIterator (see page 5559)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5562) to support iterating over the data records of the adapter.
V	ImplNextIteration (see page 5560)	Implements IIteratorSupport (see page 1054)'s NextIteration (see page 5564) method to support iterating over the records of the adapter.
V	ImplNotifyActivate (see page 5560)	Called when the web module is activated.
V	ImplNotifyDeactivate (see page 5560)	Called when the web module is deactivated.
V	ImplSetActions (see page 5561)	Initializes the Actions (see page 5572) property.
V	ImplSetData (see page 5561)	Initializes the Data (see page 5572) property.
V	ImplSetEchoActionFieldValues (see page 5561)	Sets the echo flag for this adapter's fields.
V	ImplStartIterator (see page 5562)	Implements IIteratorSupport (see page 1054)'s StartIterator (see page 5567) method to support iterating over the records of the adapter.
	InIterator (see page 5562)	Implements IIteratorIndex (see page 1052)'s InIterator method to support iterating over the data records of the adapter.
	IsActionInUse (see page 5563)	Indicates whether a particular action has been added to the adapter.
	IsFieldInUse (see page 5563)	Indicates whether a particular field has been added to the adapter.
	ListHiddenFields (see page 5563)	Specifies the HTML form hidden fields needed by the adapter.
	ListHiddenRecordFields (see page 5564)	Specifies the HTML form hidden fields needed by the adapter.
	NextIteration (see page 5564)	Implements IIteratorSupport (see page 1054)'s NextIteration method to support iterating over the data records of the adapter.
V	Notification (see page 5565)	Clears references to deleted components.
	NotifyActivate (see page 5565)	Called when the web module is activated.
	NotifyAdapterChange (see page 5565)	Notifies components that the adapter has changed in some way.
	NotifyDeactivate (see page 5566)	Called when the web module is deactivated.
	SetActions (see page 5566)	Initializes the Actions (see page 5572) property.
V	SetData (see page 5566)	Initializes the Data (see page 5572) property.
	SetEchoActionFieldValues (see page 5567)	Sets the echo flag for this adapter's fields.
	StartIterator (see page 5567)	Implements IIteratorSupport (see page 1054)'s StartIterator method to support iterating over the records of the adapter.
V	UpdateFieldsExecuteValues (see page 5567)	Executes the adapter's fields with values passed in the HTTP request.
V	UpdateFieldsGetAnyChanges (see page 5568)	Determines whether the values in the HTTP request change any adapter fields.
V	UpdateFieldsUpdateValues (see page 5568)	Updates the adapter's fields with values passed in the HTTP request.
V	UpdateFieldsValidateValues (see page 5569)	Validate the adapter's field values passed in the HTTP request.

	UpdateRecordsGetAnyChanges (see page 5570)	Determines whether values passed in the HTTP request will change any adapter fields.
	UpdateRecordsUpdateValues (see page 5570)	Updates adapter fields with values passed in the HTTP request.
	UpdateRecordsValidateValues (see page 5571)	Validate the adapter's field values passed in the HTTP request.
	WebComponentsChange (see page 5571)	WebComponentsChange is called when the list of adapter fields or adapter actions changes.

Protected Properties

	Name	Description
	NotifyList (see page 5574)	Keeps track of components that are to be notified when the adapter is changed.
	VisibleActions (see page 5575)	Returns a list of this adapter's action components.
	VisibleFields (see page 5575)	Returns a list of this adapter's field components.

Public Methods

	Name	Description
	AddNotify (see page 1059)	Registers an interest in change notifications.
	CanAddActionClass (see page 5875)	This is CanAddActionClass, a member of class IAdapterEditor.
	CanAddFieldClass (see page 5875)	This is CanAddFieldClass, a member of class IAdapterEditor.
	ClearAdapterValues (see page 5879)	This is ClearAdapterValues, a member of class IClearAdapterValues.
	Create (see page 5536)	Constructor for TCustomAdapter (see page 5531).
	CreateActionRequestContext (see page 5880)	This is CreateActionRequestContext, a member of class ICreateActionRequestContext.
	Destroy (see page 5536)	Destructor for TCustomAdapter (see page 5531).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	FindAction (see page 1077)	This is FindAction, a member of class IWebActionsList.
	FindField (see page 1082)	This is FindField, a member of class IWebDataFields.
	GetActionsList (see page 1077)	This is GetActionsList, a member of class IWebActionsList.
	GetAdapterActions (see page 1018)	This is GetAdapterActions, a member of class IGetAdapterActions.
	GetAdapterErrors (see page 1020)	This is GetAdapterErrors, a member of class IGetAdapterErrors.
	GetAdapterErrorsList (see page 5886)	This is GetAdapterErrorsList, a member of class IGetAdapterErrorsList.
	GetAdapterFields (see page 1021)	This is GetAdapterFields, a member of class IGetAdapterFields.
	GetAdapterHiddenFields (see page 1022)	This is GetAdapterHiddenFields, a member of class IGetAdapterHiddenFields.
	GetAdapterHiddenRecordFields (see page 1022)	This is GetAdapterHiddenRecordFields, a member of class IGetAdapterHiddenFields.
	GetEchoActionFieldValues (see page 5883)	This is GetEchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	GetFieldsList (see page 1082)	This is GetFieldsList, a member of class IWebDataFields.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
	GetVisibleActions (see page 1077)	This is GetVisibleActions, a member of class IWebActionsList.
	GetVisibleFields (see page 1083)	This is GetVisibleFields, a member of class IWebDataFields.
	HasExecuteAccess (see page 982)	This is HasExecuteAccess, a member of class IAdapterAccess.
	HasModifyAccess (see page 982)	This is HasModifyAccess, a member of class IAdapterAccess.
	HasViewAccess (see page 982)	This is HasViewAccess, a member of class IAdapterAccess.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.
	IsActionInUse (see page 1078)	This is IsActionInUse, a member of class IWebActionsList.
	IsFieldInUse (see page 1083)	This is IsFieldInUse, a member of class IWebDataFields.
	NextIteration (see page 1056)	Advances to the objects next item.
	NotifyActivate (see page 6089)	This is NotifyActivate, a member of class INotifyWebActivate.
	NotifyAdapterChange (see page 5876)	This is NotifyAdapterChange, a member of class IAdapterNotifyAdapterChange.
	NotifyDeactivate (see page 6089)	This is NotifyDeactivate, a member of class INotifyWebActivate.
	RemoveNotify (see page 1059)	Unregisters interest in change notifications.
	SetEchoActionFieldValues (see page 5883)	This is SetEchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	UpdateRecords (see page 5569)	Updates the adapter's fields with the field values passed in an HTTP request.

Public Properties

	Name	Description
	EchoActionFieldValues (see page 5883)	This is EchoActionFieldValues, a member of class IEchoAdapterFieldValues.
	EchoActionFieldValues (see page 5572)	Modifies the adapter's echo flag.
R	Errors (see page 5573)	Returns an object used to track errors on behalf of this adapter.
	ExecuteAccess (see page 5573)	Defines the rights required to execute this adapter's action.
R	IteratorIndex (see page 1054)	Indicates the index of the current item.
R	VisibleActions (see page 1078)	This is VisibleActions, a member of class IWebActionsList.
R	VisibleFields (see page 1083)	This is VisibleFields, a member of class IWebDataFields.

Published Events

	Name	Description
	OnAfterExecuteAction (see page 5197)	Occurs after an adapter action has executed.
	OnAfterGetActionResponse (see page 5197)	Occurs after the adapter action response is generated.
	OnAfterUpdateFields (see page 5198)	Occurs after values in the HTTP request are used to update adapter fields.
	OnAfterValidateFields (see page 5198)	Occurs after values in the HTTP request are validated by the adapter's fields.
	OnBeforeExecuteAction (see page 5198)	Occurs before an adapter action is executed.
	OnBeforeGetActionResponse (see page 5199)	Occurs before the adapter action response is generated.
	OnBeforeUpdateFields (see page 5199)	Occurs before values in the HTTP request are used to update adapter fields.
	OnBeforeValidateFields (see page 5200)	Occurs before values in the HTTP request are validated by the adapter's fields.
	OnGetActionParams (see page 5200)	Supplies name/value pairs needed to execute an adapter action.
	OnIterateRecords (see page 5200)	Occurs when the adapter needs to iterate over its data records.

Published Properties

	Name	Description
	Actions (see page 5195)	Actions is the container for adapter actions components.
	Data (see page 5196)	Data is the container for adapter field components.
	ModifyAccess (see page 5196)	Identifies the rights required to update this adapter's fields.
	ViewAccess (see page 5196)	Identifies the rights required to view this adapter's fields.

54.1.4.2 TAdapter Properties

The properties of the TAdapter class are listed here.

Published Properties

	Name	Description
	Actions (see page 5195)	Actions is the container for adapter actions components.
	Data (see page 5196)	Data is the container for adapter field components.
	ModifyAccess (see page 5196)	Identifies the rights required to update this adapter's fields.
	ViewAccess (see page 5196)	Identifies the rights required to view this adapter's fields.

54.1.4.2.1 TAdapter.Actions Property

Actions is the container for adapter actions components.

Pascal

```
property Actions: TAdapterActions;
```

C++

```
__property TAdapterActions Actions;
```

Description

The Actions property is responsible for managing a list of child adapter fields. Responsibilities include streaming, insertion,

deletion, and lookup of adapter actions by name.

See Also

TAdapterActions (see page 5209)

54.1.4.2.2 TAdapter.Data Property

Data is the container for adapter field components.

Pascal

```
property Data: TAdapterFields;
```

C++

```
__property TAdapterFields Data;
```

Description

The Data property is responsible for managing a list of child adapter fields. Responsibilities include streaming, insertion, deletion, and lookup of adapter fields by name.

See Also

TAdapterFields (see page 5276)

54.1.4.2.3 TAdapter.ModifyAccess Property

Identifies the rights required to update this adapter's fields.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this fields of this adapter. When server-side script accesses the CanModify property, this ModifyAccess property value is checked against the end user's rights.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

ImplHasModifyAccess (see page 5558)

54.1.4.2.4 TAdapter.ViewAccess Property

Identifies the rights required to view this adapter's fields.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view fields of this adapter. When server-side script accesses

the CanView property, the ViewAccess property value is checked against the end user's rights.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

ImplHasViewAccess (see page 5559)

54.1.4.3 TAdapter Events

The events of the TAdapter class are listed here.

Published Events

	Name	Description
	OnAfterExecuteAction (see page 5197)	Occurs after an adapter action has executed.
	OnAfterGetActionResponse (see page 5197)	Occurs after the adapter action response is generated.
	OnAfterUpdateFields (see page 5198)	Occurs after values in the HTTP request are used to update adapter fields.
	OnAfterValidateFields (see page 5198)	Occurs after values in the HTTP request are validated by the adapter's fields.
	OnBeforeExecuteAction (see page 5198)	Occurs before an adapter action is executed.
	OnBeforeGetActionResponse (see page 5199)	Occurs before the adapter action response is generated.
	OnBeforeUpdateFields (see page 5199)	Occurs before values in the HTTP request are used to update adapter fields.
	OnBeforeValidateFields (see page 5200)	Occurs before values in the HTTP request are validated by the adapter's fields.
	OnGetActionParams (see page 5200)	Supplies name/value pairs needed to execute an adapter action.
	OnIterateRecords (see page 5200)	Occurs when the adapter needs to iterate over its data records.

54.1.4.3.1 TAdapter.OnAfterExecuteAction Event

Occurs after an adapter action has executed.

Pascal

```
property OnAfterExecuteAction: TAdapterActionExecuteEvent;
```

C++

```
__property TAdapterActionExecuteEvent OnAfterExecuteAction;
```

Description

Implement OnAfterExecuteAction to do something after the action has executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request.

See Also

OnAfterExecute (see page 5477)

OnBeforeExecuteAction (see page 5577)

54.1.4.3.2 TAdapter.OnAfterGetActionResponse Event

Occurs after the adapter action response is generated.

Pascal

```
property OnAfterGetActionResponse: TAdapterActionExecuteEvent;
```

C++

```
__property TAdapterActionExecuteEvent OnAfterGetActionResponse;
```

Description

Implement OnAfterGetActionResponse to do something after the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request.

See Also

OnAfterGetResponse (see page 5477)

OnBeforeGetActionResponse (see page 5578)

54.1.4.3.3 TAdapter.OnAfterUpdateFields Event

Occurs after values in the HTTP request are used to update adapter fields.

Pascal

```
property OnAfterUpdateFields: TActionRequestFieldsEvent;
```

C++

```
__property TActionRequestFieldsEvent OnAfterUpdateFields;
```

Description

Implement this event handler to perform custom updates. The AdapterFields parameter lists all of the adapter fields that have corresponding values in the HTTP request. The adapter's errors object is used to record update errors.

See Also

UpdateFieldsUpdateValues (see page 5568)

OnBeforeUpdateFields (see page 5578)

Errors (see page 5573)

54.1.4.3.4 TAdapter.OnAfterValidateFields Event

Occurs after values in the HTTP request are validated by the adapter's fields.

Pascal

```
property OnAfterValidateFields: TActionRequestFieldsEvent;
```

C++

```
__property TActionRequestFieldsEvent OnAfterValidateFields;
```

Description

Implement this event handler to perform custom validation of the HTTP request. The AdapterFields parameter lists all of the adapter fields that have corresponding values in the HTTP request. The adapter's errors object is used to record validation errors.

See Also

UpdateFieldsValidateValues (see page 5569)

OnBeforeValidateFields (see page 5578)

Errors (see page 5573)

54.1.4.3.5 TAdapter.OnBeforeExecuteAction Event

Occurs before an adapter action is executed.

Pascal

```
property OnBeforeExecuteAction: TAdapterActionExecuteHandledEvent;
```

C++

```
__property TAdapterActionExecuteHandledEvent OnBeforeExecuteAction;
```

Description

Implement OnBeforeExecuteAction to do something before the action is executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to prevent the action from being executed.

See Also

OnBeforeExecute (see page 5478)

OnAfterExecuteAction (see page 5576)

54.1.4.3.6 TAdapter.OnBeforeGetActionResponse Event

Occurs before the adapter action response is generated.

Pascal

```
property OnBeforeGetActionResponse: TAdapterActionExecuteHandledEvent;
```

C++

```
__property TAdapterActionExecuteHandledEvent OnBeforeGetActionResponse;
```

Description

Implement OnBeforeGetActionResponse to do something before the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to indicate that the response has been generated and no further processing is needed.

See Also

OnBeforeGetResponse (see page 5478)

OnAfterGetActionResponse (see page 5576)

54.1.4.3.7 TAdapter.OnBeforeUpdateFields Event

Occurs before values in the HTTP request are used to update adapter fields.

Pascal

```
property OnBeforeUpdateFields: TActionRequestFieldsHandledEvent;
```

C++

```
__property TActionRequestFieldsHandledEvent OnBeforeUpdateFields;
```

Description

Implement this event handler to perform custom updates of adapter fields. The AdapterFields parameter lists all of the adapter fields that have corresponding values in the HTTP request. Set the Handled flag to prevent any further updates. Add update errors to the adapter's errors object.

See Also

UpdateFieldsUpdateValues (see page 5568)

OnAfterUpdateFields (see page 5576)

Errors (see page 5573)

54.1.4.3.8 TAdapter.OnBeforeValidateFields Event

Occurs before values in the HTTP request are validated by the adapter's fields.

Pascal

```
property OnBeforeValidateFields: TActionRequestFieldsHandledEvent;
```

C++

```
__property TActionRequestFieldsHandledEvent OnBeforeValidateFields;
```

Description

Implement this event handler to perform custom validation of the HTTP request. The AdapterFields parameter lists all of the adapter fields that have corresponding values in the HTTP request. Set the Handled flag to prevent any further validation. Add validation errors to the adapter's errors object.

See Also

UpdateFieldsValidateValues (see page 5569)

OnAfterValidateFields (see page 5577)

Errors (see page 5573)

54.1.4.3.9 TAdapter.OnGetActionParams Event

Supplies name/value pairs needed to execute an adapter action.

Pascal

```
property OnGetActionParams: TAdapterActionGetParamsEvent;
```

C++

```
__property TAdapterActionGetParamsEvent OnGetActionParams;
```

Description

Implement this event handler to specify the name/value pairs needed to execute an action.

See Also

OnGetParams (see page 5478)

54.1.4.3.10 TAdapter.OnIterateRecords Event

Occurs when the adapter needs to iterate over its data records.

Pascal

```
property OnIterateRecords: TIterateRecordsEvent;
```

C++

```
__property TIterateRecordsEvent OnIterateRecords;
```

Description

Implement this event when the adapter supports multiple data records. This event handler is called when server-side script iterates over the records in adapter, such as when generating an HTML table displaying all records. The event handler must update an iteration pointer or cursor that adapter fields are also aware of. Adapter fields must use this iteration pointer when

called to retrieve their value.

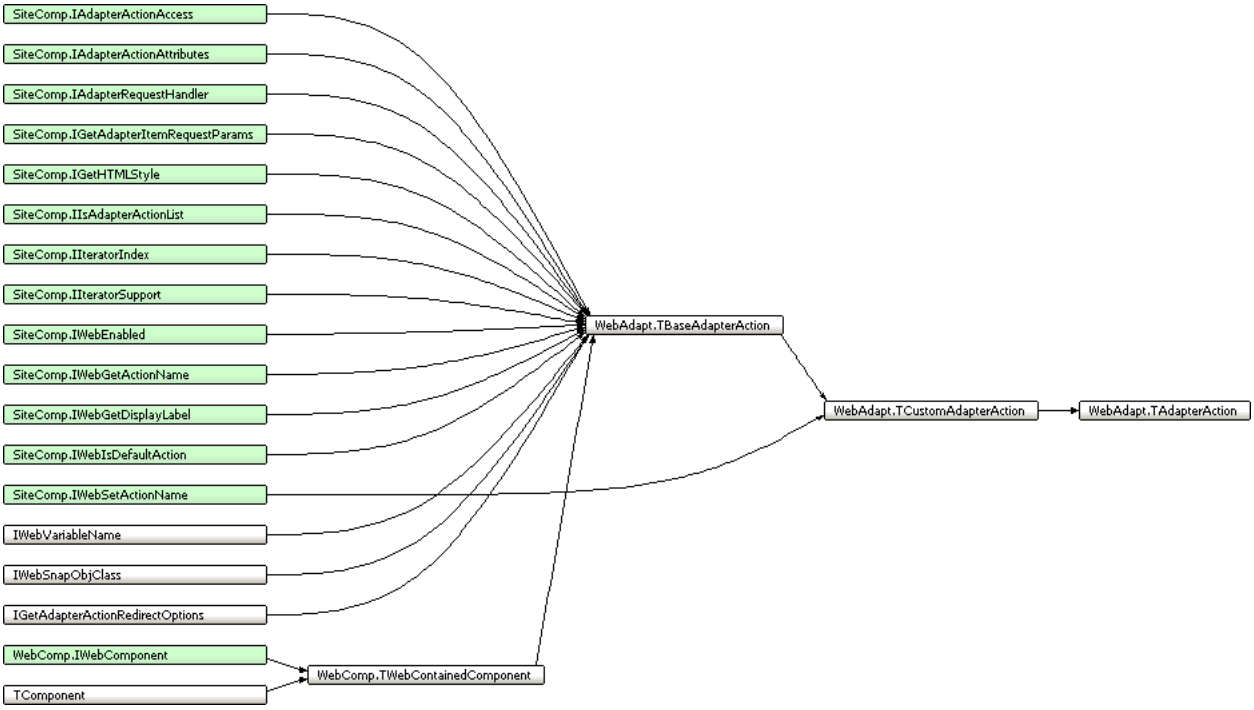
See Also

IIteratorSupport (see page 1054)

54.1.5 TAdapterAction Class

TAdapterAction is a generic adapter action that relies on event handlers.

Class Hierarchy



Pascal

```
TAdapterAction = class(TCustomAdapterAction);
```

C++

```
class TAdapterAction : public TCustomAdapterAction;
```

File

WebAdapt

Description

TAdapterAction publishes the properties in TCustomAdapterAction (see page 5579). TCustomAdapterAction (see page 5579) calls event handlers to retrieve the adapter action's parameters, get the state of the action, and execute the adapter action. Add TAdapterAction to TAdapter (see page 5190) or other adapter components types when you need an adapter action that will be controlled by event handlers. Other adapter action components declare events but also have built-in logic to work with a particular type of adapter. For example, TAdapterNextPageAction (see page 5370) has built-in logic to take the end user to the next page provided by TPagedAdapter (see page 5844). TAdapterAction, on the other hand, does not have this sort of built-in logic.

See Also

TAdapterActions (see page 5209)

TAdapter (see page 5190)

TAdapterDispatcher (see page 6148)

54.1.5.1 TAdapterAction Members

The following tables list the members exposed by TAdapterAction.

Protected Methods

	Name	Description
	CheckExecuteAccess (see page 5452)	Checks end-user rights to execute this adapter action.
	CreateRequestContext (see page 5452)	Creates an object that describes the adapter action parameters and adapter field values.
V	DoAfterExecuteActionRequest (see page 5453)	Calls event handlers after the adapter action is executed.
V	DoAfterGetExecuteActionResponse (see page 5453)	Calls event handlers after the adapter action response is formulated.
V	DoBeforeExecuteActionRequest (see page 5453)	Calls event handlers before the adapter action is executed.
V	DoBeforeGetExecuteActionResponse (see page 5454)	Calls event handlers before the adapter action response is formulated.
	EndIterator (see page 5454)	Implements IIteratorSupport (see page 1054)'s EndIterator method.
	ExecuteActionRequest (see page 5455)	Executes the adapter action using parameters passed in the HTTP request.
	GetActionName (see page 5455)	Gets the name used to reference this adapter action with server-side script.
	GetAdapter (see page 5456)	GetAdapter returns the parent adapter component.
	GetAdapterItemRequestParams (see page 5456)	Provides the name/value pairs needed to execute this adapter action.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultActionName (see page 5456)	Gets the default name used to reference this adapter action with server-side script.
V	GetDefaultDisplayLabel (see page 5457)	Provides the default display label for this adapter action.
	GetDisplayLabel (see page 5457)	Returns the suggested display label for this adapter action.
	GetDisplayStyle (see page 5457)	Returns a string value to suggest an HTML display style for this adapter action.
V	GetDisplayStyleType (see page 5458)	Suggests an HTML display type for this adapter action.
	GetErrors (see page 5458)	Returns the parent adapter's errors list.
	GetExecuteActionResponse (see page 5458)	Generates a response after the adapter action has been executed.
	GetFailureOptions (see page 5459)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	GetInputStyle (see page 5459)	Returns a string value to suggest an HTML display style for this adapter action.
	GetIsAdapterActionList (see page 5460)	Indicates whether this adapter action may have multiple commands.
V	GetItemCount (see page 5460)	Returns the number of commands defined by this adapter action.
	GetIteratorIndex (see page 5460)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method.
	GetSuccessOptions (see page 5461)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	GetVariableName (see page 5461)	Gets the name used to reference this adapter action with server-side script.
	GetViewMode (see page 5462)	Returns a string value to suggest a view mode for this adapter action.
V	GetViewModeType (see page 5462)	Suggests a view mode for this adapter action.
	GetVisible (see page 5462)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
V	GetWebSnapObjClass (see page 5463)	Returns the class type for this adapter field.
	HandleRequest (see page 5463)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 5463)	Checks the end-user's right to execute this adapter action.
	ImplCreateRequestContext (see page 5464)	Creates an object that describes the action parameters and field values.
	ImplEndIterator (see page 5464)	Implements IIteratorSupport (see page 1054)'s EndIterator (see page 5454) method.
V	ImplExecuteActionRequest (see page 5464)	Executes the adapter action using parameters passed in the HTTP request.

	ImplExecuteActionRequest (see page 5584)	Executes the adapter action using parameters passed in the HTTP request.
	ImplGetActionName (see page 5465)	Gets the name used to reference this adapter action with server-side script.
	ImplGetActionName (see page 5584)	Gets the name used to reference this adapter action with server-side script.
	ImplGetAdapterItemRequestParams (see page 5465)	Provides the name/value pairs needed to execute this adapter action.
	ImplGetAdapterItemRequestParams (see page 5584)	Provides the name/value pairs needed to execute this adapter action.
	ImplGetDisplayLabel (see page 5465)	Returns the suggested display label for this adapter action.
	ImplGetExecuteActionResponse (see page 5466)	Generates a response after the adapter action has been executed.
	ImplGetFailureOptions (see page 5466)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	ImplGetIsAdapterActionList (see page 5466)	Indicates whether this adapter action may have multiple commands.
	ImplGetIteratorIndex (see page 5467)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5460) method.
	ImplGetSuccessOptions (see page 5467)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetSuccessOptions (see page 5585)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetVariableName (see page 5467)	Gets the name used to reference this adapter action with server-side script.
	ImplGetVisible (see page 5468)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
	ImplHandleRequest (see page 5468)	Executes the adapter action and generates a response.
	ImplHasExecuteAccess (see page 5468)	Checks the end-user's right to execute this adapter action.
	ImplInIterator (see page 5469)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5471) method.
	ImplIsDefaultAction (see page 5469)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplNextIteration (see page 5470)	Implements IIteratorSupport (see page 1054)'s NextIteration (see page 5472) method.
	ImplSetActionName (see page 5585)	Sets the name that is used to reference this adapter action with server-side script.
	ImplStartIterator (see page 5470)	Implements IIteratorSupport (see page 1054)'s StartIterator (see page 5473) method.
	ImplWebEnabled (see page 5470)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	ImplWebEnabled (see page 5585)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	InIterator (see page 5471)	Implements IIteratorIndex (see page 1052)'s InIterator method.
	IsDefaultAction (see page 5471)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	NextIteration (see page 5472)	Implements IIteratorSupport (see page 1054)'s NextIteration method.
	ParentChanged (see page 5472)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetActionName (see page 5586)	Sets the name that is used to reference this adapter action with server-side script.
	SetDisplayLabel (see page 5472)	Set the value of the DisplayLabel (see page 5474) property.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartIterator (see page 5473)	Implements IIteratorSupport (see page 1054)'s StartIterator method.
	WebEnabled (see page 5473)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Protected Properties

	Name	Description
	Adapter (see page 5474)	Provides access to the parent adapter component.
	Errors (see page 5475)	Returns the parent adapter's Errors list.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.

	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	CreateRequestContext (see page 1013)	Creates an object that describes the adapter action parameters and adapter field values.
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.
	GetAdapterItemRequestParams (see page 1024)	This is GetAdapterItemRequestParams, a member of class IGetAdapterItemRequestParams.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetIsAdapterActionList (see page 1050)	This is GetIsAdapterActionList, a member of class IIsAdapterActionList.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 984)	This is GetVisible, a member of class IAdapterActionAttributes.
	HandleRequest (see page 1013)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 983)	This is HasExecuteAccess, a member of class IAdapterActionAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.
	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.
	NextIteration (see page 1056)	Advances to the objects next item.
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

Public Properties

	Name	Description
	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
	IsAdapterActionList (see page 1050)	This is IsAdapterActionList, a member of class IIsAdapterActionList.
	ItemCount (see page 5475)	Returns the number of items defined by an adapter action.
	ItemIndex (see page 5476)	Returns the index of the current item of an adapter action.
	IteratorIndex (see page 1054)	Indicates the index of the current item.
	Visible (see page 984)	This is Visible, a member of class IAdapterActionAttributes.

Published Events

	Name	Description
	OnAfterExecute (see page 5207)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5207)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5208)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5208)	Called before the adapter action response is generated.

	OnExecute (see page 5208)	Called to execute this action using parameters passed in the HTTP request.
	OnGetEnabled (see page 5209)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	OnGetParams (see page 5209)	Specifies name/value pairs needed to execute this adapter action.

Published Properties

	Name	Description
	ActionName (see page 5205)	Identifies the name of this action when using server-side script.
	DisplayLabel (see page 5205)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5206)	Defines the rights required to execute this action.
	RedirectOptions (see page 5206)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.5.2 TAdapterAction Properties

The properties of the TAdapterAction class are listed here.

Published Properties

	Name	Description
	ActionName (see page 5205)	Identifies the name of this action when using server-side script.
	DisplayLabel (see page 5205)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5206)	Defines the rights required to execute this action.
	RedirectOptions (see page 5206)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.5.2.1 TAdapterAction.ActionName Property

Identifies the name of this action when using server-side script.

Pascal

```
property ActionName: string;
```

C++

```
__property UnicodeString ActionName;__property UnicodeString ActionName;__property
UnicodeString ActionName;
```

Description

The ActionName property defines the name used to access the adapter action with server-side script.

See Also

ImplGetActionName (see page 5584)

ImplSetActionName (see page 5585)

54.1.5.2.2 TAdapterAction.DisplayLabel Property

Suggests a display label for this adapter action.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the a button or hyperlink to execute this adapter action. Typically the adapter action is displayed using server-side script, either generated or custom written. Server-side script uses the DisplayLabel property to access this value.

See Also

ImplGetDisplayLabel (see page 5465)

SetDisplayLabel (see page 5472)

54.1.5.2.3 TAdapterAction.ExecuteAccess Property

Defines the rights required to execute this action.

Pascal

```
property ExecuteAccess: string;
```

C++

```
__property UnicodeString ExecuteAccess;
```

Description

The ExecuteAccess property defines the access rights required to execute this action. When server-side script accesses the CanExecute property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to execute an adapter action that does not allow access.

See Also

TWebUserList (see page 6796)

HasExecuteAccess (see page 5552)

54.1.5.2.4 TAdapterAction.RedirectOptions Property

Indicates whether to perform an HTTP redirect after successfully executing this action.

Pascal

```
property RedirectOptions: TAdapterActionRedirectOptions;
```

C++

```
__property TAdapterActionRedirectOptions RedirectOptions;
```

Description

Set RedirectOptions to indicate that HTTP redirect should be performed after executing this adapter action. An HTTP redirect causes the browser to "forget" about the parameters passed when executing the adapter action. Without a redirect, the browser's Refresh or Reload command cause the last HTTP request to be resent, resulting in re-execution of the adapter action.

See Also

SendRedirect

54.1.5.3 TAdapterAction Events

The events of the TAdapterAction class are listed here.

Published Events

	Name	Description
	OnAfterExecute (see page 5207)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5207)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5208)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5208)	Called before the adapter action response is generated.
	OnExecute (see page 5208)	Called to execute this action using parameters passed in the HTTP request.
	OnGetEnabled (see page 5209)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	OnGetParams (see page 5209)	Specifies name/value pairs needed to execute this adapter action.

54.1.5.3.1 TAdapterAction.OnAfterExecute Event

Called after the adapter action has executed.

Pascal

```
property OnAfterExecute: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterExecute;
```

Description

Implement OnAfterExecute to do something after the action has executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterExecute is called by DoAfterExecuteActionRequest.

See Also

DoAfterExecuteActionRequest (see page 5453)

OnAfterExecuteAction (see page 5576)

OnBeforeExecute (see page 5478)

54.1.5.3.2 TAdapterAction.OnAfterGetResponse Event

Called after the adapter action response is generated.

Pascal

```
property OnAfterGetResponse: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterGetResponse;
```

Description

Implement OnAfterGetResponse to do something after the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterGetResponse is called by DoAfterGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnBeforeGetActionResponse (see page 5578)

54.1.5.3.3 TAdapterAction.OnBeforeExecute Event

Called before the adapter action is executed.

Pascal

```
property OnBeforeExecute: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeExecute;
```

Description

Implement OnBeforeExecute to do something before the action is executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to prevent the action from being executed. OnBeforeExecute is called by DoBeforeExecuteActionRequest.

See Also

DoBeforeExecuteActionRequest (see page 5453)

OnAfterExecute (see page 5477)

OnBeforeExecuteAction (see page 5577)

54.1.5.3.4 TAdapterAction.OnBeforeGetResponse Event

Called before the adapter action response is generated.

Pascal

```
property OnBeforeGetResponse: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeGetResponse;
```

Description

Implement OnBeforeGetResponse to do something before the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to indicate that the response has been generated and no further processing is needed. OnBeforeGetResponse is called by DoBeforeGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnAfterGetResponse (see page 5477)

OnBeforeGetActionResponse (see page 5578)

54.1.5.3.5 TAdapterAction.OnExecute Event

Called to execute this action using parameters passed in the HTTP request.

Pascal

```
property OnExecute: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnExecute;
```

Description

Implement this event handler to execute this adapter action. Params contains the name/value pairs that were passed in the HTTP request. OnExecute is called by ImplExecuteActionRequest.

See Also

ImplExecuteActionRequest (see page 5584)

OnGetParams (see page 5478)

54.1.5.3.6 TAdapterAction.OnGetEnabled Event

Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Pascal

```
property OnGetEnabled: TActionGetEnabledEvent;
```

C++

```
__property TActionGetEnabledEvent OnGetEnabled;
```

Description

ImplWebEnabled calls the OnGetEnabled event handler. Set the Enabled parameter to false to indicate that this adapter action should not be enabled.

See Also

ImplWebEnabled (see page 5585)

54.1.5.3.7 TAdapterAction.OnGetParams Event

Specifies name/value pairs needed to execute this adapter action.

Pascal

```
property OnGetParams: TActionGetParamsEvent;
```

C++

```
__property TActionGetParamsEvent OnGetParams;
```

Description

Implement this event handler to specify the name/value needed to execute this action. For example, an action that deletes a row in a table will need a name/value pair that identifies the row to be deleted such as "Key=123".

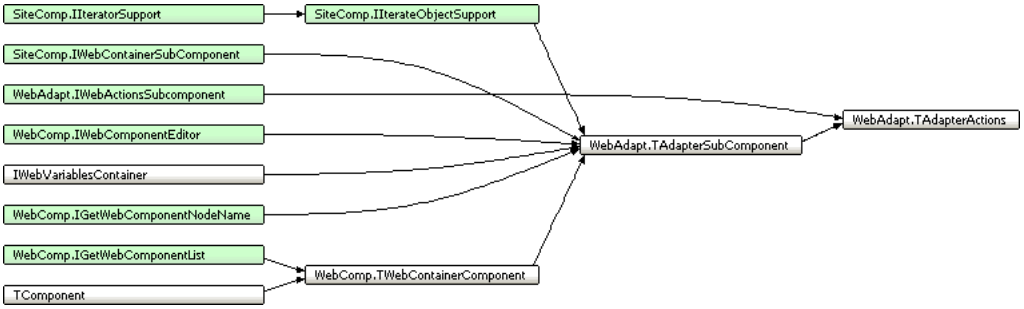
See Also

ImplGetAdapterItemRequestParams (see page 5465)

54.1.6 TAdapterActions Class

TAdapterActions manages the list of actions that belong to an adapter.

Class Hierarchy



Pascal

```
TAdapterActions = class(TAdapterSubComponent, IWebActionsSubcomponent);
```

C++

```
class TAdapterActions : public TAdapterSubComponent, public IWebActionsSubcomponent;
```

File

WebAdapt

Description

TAdapterActions is the type of the Actions property on an adapter component. It manages a list that contains all the actions that belong to the adapter. The action objects (TBaseAdapterAction (see page 5447) descendants) are available using the WebActions (see page 5214) property. TAdapterActions also includes support for associating the actions with variable names so that server-side script can execute the actions.

TAdapterActions represents the list of explicitly assigned actions. Adapters that include a set of default actions use a TAdapterDefaultActions (see page 5231) object instead.

See Also

TCustomAdapter (see page 5531)

TAdapterFields (see page 5276)

TAdapterDefaultActions (see page 5231)

TAdapterDefaultFields (see page 5237)

TBaseAdapterAction (see page 5447)

54.1.6.1 TAdapterActions Members

The following tables list the members exposed by TAdapterActions.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5212)	Indicates whether the associated adapter supports a specified class of action component.
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.

	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
V	GetChildren (see page 6065)	Executes a callback for each child Web item.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
V	GetDefaultWebComponents (see page 5411)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
V	GetDefaultWebComponents (see page 6065)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
V	GetVariablesInUse (see page 5413)	Returns the value of the VariablesInUse (see page 5419) property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	GetWebComponents (see page 6065)	Returns the list of Web items that this item manages.
V	ImplCanAddClass (see page 5212)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
V	ImplGetDefaultComponentList (see page 6066)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	ImplGetWebComponentNodeName (see page 5213)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
V	SetChildOrder (see page 6066)	Positions a child component in the list of child Web items.
V	SetDefaultWebComponents (see page 5416)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	SetDefaultWebComponents (see page 6067)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	SetWebParent (see page 5213)	Associates this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Protected Properties

	Name	Description
R	Adapter (see page 5418)	Indicates the adapter that uses this object to manage its fields or actions.
R	VariablesInUse (see page 5419)	Lists those fields or actions in the collection for which variables are defined.
R	WebContainerComponentHelper (see page 6067)	Provides access to the helper object that allows this object to manage its Web items.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
V	Create (see page 6064)	Creates and initializes an instance of TWebContainerComponent (see page 6063).
V	Destroy (see page 6064)	Frees an instance of TWebContainerComponent (see page 6063).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetComponentList (see page 6082)	This is GetComponentList, a member of class IGetWebComponentList.
	GetCurrentObject (see page 1052)	This is GetCurrentObject, a member of class IIterateObjectSupport.
	GetDefaultComponentList (see page 6082)	This is GetDefaultComponentList, a member of class IGetWebComponentList.
V	GetParentComponent (see page 5412)	Returns the associated adapter.
	GetWebComponentNodeName (see page 6083)	This is GetWebComponentNodeName, a member of class IGetWebComponentNodeName.
V	HasParent (see page 5414)	Indicates whether this component has an associated adapter.
	NextIteration (see page 1056)	Advances to the objects next item.
V	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.
V	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.

Public Properties

	Name	Description
	WebActions (see page 5214)	Lists the action components that this object manages.

54.1.6.2 TAdapterActions Methods

The methods of the TAdapterActions class are listed here.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5212)	Indicates whether the associated adapter supports a specified class of action component.
	ImplCanAddClass (see page 5212)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
	ImplGetWebComponentNodeName (see page 5213)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	SetWebParent (see page 5213)	Associates this component with an adapter.

54.1.6.2.1 TAdapterActions.AdapterCanAddClass Method

Indicates whether the associated adapter supports a specified class of action component.

Pascal

```
function AdapterCanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean AdapterCanAddClass(TComponent * AParent, TClass AClass);
```

Description

TAdapterActions (see page 5209) uses this method internally as part of its implementation for the CanAddClass (see page 5408) method. This allows the TAdapterActions (see page 5209) object to indicate, at design time, which types of action components are valid as components in the WebActions (see page 5214) property list.

AParent is the instance of TAdapterActions (see page 5209) to which the child actions are to be added.

AClass describes the class of the child component to be added to AParent.

AdapterCanAddClass returns true if the adapter recognizes and supports AClass as a child action, false otherwise.

AdapterCanAddClass calls the CanAddActionClass method of its associated adapter to determine whether it accepts the specified action class.

See Also

WebActions (see page 5214)

Adapter (see page 5418)

ImplCanAddClass (see page 5212)

CanAddActionClass (see page 5539)

54.1.6.2.2 TAdapterActions.ImplCanAddClass Method

Provides the underlying implementation for the CanAddClass (see page 5408) method.

Pascal

```
function ImplCanAddClass(AParent: TComponent; AClass: TClass): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplCanAddClass(TComponent * AParent, TClass AClass);
```

Description

The CanAddClass (see page 5408) method calls ImplCanAddClass to determine whether an object of a specified type can be added to this collection.

AParent is the TAdapterActions (see page 5209) object to which the Web item will be added.

AClass is the class of the proposed child item.

ImplCanAddClass returns true if the TAdapterActions (see page 5209) object can include a child of type AClass, false otherwise.

ImplCanAddClass returns true if one of the following two conditions is met:

AClass is an adapter action class that the associated adapter recognizes and accepts.

AClass is a custom adapter action (a descendant of TCustomAdapterAction (see page 5579) that is not a descendant of TImplementedAdapterAction (see page 5818)).

See Also

CanAddClass (see page 5408)

AdapterCanAddClass (see page 5212)

TCustomAdapterAction (see page 5579)

TImplementedAdapterAction (see page 5818)

54.1.6.2.3 TAdapterActions.ImplGetWebComponentNodeName Method

Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.

Pascal

```
function ImplGetWebComponentNodeName: string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetWebComponentNodeName();
```

Description

The GetWebComponentNodeName (see page 5413) method calls ImplGetWebComponentNodeName to obtain a label for the type of items in the collection.

ImplGetWebComponentNodeName returns the string 'Actions'.

See Also

GetWebComponentNodeName (see page 5413)

54.1.6.2.4 TAdapterActions.SetWebParent Method

Associates this component with an adapter.

Pascal

```
procedure SetWebParent(const Value: TComponent); override;
```

C++

```
virtual __fastcall SetWebParent(const TComponent * Value);
```

Description

SetWebParent sets up the association between this component and its parent adapter.

Value is the adapter component that acts as a parent to this collection.

SetWebParent assigns Value to the protected Adapter (see page 5418) property and replaces that adapter's Actions property with this TAdapterActions (see page 5209) instance.

See Also

Actions (see page 5572)

Adapter (see page 5418)

54.1.6.3 TAdapterActions Properties

The properties of the TAdapterActions class are listed here.

Public Properties

	Name	Description
	WebActions (see page 5214)	Lists the action components that this object manages.

54.1.6.3.1 TAdapterActions.WebActions Property

Lists the action components that this object manages.

Pascal

```
property WebActions: TWebComponentList;
```

C++

```
__property TWebComponentList WebActions;
```

Description

Read (see page 3634) WebActions to access the list of action components. Each component in this list is a descendant of TBaseAdapterAction (see page 5447).

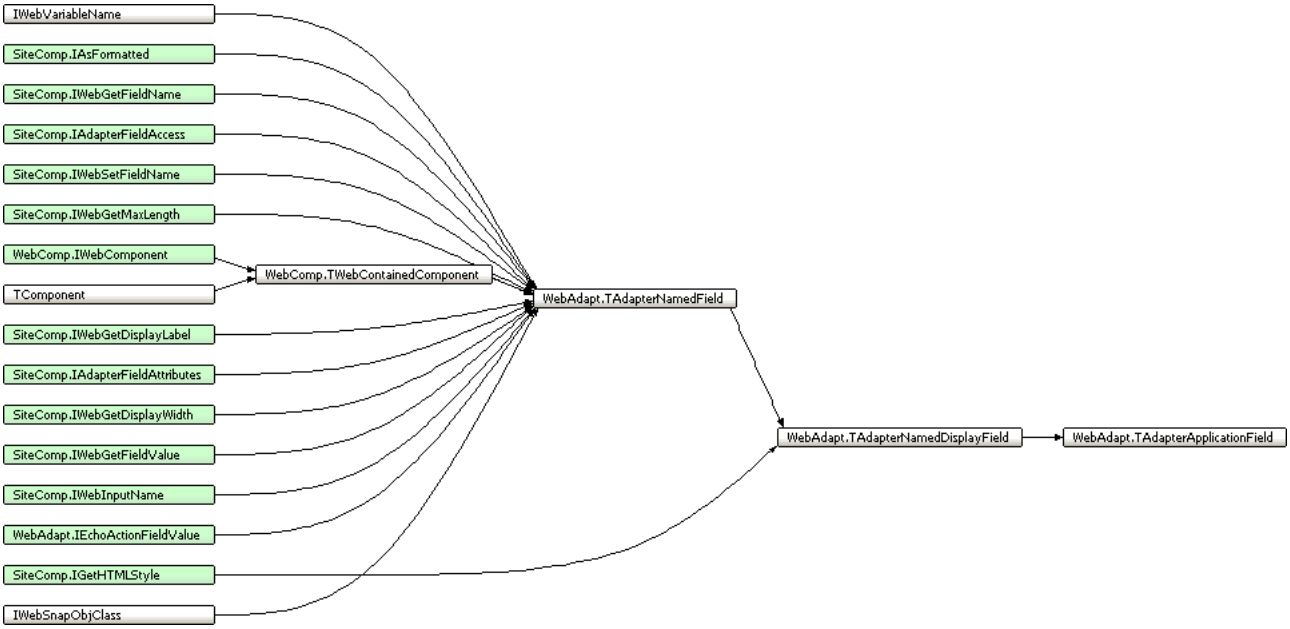
See Also

TBaseAdapterAction (see page 5447)

54.1.7 TAdapterApplicationField Class

TAdapterApplicationField is a base class for adapter field components that are children of a TApplicationAdapter (see page 5439) component.

Class Hierarchy



Pascal

```
TAdapterApplicationField = class(TAdapterNamedDisplayField);
```

C++

```
class TAdapterApplicationField : public TAdapterNamedDisplayField;
```

File

WebAdapt

Description

TAdapterApplicationField implements functionality useful to an adapter field that can be a child of TApplicationAdapter (see page 5439).

See Also

TApplicationAdapter (see page 5439)

TAdapterNamedDisplayField (see page 5343)

TAdapterApplicationTitleField (see page 5218)

54.1.7.1 TAdapterApplicationField Members

The following tables list the members exposed by TAdapterApplicationField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.

	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.

	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
R	Adapter (see page 5218)	Returns the parent adapter of this adapter field.
R	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
R	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
V	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
V	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.

	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.7.2 TAdapterApplicationField Properties

The properties of the TAdapterApplicationField class are listed here.

Protected Properties

	Name	Description
R	Adapter (see page 5218)	Returns the parent adapter of this adapter field.

54.1.7.2.1 TAdapterApplicationField.Adapter Property

Returns the parent adapter of this adapter field.

Pascal

```
property Adapter: TCustomApplicationAdapter;
```

C++

```
__property TCustomApplicationAdapter Adapter;
```

Description

Descendants use this property to access the parent adapter.

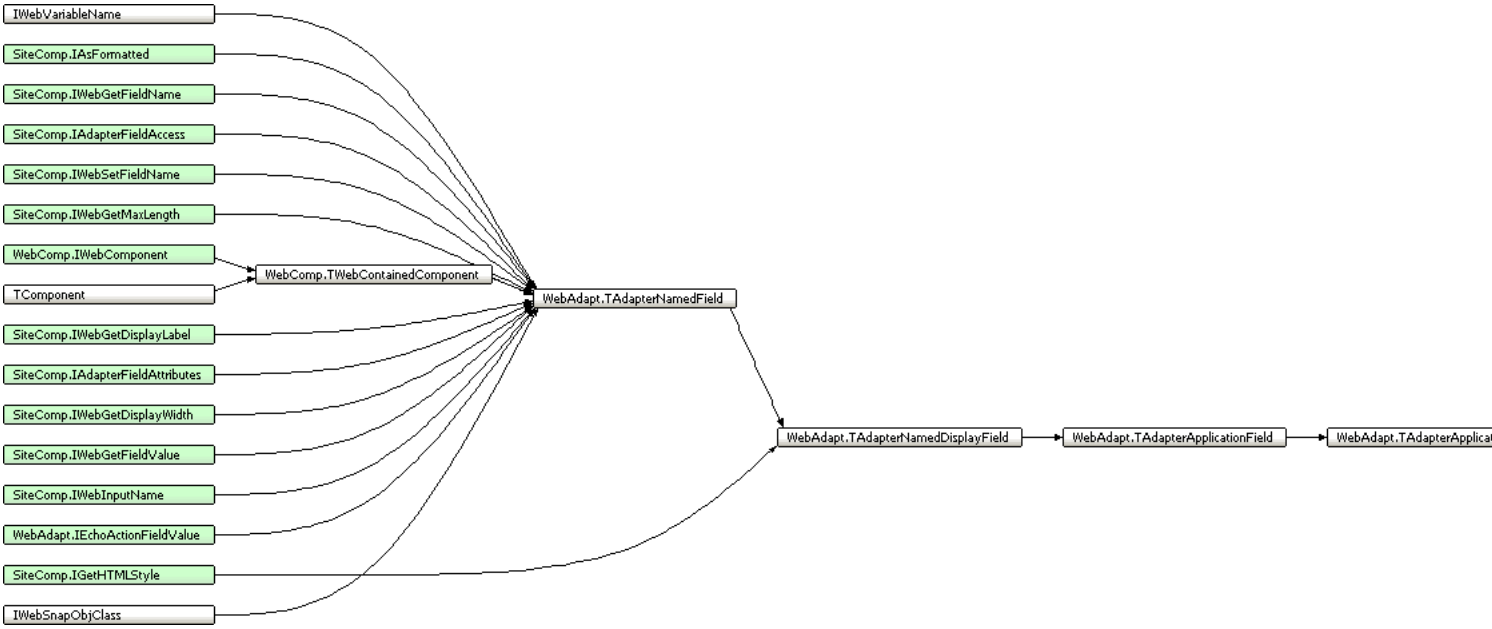
See Also

TCustomApplicationAdapter (see page 5663)

54.1.8 TAdapterApplicationTitleField Class

TAdapterApplicationTitleField is an adapter field used to access the application title.

Class Hierarchy



Pascal

```
TAdapterApplicationTitleField = class(TAdapterApplicationField);
```

C++

```
class TAdapterApplicationTitleField : public TAdapterApplicationField;
```

File

WebAdapt

Description

TAdapterApplicationTitleField is added to TApplicationAdapter (see page 5439).

See Also

TAdapterApplicationField (see page 5214)

TApplicationAdapter (see page 5439)

TCustomApplicationAdapter (see page 5663)

54.1.8.1 TAdapterApplicationTitleField Members

The following tables list the members exposed by TAdapterApplicationTitleField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.

	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5222)	Returns the name used to access this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5222)	Returns the value associated with this adapter field.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
V	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
V	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
V	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	Adapter (see page 5218)	Returns the parent adapter of this adapter field.
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.

	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.8.2 TAdapterApplicationTitleField Methods

The methods of the TAdapterApplicationTitleField class are listed here.

Protected Methods

	Name	Description
	GetDefaultFieldName (see page 5222)	Returns the name used to access this adapter field with server-side script.
	ImplGetValue (see page 5222)	Returns the value associated with this adapter field.

54.1.8.2.1 TAdapterApplicationTitleField.GetDefaultFieldName Method

Returns the name used to access this adapter field with server-side script.

Pascal

```
function GetDefaultFieldName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultFieldName();
```

Description

GetDefaultFieldName returns 'Title'. This allows server-side script to access this adapter field using the parent adapter's Title property.

54.1.8.2.2 TAdapterApplicationTitleField.ImplGetValue Method

Returns the value associated with this adapter field.

Pascal

```
function ImplGetValue: Variant; override;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

ImplGetValue returns the value of the parent adapter's Title property. Server-side script accesses the result of this function using the DisplayText property of this adapter field. Server-side script may use this value to display the application title on a Web page.

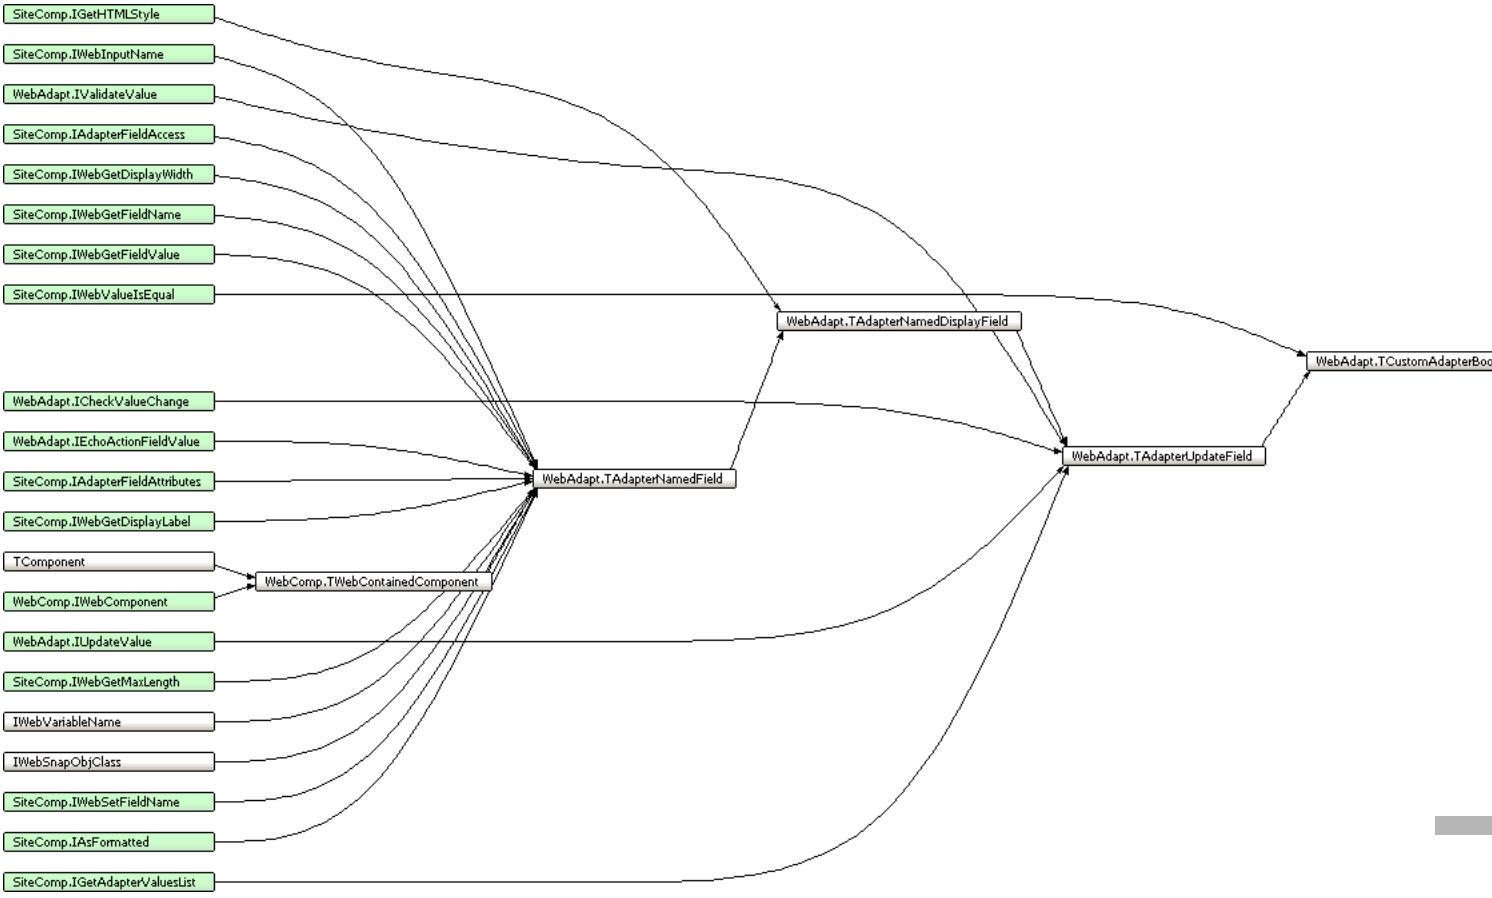
See Also

ApplicationTitle (see page 5671)

54.1.9 TAdapterBooleanField Class

TAdapterBooleanField is an event handler based adapter field that works with a Boolean value.

Class Hierarchy



Pascal

```
TAdapterBooleanField = class(TCustomAdapterBooleanField);
```

C++

```
class TAdapterBooleanField : public TCustomAdapterBooleanField;
```

File

WebAdapt

Description

TAdapterBooleanField publishes the properties in TCustomAdapterBooleanField (see page 5589). TCustomAdapterBooleanField (see page 5589) calls event handlers to retrieve the adapter field's value, validate a value entered by the end-user, and update the adapter field's value.

Add TAdapterBooleanField to TAdapter (see page 5190) or other adapter components types when you need an adapter field that works with a Boolean value. There are other adapter field components that use event handlers. They differ in the type and

number of values that are supported. See TAdapterField (see page 5267), TAdapterMultiValueField (see page 5332), TAdapterMemoField (see page 5323), TAdapterFileField (see page 5281) and TAdapterImageField (see page 5308).

See Also

TAdapter (see page 5190)

TAdapterField (see page 5267)

TAdapterMemoField (see page 5323)

TAdapterMultiValueField (see page 5332)

TAdapterFileField (see page 5281)

TAdapterImageField (see page 5308)

54.1.9.1 TAdapterBooleanField Members

The following tables list the members exposed by TAdapterBooleanField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
V	ConvertValue (see page 5594)	Retrieves a Boolean value entered by the end-user.
V	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
V	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
V	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
V	GetDisplayStyleType (see page 5594)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
V	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.
V	GetInputStyleType (see page 5595)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).

	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetValue (see page 5595)	Returns the value of this adapter field as a variant.
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplIsEqual (see page 5596)	Indicates whether the value of this field is equal to a particular Variant (see page 3421) value.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5596)	Called to update the adapter field's value with a value entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsEqual (see page 5596)	Indicates whether the value of this field is equal to a particular Variant (see page 3421) value.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.

	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnGetDisplayText (see page 5433)	Event handler called to retrieve a string representation of the adapter field's value.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	IsEqual (see page 1119)	This is IsEqual, a member of class IWebValueIsEqual.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetValue (see page 5230)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5230)	Called to update the adapter field's value with a value entered by the end-user.
	OnValidateValue (see page 5231)	Event handler called to validate value(s) entered by the end-user.

Published Properties

	Name	Description
	DisplayLabel (see page 5228)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5228)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5228)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5229)	Identifies the rights required to update this field.
	ReadOnly (see page 5229)	Indicates whether this adapter field is read-only.
	ValuesList (see page 5229)	Associates a list of values with the adapter field.
	ViewAccess (see page 5230)	Identifies the rights required to view this field.

54.1.9.2 TAdapterBooleanField Properties

The properties of the TAdapterBooleanField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5228)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5228)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5228)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5229)	Identifies the rights required to update this field.
	ReadOnly (see page 5229)	Indicates whether this adapter field is read-only.
	ValuesList (see page 5229)	Associates a list of values with the adapter field.
	ViewAccess (see page 5230)	Identifies the rights required to view this field.

54.1.9.2.1 TAdapterBooleanField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.9.2.2 TAdapterBooleanField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.9.2.3 TAdapterBooleanField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.9.2.4 TAdapterBooleanField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.9.2.5 TAdapterBooleanField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.9.2.6 TAdapterBooleanField.ValuesList Property

Associates a list of values with the adapter field.

Pascal

```
property ValuesList: IValuesListAdapter;
```

C++

```
__property IValuesListAdapter ValuesList;
```

Description

Assign a component to the ValuesList property to define possible values for the adapter field. Server-side script can be used to enumerate the name/value pairs of the ValuesList component to generate HTML select lists, check boxes, or radio buttons.

See Also

IValuesListAdapter (see page 1072)

TStringsValuesList (see page 5857)

TDataSetValuesList

54.1.9.2.7 TAdapterBooleanField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.9.3 TAdapterBooleanField Events

The events of the TAdapterBooleanField class are listed here.

Published Events

	Name	Description
	OnGetValue (see page 5230)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5230)	Called to update the adapter field's value with a value entered by the end-user.
	OnValidateValue (see page 5231)	Event handler called to validate value(s) entered by the end-user.

54.1.9.3.1 TAdapterBooleanField.OnGetValue Event

Called to retrieve the adapter field's value.

Pascal

```
property OnGetValue: TAdapterFieldGetBooleanEvent;
```

C++

```
__property TAdapterFieldGetBooleanEvent OnGetValue;
```

Description

OnGetValue is called by ImplGetValue to retrieve the value associated with this adapter field.

See Also

ImplGetValue (see page 5595)

54.1.9.3.2 TAdapterBooleanField.OnUpdateValue Event

Called to update the adapter field's value with a value entered by the end-user.

Pascal

```
property OnUpdateValue: TAdapterFieldBooleanValueEvent;
```

C++

```
__property TAdapterFieldBooleanValueEvent OnUpdateValue;
```

Description

OnUpdateValue is called when an action request contains a value for this adapter field. If this event handler is not implemented, the value entered by the end-user will be ignored.

See Also

ImplUpdateValue (see page 5596)

54.1.9.3.3 TAdapterBooleanField.OnValidateValue Event

Event handler called to validate value(s) entered by the end-user.

Pascal

```
property OnValidateValue: TAdapterFieldValidateValueEvent;
```

C++

```
__property TAdapterFieldValidateValueEvent OnValidateValue;
```

Description

This event handler is called by DoOnValidateValue to validate the value(s) entered by the end-user. The event handler must raise an exception to indicate that the value(s) are not valid.

See Also

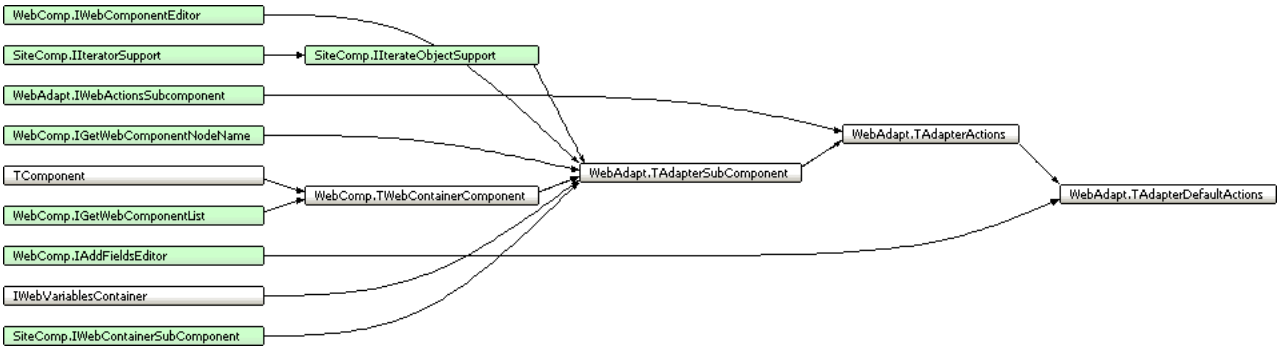
DoOnValidateValue (see page 5426)

IActionFieldValue

54.1.10 TAdapterDefaultActions Class

TAdapterDefaultActions manages the list of actions that belong to an adapter that supports a default set of actions.

Class Hierarchy



Pascal

```
TAdapterDefaultActions = class(TAdapterActions, IAddFieldsEditor);
```

C++

```
class TAdapterDefaultActions : public TAdapterActions, public IAddFieldsEditor;
```

File

WebAdapt

Description

TAdapterDefaultActions is the type of the Actions property on an adapter component. It manages two lists of actions (TBaseAdapterAction (see page 5447) descendants) that belong to the adapter: the list of actions that have been explicitly added to the adapter, and the list of actions that the adapter includes by default. The explicitly added action objects are available using the WebActions (see page 5214) property. The default actions are available using the DefaultWebComponents (see page 5237) property.

See Also

TDefaultFieldsAdapter (see page 5738)

TAdapterFields (see page 5276)

TAdapterActions (see page 5209)

TAdapterDefaultFields (see page 5237)

TBaseAdapterAction (see page 5447)

54.1.10.1 TAdapterDefaultActions Members

The following tables list the members exposed by TAdapterDefaultActions.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5212)	Indicates whether the associated adapter supports a specified class of action component.
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
V	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.
	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
	GetAddAllFieldsItem (see page 5235)	This is GetAddAllFieldsItem, a member of class TAdapterDefaultActions.
	GetAddFieldsDlgCaption (see page 5235)	This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultActions.
	GetAddFieldsItem (see page 5235)	This is GetAddFieldsItem, a member of class TAdapterDefaultActions.
V	GetChildren (see page 6065)	Executes a callback for each child Web item.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
V	GetDefaultWebComponents (see page 5235)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetNewFieldPrefix (see page 5236)	This is GetNewFieldPrefix, a member of class TAdapterDefaultActions.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
V	GetVariablesInUse (see page 5236)	Returns the value of the VariablesInUse property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	GetWebComponents (see page 6065)	Returns the list of Web items that this item manages.
V	ImplCanAddClass (see page 5212)	Provides the underlying implementation for the CanAddClass (see page 5408) method.

	ImplCanAddClass (see page 5414)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
	ImplGetDefaultComponentList (see page 6066)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
	ImplGetWebComponentNodeName (see page 5213)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	ImplGetWebComponentNodeName (see page 5415)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
	SetChildOrder (see page 6066)	Positions a child component in the list of child Web items.
	SetDefaultWebComponents (see page 5236)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
	SetWebParent (see page 5213)	Associates this component with an adapter.
	SetWebParent (see page 5417)	Introduces a method to associate this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Protected Properties

	Name	Description
	Adapter (see page 5418)	Indicates the adapter that uses this object to manage its fields or actions.
	VariablesInUse (see page 5419)	Lists those fields or actions in the collection for which variables are defined.
	WebContainerComponentHelper (see page 6067)	Provides access to the helper object that allows this object to manage its Web items.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
	ClearDefaultComponents (see page 5234)	Empties the list of default actions that is the value of the DefaultWebComponents (see page 5237) property.
	Create (see page 6064)	Creates and initializes an instance of TWebContainerComponent (see page 6063).
	Destroy (see page 5233)	Frees an instance of TAdapterDefaultActions (see page 5231).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetComponentList (see page 6082)	This is GetComponentList, a member of class IGetWebComponentList.
	GetCurrentObject (see page 1052)	This is GetCurrentObject, a member of class IIterateObjectSupport.
	GetDefaultComponentList (see page 6082)	This is GetDefaultComponentList, a member of class IGetWebComponentList.
	GetParentComponent (see page 5412)	Returns the associated adapter.
	GetWebComponentNodeName (see page 6083)	This is GetWebComponentNodeName, a member of class IGetWebComponentNodeName.
	HasParent (see page 5414)	Indicates whether this component has an associated adapter.
	NextIteration (see page 1056)	Advances to the objects next item.
	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.

Public Properties

	Name	Description
	DefaultWebComponents (see page 5237)	Lists the action components that the associated adapter includes by default.
	WebActions (see page 5214)	Lists the action components that this object manages.

54.1.10.2 TAdapterDefaultActions.Destroy Destructor

Frees an instance of TAdapterDefaultActions (see page 5231).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAdapterDefaultActions();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks for a nil reference before calling Destroy.

See Also

System::TObject::Free (see page 3372)

54.1.10.3 TAdapterDefaultActions Methods

The methods of the TAdapterDefaultActions class are listed here.

Protected Methods

	Name	Description
	GetAddAllFieldsItem (see page 5235)	This is GetAddAllFieldsItem, a member of class TAdapterDefaultActions.
	GetAddFieldsDlgCaption (see page 5235)	This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultActions.
	GetAddFieldsItem (see page 5235)	This is GetAddFieldsItem, a member of class TAdapterDefaultActions.
	GetDefaultWebComponents (see page 5235)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetNewFieldPrefix (see page 5236)	This is GetNewFieldPrefix, a member of class TAdapterDefaultActions.
	GetVariablesInUse (see page 5236)	Returns the value of the VariablesInUse property.
	SetDefaultWebComponents (see page 5236)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.

Public Methods

	Name	Description
	ClearDefaultComponents (see page 5234)	Empties the list of default actions that is the value of the DefaultWebComponents (see page 5237) property.

54.1.10.3.1 TAdapterDefaultActions.ClearDefaultComponents Method

Empties the list of default actions that is the value of the DefaultWebComponents (see page 5237) property.

Pascal

```
procedure ClearDefaultComponents; virtual;
```

C++

```
virtual __fastcall ClearDefaultComponents();
```

Description

The associated adapter calls ClearDefaultComponents when it changes its set of default actions. After a call to ClearDefaultComponents, the adapter generates a new set of default components the next time the application reads the default actions.

See Also

DefaultWebComponents (see page 5237)

54.1.10.3.2 TAdapterDefaultActions.GetAddAllFieldsItem Method

Pascal

```
function GetAddAllFieldsItem: string;
```

C++

```
__fastcall UnicodeString GetAddAllFieldsItem();
```

Description

This is GetAddAllFieldsItem, a member of class TAdapterDefaultActions.

54.1.10.3.3 TAdapterDefaultActions.GetAddFieldsDlgCaption Method

Pascal

```
function GetAddFieldsDlgCaption: string;
```

C++

```
__fastcall UnicodeString GetAddFieldsDlgCaption();
```

Description

This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultActions.

54.1.10.3.4 TAdapterDefaultActions.GetAddFieldsItem Method

Pascal

```
function GetAddFieldsItem: string;
```

C++

```
__fastcall UnicodeString GetAddFieldsItem();
```

Description

This is GetAddFieldsItem, a member of class TAdapterDefaultActions.

54.1.10.3.5 TAdapterDefaultActions.GetDefaultWebComponents Method

Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.

Pascal

```
function GetDefaultWebComponents: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetDefaultWebComponents();
```

Description

GetDefaultWebComponents supplies the default set of child items for this component. As implemented in TAdapterSubComponent, GetDefaultWebComponents always returns nil (Delphi) or NULL (C++) because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and TAdapterDefaultFields) override this method to return the list of default fields or actions.

See Also

GetWebComponents (see page 6065)

TAdapterDefaultActions (see page 5231)

TAdapterDefaultFields (see page 5237)

54.1.10.3.6 TAdapterDefaultActions.GetNewFieldPrefix Method

Pascal

```
function GetNewFieldPrefix: string;
```

C++

```
__fastcall UnicodeString GetNewFieldPrefix();
```

Description

This is GetNewFieldPrefix, a member of class TAdapterDefaultActions.

54.1.10.3.7 TAdapterDefaultActions.GetVariablesInUse Method

Returns the value of the VariablesInUse property.

Pascal

```
function GetVariablesInUse: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetVariablesInUse();
```

Description

GetVariablesInUse is the protected read implementation for the VariablesInUse property.

In TAdapterSubComponent, GetVariablesInUse calls the GetWebComponents method to return a list of all the items in the list. Descendant classes can override this method to return only those items that meet a certain criterion.

See Also

VariablesInUse (see page 5419)

GetWebComponents (see page 6065)

54.1.10.3.8 TAdapterDefaultActions.SetDefaultWebComponents Method

Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.

Pascal

```
procedure SetDefaultWebComponents(AList: TWebComponentList); override;
```

C++

```
virtual __fastcall SetDefaultWebComponents(TWebComponentList AList);
```

Description

GetDefaultWebComponents supplies the default set of child items for this component. As implemented in TAdapterSubComponent, GetDefaultWebComponents always returns nil (Delphi) or NULL (C++) because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and TAdapterDefaultFields) override this method to return the list of default fields or actions.

SetDefaultWebComponents assigns the default set of child items for this component. As implemented in TWebContainerComponent, SetDefaultWebComponents does nothing because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and

TAdapterDefaultFields) override this method to store the list of default fields or actions.

See Also

GetDefaultWebComponents (see page 5411)

IsDefaultField (see page 6042)

54.1.10.4 TAdapterDefaultActions Properties

The properties of the TAdapterDefaultActions class are listed here.

Public Properties

	Name	Description
	DefaultWebComponents (see page 5237)	Lists the action components that the associated adapter includes by default.

54.1.10.4.1 TAdapterDefaultActions.DefaultWebComponents Property

Lists the action components that the associated adapter includes by default.

Pascal

```
property DefaultWebComponents: TWebComponentList;
```

C++

```
__property TWebComponentList DefaultWebComponents;
```

Description

Read (see page 3634) DefaultWebComponents to access the list of action components that the adapter uses when you do not explicitly add any actions to this object. Each default action is a descendant of TAdapterNamedAction.

If you explicitly add action components to this object, the adapter uses the actions in the WebActions (see page 5214) property instead.

See Also

TBaseAdapterAction (see page 5447)

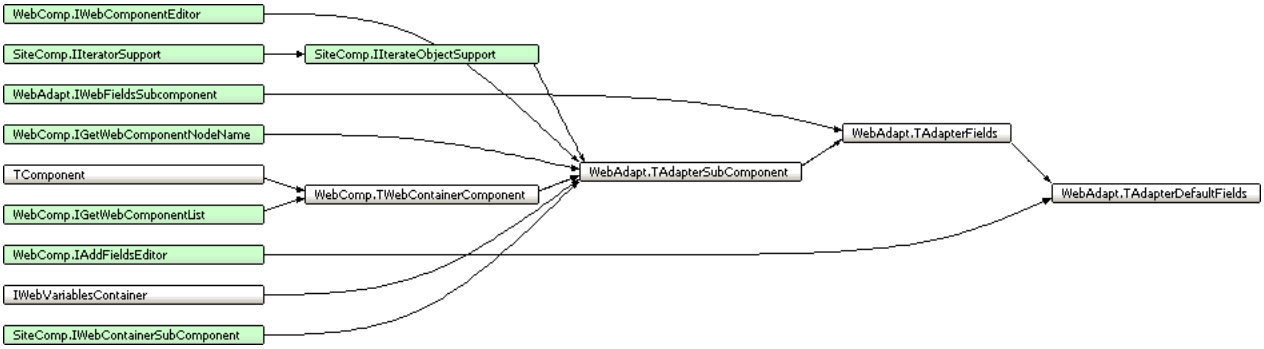
WebActions (see page 5214)

Adapter (see page 5418)

54.1.11 TAdapterDefaultFields Class

TAdapterDefaultFields manages the list of fields that belong to an adapter that supports a default set of fields.

Class Hierarchy



Pascal

```
TAdapterDefaultFields = class(TAdapterFields, IAddFieldsEditor);
```

C++

```
class TAdapterDefaultFields : public TAdapterFields, public IAddFieldsEditor;
```

File

WebAdapt

Description

TAdapterDefaultFields is the type of the Data property on an adapter component. It manages two lists of fields (TAdapterNamedField (see page 5351) descendants) that belong to the adapter: the list of fields that have been explicitly added to the adapter, and the list of fields that the adapter includes by default. The explicitly added field objects are available using the WebFields (see page 5281) property. The default fields are available using the DefaultWebComponents (see page 5243) property.

See Also

TDefaultFieldsAdapter (see page 5738)

TAdapterActions (see page 5209)

TAdapterDefaultActions (see page 5231)

TAdapterFields (see page 5276)

TAdapterNamedField (see page 5351)

54.1.11.1 TAdapterDefaultFields Members

The following tables list the members exposed by TAdapterDefaultFields.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5278)	Indicates whether the associated adapter supports a specified class of field component.
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.

	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
	GetAddAllFieldsItem (see page 5241)	This is GetAddAllFieldsItem, a member of class TAdapterDefaultFields.
	GetAddFieldsDlgCaption (see page 5241)	This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultFields.
	GetAddFieldsItem (see page 5241)	This is GetAddFieldsItem, a member of class TAdapterDefaultFields.
V	GetChildren (see page 6065)	Executes a callback for each child Web item.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
V	GetDefaultWebComponents (see page 5241)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetNewFieldPrefix (see page 5242)	This is GetNewFieldPrefix, a member of class TAdapterDefaultFields.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
V	GetVariablesInUse (see page 5242)	Returns the value of the VariablesInUse property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	GetWebComponents (see page 6065)	Returns the list of Web items that this item manages.
V	ImplCanAddClass (see page 5279)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
V	ImplCanAddClass (see page 5414)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
V	ImplGetDefaultComponentList (see page 6066)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	ImplGetWebComponentNodeName (see page 5280)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
V	ImplGetWebComponentNodeName (see page 5415)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
V	SetChildOrder (see page 6066)	Positions a child component in the list of child Web items.
V	SetDefaultWebComponents (see page 5242)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	SetWebParent (see page 5280)	Associates this component with an adapter.
V	SetWebParent (see page 5417)	Introduces a method to associate this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Protected Properties

	Name	Description
R	Adapter (see page 5418)	Indicates the adapter that uses this object to manage its fields or actions.
R	VariablesInUse (see page 5419)	Lists those fields or actions in the collection for which variables are defined.
R	WebContainerComponentHelper (see page 6067)	Provides access to the helper object that allows this object to manage its Web items.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
V	ClearDefaultComponents (see page 5240)	Empties the list of default fields that is the value of the DefaultWebComponents (see page 5243) property.
V	Create (see page 6064)	Creates and initializes an instance of TWebContainerComponent (see page 6063).
V	Destroy (see page 5240)	Frees an instance of TAdapterDefaultFields (see page 5237).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetComponentList (see page 6082)	This is GetComponentList, a member of class IGetWebComponentList.
	GetCurrentObject (see page 1052)	This is GetCurrentObject, a member of class IIterateObjectSupport.
	GetDefaultComponentList (see page 6082)	This is GetDefaultComponentList, a member of class IGetWebComponentList.
V	GetParentComponent (see page 5412)	Returns the associated adapter.
	GetWebComponentNodeName (see page 6083)	This is GetWebComponentNodeName, a member of class IGetWebComponentNodeName.
V	HasParent (see page 5414)	Indicates whether this component has an associated adapter.

	NextIteration (see page 1056)	Advances to the objects next item.
V	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.
V	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.

Public Properties

	Name	Description
R	DefaultWebComponents (see page 5243)	Lists the field components that the associated adapter includes by default.
R	WebFields (see page 5281)	Lists the field components that this object manages.

54.1.11.2 TAdapterDefaultFields.Destroy Destructor

Frees an instance of TAdapterDefaultFields (see page 5237).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAdapterDefaultFields();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks for a nil reference before calling Destroy.

See Also

System::TObject::Free (see page 3372)

54.1.11.3 TAdapterDefaultFields Methods

The methods of the TAdapterDefaultFields class are listed here.

Protected Methods

	Name	Description
	GetAddAllFieldsItem (see page 5241)	This is GetAddAllFieldsItem, a member of class TAdapterDefaultFields.
	GetAddFieldsDlgCaption (see page 5241)	This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultFields.
	GetAddFieldsItem (see page 5241)	This is GetAddFieldsItem, a member of class TAdapterDefaultFields.
V	GetDefaultWebComponents (see page 5241)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetNewFieldPrefix (see page 5242)	This is GetNewFieldPrefix, a member of class TAdapterDefaultFields.
V	GetVariablesInUse (see page 5242)	Returns the value of the VariablesInUse property.
V	SetDefaultWebComponents (see page 5242)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.

Public Methods

	Name	Description
V	ClearDefaultComponents (see page 5240)	Empties the list of default fields that is the value of the DefaultWebComponents (see page 5243) property.

54.1.11.3.1 TAdapterDefaultFields.ClearDefaultComponents Method

Empties the list of default fields that is the value of the DefaultWebComponents (see page 5243) property.

Pascal

```
procedure ClearDefaultComponents; virtual;
```

C++

```
virtual __fastcall ClearDefaultComponents();
```

Description

The associated adapter calls ClearDefaultComponents when it changes its set of default fields. After a call to ClearDefaultComponents, the adapter generates a new set of default components the next time the application reads the default fields.

See Also

DefaultWebComponents (see page 5243)

54.1.11.3.2 TAdapterDefaultFields.GetAddAllFieldsItem Method

Pascal

```
function GetAddAllFieldsItem: string;
```

C++

```
__fastcall UnicodeString GetAddAllFieldsItem();
```

Description

This is GetAddAllFieldsItem, a member of class TAdapterDefaultFields.

54.1.11.3.3 TAdapterDefaultFields.GetAddFieldsDlgCaption Method

Pascal

```
function GetAddFieldsDlgCaption: string;
```

C++

```
__fastcall UnicodeString GetAddFieldsDlgCaption();
```

Description

This is GetAddFieldsDlgCaption, a member of class TAdapterDefaultFields.

54.1.11.3.4 TAdapterDefaultFields.GetAddFieldsItem Method

Pascal

```
function GetAddFieldsItem: string;
```

C++

```
__fastcall UnicodeString GetAddFieldsItem();
```

Description

This is GetAddFieldsItem, a member of class TAdapterDefaultFields.

54.1.11.3.5 TAdapterDefaultFields.GetDefaultWebComponents Method

Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.

Pascal

```
function GetDefaultWebComponents: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetDefaultWebComponents();
```

Description

GetDefaultWebComponents supplies the default set of child items for this component. As implemented in TAdapterSubComponent, GetDefaultWebComponents always returns nil (Delphi) or NULL (C++) because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and TAdapterDefaultFields) override this method to return the list of default fields or actions.

See Also

GetWebComponents (see page 6065)

TAdapterDefaultActions (see page 5231)

TAdapterDefaultFields (see page 5237)

54.1.11.3.6 TAdapterDefaultFields.GetNewFieldPrefix Method

Pascal

```
function GetNewFieldPrefix: string;
```

C++

```
__fastcall UnicodeString GetNewFieldPrefix();
```

Description

This is GetNewFieldPrefix, a member of class TAdapterDefaultFields.

54.1.11.3.7 TAdapterDefaultFields.GetVariablesInUse Method

Returns the value of the VariablesInUse property.

Pascal

```
function GetVariablesInUse: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetVariablesInUse();
```

Description

GetVariablesInUse is the protected read implementation for the VariablesInUse property.

In TAdapterSubComponent, GetVariablesInUse calls the GetWebComponents method to return a list of all the items in the list. Descendant classes can override this method to return only those items that meet a certain criterion.

See Also

VariablesInUse (see page 5419)

GetWebComponents (see page 6065)

54.1.11.3.8 TAdapterDefaultFields.SetDefaultWebComponents Method

Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.

Pascal

```
procedure SetDefaultWebComponents(AList: TWebComponentList); override;
```

C++

```
virtual __fastcall SetDefaultWebComponents(TWebComponentList AList);
```

Description

GetDefaultWebComponents supplies the default set of child items for this component. As implemented in TAdapterSubComponent, GetDefaultWebComponents always returns nil (Delphi) or NULL (C++) because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and TAdapterDefaultFields) override this method to return the list of default fields or actions.

SetDefaultWebComponents assigns the default set of child items for this component. As implemented in TWebContainerComponent, SetDefaultWebComponents does nothing because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions and TAdapterDefaultFields) override this method to store the list of default fields or actions.

See Also

GetDefaultWebComponents (see page 5411)

IsDefaultField (see page 6042)

54.1.11.4 TAdapterDefaultFields Properties

The properties of the TAdapterDefaultFields class are listed here.

Public Properties

	Name	Description
	DefaultWebComponents (see page 5243)	Lists the field components that the associated adapter includes by default.

54.1.11.4.1 TAdapterDefaultFields.DefaultWebComponents Property

Lists the field components that the associated adapter includes by default.

Pascal

```
property DefaultWebComponents: TWebComponentList;
```

C++

```
__property TWebComponentList DefaultWebComponents;
```

Description

Read (see page 3634) DefaultWebComponents to access the list of field components that the adapter uses when you do not explicitly add any field components to this object. Each default field component is a descendant of TAdapterNamedField (see page 5351).

If you explicitly add field components to this object, the adapter uses the fields in the WebFields (see page 5281) property instead.

See Also

TAdapterNamedField (see page 5351)

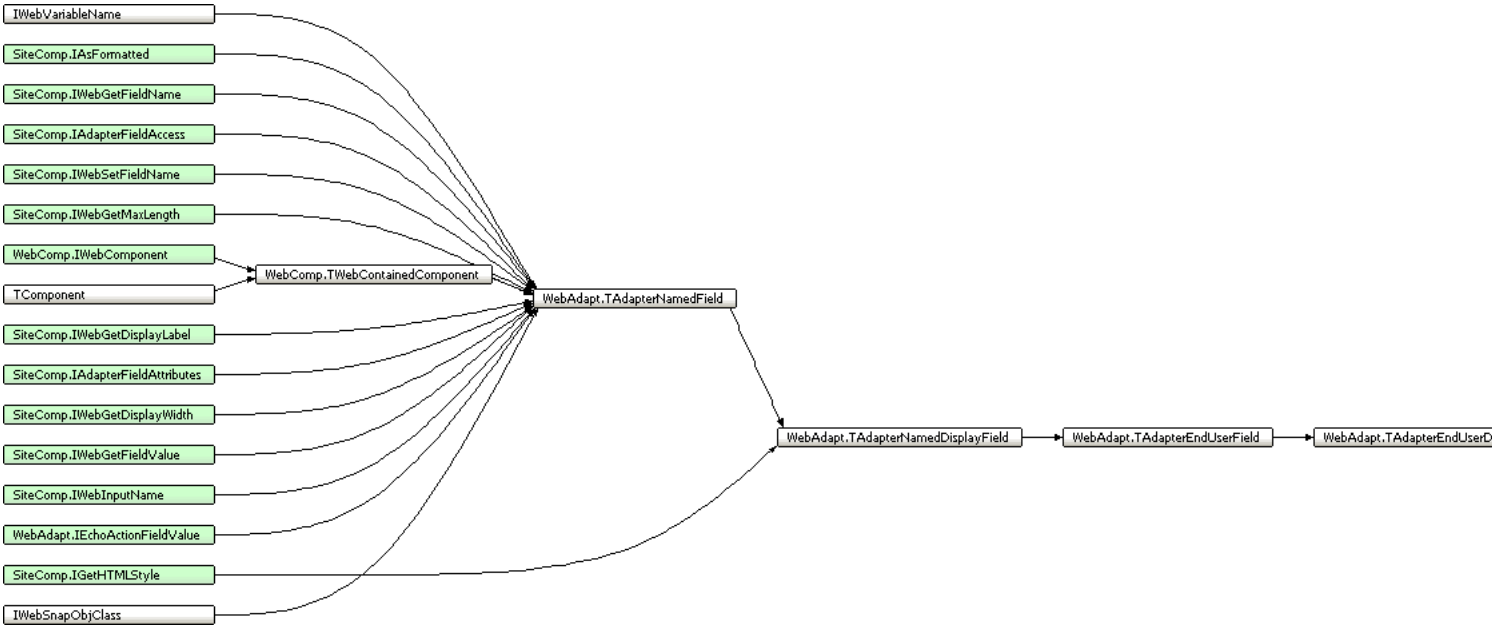
WebFields (see page 5281)

Adapter (see page 5418)

54.1.12 TAdapterEndUserDisplayNameField Class

TAdapterEndUserDisplayNameField is an adapter field used to access the end-user's name.

Class Hierarchy



Pascal

```
TAdapterEndUserDisplayNameField = class(TAdapterEndUserField);
```

C++

```
class TAdapterEndUserDisplayNameField : public TAdapterEndUserField;
```

File

WebAdapt

Description

TAdapterEndUserDisplayNameField is added to TApplicationAdapter (see page 5439).

See Also

TAdapterEndUserField (see page 5248)

TEndUserAdapter (see page 5764)

TEndUserSessionAdapter (see page 5792)

54.1.12.1 TAdapterEndUserDisplayNameField Members

The following tables list the members exposed by TAdapterEndUserDisplayNameField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5247)	Returns the name used to access this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5247)	Returns the value associated with this adapter field.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
V	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.

	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	Adapter (see page 5251)	Returns the parent adapter of this adapter field.
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.

	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.12.2 TAdapterEndUserDisplayNameField Methods

The methods of the TAdapterEndUserDisplayNameField class are listed here.

Protected Methods

	Name	Description
V	GetDefaultFieldName (see page 5247)	Returns the name used to access this adapter field with server-side script.
V	ImplGetValue (see page 5247)	Returns the value associated with this adapter field.

54.1.12.2.1 TAdapterEndUserDisplayNameField.GetDefaultFieldName Method

Returns the name used to access this adapter field with server-side script.

Pascal

```
function GetDefaultFieldName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultFieldName();
```

Description

GetDefaultFieldName returns 'DisplayName'. This allows server-side script to access this adapter field using the parent adapter's DisplayName property.

54.1.12.2.2 TAdapterEndUserDisplayNameField.ImplGetValue Method

Returns the value associated with this adapter field.

Pascal

```
function ImplGetValue: Variant; override;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

ImplGetValue returns the result of GetDisplayNameValue. Server-side script accesses the result of this function using the

DisplayText property of this adapter field. Server-side script may use this value to display the end-user's name on a Web page.

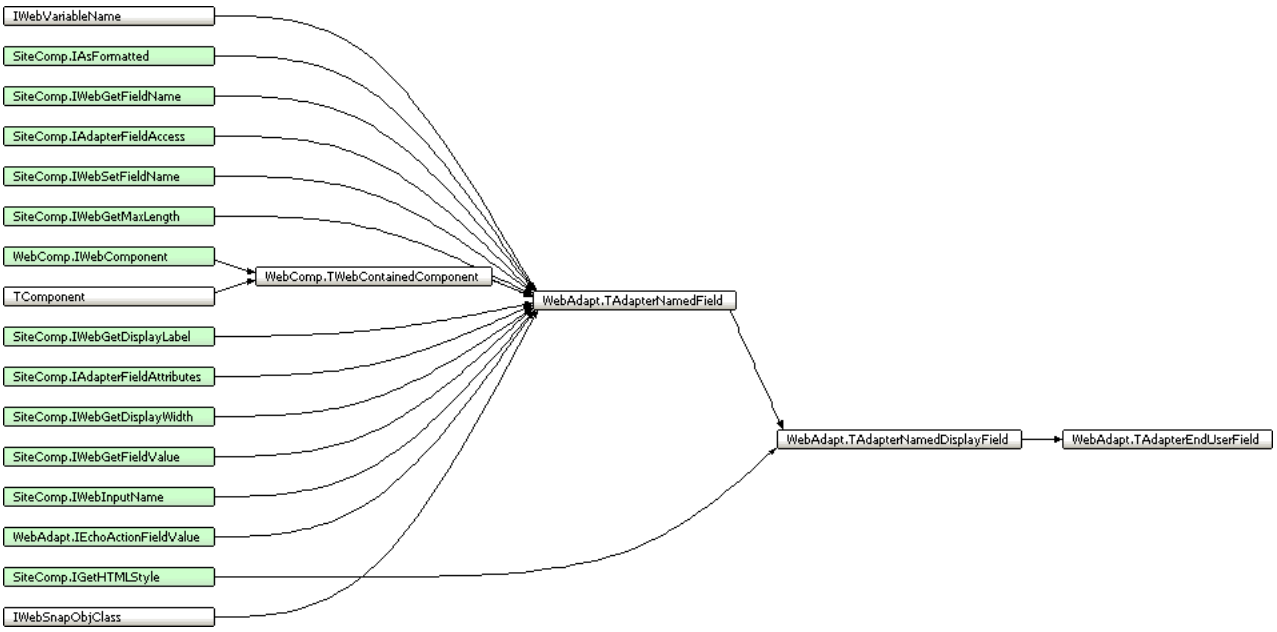
See Also

GetDisplayNameValue (see page 5507)

54.1.13 TAdapterEndUserField Class

TAdapterEndUserField is a base class for adapter field components that are children of an end-user adapter component.

Class Hierarchy



Pascal

```
TAdapterEndUserField = class(TAdapterNamedDisplayField);
```

C++

```
class TAdapterEndUserField : public TAdapterNamedDisplayField;
```

File

WebAdapt

Description

TAdapterEndUserField implements functionality useful to an adapter field that can be a child of TEndUserAdapter (see page 5764) or TEndUserSessionAdapter (see page 5792).

See Also

TAdapterNamedDisplayField (see page 5343)

TBaseEndUserAdapter (see page 5497)

TEndUserAdapter (see page 5764)

TEndUserSessionAdapter (see page 5792)

TAdapterEndUserLoggedInField (see page 5252)

TAdapterEndUserDisplayNameField (see page 5244)

54.1.13.1 TAdapterEndUserField Members

The following tables list the members exposed by TAdapterEndUserField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.

	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	Adapter (see page 5251)	Returns the parent adapter of this adapter field.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.13.2 TAdapterEndUserField Properties

The properties of the TAdapterEndUserField class are listed here.

Protected Properties

	Name	Description
R	Adapter (see page 5251)	Returns the parent adapter of this adapter field.

54.1.13.2.1 TAdapterEndUserField.Adapter Property

Returns the parent adapter of this adapter field.

Pascal

```
property Adapter: TBaseEndUserAdapter;
```

C++

```
__property TBaseEndUserAdapter Adapter;
```

Description

Descendants use this property to access the parent adapter.

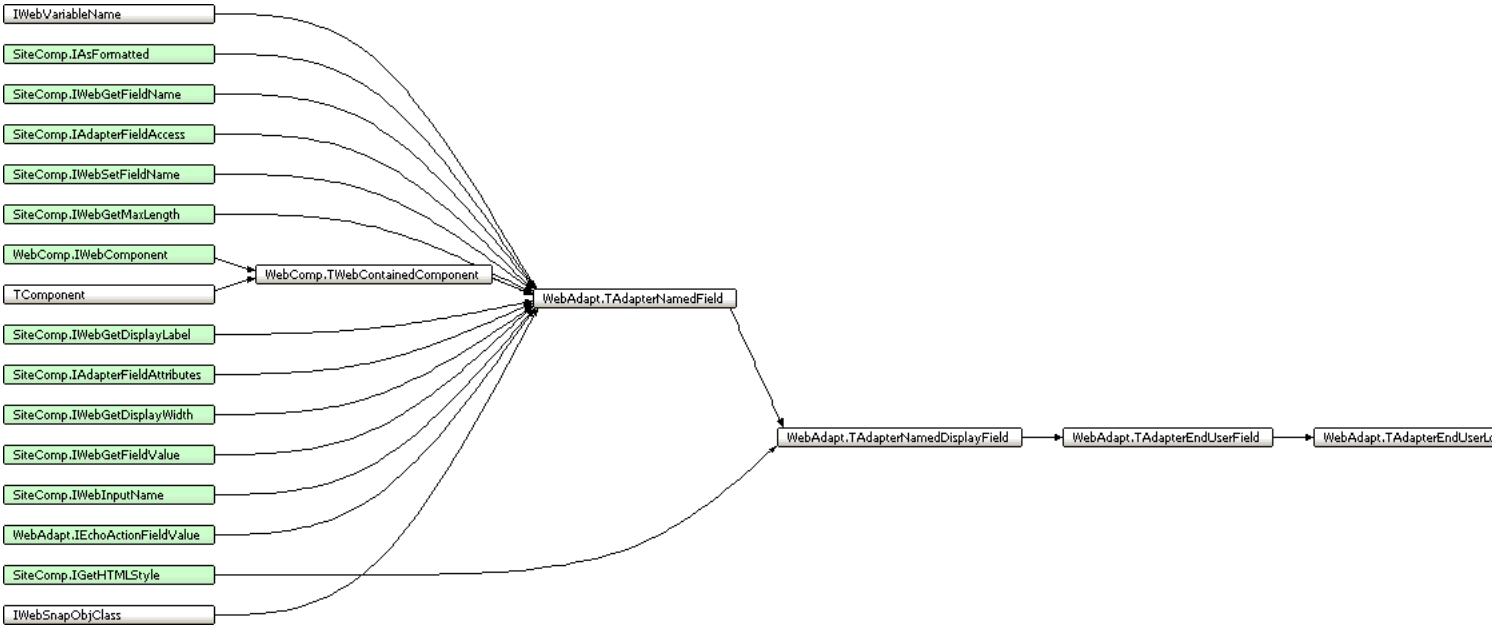
See Also

TBaseEndUserAdapter (see page 5497)

54.1.14 TAdapterEndUserLoggedInField Class

TAdapterEndUserLoggedInField is an adapter field used to access the end-user logged in flag.

Class Hierarchy



Pascal

```
TAdapterEndUserLoggedInField = class(TAdapterEndUserField);
```

C++

```
class TAdapterEndUserLoggedInField : public TAdapterEndUserField;
```

File

WebAdapt

Description

TAdapterEndUserLoggedInField is added to TApplicationAdapter (see page 5439). The logged-in flag indicates whether the user is logged-in. This value may be used by server-side script to conditionally generate HTML. For example, when the end-user is logged in, a logout hyperlink is displayed. When the end-user is not logged in, a logout hyperlink is not displayed.

See Also

TApplicationAdapter (see page 5439)

TEndUserAdapter (see page 5764)

TEndUserSessionAdapter (see page 5792)

54.1.14.1 TAdapterEndUserLoggedInField Members

The following tables list the members exposed by TAdapterEndUserLoggedInField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5255)	Returns the name used to access this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5255)	Returns the value associated with this adapter field.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
V	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.

	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	Adapter (see page 5251)	Returns the parent adapter of this adapter field.
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.

	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.14.2 TAdapterEndUserLoggedInField Methods

The methods of the TAdapterEndUserLoggedInField class are listed here.

Protected Methods

	Name	Description
V	GetDefaultFieldName (see page 5255)	Returns the name used to access this adapter field with server-side script.
V	ImplGetValue (see page 5255)	Returns the value associated with this adapter field.

54.1.14.2.1 TAdapterEndUserLoggedInField.GetDefaultFieldName Method

Returns the name used to access this adapter field with server-side script.

Pascal

```
function GetDefaultFieldName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultFieldName();
```

Description

GetDefaultFieldName returns 'LoggedIn'. This allows server-side script to access this adapter field using the parent adapter's LoggedIn property.

54.1.14.2.2 TAdapterEndUserLoggedInField.ImplGetValue Method

Returns the value associated with this adapter field.

Pascal

```
function ImplGetValue: Variant; override;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

ImplGetValue returns the result of GetLoggedInValue. Server-side script accesses the result of this function using the Value (

see page 5369) property of this adapter field. This value may be used by server-side script to conditionally generate HTML. For example, when the end-user is logged in, a logout hyperlink is displayed. When the end-user is not logged in, a logout hyperlink is not displayed.

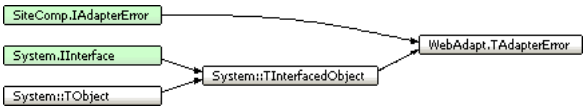
See Also

GetLoggedInValue (see page 5508)

54.1.15 TAdapterError Class

TAdapterError is the implementation of IAdapterError (see page 992).

Class Hierarchy



Pascal

```
TAdapterError = class(TInterfacedObject, IAdapterError);
```

C++

```
class TAdapterError : public TInterfacedObject, public IAdapterError;
```

File

WebAdapt

Description

TAdapterError is the implementation class for IAdapterError (see page 992).

See Also

IAdapterError (see page 992)

54.1.15.1 TAdapterError Members

The following tables list the members exposed by TAdapterError.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	GetErrorText (see page 5258)	Returns the value of the ErrorText property.
	GetField (see page 5258)	Returns the value of the Field property.
	GetID (see page 5259)	Returns the value of the ID property.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5258)	Create instantiates an instance of TAdapterError (see page 5256). Do not call this constructor in application code. The adapter errors list object instantiates adapter error objects as needed.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	ErrorText (see page 994)	Returns text describing the error.
R	Field (see page 994)	Returns text describing the error.
R	ID (see page 994)	Returns error ID.
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

54.1.15.2 TAdapterError.Create Constructor

Create instantiates an instance of TAdapterError (see page 5256). Do not call this constructor in application code. The adapter errors list object instantiates adapter error objects as needed.

Pascal

```
constructor Create(AErrors: TAdapterErrorsList; AIndex: Integer);
```

C++

```
__fastcall TAdapterError(TAdapterErrorsList AErrors, int AIndex);
```

Description

```
constructor Create(AErrors: TAdapterErrorsListTAdapterErrorsList; AIndex: Integer); public;
```

Create instantiates an instance of TAdapterError (see page 5256). Do not call this constructor in application code. The adapter errors list object instantiates adapter error objects as needed.

AErrors is the adapter errors list object that creates this TAdapterError (see page 5256) object.

AIndex is the index of this adapter error in the list that AErrors maintains.

54.1.15.3 TAdapterError Methods

The methods of the TAdapterError class are listed here.

Protected Methods

	Name	Description
	GetErrorText (see page 5258)	Returns the value of the ErrorText property.
	GetField (see page 5258)	Returns the value of the Field property.
	GetID (see page 5259)	Returns the value of the ID property.

54.1.15.3.1 TAdapterError.GetErrorText Method

Returns the value of the ErrorText property.

Pascal

```
function GetErrorText: string;
```

C++

```
__fastcall UnicodeString GetErrorText();
```

Description

GetErrorText is the read implementation of the ErrorText property.

See Also

ErrorText (see page 994)

54.1.15.3.2 TAdapterError.GetField Method

Returns the value of the Field property.

Pascal

```
function GetField: TComponent;
```

C++

```
__fastcall TComponent * GetField();
```

Description

GetField is the read implementation of the Field property.

See Also

Field (see page 994)

54.1.15.3.3 TAdapterError.GetID Method

Returns the value of the ID property.

Pascal

```
function GetID: integer;
```

C++

```
__fastcall int GetID();
```

Description

GetID is the read implementation of the ID property.

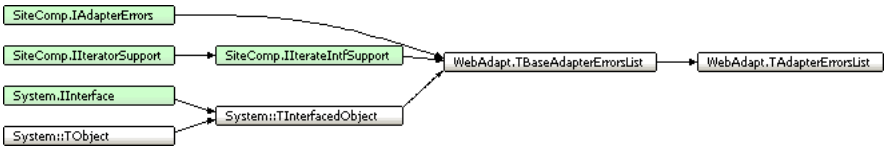
See Also

ID (see page 994)

54.1.16 TAdapterErrorsList Class

TAdapterErrorsList keeps track of errors that an adapter encounters.

Class Hierarchy



Pascal

```
TAdapterErrorsList = class(TBaseAdapterErrorsList);
```

C++

```
class TAdapterErrorsList : public TBaseAdapterErrorsList;
```

File

WebAdapt

Description

TAdapterErrorsList acts as a repository for all the errors an adapter (or any of its subcomponents) encounters while processing an HTTP request message. Adapter components create an instance of this class to implement their Errors (see page 5487) property. Server-side scripts can use the Errors (see page 5487) property to access the errors in this list. The usual purpose of such a script is to display error messages to the end user.

To add new error objects to the list, call the AddError (see page 5263) method. To access the errors in the list, read its Errors (see page 5487) property. Errors (see page 5487) lists the IAdapterError (see page 992) interfaces of adapter error objects (TAdapterError (see page 5256)) that represent each error in the list. You can also access the individual properties of those error objects using the FieldNames (see page 5266), IDs (see page 5266), and Messages (see page 5266) properties of the TAdapterErrorsList instance.

TAdapterErrorsList implements the IAdapterErrorsList interface.

Note: Do not confuse TAdapterErrorsList with TAdapterErrorList. TAdapterErrorsList stores the errors that the WebSnap application encounters when using an adapter. TAdapterErrorList is a display component that displays the errors from a TAdapterErrorsList object.

See Also

TAdapterErrorList (see page 6397)

TCustomAdapter (see page 5531)

TAdapterError (see page 5256)

IAdapterErrors (see page 995)

IAdapterError (see page 992)

54.1.16.1 TAdapterErrorsList Members

The following tables list the members exposed by TAdapterErrorsList.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	EndIterator (see page 5483)	Signals the end of the iterating operation.
	GetCurrentIntf (see page 5483)	This is GetCurrentIntf, a member of class TBaseAdapterErrorsList.
	GetError (see page 5484)	Returns a particular error.
	GetErrorCount (see page 5484)	Return the number of errors in the errors list.
	GetObjectErrors (see page 5484)	Returns an object that is used to enumerate all errors associated with an adapter field.
	HasObjectErrors (see page 5484)	Indicates whether the errors list contains objects associated with a particular adapter field.
	ImplClearErrors (see page 5264)	This is ImplClearErrors, a member of class TAdapterErrorsList.
	ImplDefineLabel (see page 5264)	This is ImplDefineLabel, a member of class TAdapterErrorsList.
	ImplGetError (see page 5264)	This is ImplGetError, a member of class TAdapterErrorsList.
	ImplGetErrorCount (see page 5265)	This is ImplGetErrorCount, a member of class TAdapterErrorsList.
	ImplGetObjectErrors (see page 5265)	This is ImplGetObjectErrors, a member of class TAdapterErrorsList.
	ImplHasObjectErrors (see page 5265)	This is ImplHasObjectErrors, a member of class TAdapterErrorsList.
	NextIteration (see page 5486)	Advances to the objects next item.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	StartIterator (see page 5486)	Positions the object on its first item and starts the iteration process.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	AddError (see page 5263)	This is the overview for the AddError method overload.
	AddError (see page 5481)	This is the overview for the AddError method overload.
	AfterConstruction (see page 3345)	Responds after the last constructor executes.
	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearErrors (see page 996)	Clears the errors list.
	ClearErrors (see page 5482)	Clear error list.
	Create (see page 5262)	Creates and initializes an instance of TAdapterErrorsList (see page 5259).
	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
	DefineLabel (see page 996)	Associates a label with all errors associated with a particular adapter field.
	DefineLabel (see page 5483)	Define error label for field.
	Destroy (see page 5262)	Frees an instance of TAdapterErrorsList (see page 5259).
	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetCurrentIntf (see page 1051)	This is GetCurrentIntf, a member of class IIterateIntfSupport.
	GetError (see page 996)	Returns a particular error.
	GetErrorCount (see page 997)	Return the number of errors in the errors list.
	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetObjectErrors (see page 997)	Returns an object that is used to enumerate all errors associated with an adapter field.
	HasObjectErrors (see page 997)	Indicates whether the errors list contains objects associated with a particular adapter field.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NextIteration (see page 1056)	Advances to the objects next item.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.

	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	ErrorCount (see page 998)	Returns the number of errors in the errors list.
	ErrorCount (see page 5487)	Number of error objects contained.
	Errors (see page 998)	Returns an error from the list.
	Errors (see page 5487)	Access to error objects.
	FieldNames (see page 5266)	Lists the names of the objects that encountered the errors in the list.
	IDs (see page 5266)	Lists the error codes of the errors in the list.
	Messages (see page 5266)	Lists the error messages for the errors in the list.
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

54.1.16.2 TAdapterErrorsList.Create Constructor

Creates and initializes an instance of TAdapterErrorsList (see page 5259).

Pascal

```
constructor Create(AAdapter: TObject);
```

C++

```
__fastcall TAdapterErrorsList(TObject * AAdapter);
```

Description

Typically, WebSnap applications do not create their own instances of TAdapterErrorsList (see page 5259). Adapter objects instantiate this class to implement their Errors (see page 5487) property.

AAdapter is the adapter component that uses this object to implement its Errors (see page 5487) property.

See Also

Errors (see page 5573)

54.1.16.3 TAdapterErrorsList.Destroy Destructor

Frees an instance of TAdapterErrorsList (see page 5259).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAdapterErrorsList();
```

Description

Do not call Destroy directly. Instead, call the Free method, which checks whether the reference to the errors list is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

54.1.16.4 TAdapterErrorsList Methods

The methods of the TAdapterErrorsList class are listed here.

Protected Methods

	Name	Description
	ImplClearErrors (see page 5264)	This is ImplClearErrors, a member of class TAdapterErrorsList.
	ImplDefineLabel (see page 5264)	This is ImplDefineLabel, a member of class TAdapterErrorsList.
	ImplGetError (see page 5264)	This is ImplGetError, a member of class TAdapterErrorsList.
	ImplGetErrorCount (see page 5265)	This is ImplGetErrorCount, a member of class TAdapterErrorsList.
	ImplGetObjectErrors (see page 5265)	This is ImplGetObjectErrors, a member of class TAdapterErrorsList.
	ImplHasObjectErrors (see page 5265)	This is ImplHasObjectErrors, a member of class TAdapterErrorsList.

Public Methods

	Name	Description
	AddError (see page 5263)	This is the overview for the AddError method overload.

54.1.16.4.1 AddError Method

This is the overview for the AddError method overload.

Overload List

	Name	Description
	TAdapterErrorsList.AddError (Exception, string) (see page 5263)	Adds an error to the list.
	TAdapterErrorsList.AddError (Exception, TObject) (see page 5263)	Adds an error to the list.
	TAdapterErrorsList.AddError (string, string, Integer) (see page 5263)	Adds an error to the list.
	TAdapterErrorsList.AddError (string, TObject, Integer) (see page 5263)	Adds an error to the list.

54.1.16.4.1.1 TAdapterErrorsList.AddError Method (Exception, TObject)

Adds an error to the list.

Pascal

```
procedure AddError(AException: Exception; const AObjectName: string = ''); override;
procedure AddError(const AMessage: string; const AObjectName: string = ''; AID: Integer = 0);
override;
procedure AddError(const AMessage: string; AObject: TObject; AID: Integer = 0); override;
procedure AddError(AException: Exception; AObject: TObject); override;
```

C++

```
virtual __fastcall AddError(Exception AException, const UnicodeString AObjectName = '');
virtual __fastcall AddError(const UnicodeString AMessage, const UnicodeString AObjectName =
'', int AID = 0);
virtual __fastcall AddError(const UnicodeString AMessage, TObject * AObject, int AID = 0);
virtual __fastcall AddError(Exception AException, TObject * AObject);
```

Description

AddError adds an error to the object's internal list. An error is described by three pieces of information:

An error message string. You can specify this string directly with the AMessage parameter, or using an Exception (see page 3949) object (with the AException parameter). If you specify an Exception (see page 3949) object, the object's Message property becomes the message string.

The name of an object (Variable) related to the error. You can specify this value as a string (with the AObjectName parameter) or as an object reference (with the AObject parameter). If you omit both these parameters, but supply an EAdapterFieldException (see page 5178) object as the AException parameter, TAdapterErrorsList (see page 5259) uses the FieldName property of that exception object. If you do not supply an AObject parameter, an AObjectName parameter, or an EAdapterFieldException (see page 5178) object as the AException parameter, TAdapterErrorsList (see page 5259) uses an empty string.

An error ID value. You can specify this value using the AID parameter. If you do not supply a value for AID but specify an EAdapterException (see page 5177) object as the AException parameter, TAdapterErrorsList (see page 5259) uses the ID property of that exception object. If you do not supply an AID parameter or an EAdapterException (see page 5177) object, TAdapterErrorsList (see page 5259) uses 0.

See Also

FieldName (see page 5180)

ID (see page 5178)

Messages (see page 5266)

FieldNames (see page 5266)

IDs (see page 5266)

54.1.16.4.2 TAdapterErrorsList.ImplClearErrors Method

Pascal

```
procedure ImplClearErrors; override;
```

C++

```
virtual __fastcall ImplClearErrors();
```

Description

This is ImplClearErrors, a member of class TAdapterErrorsList.

54.1.16.4.3 TAdapterErrorsList.ImplDefineLabel Method

Pascal

```
procedure ImplDefineLabel(const AName: string; const ALabel: string); override;
```

C++

```
virtual __fastcall ImplDefineLabel(const UnicodeString AName, const UnicodeString ALabel);
```

Description

This is ImplDefineLabel, a member of class TAdapterErrorsList.

54.1.16.4.4 TAdapterErrorsList.ImplGetError Method

Pascal

```
function ImplGetError(I: Integer): IAdapterError; override;
```

C++

```
virtual __fastcall IAdapterError ImplGetError(int I);
```

Description

This is ImplGetError, a member of class TAdapterErrorsList.

54.1.16.4.5 TAdapterErrorsList.ImplGetErrorCount Method

Pascal

```
function ImplGetErrorCount: Integer; override;
```

C++

```
virtual __fastcall int ImplGetErrorCount();
```

Description

This is ImplGetErrorCount, a member of class TAdapterErrorsList.

54.1.16.4.6 TAdapterErrorsList.ImplGetObjectErrors Method

Pascal

```
function ImplGetObjectErrors(const AName: string): TObject; override;
```

C++

```
virtual __fastcall TObject * ImplGetObjectErrors(const UnicodeString AName);
```

Description

This is ImplGetObjectErrors, a member of class TAdapterErrorsList.

54.1.16.4.7 TAdapterErrorsList.ImplHasObjectErrors Method

Pascal

```
function ImplHasObjectErrors(const AName: string): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplHasObjectErrors(const UnicodeString AName);
```

Description

This is ImplHasObjectErrors, a member of class TAdapterErrorsList.

54.1.16.5 TAdapterErrorsList Properties

The properties of the TAdapterErrorsList class are listed here.

Public Properties

	Name	Description
	FieldNames (see page 5266)	Lists the names of the objects that encountered the errors in the list.
	IDs (see page 5266)	Lists the error codes of the errors in the list.
	Messages (see page 5266)	Lists the error messages for the errors in the list.

54.1.16.5.1 TAdapterErrorsList.FieldNames Property

Lists the names of the objects that encountered the errors in the list.

Pascal

```
property FieldNames [I: Integer]: string;
```

C++

```
__property UnicodeString FieldNames[int I];
```

Description

Use FieldNames to access the name of the object associated with a specified error. FieldNames values typically reflect the name of an adapter field that was the cause of the error. However, they can be any object reference for which there is a defined Variable that can be accessed from server-side script. If there is no object associated with an error, the value of FieldNames is an empty string.

I is the index of the error in the list, where 0 specifies the first error, 1 specifies the second error, and so on.

The value of FieldNames for an error is set by the AddError (see page 5263) method when the error is added to the list.

See Also

AddError (see page 5263)

Field (see page 994)

FieldName (see page 5180)

54.1.16.5.2 TAdapterErrorsList.IDs Property

Lists the error codes of the errors in the list.

Pascal

```
property IDs [I: Integer]: integer;
```

C++

```
__property int IDs[int I];
```

Description

Use IDs to access the ID (error code) of a specified error in the list. If the error has no error code, the value of IDs is 0.

I is the index of the error in the list, where 0 specifies the first error, 1 specifies the second error, and so on.

The value of IDs for an error is set by the AddError (see page 5263) method when the error is added to the list.

See Also

AddError (see page 5263)

ID (see page 994)

ID (see page 5178)

54.1.16.5.3 TAdapterErrorsList.Messages Property

Lists the error messages for the errors in the list.

Pascal

```
property Messages [I: Integer]: string;
```

C++

```
__property UnicodeString Messages[int I];
```

Description

Use Messages to access the error message for a specified error in the list.

I is the index of the error in the list, where 0 specifies the first error, 1 specifies the second error, and so on.

The value of Messages for an error is set by the AddError (see page 5263) method when the error is added to the list.

See Also

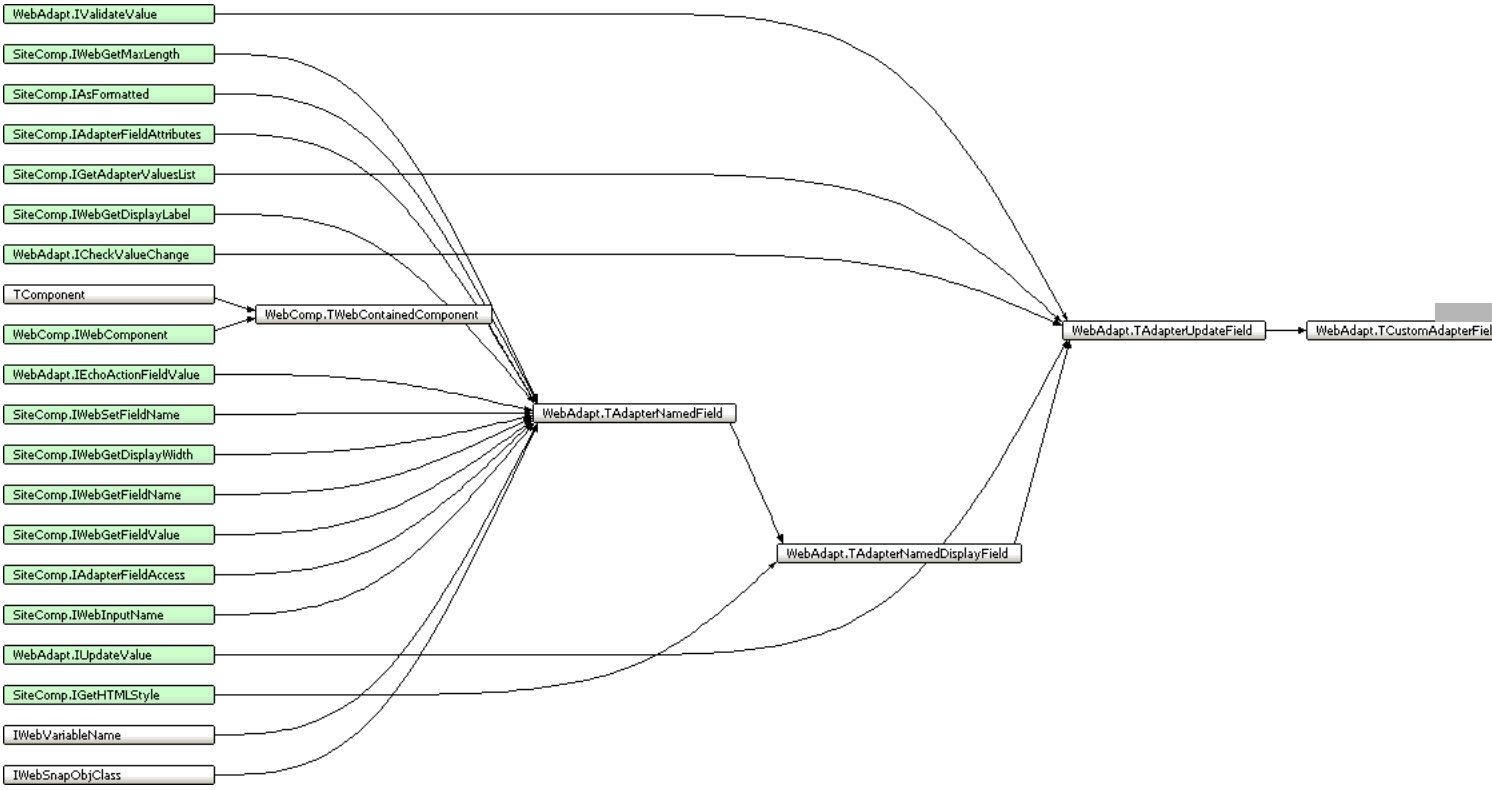
AddError (see page 5263)

ErrorText (see page 994)

54.1.17 TAdapterField Class

TAdapterField is an event handler based adapter field that provides a single value.

Class Hierarchy



Pascal

```
TAdapterField = class(TCustomAdapterField);
```

C++

```
class TAdapterField : public TCustomAdapterField;
```

File

WebAdapt

Description

TAdapterField publishes the properties in TCustomAdapterField (see page 5597). TCustomAdapterField (see page 5597) calls event handlers to retrieve the adapter field's value, validate a value entered by the end-user, and update the adapter field's value.

Add TAdapterField to TAdapter (see page 5190) or other adapter components types when you need an adapter field that supports a single value using event handlers. Event handlers are used to provide the adapter field value(s), validate a value entered by the end-user, and update the adapter field with a value entered by the end-user.

There are other adapter field components that use event handlers. They differ in the type and number of values that are supported. For example, TAdapterMultiValue field is used when the end-user can enter multiple values using a group of check boxes or a multiple selection select list. TAdapterFileField (see page 5281), TAdapterMemoField (see page 5323), TAdapterBooleanField (see page 5223) and TAdapterImageField (see page 5308) are other event driven adapter fields.

See Also

TAdapterUpdateField (see page 5419)

TCustomAdapterField (see page 5597)

TAdapter (see page 5190)

TAdapterMultiValueField (see page 5332)

TAdapterMemoField (see page 5323)

TAdapterFileField (see page 5281)

TAdapterBooleanField (see page 5223)

TAdapterImageField (see page 5308)

54.1.17.1 TAdapterField Members

The following tables list the members exposed by TAdapterField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
V	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
V	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
V	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
V	DoOnValidateValue (see page 5602)	Validates a single value entered by the end-user.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.

	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
V	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
V	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
V	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
V	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetValue (see page 5602)	Returns the value of this adapter field as a variant.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.

	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5603)	Called to update the adapter field's value with a value entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.

	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetDisplayText (see page 5275)	Event handler called to retrieve a string representation of the adapter field's value.
	OnGetValue (see page 5275)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5275)	Called to update the adapter field's value with a value entered by the end-user.
	OnValidateValue (see page 5276)	Event handler called to validate value(s) entered by the end-user.

Published Properties

	Name	Description
	DisplayLabel (see page 5272)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5272)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5272)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5273)	Identifies the rights required to update this field.
	ReadOnly (see page 5273)	Indicates whether this adapter field is read-only.
	Required (see page 5273)	Indicates whether the end-user must enter a value for this adapter field.
	ValuesList (see page 5274)	Associates a list of values with the adapter field.
	ViewAccess (see page 5274)	Identifies the rights required to view this field.

54.1.17.2 TAdapterField Properties

The properties of the TAdapterField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5272)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5272)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5272)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5273)	Identifies the rights required to update this field.
	ReadOnly (see page 5273)	Indicates whether this adapter field is read-only.
	Required (see page 5273)	Indicates whether the end-user must enter a value for this adapter field.
	ValuesList (see page 5274)	Associates a list of values with the adapter field.
	ViewAccess (see page 5274)	Identifies the rights required to view this field.

54.1.17.2.1 TAdapterField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.17.2.2 TAdapterField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.17.2.3 TAdapterField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.17.2.4 TAdapterField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.17.2.5 TAdapterField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.17.2.6 TAdapterField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

See Also

GetRequired (see page 5359)

54.1.17.2.7 TAdapterField.ValuesList Property

Associates a list of values with the adapter field.

Pascal

```
property ValuesList: IValuesListAdapter;
```

C++

```
__property IValuesListAdapter ValuesList;
```

Description

Assign a component to the ValuesList property to define possible values for the adapter field. Server-side script can be used to enumerate the name/value pairs of the ValuesList component to generate HTML select lists, check boxes, or radio buttons.

See Also

IValuesListAdapter (see page 1072)

TStringsValuesList (see page 5857)

TDataSetValuesList

54.1.17.2.8 TAdapterField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.17.3 TAdapterField Events

The events of the TAdapterField class are listed here.

Published Events

	Name	Description
	OnGetDisplayText (see page 5275)	Event handler called to retrieve a string representation of the adapter field's value.
	OnGetValue (see page 5275)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5275)	Called to update the adapter field's value with a value entered by the end-user.
	OnValidateValue (see page 5276)	Event handler called to validate value(s) entered by the end-user.

54.1.17.3.1 TAdapterField.OnGetDisplayText Event

Event handler called to retrieve a string representation of the adapter field's value.

Pascal

```
property OnGetDisplayText: TAdapterFieldGetStringEvent;
```

C++

```
__property TAdapterFieldGetStringEvent OnGetDisplayText;
```

Description

The OnGetDisplayText event handler is called to retrieve a string representation an adapter field's value appropriate for a read-only display. If OnGetDisplayText is nil (Delphi) or NULL (C++), then the value of the adapter field will be used (after conversion to a string).

See Also

ImplAsFormatted (see page 5427)

54.1.17.3.2 TAdapterField.OnGetValue Event

Called to retrieve the adapter field's value.

Pascal

```
property OnGetValue: TAdapterFieldGetValueEvent;
```

C++

```
__property TAdapterFieldGetValueEvent OnGetValue;
```

Description

OnGetValue is called by ImplGetValue to retrieve the value associated with this adapter field.

See Also

ImplGetValue (see page 5602)

54.1.17.3.3 TAdapterField.OnUpdateValue Event

Called to update the adapter field's value with a value entered by the end-user.

Pascal

```
property OnUpdateValue: TAdapterFieldValueEvent;
```

C++

```
__property TAdapterFieldValueEvent OnUpdateValue;
```

Description

OnUpdateValue is called when an action request contains a value for this adapter field. If this event handler is not implemented, the value entered by the end-user will be ignored.

54.1.17.3.4 TAdapterField.OnValidateValue Event

Event handler called to validate value(s) entered by the end-user.

Pascal

```
property OnValidateValue: TAdapterFieldValidateValueEvent;
```

C++

```
__property TAdapterFieldValidateValueEvent OnValidateValue;
```

Description

This event handler is called by DoOnValidateValue to validate the value(s) entered by the end-user. The event handler must raise an exception to indicate that the value(s) are not valid.

See Also

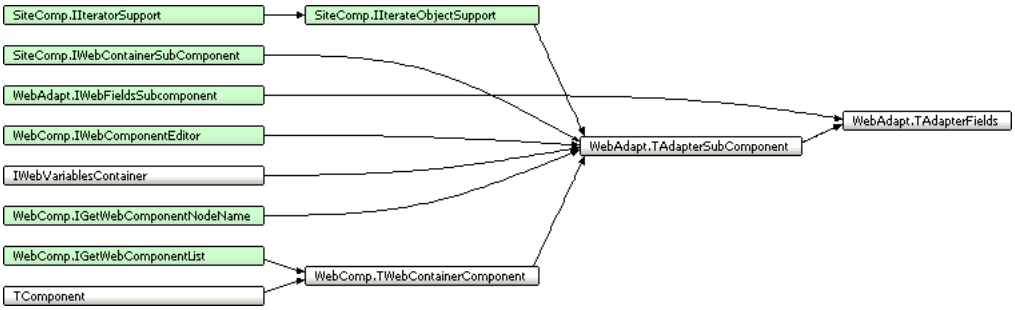
DoOnValidateValue (see page 5426)

IActionFieldValue

54.1.18 TAdapterFields Class

TAdapterFields manages the list of fields that belong to an adapter.

Class Hierarchy



Pascal

```
TAdapterFields = class(TAdapterSubComponent, IWebFieldsSubcomponent);
```

C++

```
class TAdapterFields : public TAdapterSubComponent, public IWebFieldsSubcomponent;
```

File

WebAdapt

Description

TAdapterFields is the type of the Data property on an adapter component. It manages a list that contains all the fields that belong to the adapter. The field objects (TAdapterNamedField (see page 5351) descendants) are available using the WebFields (see page 5281) property. TAdapterFields also includes support for associating the fields with variable names so that server-side script can use the field values.

TAdapterFields represents the list of explicitly assigned fields. Adapters that include a set of default fields use a TAdapterDefaultFields (see page 5237) object instead.

See Also

TCustomAdapter (see page 5531)

TAdapterActions (see page 5209)

TAdapterDefaultActions (see page 5231)

TAdapterDefaultFields (see page 5237)

TAdapterNamedField (see page 5351)

54.1.18.1 TAdapterFields Members

The following tables list the members exposed by TAdapterFields.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5278)	Indicates whether the associated adapter supports a specified class of field component.
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
V	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.
	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
V	GetChildren (see page 6065)	Executes a callback for each child Web item.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
V	GetDefaultWebComponents (see page 5411)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
V	GetDefaultWebComponents (see page 6065)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
V	GetVariablesInUse (see page 5413)	Returns the value of the VariablesInUse (see page 5419) property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	GetWebComponents (see page 6065)	Returns the list of Web items that this item manages.
V	ImplCanAddClass (see page 5279)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
V	ImplGetDefaultComponentList (see page 6066)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	ImplGetWebComponentNodeName (see page 5280)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
V	SetChildOrder (see page 6066)	Positions a child component in the list of child Web items.

	SetDefaultWebComponents (see page 5416)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
	SetDefaultWebComponents (see page 6067)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
	SetWebParent (see page 5280)	Associates this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Protected Properties

	Name	Description
	Adapter (see page 5418)	Indicates the adapter that uses this object to manage its fields or actions.
	VariablesInUse (see page 5419)	Lists those fields or actions in the collection for which variables are defined.
	WebContainerComponentHelper (see page 6067)	Provides access to the helper object that allows this object to manage its Web items.

Public Methods

	Name	Description
	CanAddClass (see page 6101)	Indicates whether a specified class can be used as a child Web item.
	Create (see page 6064)	Creates and initializes an instance of TWebContainerComponent (see page 6063).
	Destroy (see page 6064)	Frees an instance of TWebContainerComponent (see page 6063).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetComponentList (see page 6082)	This is GetComponentList, a member of class IGetWebComponentList.
	GetCurrentObject (see page 1052)	This is GetCurrentObject, a member of class IIterateObjectSupport.
	GetDefaultComponentList (see page 6082)	This is GetDefaultComponentList, a member of class IGetWebComponentList.
	GetParentComponent (see page 5412)	Returns the associated adapter.
	GetWebComponentNodeName (see page 6083)	This is GetWebComponentNodeName, a member of class IGetWebComponentNodeName.
	HasParent (see page 5414)	Indicates whether this component has an associated adapter.
	NextIteration (see page 1056)	Advances to the objects next item.
	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.

Public Properties

	Name	Description
	WebFields (see page 5281)	Lists the field components that this object manages.

54.1.18.2 TAdapterFields Methods

The methods of the TAdapterFields class are listed here.

Protected Methods

	Name	Description
	AdapterCanAddClass (see page 5278)	Indicates whether the associated adapter supports a specified class of field component.
	ImplCanAddClass (see page 5279)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
	ImplGetWebComponentNodeName (see page 5280)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	SetWebParent (see page 5280)	Associates this component with an adapter.

54.1.18.2.1 TAdapterFields.AdapterCanAddClass Method

Indicates whether the associated adapter supports a specified class of field component.

Pascal

```
function AdapterCanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean AdapterCanAddClass(TComponent * AParent, TClass AClass);
```

Description

TAdapterActions (see page 5209) uses this method internally as part of its implementation for the CanAddClass (see page 5408) method. This allows the TAdapterFields (see page 5276) object to indicate, at design time, which types of components are valid as members of the WebFields (see page 5281) property list.

AParent is the instance of TAdapterFields (see page 5276) to which the child fields are to be added.

AClass describes the class of the child component to be added to AParent.

AdapterCanAddClass returns true if the adapter recognizes and supports AClass as a child field, false otherwise.

AdapterCanAddClass calls the CanAddFieldClass method of its associated adapter to determine whether it accepts the specified field class.

See Also

WebFields (see page 5281)

Adapter (see page 5418)

ImplCanAddClass (see page 5279)

CanAddFieldClass (see page 5540)

54.1.18.2.2 TAdapterFields.ImplCanAddClass Method

Provides the underlying implementation for the CanAddClass (see page 5408) method.

Pascal

```
function ImplCanAddClass(AParent: TComponent; AClass: TClass): Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplCanAddClass(TComponent * AParent, TClass AClass);
```

Description

The CanAddClass (see page 5408) method calls ImplCanAddClass to determine whether an object of a specified type can be added to this collection.

AParent is the TAdapterFields (see page 5276) object to which the Web item will be added.

AClass is the class of the proposed child item.

ImplCanAddClass returns true if the TAdapterFields (see page 5276) object can include a child of type AClass, false otherwise.

ImplCanAddClass returns true if one of the following two conditions is met:

AClass is an adapter field class that the associated adapter recognizes and accepts.

AClass is a data entry field (a descendant of TAdapterUpdateField (see page 5419)).

See Also

CanAddClass (see page 5408)

AdapterCanAddClass (see page 5278)

TAdapterUpdateField (see page 5419)

54.1.18.2.3 TAdapterFields.ImplGetWebComponentNodeName Method

Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.

Pascal

```
function ImplGetWebComponentNodeName: string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetWebComponentNodeName();
```

Description

The GetWebComponentNodeName (see page 5413) method calls ImplGetWebComponentNodeName to obtain a label for the type of items in the collection.

ImplGetWebComponentNodeName returns the string 'Fields'.

See Also

GetWebComponentNodeName (see page 5413)

54.1.18.2.4 TAdapterFields.SetWebParent Method

Associates this component with an adapter.

Pascal

```
procedure SetWebParent(const Value: TComponent); override;
```

C++

```
virtual __fastcall SetWebParent(const TComponent * Value);
```

Description

SetWebParent sets up the association between this component and its parent adapter.

Value is the adapter component that acts as a parent to this collection.

SetWebParent assigns Value to the protected Adapter (see page 5418) property and replaces that adapter's Data property with this TAdapterFields (see page 5276) instance.

See Also

Data (see page 5572)

Adapter (see page 5418)

54.1.18.3 TAdapterFields Properties

The properties of the TAdapterFields class are listed here.

Public Properties

	Name	Description
	WebFields (see page 5281)	Lists the field components that this object manages.

54.1.18.3.1 TAdapterFields.WebFields Property

Lists the field components that this object manages.

Pascal

```
property WebFields: TWebComponentList;
```

C++

```
__property TWebComponentList WebFields;
```

Description

Read (see page 3634) WebFields to access the list of field components. Each component in this list is a descendant of TAdapterNamedField (see page 5351).

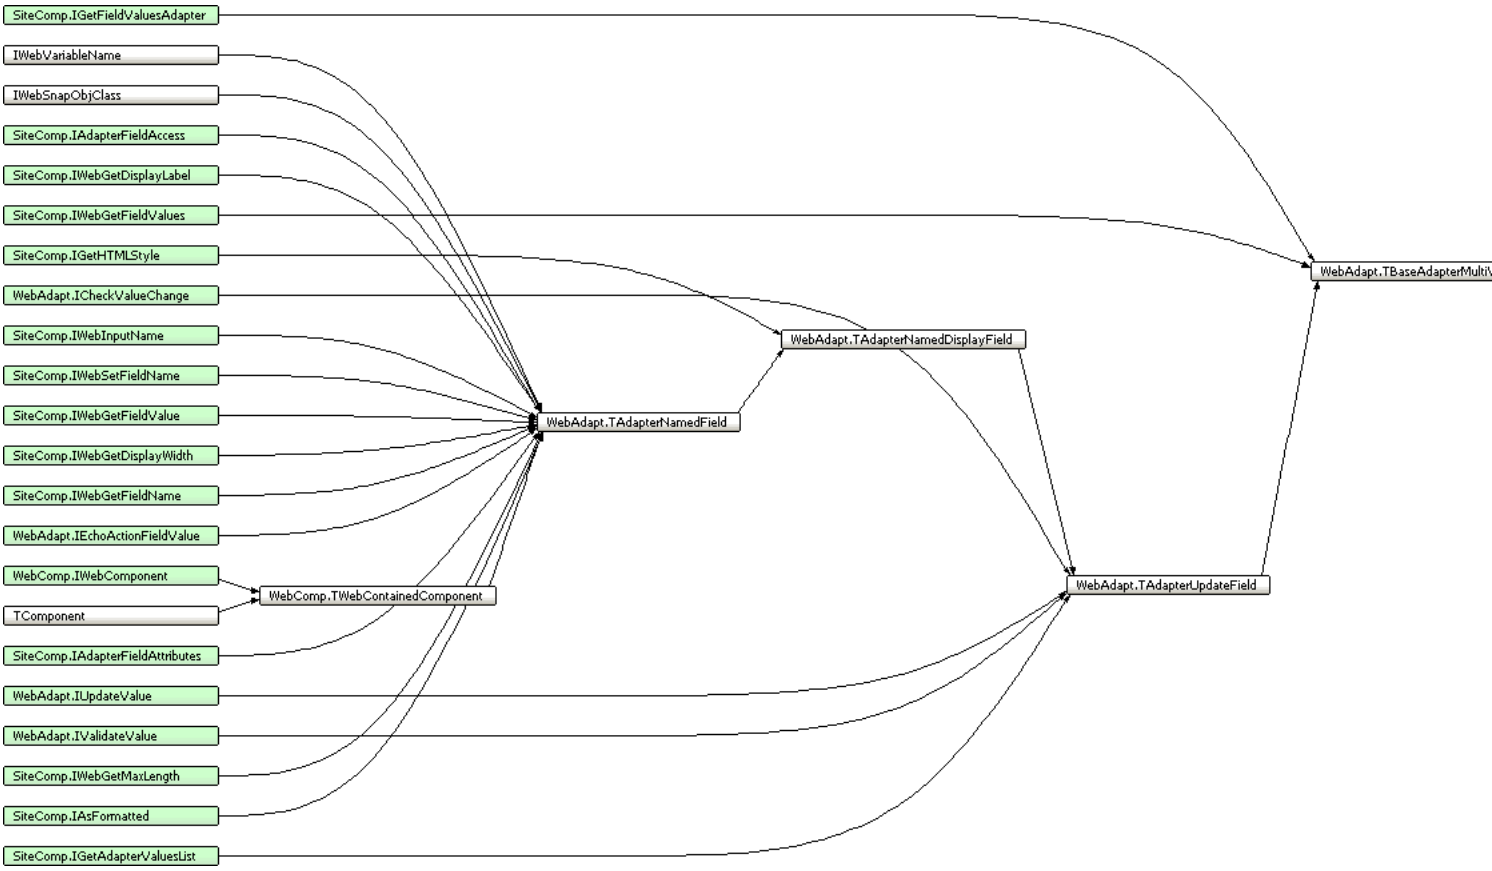
See Also

TAdapterNamedField (see page 5351)

54.1.19 TAdapterFileField Class

TAdapterFileField is an event handler based adapter field that can accept uploaded files.

Class Hierarchy



Pascal

```
TAdapterFileField = class(TCustomAdapterFileField);
```

C++

```
class TAdapterFileField : public TCustomAdapterFileField;
```

File

WebAdapt

Description

TAdapterFileField publishes the properties in TCustomAdapterFileField (see page 5604). TCustomAdapterFileField (see page 5604) calls event handlers to retrieve the adapter field's filenames, validate files uploaded by the end-user, and update the adapter field's files.

Add TAdapterFileField to TAdapter (see page 5190) or other adapter components types when you need an adapter field that supports files using event handlers. There are other adapter field components that use event handlers. They differ in the type and number of values that are supported. See TAdapterField (see page 5267), TAdapterMultiValueField (see page 5332), TAdapterMemoField (see page 5323), TAdapterBooleanField (see page 5223) and TAdapterImageField (see page 5308).

See Also

TCustomAdapterFileField (see page 5604)

TAdapter (see page 5190)

TAdapterField (see page 5267)

TAdapterMemoField (see page 5323)

TAdapterMultiValueField (see page 5332)

TAdapterBooleanField (see page 5223)

TAdapterImageField (see page 5308)

54.1.19.1 TAdapterFileField Members

The following tables list the members exposed by TAdapterFileField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
V	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
V	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
V	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
V	DoOnValidateValue (see page 5609)	Validates files uploaded by the end-user.
	EndValueIterator (see page 5493)	Completes iteration.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
	GetCurrentValue (see page 5494)	Implements IWebGetFieldValues (see page 1092)' GetCurrentValue.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
V	GetDisplayStyleType (see page 5609)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetFieldValuesAdapter (see page 5494)	Returns the adapter object that implements the Values property.
	GetFileNames (see page 5610)	Returns the count of files associated with this adapter field.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
V	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.
V	GetInputStyleType (see page 5610)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
V	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
V	GetValueCount (see page 5494)	Returns the number of values associated with this adapter field.

	GetValueCount (see page 5610)	Returns the number of values associated with this adapter field.
	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetValues (see page 5495)	Returns one of the values associated with the adapter field.
	GetValues (see page 5611)	Returns one of the values associated with the adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasValue (see page 5495)	Implements IWebGetFieldValues (see page 1092)' HasValue method.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
	ImplCheckValueChange (see page 5611)	Indicates whether the end-user may have uploaded new files for this adapter field.
	ImplGetCurrentValue (see page 5495)	Implements IWebGetFieldValues (see page 1092)' GetCurrentValue (see page 5494) method.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplGetFieldValuesAdapter (see page 5496)	Returns the adapter object that implements the Values property.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasValue (see page 5496)	Implements IWebGetFieldValues (see page 1092)' HasValue (see page 5495) method.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5611)	Updates the adapter field with value(s) entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	NextValueIteration (see page 5496)	Implements IWebGetFieldValues (see page 1092)' NextValueIteration method.

	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartValueIterator (see page 5497)	Implements IWebGetFieldValues (see page 1092)' StartValueIterator method.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnGetDisplayText (see page 5433)	Event handler called to retrieve a string representation of the adapter field's value.
	OnValidateValue (see page 5433)	Event handler called to validate value(s) entered by the end-user.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
	Create (see page 5492)	Constructor for TBaseAdapterMultiValueField (see page 5488).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 5492)	Destructor for TBaseAdapterMultiValueField (see page 5488).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndValueIterator (see page 1093)	Indicate the iteration is finished.
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetCurrentValue (see page 1094)	Retrieves the current value as a variant.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetFieldValuesAdapter (see page 1031)	This is GetFieldValuesAdapter, a member of class IGetFieldValuesAdapter.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.

	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasValue (see page 1094)	Indicates whether the adapter field has a matching value.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	NextValueIteration (see page 1094)	Position the iteration pointer on the next value.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartValueIterator (see page 1095)	Reset (see page 3643) the iteration pointer to the first item.
	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FileCount (see page 5612)	Returns one of the filenames associated with this adapter field.
R	FileNames (see page 5612)	Returns a file associated with this adapter field.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
	ValuesList (see page 5432)	Associates a list of values with the adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetFileCount (see page 5289)	Returns the number of values associated with this adapter field.
	OnGetFileNames (see page 5290)	Returns one of the filenames associated with the adapter field.
	OnUploadFiles (see page 5290)	Updates the adapter field with value(s) entered by the end-user.
	OnValidateFiles (see page 5290)	Validates values entered by the end-user.

Published Properties

	Name	Description
	DisplayLabel (see page 5287)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5287)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5288)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5288)	Identifies the rights required to update this field.
	ReadOnly (see page 5288)	Indicates whether this adapter field is read-only.
	Required (see page 5289)	Indicates whether the end-user must enter a value for this adapter field.
	ViewAccess (see page 5289)	Identifies the rights required to view this field.

54.1.19.2 TAdapterFileField Properties

The properties of the TAdapterFileField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5287)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5287)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5288)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5288)	Identifies the rights required to update this field.
	ReadOnly (see page 5288)	Indicates whether this adapter field is read-only.
	Required (see page 5289)	Indicates whether the end-user must enter a value for this adapter field.
	ViewAccess (see page 5289)	Identifies the rights required to view this field.

54.1.19.2.1 TAdapterFileField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.19.2.2 TAdapterFileField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.19.2.3 TAdapterFileField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.19.2.4 TAdapterFileField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.19.2.5 TAdapterFileField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.19.2.6 TAdapterFileField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

See Also

GetRequired (see page 5359)

54.1.19.2.7 TAdapterFileField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.19.3 TAdapterFileField Events

The events of the TAdapterFileField class are listed here.

Published Events

	Name	Description
	OnGetFileCount (see page 5289)	Returns the number of values associated with this adapter field.
	OnGetFileNames (see page 5290)	Returns one of the filenames associated with the adapter field.
	OnUploadFiles (see page 5290)	Updates the adapter field with value(s) entered by the end-user.
	OnValidateFiles (see page 5290)	Validates values entered by the end-user.

54.1.19.3.1 TAdapterFileField.OnGetFileCount Event

Returns the number of values associated with this adapter field.

Pascal

```
property OnGetFileCount: TAdapterFieldGetValueCountEvent;
```

C++

```
__property TAdapterFieldGetValueCountEvent OnGetFileCount;
```

Description

Write an OnGetFileCount event handler to indicate the number of filenames associated with this adapter field.

See Also

GetValueCount (see page 5610)

54.1.19.3.2 TAdapterFileField.OnGetFileNames Event

Returns one of the filenames associated with the adapter field.

Pascal

```
property OnGetFileNames: TAdapterFieldGetMultiValueStringEvent;
```

C++

```
__property TAdapterFieldGetMultiValueStringEvent OnGetFileNames;
```

Description

Write an OnGetFileNames event handler to provide the names of files associated with this adapter field.

See Also

GetFileNames (see page 5610)

54.1.19.3.3 TAdapterFileField.OnUploadFiles Event

Updates the adapter field with value(s) entered by the end-user.

Pascal

```
property OnUploadFiles: TAdapterFieldFileListEvent;
```

C++

```
__property TAdapterFieldFileListEvent OnUploadFiles;
```

Description

OnUploadFiles is called by ImplUpdateValue. Write an OnUploadFiles event handler to accept files uploaded by the end-user. Raise an exception to indicate an error.

See Also

ImplUpdateValue (see page 5611)

TUpdateFileList (see page 5864)

54.1.19.3.4 TAdapterFileField.OnValidateFiles Event

Validates values entered by the end-user.

Pascal

```
property OnValidateFiles: TAdapterFieldFileListEvent;
```

C++

```
__property TAdapterFieldFileListEvent OnValidateFiles;
```

Description

OnValidateFiles is called by DoOnValidateValue. Implement this event handler to validate files uploaded by the end-user. Raise an exception to indicate a validation error.

See Also

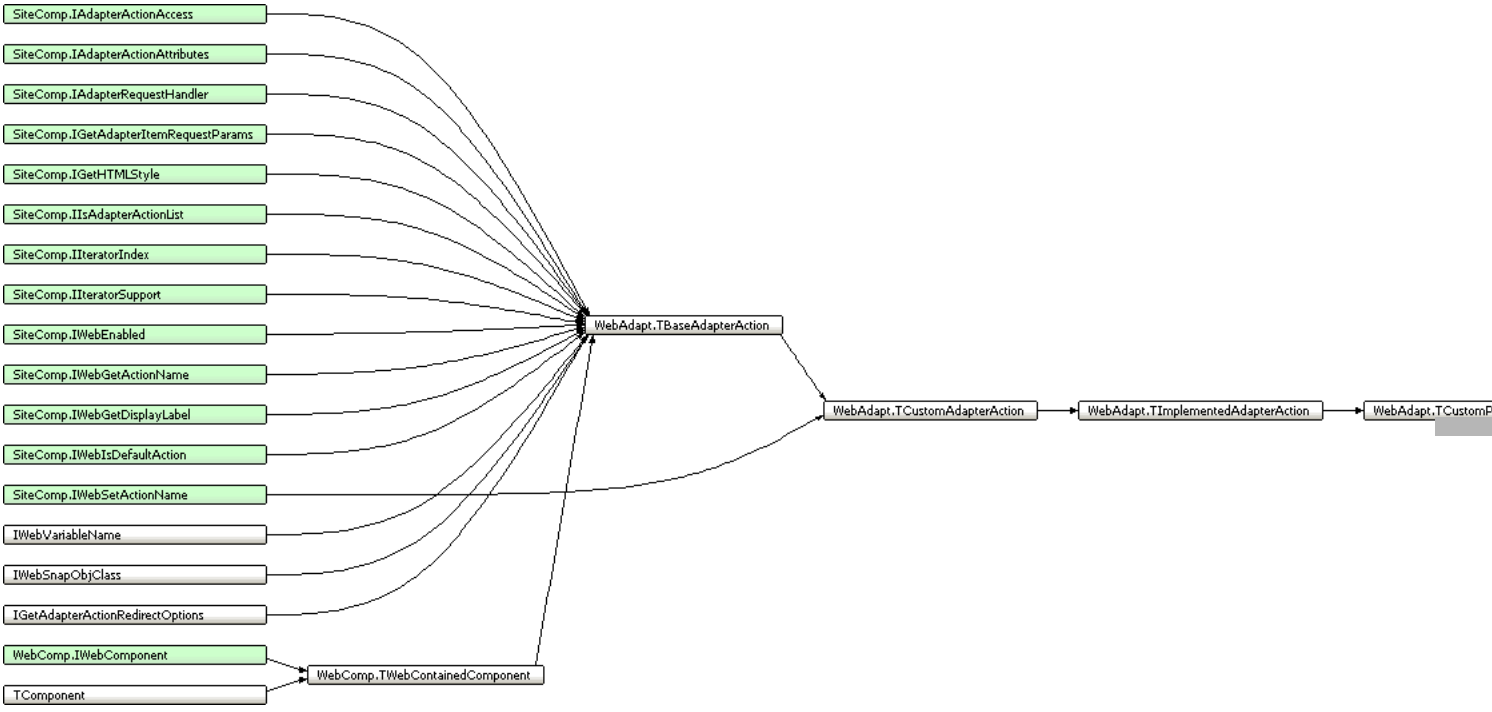
DoOnValidateValue (see page 5609)

TUpdateFileList (see page 5864)

54.1.20 TAdapterGotoPageAction Class

TAdapterGotoPageAction is an adapter action that supports commands to go to a page of a TDefaultFieldsPagedAdapter (see page 5747).

Class Hierarchy



Pascal

```
TAdapterGotoPageAction = class(TCustomAdapterGotoPageAction);
```

C++

```
class TAdapterGotoPageAction : public TCustomAdapterGotoPageAction;
```

File

WebAdapt

Description

TAdapterGotoPageAction is an adapter action that has a list of commands. Each command has a parameter that identifies a page in the parent adapter. When executed, TAdapterGotoPageAction changes the current page in the parent adapter. TAdapterGotoPageAction publishes the properties of TCustomAdapterGotoPageAction (see page 5614). Add TAdapterGotoPageAction to a descendant class of TDefaultFieldsPagedAdapter (see page 5747) such as TPagedAdapter (see page 5844).

See Also

TCustomAdapterGotoPageAction (see page 5614)

TDefaultFieldsPagedAdapter (see page 5747)

TPagedAdapter (see page 5844)

TAdapterNextPageAction (see page 5370)

TAdapterPrevPageAction (see page 5396)

54.1.20.1 TAdapterGotoPageAction Members

The following tables list the members exposed by TAdapterGotoPageAction.

Protected Methods

	Name	Description
	CheckExecuteAccess (see page 5452)	Checks end-user rights to execute this adapter action.
	CreateRequestContext (see page 5452)	Creates an object that describes the adapter action parameters and adapter field values.
V	DoAfterExecuteActionRequest (see page 5453)	Calls event handlers after the adapter action is executed.
V	DoAfterGetExecuteActionResponse (see page 5453)	Calls event handlers after the adapter action response is formulated.
V	DoBeforeExecuteActionRequest (see page 5453)	Calls event handlers before the adapter action is executed.
V	DoBeforeGetExecuteActionResponse (see page 5454)	Calls event handlers before the adapter action response is formulated.
	EndIterator (see page 5454)	Implements IIteratorSupport (see page 1054)'s EndIterator method.
	ExecuteActionRequest (see page 5455)	Executes the adapter action using parameters passed in the HTTP request.
	GetActionName (see page 5455)	Gets the name used to reference this adapter action with server-side script.
	GetAdapter (see page 5456)	GetAdapter returns the parent adapter component.
	GetAdapter (see page 5727)	Returns the parent adapter of this adapter action.
	GetAdapterItemRequestParams (see page 5456)	Provides the name/value pairs needed to execute this adapter action.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultActionName (see page 5456)	Gets the default name used to reference this adapter action with server-side script.
V	GetDefaultActionName (see page 5619)	Gets the name used to reference this adapter action with server-side script.
V	GetDefaultDisplayLabel (see page 5457)	Provides the default display label for this adapter action.
	GetDisplayLabel (see page 5457)	Returns the suggested display label for this adapter action.
	GetDisplayStyle (see page 5457)	Returns a string value to suggest an HTML display style for this adapter action.
V	GetDisplayStyleType (see page 5458)	Suggests an HTML display type for this adapter action.
V	GetDisplayStyleType (see page 5619)	Suggests an HTML display type for this adapter action.
	GetErrors (see page 5458)	Returns the parent adapter's errors list.
	GetExecuteActionResponse (see page 5458)	Generates a response after the adapter action has been executed.
	GetFailureOptions (see page 5459)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	GetInputStyle (see page 5459)	Returns a string value to suggest an HTML display style for this adapter action.
	GetIsAdapterActionList (see page 5460)	Indicates whether this adapter action may have multiple commands.
V	GetItemCount (see page 5460)	Returns the number of commands defined by this adapter action.
V	GetItemCount (see page 5620)	Returns the number of commands defined by this adapter action.

	GetIteratorIndex (see page 5460)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method.
	GetSuccessOptions (see page 5461)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	GetVariableName (see page 5461)	Gets the name used to reference this adapter action with server-side script.
	GetViewMode (see page 5462)	Returns a string value to suggest a view mode for this adapter action.
V	GetViewModeType (see page 5462)	Suggests a view mode for this adapter action.
	GetVisible (see page 5462)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
V	GetWebSnapObjClass (see page 5463)	Returns the class type for this adapter field.
	HandleRequest (see page 5463)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 5463)	Checks the end-user's right to execute this adapter action.
	ImplCreateRequestContext (see page 5464)	Creates an object that describes the action parameters and field values.
	ImplEndIterator (see page 5464)	Implements IIteratorSupport (see page 1054)'s EndIterator (see page 5454) method.
V	ImplExecuteActionRequest (see page 5464)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplExecuteActionRequest (see page 5584)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplExecuteActionRequest (see page 5620)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplGetActionName (see page 5465)	Gets the name used to reference this adapter action with server-side script.
V	ImplGetActionName (see page 5584)	Gets the name used to reference this adapter action with server-side script.
V	ImplGetAdapterItemRequestParams (see page 5465)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetAdapterItemRequestParams (see page 5584)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetAdapterItemRequestParams (see page 5620)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetDisplayLabel (see page 5465)	Returns the suggested display label for this adapter action.
V	ImplGetDisplayLabel (see page 5621)	Returns the suggested display label for this adapter action.
V	ImplGetExecuteActionResponse (see page 5466)	Generates a response after the adapter action has been executed.
V	ImplGetFailureOptions (see page 5466)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
V	ImplGetIsAdapterActionList (see page 5466)	Indicates whether this adapter action may have multiple commands.
V	ImplGetIsAdapterActionList (see page 5621)	Indicates whether this adapter action may have multiple commands.
V	ImplGetIteratorIndex (see page 5467)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5460) method.
V	ImplGetSuccessOptions (see page 5467)	Indicates whether to perform an HTTP redirect after successfully executing this action.
V	ImplGetSuccessOptions (see page 5585)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetVariableName (see page 5467)	Gets the name used to reference this adapter action with server-side script.
V	ImplGetVisible (see page 5468)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
V	ImplHandleRequest (see page 5468)	Executes the adapter action and generates a response.
V	ImplHasExecuteAccess (see page 5468)	Checks the end-user's right to execute this adapter action.
V	ImplInIterator (see page 5469)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5471) method.
V	ImplIsDefaultAction (see page 5469)	Indicates whether this adapter action should be added, by default, to the parent adapter.
V	ImplIsDefaultAction (see page 5622)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplNextIteration (see page 5470)	Implements IIteratorSupport (see page 1054)'s NextIteration (see page 5472) method.
	ImplSetActionName (see page 5585)	Sets the name that is used to reference this adapter action with server-side script.
	ImplStartIterator (see page 5470)	Implements IIteratorSupport (see page 1054)'s StartIterator (see page 5473) method.
V	ImplWebEnabled (see page 5470)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
V	ImplWebEnabled (see page 5585)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
V	ImplWebEnabled (see page 5622)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	InIterator (see page 5471)	Implements IIteratorIndex (see page 1052)'s InIterator method.

	IsDefaultAction (see page 5471)	Indicates whether this adapter action should be added, by default, to the parent adapter.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	NextIteration (see page 5472)	Implements IIteratorSupport (see page 1054)'s NextIteration method.
V	ParentChanged (see page 5472)	Handles movement of the component to a different parent.
V	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
V	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetActionName (see page 5586)	Sets the name that is used to reference this adapter action with server-side script.
	SetDisplayLabel (see page 5472)	Set the value of the DisplayLabel (see page 5474) property.
V	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartIterator (see page 5473)	Implements IIteratorSupport (see page 1054)'s StartIterator method.
	WebEnabled (see page 5473)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Protected Properties

	Name	Description
R	Adapter (see page 5474)	Provides access to the parent adapter component.
R	Adapter (see page 5727)	Returns the parent adapter of this adapter action.
R	Errors (see page 5475)	Returns the parent adapter's Errors list.
R	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
R	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnExecute (see page 5588)	Called to execute this action using parameters passed in the HTTP request.
	OnGetEnabled (see page 5589)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Public Methods

	Name	Description
V	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	CreateRequestContext (see page 1013)	Creates an object that describes the adapter action parameters and adapter field values.
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.
	GetAdapterItemRequestParams (see page 1024)	This is GetAdapterItemRequestParams, a member of class IGetAdapterItemRequestParams.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetIsAdapterActionList (see page 1050)	This is GetIsAdapterActionList, a member of class IIsAdapterActionList.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 984)	This is GetVisible, a member of class IAdapterActionAttributes.
	HandleRequest (see page 1013)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 983)	This is HasExecuteAccess, a member of class IAdapterActionAccess.

V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.
	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.
	NextIteration (see page 1056)	Advances to the objects next item.
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

Public Properties

	Name	Description
R	ActionName (see page 1087)	This is ActionName, a member of class IWebGetActionName.
R	ActionName (see page 5474)	Identifies the name of this action when using server-side script.
	ActionName (see page 5586)	Identifies the name of this action when using server-side script.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5474)	Suggests a display label for this adapter action.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	IsAdapterActionList (see page 1050)	This is IsAdapterActionList, a member of class IIsAdapterActionList.
R	ItemCount (see page 5475)	Returns the number of items defined by an adapter action.
R	ItemIndex (see page 5476)	Returns the index of the current item of an adapter action.
R	IteratorIndex (see page 1054)	Indicates the index of the current item.
R	Visible (see page 984)	This is Visible, a member of class IAdapterActionAttributes.

Published Events

	Name	Description
	OnAfterExecute (see page 5297)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5297)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5297)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5298)	Called before the adapter action response is generated.
	OnGetPageName (see page 5298)	Provides the display labels for each goto page command.
	OnGetParams (see page 5298)	Specifies name/value pairs needed to execute this adapter action.

Published Properties

	Name	Description
	ExecuteAccess (see page 5296)	Defines the rights required to execute this action.
	RedirectOptions (see page 5296)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.20.2 TAdapterGotoPageAction Properties

The properties of the TAdapterGotoPageAction class are listed here.

Published Properties

	Name	Description
	ExecuteAccess (see page 5296)	Defines the rights required to execute this action.
	RedirectOptions (see page 5296)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.20.2.1 TAdapterGotoPageAction.ExecuteAccess Property

Defines the rights required to execute this action.

Pascal

```
property ExecuteAccess: string;
```

C++

```
__property UnicodeString ExecuteAccess;
```

Description

The ExecuteAccess property defines the access rights required to execute this action. When server-side script accesses the CanExecute property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to execute an adapter action that does not allow access.

See Also

TWebUserList (see page 6796)

HasExecuteAccess (see page 5552)

54.1.20.2.2 TAdapterGotoPageAction.RedirectOptions Property

Indicates whether to perform an HTTP redirect after successfully executing this action.

Pascal

```
property RedirectOptions: TAdapterActionRedirectOptions;
```

C++

```
__property TAdapterActionRedirectOptions RedirectOptions;
```

Description

Set RedirectOptions to indicate that HTTP redirect should be performed after executing this adapter action. An HTTP redirect causes the browser to "forget" about the parameters passed when executing the adapter action. Without a redirect, the browser's Refresh or Reload command cause the last HTTP request to be resent, resulting in re-execution of the adapter action.

See Also

SendRedirect

54.1.20.3 TAdapterGotoPageAction Events

The events of the TAdapterGotoPageAction class are listed here.

Published Events

	Name	Description
	OnAfterExecute (see page 5297)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5297)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5297)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5298)	Called before the adapter action response is generated.
	OnGetPageName (see page 5298)	Provides the display labels for each goto page command.
	OnGetParams (see page 5298)	Specifies name/value pairs needed to execute this adapter action.

54.1.20.3.1 TAdapterGotoPageAction.OnAfterExecute Event

Called after the adapter action has executed.

Pascal

```
property OnAfterExecute: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterExecute;
```

Description

Implement OnAfterExecute to do something after the action has executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterExecute is called by DoAfterExecuteActionRequest.

See Also

DoAfterExecuteActionRequest (see page 5453)

OnAfterExecuteAction (see page 5576)

OnBeforeExecute (see page 5478)

54.1.20.3.2 TAdapterGotoPageAction.OnAfterGetResponse Event

Called after the adapter action response is generated.

Pascal

```
property OnAfterGetResponse: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterGetResponse;
```

Description

Implement OnAfterGetResponse to do something after the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterGetResponse is called by DoAfterGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnBeforeGetActionResponse (see page 5578)

54.1.20.3.3 TAdapterGotoPageAction.OnBeforeExecute Event

Called before the adapter action is executed.

Pascal

```
property OnBeforeExecute: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeExecute;
```

Description

Implement OnBeforeExecute to do something before the action is executed. The Params parameter contains the adapter action

parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to prevent the action from being executed. OnBeforeExecute is called by DoBeforeExecuteActionRequest.

See Also

DoBeforeExecuteActionRequest (see page 5453)

OnAfterExecute (see page 5477)

OnBeforeExecuteAction (see page 5577)

54.1.20.3.4 TAdapterGotoPageAction.OnBeforeGetResponse Event

Called before the adapter action response is generated.

Pascal

```
property OnBeforeGetResponse: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeGetResponse;
```

Description

Implement OnBeforeGetResponse to do something before the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to indicate that the response has been generated and no further processing is needed. OnBeforeGetResponse is called by DoBeforeGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnAfterGetResponse (see page 5477)

OnBeforeGetActionResponse (see page 5578)

54.1.20.3.5 TAdapterGotoPageAction.OnGetPageName Event

Provides the display labels for each goto page command.

Pascal

```
property OnGetPageName: TWebFormGetPageNameEvent;
```

C++

```
__property TWebFormGetPageNameEvent OnGetPageName;
```

Description

Implement this event handler to specify display labels for the commands that goto pages in the parent adapter. APageIndex is the zero-based index of the page to goto.

See Also

ImplGetDisplayLabel (see page 5621)

54.1.20.3.6 TAdapterGotoPageAction.OnGetParams Event

Specifies name/value pairs needed to execute this adapter action.

Pascal

```
property OnGetParams: TActionGetParamsEvent;
```

C++

```
__property TActionGetParamsEvent OnGetParams;
```

Description

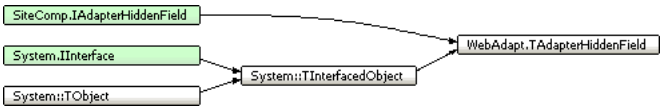
Implement this event handler to specify the name/value needed to execute this action. For example, an action that deletes a row in a table will need a name/value pair that identifies the row to be deleted such as "Key=123".

See Also

ImplGetAdapterItemRequestParams (see page 5465)

54.1.21 TAdapterHiddenField Class

Class Hierarchy



Pascal

```
TAdapterHiddenField = class(TInterfacedObject, IAdapterHiddenField);
```

C++

```
class TAdapterHiddenField : public TInterfacedObject, public IAdapterHiddenField;
```

File

WebAdapt

Description

This is class WebAdapt.TAdapterHiddenField.

54.1.21.1 TAdapterHiddenField Members

The following tables list the members exposed by TAdapterHiddenField.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	GetName (see page 5301)	This is GetName, a member of class TAdapterHiddenField.
	GetValue (see page 5301)	This is GetValue, a member of class TAdapterHiddenField.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5301)	This is Create, a member of class TAdapterHiddenField.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	Name (see page 1003)	This is Name, a member of class IAdapterHiddenField.
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.
R	Value (see page 1003)	This is Value, a member of class IAdapterHiddenField.

54.1.21.2 TAdapterHiddenField.Create Constructor

Pascal

```
constructor Create(AHiddenFields: TAdapterHiddenFieldsList; AIndex: Integer);
```

C++

```
__fastcall TAdapterHiddenField(TAdapterHiddenFieldsList AHiddenFields, int AIndex);
```

Description

This is Create, a member of class TAdapterHiddenField.

54.1.21.3 TAdapterHiddenField Methods

The methods of the TAdapterHiddenField class are listed here.

Protected Methods

	Name	Description
	GetName (see page 5301)	This is GetName, a member of class TAdapterHiddenField.
	GetValue (see page 5301)	This is GetValue, a member of class TAdapterHiddenField.

54.1.21.3.1 TAdapterHiddenField.GetName Method

Pascal

```
function GetName: string;
```

C++

```
__fastcall UnicodeString GetName();
```

Description

This is GetName, a member of class TAdapterHiddenField.

54.1.21.3.2 TAdapterHiddenField.GetValue Method

Pascal

```
function GetValue: string;
```

C++

```
__fastcall UnicodeString GetValue();
```

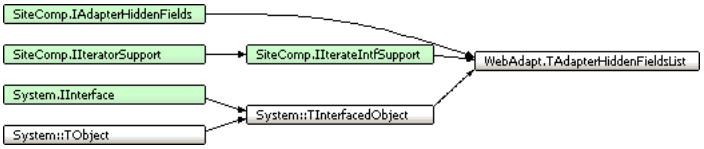
Description

This is GetValue, a member of class TAdapterHiddenField.

54.1.22 TAdapterHiddenFieldsList Class

TAdapterHiddenFieldsList maintains a collection of name/value pairs that an adapter includes as hidden fields in an HTML form.

Class Hierarchy



Pascal

```
TAdapterHiddenFieldsList = class(TInterfacedObject, IAdapterHiddenFields, IIterateIntfSupport);
```

C++

```
class TAdapterHiddenFieldsList : public TInterfacedObject, public IAdapterHiddenFields, public
IIterateIntfSupport;
```

File

WebAdapt

Description

Adapter components create instances of TAdapterHiddenFieldsList to store the name/value pairs they include as hidden fields in HTML forms. Each entry in the list has a field name and a value for that field. The adapter uses the methods of TAdapterHiddenFieldsList to add name/value pairs to the list, based on its hidden field options. When an adapter page producer generates a form using the adapter, it includes hidden fields for every name/value pair in the list. Those hidden fields are then included in any request that originates from the resulting HTML form, so that the adapter and its subcomponents can access those values to respond to the request.

For example, dataset adapters that have a Mode property that indicates whether the form is used for read-only browsing, inserting a new record, editing an existing record, or generating a query. The adapter includes the current mode as a hidden field. When the WebSnap application receives a message from the HTML form with that hidden field, the adapter can reestablish the correct mode for processing the request.

TCustomAdapter (see page 5531)

TAdapterPageProducer (see page 1136)

TCustomDataSetAdapter

54.1.22.1 TAdapterHiddenFieldsList Members

The following tables list the members exposed by TAdapterHiddenFieldsList.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	EndIterator (see page 5305)	Signals the end of the iterating operation.
	GetCurrentIntf (see page 5306)	This is GetCurrentIntf, a member of class TAdapterHiddenFieldsList.

	GetField (see page 5306)	This is GetField, a member of class TAdapterHiddenFieldsList.
	GetFieldCount (see page 5306)	This is GetFieldCount, a member of class TAdapterHiddenFieldsList.
	NextIteration (see page 5307)	Advances to the objects next item.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	StartIterator (see page 5307)	Positions the object on its first item and starts the iteration process.

Protected Properties

	Name	Description
R	FieldCount (see page 5308)	This is FieldCount, a member of class TAdapterHiddenFieldsList.
R	Fields (see page 5308)	This is Fields, a member of class TAdapterHiddenFieldsList.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
	Add (see page 5305)	Adds a name/value pair to the list.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5305)	Clears the list of all the name/value pairs it currently holds.
	Create (see page 5304)	Creates and initializes a TAdapterHiddenFieldsList (see page 5301) object.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.
V	Destroy (see page 5304)	Frees an instance of TAdapterHiddenFieldsList (see page 5301).
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.

	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

54.1.22.2 TAdapterHiddenFieldsList.Create Constructor

Creates and initializes a TAdapterHiddenFieldsList (see page 5301) object.

Pascal

```
constructor Create;
```

C++

```
__fastcall TAdapterHiddenFieldsList();
```

Description

Typically, applications have no need to create TAdapterHiddenFieldsList (see page 5301) instances. The adapter component creates and maintains its own internal TAdapterHiddenFieldsList (see page 5301) objects, which it uses to store the hidden fields it needs to add to HTML forms.

See Also

ListHiddenFields (see page 5563)

ListHiddenRecordFields (see page 5564)

54.1.22.3 TAdapterHiddenFieldsList.Destroy Destructor

Frees an instance of TAdapterHiddenFieldsList (see page 5301).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAdapterHiddenFieldsList();
```

Description

Do not use the Destroy method directly to free a TAdapterHiddenFieldsList (see page 5301) instance. Instead, use the Free method, which checks that the TAdapterHiddenFieldsList (see page 5301) reference is not nil before calling Destroy.

See Also

System::TObject::Free (see page 3372)

54.1.22.4 TAdapterHiddenFieldsList Methods

The methods of the TAdapterHiddenFieldsList class are listed here.

Protected Methods

	Name	Description
	EndIterator (see page 5305)	Signals the end of the iterating operation.
	GetCurrentIntf (see page 5306)	This is GetCurrentIntf, a member of class TAdapterHiddenFieldsList.

	GetField (see page 5306)	This is GetField, a member of class TAdapterHiddenFieldsList.
	GetFieldCount (see page 5306)	This is GetFieldCount, a member of class TAdapterHiddenFieldsList.
	NextIteration (see page 5307)	Advances to the objects next item.
	StartIterator (see page 5307)	Positions the object on its first item and starts the iteration process.

Public Methods

	Name	Description
	Add (see page 5305)	Adds a name/value pair to the list.
	Clear (see page 5305)	Clears the list of all the name/value pairs it currently holds.

54.1.22.4.1 TAdapterHiddenFieldsList.Add Method

Adds a name/value pair to the list.

Pascal

```
procedure Add(const AName: string; const AValue: string);
```

C++

```
__fastcall Add(const UnicodeString AName, const UnicodeString AValue);
```

Description

Call Add to add a new name/value pair to the list of hidden fields that the adapter maintains.

AName is the name of the field.

AValue is the value of the field.

See Also

Clear (see page 5305)

54.1.22.4.2 TAdapterHiddenFieldsList.Clear Method

Clears the list of all the name/value pairs it currently holds.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the TAdapterHiddenFieldsList (see page 5301) object. Clear discards any name/value pairs that have been added previously by a call to the Add (see page 5305) method.

See Also

Add (see page 5305)

54.1.22.4.3 TAdapterHiddenFieldsList.EndIterator Method

Signals the end of the iterating operation.

Pascal

```
procedure EndIterator(OwnerData: Pointer);
```

C++

```
__fastcall EndIterator(void * OwnerData);
```

Description

Server-side script calls EndIterator when it stops iterating over the object's items. The object uses this method to perform any clean-up to reflect the fact that it is no longer iterating over its items.

OwnerData is a pointer to information that the object can use to influence the iteration process. Each object stores and uses this information in its own way. This information is first supplied by the initial call to the StartIterator method. It is passed to each NextIteration call (which can modify the information), and finally supplied to the EndIterator method, which can free the memory used to store the information.

See Also

StartIterator (see page 1056)

NextIteration (see page 1056)

54.1.22.4.4 TAdapterHiddenFieldsList.GetCurrentIntf Method

Pascal

```
function GetCurrentIntf(OwnerData: Pointer): IUnknown;
```

C++

```
__fastcall IUnknown GetCurrentIntf(void * OwnerData);
```

Description

This is GetCurrentIntf, a member of class TAdapterHiddenFieldsList.

54.1.22.4.5 TAdapterHiddenFieldsList.GetField Method

Pascal

```
function GetField(I: Integer): IAdapterHiddenField;
```

C++

```
__fastcall IAdapterHiddenField GetField(int I);
```

Description

This is GetField, a member of class TAdapterHiddenFieldsList.

54.1.22.4.6 TAdapterHiddenFieldsList.GetFieldCount Method

Pascal

```
function GetFieldCount: Integer;
```

C++

```
__fastcall int GetFieldCount();
```

Description

This is GetFieldCount, a member of class TAdapterHiddenFieldsList.

54.1.22.4.7 TAdapterHiddenFieldsList.NextIteration Method

Advances to the objects next item.

Pascal

```
function NextIteration(var OwnerData: Pointer): Boolean;
```

C++

```
__fastcall Boolean NextIteration(void * OwnerData);
```

Description

Server-side script calls NextIteration to move to the next item.

OwnerData is a pointer to information that the object can use to influence the iteration process. Each object stores and uses this information in its own way. This information is first supplied by the initial call to the StartIterator method. NextIteration can modify the information, after which it is supplied to the next call to the NextIteration or EndIterator method.

NextIteration returns true if it successfully moves to the next item, false if there were no more items.

See Also

StartIterator (see page 1056)

EndIterator (see page 1056)

54.1.22.4.8 TAdapterHiddenFieldsList.StartIterator Method

Positions the object on its first item and starts the iteration process.

Pascal

```
function StartIterator(var OwnerData: Pointer): Boolean;
```

C++

```
__fastcall Boolean StartIterator(void * OwnerData);
```

Description

Server-side script calls StartIterator to begin iterating over the object's items.

OwnerData returns a pointer to information that the object can use to influence the iteration process. StartIterator initializes this information to reflect what ever information the object needs to communicate to itself as it advances over its items. This pointer is then passed to the next call to the NextIteration or EndIterator method.

StartIterator returns true if it successfully moves to the first item, false if there are no items to iterate.

See Also

NextIteration (see page 1056)

EndIterator (see page 1056)

54.1.22.5 TAdapterHiddenFieldsList Properties

The properties of the TAdapterHiddenFieldsList class are listed here.

Protected Properties

	Name	Description
	FieldCount (see page 5308)	This is FieldCount, a member of class TAdapterHiddenFieldsList.
	Fields (see page 5308)	This is Fields, a member of class TAdapterHiddenFieldsList.

54.1.22.5.1 TAdapterHiddenFieldsList.FieldCount Property

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

This is FieldCount, a member of class TAdapterHiddenFieldsList.

54.1.22.5.2 TAdapterHiddenFieldsList.Fields Property

Pascal

```
property Fields [I: Integer]: IAdapterHiddenField;
```

C++

```
__property IAdapterHiddenField Fields[int I];
```

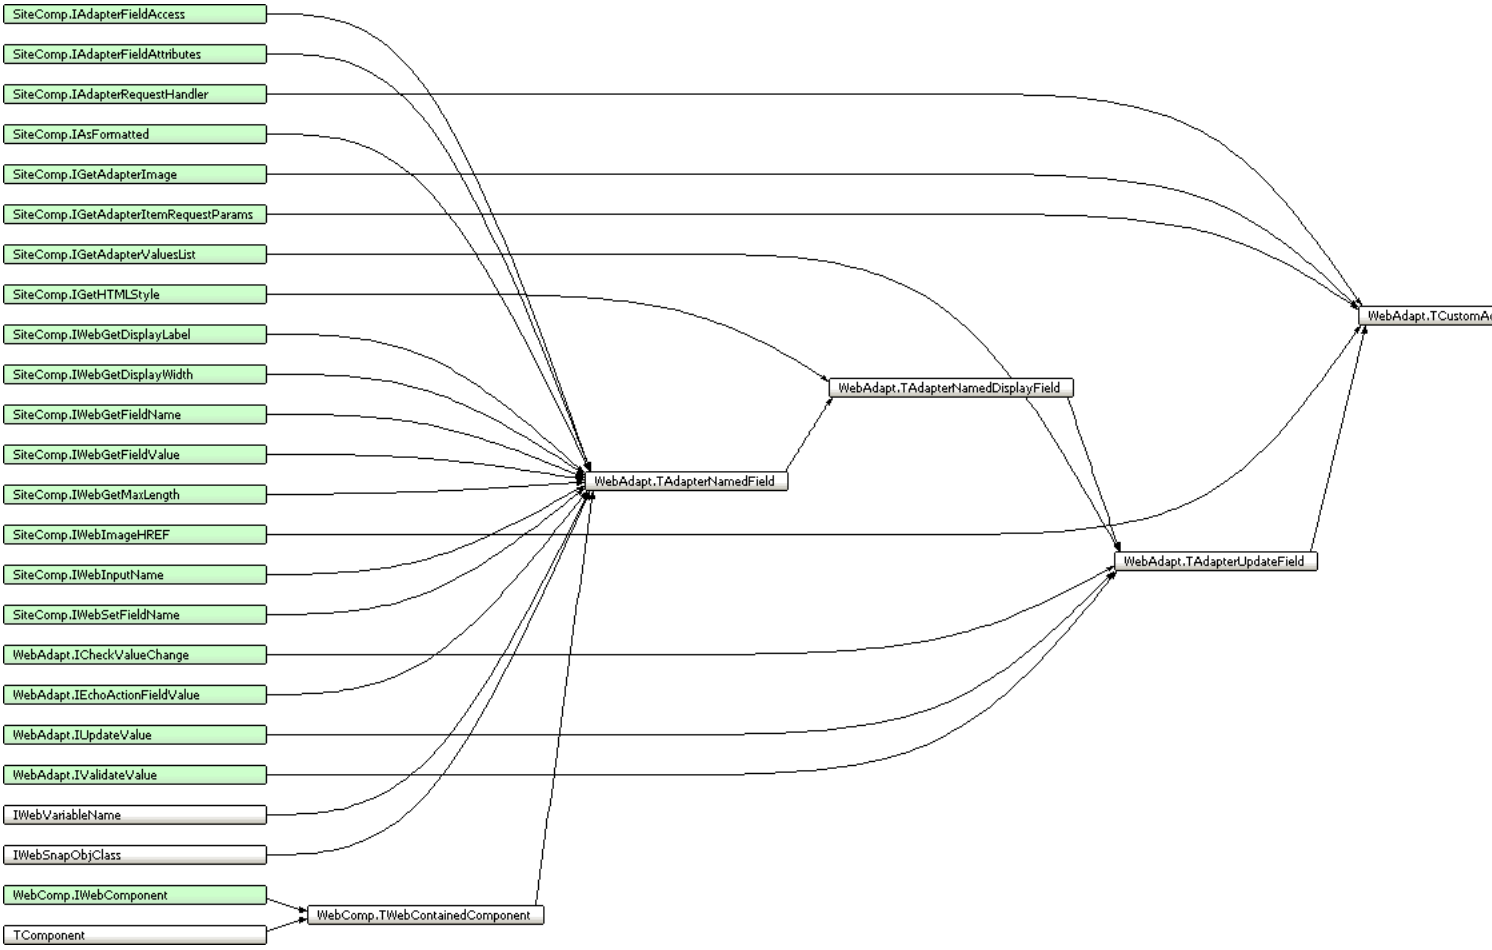
Description

This is Fields, a member of class TAdapterHiddenFieldsList.

54.1.23 TAdapterImageField Class

TAdapterImageField is an event handler based adapter field that can provide the URL of an image file and also accept an uploaded image file.

Class Hierarchy



Pascal

```
TAdapterImageField = class(TCustomAdapterImageField);
```

C++

```
class TAdapterImageField : public TCustomAdapterImageField;
```

File

WebAdapt

Description

TAdapterImageField publishes the properties in TCustomAdapterImageField (see page 5623). TCustomAdapterImageField (see page 5623) calls event handlers to retrieve the adapter field's image file name, image file, and image file URL. It also defines event handler that are called to validate files uploaded by the end-user, and update the adapter field's image file.

Add TAdapterFileField (see page 5281) to TAdapter (see page 5190) or other adapter components types when you need an adapter field that supports an image using event handlers. There are other adapter field components that use event handlers. They differ in the type and number of values that are supported. See TAdapterField (see page 5267), TAdapterMultiValueField (see page 5332), TAdapterMemoField (see page 5323), TAdapterBooleanField (see page 5223) and TAdapterFileField (see page 5281).

See Also

TCustomAdapterImageField (see page 5623)

TAdapter (see page 5190)

TAdapterField (see page 5267)

TAdapterMemoField (see page 5323)

TAdapterMultiValueField (see page 5332)

TAdapterBooleanField (see page 5223)

TAdapterFileField (see page 5281)

54.1.23.1 TAdapterImageField Members

The following tables list the members exposed by TAdapterImageField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
	CreateRequestContext (see page 5628)	Creates AdapterRequest and AdapterResponse objects.
	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
	DoOnValidateValue (see page 5628)	Validates files uploaded by the end-user.
	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterImage (see page 5629)	Provides an object that can be used to access the image properties of this adapter field.
	GetAdapterItemRequestParams (see page 5629)	Provides a unique identifier and a set of name/value pairs that will be used to create a URL and also be used later when a request is received to generate the adapter field's image file.
	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayStyleType (see page 5630)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.

	GetInputStyleType (see page 5630)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HandleRequest (see page 5630)	Handles a request for the image file associated with this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
	ImplCheckValueChange (see page 5631)	Indicates whether the end-user may have uploaded a new image file for this adapter field.
	ImplCreateRequestContext (see page 5631)	Creates AdapterRequest and AdapterResponse objects.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetValue (see page 5632)	Returns the name of the image file associated with this adapter field.
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHandleRequest (see page 5632)	Handles a request for the image file associated with this adapter field.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5632)	Updates the adapter field with value entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	ImplWebImageHREF (see page 5633)	Returns a URL that can be used to access the image file associated with this adapter field.

	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	RenderAdapterImage (see page 5633)	Responds to a request for an image file by providing a stream containing the image.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.
	WebImageHREF (see page 5634)	Returns a URL that can be used to access the image file associated with this adapter field.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnGetDisplayText (see page 5433)	Event handler called to retrieve a string representation of the adapter field's value.
	OnValidateValue (see page 5433)	Event handler called to validate value(s) entered by the end-user.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	CreateRequestContext (see page 1013)	Creates an object that describes the adapter action parameters and adapter field values.
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetAdapterImage (see page 1023)	This is GetAdapterImage, a member of class IGetAdapterImage.
	GetAdapterItemRequestParams (see page 1024)	This is GetAdapterItemRequestParams, a member of class IGetAdapterItemRequestParams.
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.

	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HandleRequest (see page 1013)	Executes the adapter action and generates a response.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.
	WebImageHREF (see page 1098)	Retrieves a URL for an external image file.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetHREF (see page 5317)	Provides the URL of an external image file associated with this adapter field.
	OnGetImage (see page 5318)	Retrieves a stream containing the image file associated with this adapter field.
	OnGetImageName (see page 5318)	Returns the name of the image file associated with this adapter field.
	OnGetParams (see page 5318)	Provides name/value pairs that identify this adapter field's image.
	OnUploadFile (see page 5319)	Updates this adapter field with an image file uploaded by the end-user.
	OnValidateFile (see page 5319)	Used to validate files uploaded by the end user.

Published Properties

	Name	Description
	DisplayLabel (see page 5314)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5314)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5315)	Identifies the name of this field when using server-side script.
	HREF (see page 5315)	Defines a URL that references the image associated with the adapter field.
	ModifyAccess (see page 5315)	Identifies the rights required to update this field.
	ReadOnly (see page 5316)	Indicates whether this adapter field is read-only.
	Required (see page 5316)	Indicates whether the end-user must enter a value for this adapter field.

	ValuesList (see page 5316)	Associates a list of values with the adapter field.
	ViewAccess (see page 5317)	Identifies the rights required to view this field.

54.1.23.2 TAdapterImageField Properties

The properties of the TAdapterImageField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5314)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5314)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5315)	Identifies the name of this field when using server-side script.
	HREF (see page 5315)	Defines a URL that references the image associated with the adapter field.
	ModifyAccess (see page 5315)	Identifies the rights required to update this field.
	ReadOnly (see page 5316)	Indicates whether this adapter field is read-only.
	Required (see page 5316)	Indicates whether the end-user must enter a value for this adapter field.
	ValuesList (see page 5316)	Associates a list of values with the adapter field.
	ViewAccess (see page 5317)	Identifies the rights required to view this field.

54.1.23.2.1 TAdapterImageField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.23.2.2 TAdapterImageField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.23.2.3 TAdapterImageField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.23.2.4 TAdapterImageField.HREF Property

Defines a URL that references the image associated with the adapter field.

Pascal

```
property HREF: string;
```

C++

```
__property UnicodeString HREF;
```

Description

Use the HREF property when this adapter field is associated with an external image file URL. Use the OnGetHREF event to dynamically define an external image file URL. If the image file will be dynamically generated, use the OnGetImage and OnGetImageParams event handlers instead of the HREF property or the OnGetHREF event handler.

See Also

ImplWebImageHREF (see page 5633)

OnGetHREF (see page 5635)

OnGetImage (see page 5636)

OnGetImageName (see page 5636)

54.1.23.2.5 TAdapterImageField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user

attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.23.2.6 TAdapterImageField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.23.2.7 TAdapterImageField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

See Also

GetRequired (see page 5359)

54.1.23.2.8 TAdapterImageField.ValuesList Property

Associates a list of values with the adapter field.

Pascal

```
property ValuesList: IValuesListAdapter;
```

C++

```
__property IValuesListAdapter ValuesList;
```

Description

Assign a component to the ValuesList property to define possible values for the adapter field. Server-side script can be used to

enumerate the name/value pairs of the ValuesList component to generate HTML select lists, check boxes, or radio buttons.

See Also

IValuesListAdapter (see page 1072)

TStringsValuesList (see page 5857)

TDataSetValuesList

54.1.23.2.9 TAdapterImageField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.23.3 TAdapterImageField Events

The events of the TAdapterImageField class are listed here.

Published Events

	Name	Description
	OnGetHREF (see page 5317)	Provides the URL of an external image file associated with this adapter field.
	OnGetImage (see page 5318)	Retrieves a stream containing the image file associated with this adapter field.
	OnGetImageName (see page 5318)	Returns the name of the image file associated with this adapter field.
	OnGetParams (see page 5318)	Provides name/value pairs that identify this adapter field's image.
	OnUploadFile (see page 5319)	Updates this adapter field with an image file uploaded by the end-user.
	OnValidateFile (see page 5319)	Used to validate files uploaded by the end user.

54.1.23.3.1 TAdapterImageField.OnGetHREF Event

Provides the URL of an external image file associated with this adapter field.

Pascal

```
property OnGetHREF: TImageFieldGetHREFEvent;
```

C++

```
__property TImageFieldGetHREFEvent OnGetHREF;
```

Description

Implement OnGetHREF to dynamically identify the URL of an external image file associated with this adapter field. When

OnGetHREF is called, the HREF parameter will contain the value of the HREF property. To dynamically generate an image file for this adapter file, implement the OnGetImage event handler instead.

See Also

ImplWebImageHREF (see page 5633)

HREF (see page 5634)

OnGetImage (see page 5636)

54.1.23.3.2 TAdapterImageField.OnGetImage Event

Retrieves a stream containing the image file associated with this adapter field.

Pascal

```
property OnGetImage: TImageFieldGetImageEvent;
```

C++

```
__property TImageFieldGetImageEvent OnGetImage;
```

Description

Implement OnGetImage to dynamically generate an image file associated with this adapter field. Don't implement OnGetImage if the image file is external. Instead implement OnGetHREF event handler or use the HREF property to specify the URL of an external image.

See Also

RenderAdapterImage (see page 5633)

OnGetParams (see page 5636)

OnGetHREF (see page 5635)

HREF (see page 5634)

54.1.23.3.3 TAdapterImageField.OnGetImageName Event

Returns the name of the image file associated with this adapter field.

Pascal

```
property OnGetImageName: TAdapterFieldGetStringEvent;
```

C++

```
__property TAdapterFieldGetStringEvent OnGetImageName;
```

Description

Implement this event handler to identify the name of the image file associated with this adapter field.

See Also

ImplGetValue (see page 5632)

54.1.23.3.4 TAdapterImageField.OnGetParams Event

Provides name/value pairs that identify this adapter field's image.

Pascal

```
property OnGetParams: TImageFieldGetParamsEvent;
```

C++

```
__property TImageFieldGetParamsEvent OnGetParams;
```

Description

Implement this event handler to provide name/value pairs that are needed to identify this adapter field's image file. OnGetParams is called while generating an HTML page with a URL reference to this adapter field's image. The parameters returned by OnGetParams will be passed to OnGetImage when the image file is requested.

See Also

GetAdapterItemRequestParams (see page 5629)

OnGetImage (see page 5636)

54.1.23.3.5 TAdapterImageField.OnUploadFile Event

Updates this adapter field with an image file uploaded by the end-user.

Pascal

```
property OnUploadFile: TAdapterFieldFileEvent;
```

C++

```
__property TAdapterFieldFileEvent OnUploadFile;
```

Description

This event handler is called by ImplUpdateValue. This event handler should store the uploaded image file. Raise an exception to indicate an error.

See Also

ImplUpdateValue (see page 5632)

TAbstractWebRequestFile

54.1.23.3.6 TAdapterImageField.OnValidateFile Event

Used to validate files uploaded by the end user.

Pascal

```
property OnValidateFile: TAdapterFieldFileEvent;
```

C++

```
__property TAdapterFieldFileEvent OnValidateFile;
```

Description

Validates the file uploaded by the end-user. Raise an exception to indicate an error. For example, it raises an exception if the Mime type of the file is not supported.

See Also

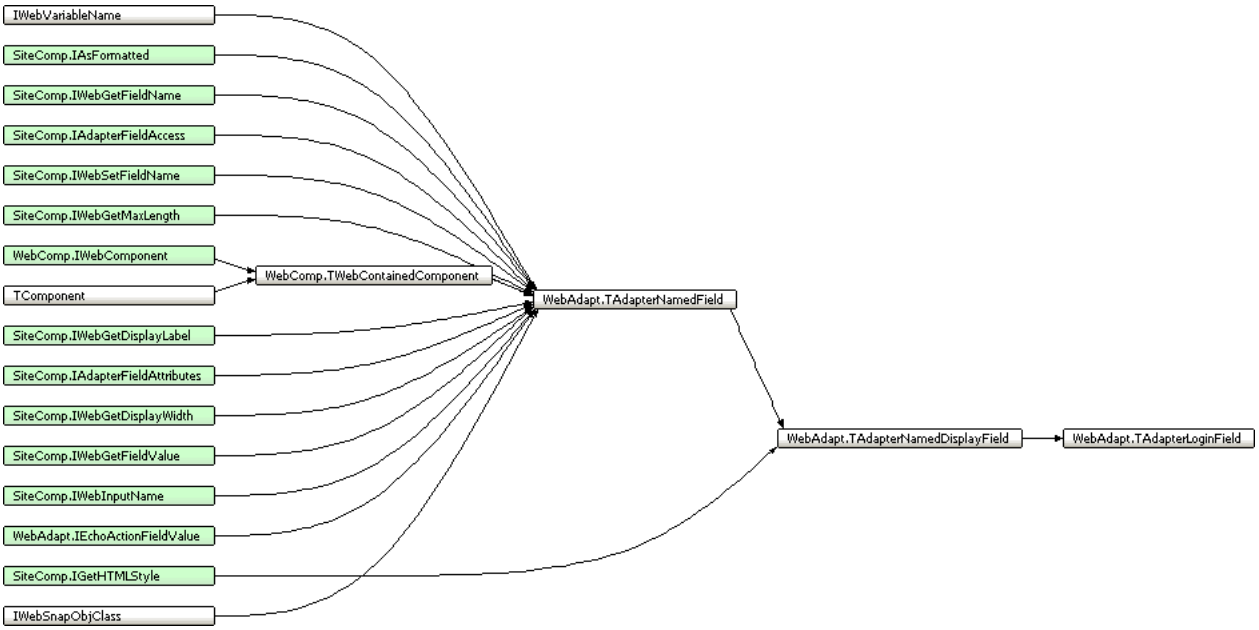
DoOnValidateValue (see page 5628)

TAbstractWebRequestFile

54.1.24 TAdapterLoginField Class

TAdaperLoginField is a base class for adapter field components that are children of a TLoginFormAdapter (see page 5824) component.

Class Hierarchy



Pascal

```
TAdapterLoginField = class(TAdapterNamedDisplayField);
```

C++

```
class TAdapterLoginField : public TAdapterNamedDisplayField;
```

File

WebAdapt

Description

TAdapterLoginField implements functionality that is used by an adapter field that is a child of TLoginFormAdapter (see page 5824).

See Also

TLoginFormAdapter (see page 5824)

TAdapterNamedDisplayField (see page 5343)

TAdapterUserNameField (see page 5433)

TAdapterPasswordField (see page 5391)

54.1.24.1 TAdapterLoginField Members

The following tables list the members exposed by TAdapterLoginField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.

	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
	Adapter (see page 5323)	Returns the parent adapter of this adapter field.

W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
R	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.24.2 TAdapterLoginField Properties

The properties of the TAdapterLoginField class are listed here.

Public Properties

	Name	Description
R	Adapter (see page 5323)	Returns the parent adapter of this adapter field.

54.1.24.2.1 TAdapterLoginField.Adapter Property

Returns the parent adapter of this adapter field.

Pascal

```
property Adapter: TCustomLoginFormAdapter;
```

C++

```
__property TCustomLoginFormAdapter Adapter;
```

Description

Descendants use this property to access the parent adapter. GetAdapter (see page 5356) implements this property.

See Also

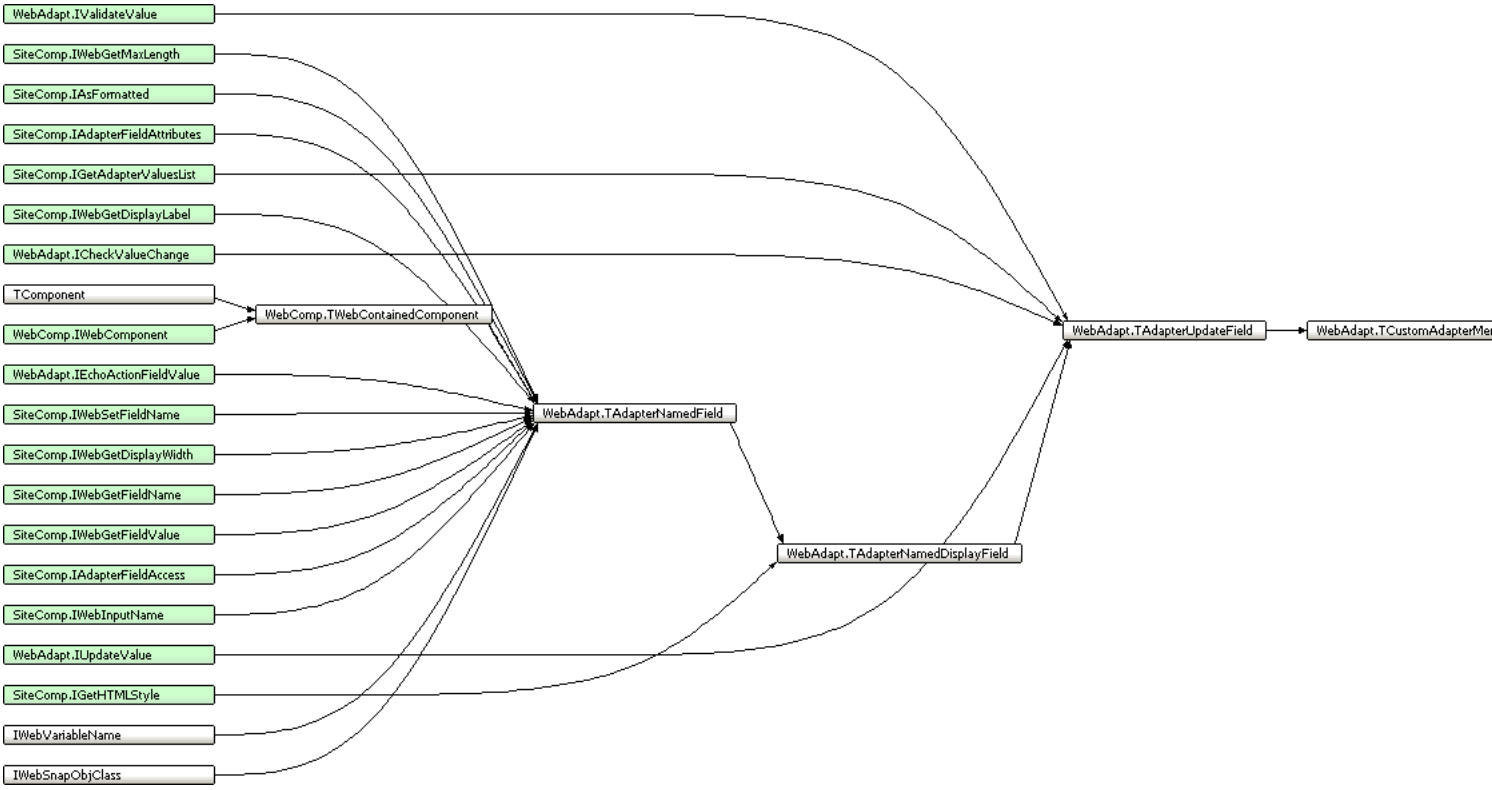
TCustomLoginFormAdapter (see page 5701)

GetAdapter (see page 5356)

54.1.25 TAdapterMemoField Class

TAdapterMemoField is an event handler based adapter field that supports a multi-line text value.

Class Hierarchy



Pascal

```
TAdapterMemoField = class(TCustomAdapterMemoField);
```

C++

```
class TAdapterMemoField : public TCustomAdapterMemoField;
```

File

WebAdapt

Description

TAdapterMemoField publishes the properties in TCustomAdapterMemoField (see page 5638). TCustomAdapterMemoField (see page 5638) calls event handlers to retrieve the adapter field's text value, validate a value entered end-user, and update the adapter field's value.

Add TAdapterMemoField to TAdapter (see page 5190) or other adapter components types when you need an adapter field that supports a multi-line text value. There are other adapter field components that use event handlers. They differ in the type and number of values that are supported. See TAdapterField (see page 5267), TAdapterMultiValueField (see page 5332), TAdapterFileField (see page 5281), TAdapterBooleanField (see page 5223) and TAdapterImageField (see page 5308).

See Also

TCustomAdapterMemoField (see page 5638)

TAdapter (see page 5190)

TAdapterField (see page 5267)

TAdapterFileField (see page 5281)

TAdapterMultiValueField (see page 5332)

TAdapterBooleanField (see page 5223)

TAdapterImageField (see page 5308)

54.1.25.1 TAdapterMemoField Members

The following tables list the members exposed by TAdapterMemoField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
V	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
V	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
V	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
V	DoOnValidateValue (see page 5642)	Validates a value entered by the end user.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
V	GetDisplayStyleType (see page 5642)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
V	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.
V	GetInputStyleType (see page 5643)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
V	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
V	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.

	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
	ImplCheckValueChange (see page 5643)	Indicates whether the end-user may have entered a new value for this adapter field.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetValue (see page 5644)	Returns the value of this adapter field as a variant.
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5644)	Updates the adapter field with value entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.

Protected Properties

	Name	Description
R	Adapter (see page 5368)	Returns the parent adapter component.
R	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
R	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnGetDisplayText (see page 5433)	Event handler called to retrieve a string representation of the adapter field's value.
	OnValidateValue (see page 5433)	Event handler called to validate value(s) entered by the end-user.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
V	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
V	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
V	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.

	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
	ValuesList (see page 5432)	Associates a list of values with the adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetValue (see page 5331)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5331)	Called to update the adapter field's value with a text value entered by the end-user.
	OnUploadFile (see page 5332)	Called to update the adapter field's value with a file uploaded by the end-user.

Published Properties

	Name	Description
	DisplayLabel (see page 5328)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5329)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5329)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5329)	Identifies the rights required to update this field.
	ReadOnly (see page 5330)	Indicates whether this adapter field is read-only.
	Required (see page 5330)	Indicates whether the end-user must enter a value for this adapter field.
	ViewAccess (see page 5330)	Identifies the rights required to view this field.

54.1.25.2 TAdapterMemoField Properties

The properties of the TAdapterMemoField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5328)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5329)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5329)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5329)	Identifies the rights required to update this field.
	ReadOnly (see page 5330)	Indicates whether this adapter field is read-only.
	Required (see page 5330)	Indicates whether the end-user must enter a value for this adapter field.
	ViewAccess (see page 5330)	Identifies the rights required to view this field.

54.1.25.2.1 TAdapterMemoField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.25.2.2 TAdapterMemoField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.25.2.3 TAdapterMemoField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.25.2.4 TAdapterMemoField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user

attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.25.2.5 TAdapterMemoField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.25.2.6 TAdapterMemoField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

See Also

GetRequired (see page 5359)

54.1.25.2.7 TAdapterMemoField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView

property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.25.3 TAdapterMemoField Events

The events of the TAdapterMemoField class are listed here.

Published Events

	Name	Description
	OnGetValue (see page 5331)	Called to retrieve the adapter field's value.
	OnUpdateValue (see page 5331)	Called to update the adapter field's value with a text value entered by the end-user.
	OnUploadFile (see page 5332)	Called to update the adapter field's value with a file uploaded by the end-user.

54.1.25.3.1 TAdapterMemoField.OnGetValue Event

Called to retrieve the adapter field's value.

Pascal

```
property OnGetValue: TAdapterFieldGetStringEvent;
```

C++

```
__property TAdapterFieldGetStringEvent OnGetValue;
```

Description

OnGetValue is called by ImplGetValue to retrieve the value associated with this adapter field.

See Also

ImplGetValue (see page 5644)

54.1.25.3.2 TAdapterMemoField.OnUpdateValue Event

Called to update the adapter field's value with a text value entered by the end-user.

Pascal

```
property OnUpdateValue: TAdapterFieldStringEvent;
```

C++

```
__property TAdapterFieldStringEvent OnUpdateValue;
```

Description

OnUpdateValue is called when an action request contains a value for this adapter field. If this event handler is not implemented, the value entered by the end-user will be ignored.

See Also

ImplUpdateValue (see page 5644)

54.1.25.3.3 TAdapterMemoField.OnUploadFile Event

Called to update the adapter field's value with a file uploaded by the end-user.

Pascal

```
property OnUploadFile: TAdapterFieldFileEvent;
```

C++

```
__property TAdapterFieldFileEvent OnUploadFile;
```

Description

OnUploadFile is called when an action request contains an uploaded file for this adapter field. If this event handler is not implemented, the file uploaded by the end-user will be ignored.

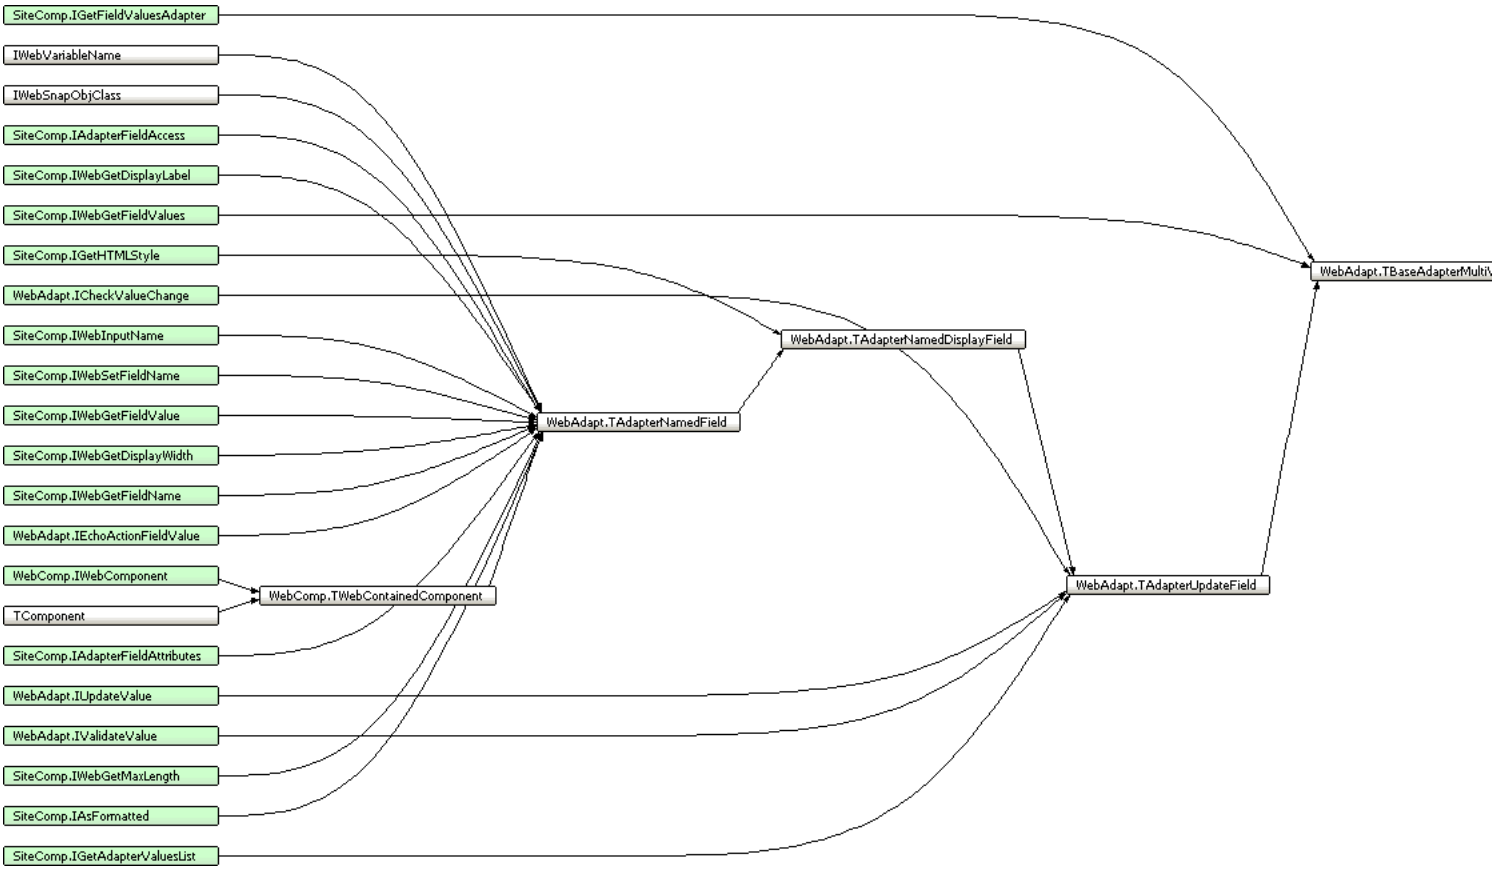
See Also

ImplUpdateValue (see page 5644)

54.1.26 TAdapterMultiValueField Class

TAdapterMultiValueField is an event handler based adapter field that provides zero or more values.

Class Hierarchy



Pascal

```
TAdapterMultiValueField = class(TCustomAdapterMultiValueField);
```

C++

```
class TAdapterMultiValueField : public TCustomAdapterMultiValueField;
```

File

WebAdapt

Description

TAdapterMultiValueField publishes the properties in TCustomAdapterMultiValueField (see page 5646). TCustomAdapterMultiValueField (see page 5646) calls event handlers to retrieve the adapter field's values, validate values entered by the end-user, and update the adapter field's values.

Add TAdapterMultiValueField to TAdapter (see page 5190) or other adapter components types when you need an adapter field that supports a multiple values using event handlers. There are other adapter field components that use event handlers. They differ in the type and number of values that are supported. See TAdapterField (see page 5267), TAdapterFileField (see page 5281), TAdapterMemoField (see page 5323), TAdapterBooleanField (see page 5223) and TAdapterImageField (see page 5308).

See Also

TCustomAdapterMultiValueField (see page 5646)

TAdapter (see page 5190)

TAdapterField (see page 5267)

TAdapterMemoField (see page 5323)

TAdapterFileField (see page 5281)

TAdapterBooleanField (see page 5223)

TAdapterImageField (see page 5308)

54.1.26.1 TAdapterMultiValueField Members

The following tables list the members exposed by TAdapterMultiValueField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckValueChange (see page 5424)	Checks the value(s) entered by the end-user against the value associated with this adapter field.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	ConvertValue (see page 5425)	Retrieves a value entered by the end-user.
V	ConvertValueCount (see page 5425)	Retrieves the number of values entered by the end-user.
V	ConvertValues (see page 5425)	Retrieves a value entered by the end-user.
V	DoOnValidateValue (see page 5426)	Validates field values entered by the end-user.
V	DoOnValidateValue (see page 5651)	Validates values entered by the end-user.
	EndValueIterator (see page 5493)	Completes iteration.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterValuesList (see page 5426)	Provides an interface to a component that can be used to generate a list of possible values for this adapter field.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
	GetCurrentValue (see page 5494)	Implements IWebGetFieldValues (see page 1092)' GetCurrentValue.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
V	GetDisplayStyleType (see page 5651)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetFieldValuesAdapter (see page 5494)	Returns the adapter object that implements the Values property.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
V	GetInputStyleType (see page 5426)	Indicates the preferred HTML element to use when editing this adapter field's value.
V	GetInputStyleType (see page 5651)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
V	GetValueCount (see page 5427)	Provides the number of values associated with this adapter field.
V	GetValueCount (see page 5494)	Returns the number of values associated with this adapter field.
V	GetValueCount (see page 5652)	Returns the number of values associated with this adapter field.

	GetValues (see page 5427)	Returns one of the values provided by this adapter field.
	GetValues (see page 5495)	Returns one of the values associated with the adapter field.
	GetValues (see page 5652)	Returns one of the values associated with the adapter field.
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasValue (see page 5495)	Implements IWebGetFieldValues (see page 1092)' HasValue method.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
	ImplAsFormatted (see page 5427)	Returns a string representation of the adapter field's value that is appropriate for a read-only display.
	ImplCheckValueChange (see page 5428)	Checks the value(s) entered by the end-user against the value(s) associated with this adapter field.
	ImplGetCurrentValue (see page 5495)	Implements IWebGetFieldValues (see page 1092)' GetCurrentValue (see page 5494) method.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
	ImplGetDisplayLabel (see page 5428)	Gets the preferred display label for this adapter field.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
	ImplGetDisplayWidth (see page 5428)	Returns the preferred display width for the HTML element used to edit or display this adapter field's value.
	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
	ImplGetEchoActionFieldValue (see page 5429)	Gets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplGetFieldValuesAdapter (see page 5496)	Returns the adapter object that implements the Values property.
	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
	ImplGetVariableName (see page 5429)	Gets the name used to access this adapter field with server-side script.
	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
	ImplHasValue (see page 5496)	Implements IWebGetFieldValues (see page 1092)' HasValue (see page 5495) method.
	ImplHasValue (see page 5653)	Implements IWebGetFieldValues (see page 1092)' HasValue (see page 5495) method.
	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
	ImplSetEchoActionFieldValue (see page 5429)	Sets a flag that causes the adapter field to return the value(s) entered by the end-user.
	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	ImplSetFieldName (see page 5429)	Sets the name used to access this adapter field with server-side script.
	ImplUpdateValue (see page 5430)	Updates the adapter field with value(s) entered by the end-user.
	ImplUpdateValue (see page 5653)	Updates the adapter field with value(s) entered by the end-user.
	ImplValidateValue (see page 5430)	Validates values(s) entered by the end-user.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	IsMultiValueField (see page 5430)	Indicates whether this adapter field can support multiple values.
	NextValueIteration (see page 5496)	Implements IWebGetFieldValues (see page 1092)' NextValueIteration method.

	Notification (see page 5431)	Clears references to a deleted component.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartValueIterator (see page 5497)	Implements IWebGetFieldValues (see page 1092)' StartValueIterator method.
	UpdateValue (see page 5431)	Updates the adapter field with value(s) entered by the end-user.
	ValidateValue (see page 5431)	Validates values(s) entered by the end-user.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnGetDisplayText (see page 5433)	Event handler called to retrieve a string representation of the adapter field's value.
	OnValidateValue (see page 5433)	Event handler called to validate value(s) entered by the end-user.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	CheckValueChange (see page 5878)	This is CheckValueChange, a member of class ICheckValueChange.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 5423)	Creates an instance of TAdapterUpdateField (see page 5419).
	Create (see page 5492)	Constructor for TBaseAdapterMultiValueField (see page 5488).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 5492)	Destructor for TBaseAdapterMultiValueField (see page 5488).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndValueIterator (see page 1093)	Indicate the iteration is finished.
	GetAdapterValuesList (see page 1027)	This is GetAdapterValuesList, a member of class IGetAdapterValuesList.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetCurrentValue (see page 1094)	Retrieves the current value as a variant.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetFieldValuesAdapter (see page 1031)	This is GetFieldValuesAdapter, a member of class IGetFieldValuesAdapter.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.

	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasValue (see page 1094)	Indicates whether the adapter field has a matching value.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	NextValueIteration (see page 1094)	Position the iteration pointer on the next value.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartValueIterator (see page 1095)	Reset (see page 3643) the iteration pointer to the first item.
	UpdateValue (see page 5892)	This is UpdateValue, a member of class IUpdateValue.
	ValidateValue (see page 5893)	This is ValidateValue, a member of class IValidateValue.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
R	Value (see page 5432)	Retrieves the value associated with this adapter field.
R	ValueCount (see page 5653)	Returns the number of values associated with this adapter field.
R	Values (see page 5654)	Returns one of the values associated with the adapter field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Events

	Name	Description
	OnGetValueCount (see page 5341)	Responsible for returning the count of values associated with the adapter field.
	OnGetValues (see page 5341)	Responsible for returning one of the values associated with the adapter field.
	OnHasValue (see page 5342)	Indicates whether a particular value is associated with this adapter field.
	OnUpdateValues (see page 5342)	Updates the adapter field with value(s) entered by the end-user.
	OnValidateValues (see page 5342)	Validates field values entered by the end-user.

Published Properties

	Name	Description
	DisplayLabel (see page 5338)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5338)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5339)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5339)	Identifies the rights required to update this field.
	ReadOnly (see page 5339)	Indicates whether this adapter field is read-only.
	Required (see page 5340)	Indicates whether the end-user must enter a value for this adapter field.
	ValuesList (see page 5340)	Associates a list of values with the adapter field.
	ViewAccess (see page 5340)	Identifies the rights required to view this field.

54.1.26.2 TAdapterMultiValueField Properties

The properties of the TAdapterMultiValueField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5338)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5338)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5339)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5339)	Identifies the rights required to update this field.
	ReadOnly (see page 5339)	Indicates whether this adapter field is read-only.
	Required (see page 5340)	Indicates whether the end-user must enter a value for this adapter field.
	ValuesList (see page 5340)	Associates a list of values with the adapter field.
	ViewAccess (see page 5340)	Identifies the rights required to view this field.

54.1.26.2.1 TAdapterMultiValueField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.26.2.2 TAdapterMultiValueField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.26.2.3 TAdapterMultiValueField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.26.2.4 TAdapterMultiValueField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.26.2.5 TAdapterMultiValueField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.26.2.6 TAdapterMultiValueField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

See Also

GetRequired (see page 5359)

54.1.26.2.7 TAdapterMultiValueField.ValuesList Property

Associates a list of values with the adapter field.

Pascal

```
property ValuesList: IValuesListAdapter;
```

C++

```
__property IValuesListAdapter ValuesList;
```

Description

Assign a component to the ValuesList property to define possible values for the adapter field. Server-side script can be used to enumerate the name/value pairs of the ValuesList component to generate HTML select lists, check boxes, or radio buttons.

See Also

IValuesListAdapter (see page 1072)

TStringsValuesList (see page 5857)

TDataSetValuesList

54.1.26.2.8 TAdapterMultiValueField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.26.3 TAdapterMultiValueField Events

The events of the TAdapterMultiValueField class are listed here.

Published Events

	Name	Description
	OnGetValueCount (see page 5341)	Responsible for returning the count of values associated with the adapter field.
	OnGetValues (see page 5341)	Responsible for returning one of the values associated with the adapter field.
	OnHasValue (see page 5342)	Indicates whether a particular value is associated with this adapter field.
	OnUpdateValues (see page 5342)	Updates the adapter field with value(s) entered by the end-user.
	OnValidateValues (see page 5342)	Validates field values entered by the end-user.

54.1.26.3.1 TAdapterMultiValueField.OnGetValueCount Event

Responsible for returning the count of values associated with the adapter field.

Pascal

```
property OnGetValueCount: TAdapterFieldGetValueCountEvent;
```

C++

```
__property TAdapterFieldGetValueCountEvent OnGetValueCount;
```

Description

Implement this event handler to provide the count of values associated with an adapter field. Also implement OnGetValues to provide the individual values.

See Also

GetValueCount (see page 5652)

OnGetValues (see page 5655)

54.1.26.3.2 TAdapterMultiValueField.OnGetValues Event

Responsible for returning one of the values associated with the adapter field.

Pascal

```
property OnGetValues: TAdapterFieldGetMultiValueEvent;
```

C++

```
__property TAdapterFieldGetMultiValueEvent OnGetValues;
```

Description

Implement this event handler to provide the values associated with an adapter field. The Index parameter is zero-based. Also implement OnGetValueCount to provide the count of values associated with this adapter field.

See Also

GetValues (see page 5652)

OnGetValueCount (see page 5654)

54.1.26.3.3 TAdapterMultiValueField.OnHasValue Event

Indicates whether a particular value is associated with this adapter field.

Pascal

```
property OnHasValue: TAdapterFieldHasValueEvent;
```

C++

```
__property TAdapterFieldHasValueEvent OnHasValue;
```

Description

ImplHasValue calls this event handler. Implement this event handler to lookup a matching value. Implementation of this event handler is optional. If OnHasValue is nil, ImplHasValue will search for a matching value the Values and ValueCount properties.

See Also

ImplHasValue (see page 5653)

ValueCount (see page 5653)

Values (see page 5654)

54.1.26.3.4 TAdapterMultiValueField.OnUpdateValues Event

Updates the adapter field with value(s) entered by the end-user.

Pascal

```
property OnUpdateValues: TAdapterFieldStringsEvent;
```

C++

```
__property TAdapterFieldStringsEvent OnUpdateValues;
```

Description

Implement this event handler to process values entered by the end-user. Raise an exception if an error occurs.

See Also

OnValidateValues (see page 5656)

ImplUpdateValue (see page 5653)

54.1.26.3.5 TAdapterMultiValueField.OnValidateValues Event

Validates field values entered by the end-user.

Pascal

```
property OnValidateValues: TAdapterFieldStringsEvent;
```

C++

```
__property TAdapterFieldStringsEvent OnValidateValues;
```

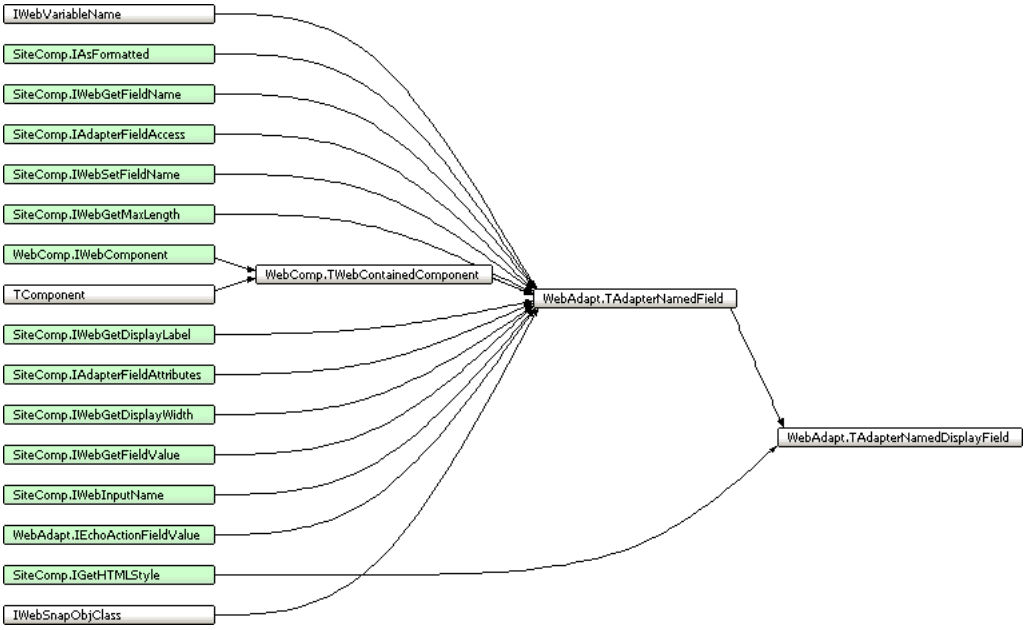
Description

Implement this event handler to validate values entered by the end-user. Raise an exception if an error occurs.

54.1.27 TAdapterNamedDisplayField Class

The AdapterNamedDisplayField is a base class for adapter fields.

Class Hierarchy



Pascal

```
TAdapterNamedDisplayField = class(TAdapterNamedField, IGetHTMLStyle);
```

C++

```
class TAdapterNamedDisplayField : public TAdapterNamedField, public IGetHTMLStyle;
```

File

WebAdapt

Description

TAdapterNameDisplayField implements the IGetHTMLStyle (see page 1031) interface used to inquire how this adapter field should be displayed in an HTML form. For example, IGetHTMLStyle (see page 1031)'s GetInputStyle (see page 5347) method may indicate that this field should be displayed using a select list. TAdapterNamedField (see page 5351) also declares properties that may be modified at design-time to control how the adapter field should be displayed. For example, the DisplayLabel (see page 5350) property is used to suggest display label for this adapter field.

See Also

TAdapterNamedField (see page 5351)

TCustomAdapter (see page 5531)

TAdapter (see page 5190)

IGetHTMLStyle (see page 1031)

54.1.27.1 TAdapterNamedDisplayField Members

The following tables list the members exposed by TAdapterNamedDisplayField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.

V	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
V	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
V	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
R	Adapter (see page 5368)	Returns the parent adapter component.
R	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
R	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
V	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.

	FieldName (see page 1091)	This is FieldName, a member of class IWebGetFieldName.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.27.2 TAdapterNamedDisplayField.Create Constructor

Creates an instance of TAdapterNamedDisplayField (see page 5343).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAdapterNamedDisplayField(TComponent * AOwner);
```

Description

Do not call Create. It will be called automatically when the TAdapterNamedDisplayField (see page 5343) object is created

54.1.27.3 TAdapterNamedDisplayField Methods

The methods of the TAdapterNamedDisplayField class are listed here.

Protected Methods

	Name	Description
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
	GetInputStyleType (see page 5347)	Suggests an HTML input type for this adapter field.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.

54.1.27.3.1 TAdapterNamedDisplayField.GetDisplayStyle Method

Returns a string value to suggest an HTML display style for this adapter field.

Pascal

```
function GetDisplayStyle(const AAdapterMode: string): string;
```

C++

```
__fastcall UnicodeString GetDisplayStyle(const UnicodeString AAdapterMode);
```

Description

GetDisplayStyle implements IGetHTMLStyle (see page 1031)'s GetDisplayStyle by translating the result value of GetDisplayStyleType (see page 5347) into a string.

See Also

GetDisplayStyle (see page 1032)

GetDisplayStyleType (see page 5347)

54.1.27.3.2 TAdapterNamedDisplayField.GetDisplayStyleType Method

Suggests an HTML display type for this adapter field.

Pascal

```
function GetDisplayStyleType(const AAdapterMode: string): TAdapterDisplayHTMLElementType;
virtual;
```

C++

```
virtual __fastcall TAdapterDisplayHTMLElementType GetDisplayStyleType(const UnicodeString
AAdapterMode);
```

Description

GetDisplayStyleType returns htmldText, indicating that this adapter field should be displayed by simple text. Descendant classes may override this method to suggest other HTML display types.

See Also

GetDisplayStyle (see page 5346)

54.1.27.3.3 TAdapterNamedDisplayField.GetInputStyle Method

Returns a string value to suggest an HTML input style for this adapter field.

Pascal

```
function GetInputStyle(const AAdapterMode: string): string;
```

C++

```
__fastcall UnicodeString GetInputStyle(const UnicodeString AAdapterMode);
```

Description

GetInputStyle implements IGetHTMLStyle (see page 1031)'s GetInputType method by translating the result value of GetInputStyleType (see page 5347) into a string.

See Also

GetInputStyle (see page 1033)

GetInputStyleType (see page 5347)

54.1.27.3.4 TAdapterNamedDisplayField.GetInputStyleType Method

Suggests an HTML input type for this adapter field.

Pascal

```
function GetInputStyleType(const AAdapterMode: string): TAdapterInputHTMLElementType; virtual;
```

C++

```
virtual __fastcall TAdapterInputHTMLElementType GetInputStyleType(const UnicodeString
AAdapterMode);
```

Description

GetInputStyleType returns htmliTextInput, indicating that this adapter field should be edited by a single line input field. Descendant classes may override this method to suggest a different HTML input type.

See Also

GetInputStyle (see page 5347)

54.1.27.3.5 TAdapterNamedDisplayField.GetViewMode Method

Returns a string value to suggest a view mode for this adapter field.

Pascal

```
function GetViewMode(const AAdapterMode: string): string;
```

C++

```
__fastcall UnicodeString GetViewMode(const UnicodeString AAdapterMode);
```

Description

GetViewMode implements IGetHTMLStyle (see page 1031)'s GetViewMode method by translating the result value of GetViewModeType (see page 5348) into a string.

See Also

GetViewMode (see page 1033)

GetViewModeType (see page 5348)

54.1.27.3.6 TAdapterNamedDisplayField.GetViewModeType Method

Suggests a view mode for this adapter field.

Pascal

```
function GetViewModeType(const AAdapterMode: string): TAdapterDisplayViewModeType; virtual;
```

C++

```
virtual __fastcall TAdapterDisplayViewModeType GetViewModeType(const UnicodeString
AAdapterMode);
```

Description

GetViewModeType returns htmlvmDisplay if the ReadOnly (see page 5351) property is true. Otherwise, htmlvmInput is returned.

See Also

ReadOnly (see page 5351)

GetViewMode (see page 5348)

54.1.27.3.7 TAdapterNamedDisplayField.ImplGetDisplayLabel Method

Implements interface access to the DisplayLabel (see page 5350) property.

Pascal

```
function ImplGetDisplayLabel: string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetDisplayLabel();
```

Description

ImplGetDisplayLabel returns the value of the DisplayLabel (see page 5350) property.

See Also

DisplayLabel (see page 5350)

54.1.27.3.8 TAdapterNamedDisplayField.ImplGetDisplayWidth Method

Implements interface access to the DisplayWidth (see page 5350) property.

Pascal

```
function ImplGetDisplayWidth: Integer; override;
```

C++

```
virtual __fastcall int ImplGetDisplayWidth();
```

Description

ImplGetDisplayWidth returns the value of the DisplayWidth (see page 5350) property.

See Also

DisplayWidth (see page 5350)

54.1.27.3.9 TAdapterNamedDisplayField.ImplGetRequired Method

Implements interface access to the Required (see page 5351) property.

Pascal

```
function ImplGetRequired: Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplGetRequired();
```

Description

ImplGetRequired returns the value of the Required (see page 5351) property.

See Also

Required (see page 5351)

54.1.27.3.10 TAdapterNamedDisplayField.SetDisplayLabel Method

SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.

Pascal

```
procedure SetDisplayLabel(const AValue: string);
```

C++

```
__fastcall SetDisplayLabel(const UnicodeString AValue);
```

Description

Use SetDisplayLabel to set the value of the DisplayLabel (see page 5350) property to AValue.

See Also

DisplayLabel (see page 5350)

54.1.27.4 TAdapterNamedDisplayField Properties

The properties of the TAdapterNamedDisplayField class are listed here.

Public Properties

	Name	Description
	DisplayLabel (see page 5350)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5350)	Suggests a display width, in characters, for this adapter field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.

54.1.27.4.1 TAdapterNamedDisplayField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.27.4.2 TAdapterNamedDisplayField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.27.4.3 TAdapterNamedDisplayField.ReadOnly Property

Indicates whether this adapter field is read-only.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set this property to true to indicate that this field should be represented as a read-only field in the HTML form. Set this property to false to indicate that this field should be represented as an editable field in the HTML form. The value of this property affects the value returned by GetViewMode (see page 5348) which, in turn, may affect the server-side script generated to represent this adapter field.

See Also

GetViewMode (see page 5348)

54.1.27.4.4 TAdapterNamedDisplayField.Required Property

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
property Required: Boolean;
```

C++

```
__property Boolean Required;
```

Description

Use this property to indicate whether a value must be entered by the end user before submitting a form. Typically, an exception is raised when a required adapter field is not found when processing an adapter action.

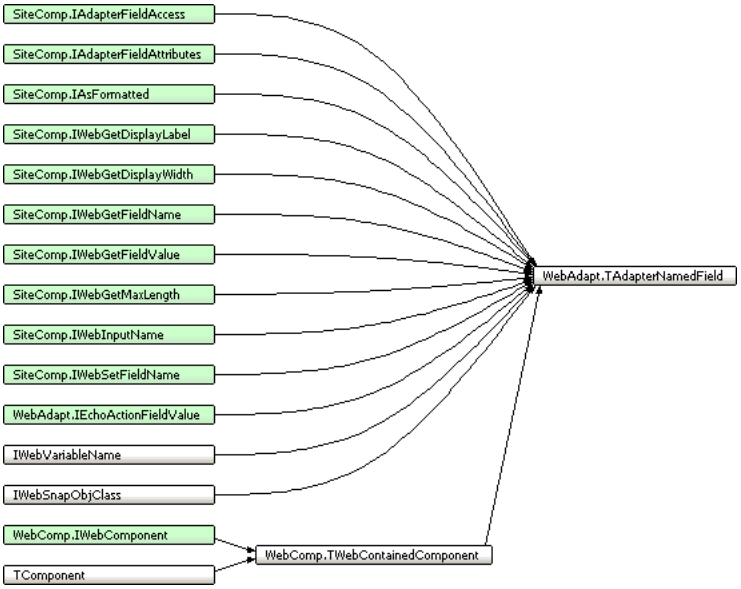
See Also

GetRequired (see page 5359)

54.1.28 TAdapterNamedField Class

TAdapterNamedField is a based class for adapter field components.

Class Hierarchy



Pascal

```
TAdapterNamedField = class(TWebContainedComponent, IWebVariableName, IWebInputName,
IWebGetFieldValue, IEchoActionFieldValue, IAsFormatted, IWebGetFieldName, IWebSetFieldName,
IWebGetDisplayWidth, IWebGetDisplayLabel, IWebGetMaxLength, IWebSnapObjClass,
IAdapterFieldAccess, IAdapterFieldAttributes);
```

C++

```
class TAdapterNamedField : public TWebContainedComponent, public IWebVariableName, public
IWebInputName, public IWebGetFieldValue, public IEchoActionFieldValue, public IAsFormatted,
public IWebGetFieldName, public IWebSetFieldName, public IWebGetDisplayWidth, public
IWebGetDisplayLabel, public IWebGetMaxLength, public IWebSnapObjClass, public
IAdapterFieldAccess, public IAdapterFieldAttributes;
```

File

WebAdapt

Description

TAdapterNamedField implements interfaces used to access an adapter field's properties using server-side script. Most of the interface implementation methods call virtual functions. When defining new derived classes, override these virtual functions to customize the behavior of the adapter field class.

See Also

TAdapterNamedDisplayField (see page 5343)

TAdapter (see page 5190)

54.1.28.1 TAdapterNamedField Members

The following tables list the members exposed by TAdapterNamedField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
V	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
V	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
R	Adapter (see page 5368)	Returns the parent adapter component.

R	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
R	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
V	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

54.1.28.2 TAdapterNamedField Methods

The methods of the TAdapterNamedField class are listed here.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.

	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5363)	Gets the value of this adapter field as a Variant (see page 3421).
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
V	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.

54.1.28.2.1 TAdapterNamedField.AsFormatted Method

Returns text used to generate a representation of the adapter field value.

Pascal

```
function AsFormatted: string;
```

C++

```
__fastcall UnicodeString AsFormatted();
```

Description

This function returns a text that is typically used when generating a read-only representation of the adapter field value. The value returned by this function can be accessed with server-side script using the DisplayText property.

See Also

ImplAsFormatted (see page 5361)

54.1.28.2.2 TAdapterNamedField.CheckModifyAccess Method

Checks end-user rights to modify the adapter field value.

Pascal

```
procedure CheckModifyAccess;
```

C++

```
__fastcall CheckModifyAccess();
```

Description

This procedure is called to verify that the current user has rights to modify this field. An exception will be raised if access is denied.

See Also

ModifyAccess (see page 5369)

HasModifyAccess (see page 5361)

54.1.28.2.3 TAdapterNamedField.CheckViewAccess Method

Checks end-user rights to view the adapter field value.

Pascal

```
procedure CheckViewAccess;
```

C++

```
__fastcall CheckViewAccess();
```

Description

This procedure is called to verify that the current user has rights to view this field. An exception will be raised if access is denied.

See Also

ViewAccess (see page 5370)

HasModifyAccess (see page 5361)

54.1.28.2.4 TAdapterNamedField.FullyQualifyInputName Method

Indicates whether the HTML input names must be qualified with the name of the adapter.

Pascal

```
function FullyQualifyInputName: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean FullyQualifyInputName();
```

Description

This functions returns true if, when generating an HTML input referencing this adapter field, the name of the HTML input must be qualified with the name of the adapter component. Input (see page 3827) names must be fully qualified when a single HTML form is used to input values for multiple adapters.

See Also

MasterAdapter

54.1.28.2.5 TAdapterNamedField.GetAdapter Method

GetAdapter returns the parent adapter component.

Pascal

```
function GetAdapter: TCustomAdapter;
```

C++

```
__fastcall TCustomAdapter GetAdapter();
```

Description

To improve the efficiency of this function, a reference to the parent adapter component is cached in an instance variable.

54.1.28.2.6 TAdapterNamedField.GetDefaultDisplayLabel Method

Provides the default display label for this adapter field.

Pascal

```
function GetDefaultDisplayLabel: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDefaultDisplayLabel();
```

Description

When the display label for the field matches this value then the display label property does not need to be stored in the form file.

54.1.28.2.7 TAdapterNamedField.GetDefaultFieldName Method

Gets the default name used to reference this adapter field with server-side script.

Pascal

```
function GetDefaultFieldName: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDefaultFieldName();
```

Description

This function returns the default field name for the field. This name will be used when a field name has not be set using ImplSetFieldName (see page 5366). GetDefaultFieldName returns the name of the adapter field component. Descendants may override this function.

See Also

ImplGetVariableName (see page 5364)

ImplSetFieldName (see page 5366)

54.1.28.2.8 TAdapterNamedField.GetDisplayLabel Method

Returns the suggested display label for this adapter field.

Pascal

```
function GetDisplayLabel: string;
```

C++

```
__fastcall UnicodeString GetDisplayLabel();
```

Description

GetDisplayLabel provides label that may be used when generating HTML to display the value of this adapter field. The value

returned by this function can be accessed with server-side script using the DisplayLabel property. GetDisplayLabel calls ImplGetDisplayLabel (see page 5361).

See Also

ImplGetDisplayLabel (see page 5361)

54.1.28.2.9 TAdapterNamedField.GetDisplayWidth Method

Returns the suggested display width for this adapter field.

Pascal

```
function GetDisplayWidth: Integer;
```

C++

```
__fastcall int GetDisplayWidth();
```

Description

This function returns the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. The value returned by this function can be accessed with server-side script using the DisplayWidth property. GetDisplayWidth calls ImplGetDisplayWidth (see page 5362).

See Also

ImplGetDisplayWidth (see page 5362)

54.1.28.2.10 TAdapterNamedField.GetEchoActionFieldValue Method

Returns the value of the echo flag.

Pascal

```
function GetEchoActionFieldValue: Boolean;
```

C++

```
__fastcall Boolean GetEchoActionFieldValue();
```

Description

EchoActionFieldValue (see page 5368) calls ImplEchoActionFieldValue.

See Also

EchoActionFieldValue (see page 5368)

54.1.28.2.11 TAdapterNamedField.GetInputName Method

Identifies the name to use when generating an HTML input for this adapter field.

Pascal

```
function GetInputName: string;
```

C++

```
__fastcall UnicodeString GetInputName();
```

Description

This functions returns the name used for an HTML input associated with this adapter field. This value is accessed with server-side script using the InputName property. GetInputName calls ImplGetInputName (see page 5362).

See Also

ImplGetInputName (see page 5362)

54.1.28.2.12 TAdapterNamedField.GetMaxLength Method

Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.

Pascal

```
function GetMaxLength: Integer;
```

C++

```
__fastcall int GetMaxLength();
```

Description

The value returned by this function can be accessed with server-side script using the MaxLength property. Server-side script may use this value to define HTML elements that limit the number of characters that can be entered by the end-user. GetMaxLength calls ImplGetMaxLength (see page 5363).

See Also

ImplGetMaxLength (see page 5363)

54.1.28.2.13 TAdapterNamedField.GetRequired Method

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
function GetRequired: Boolean;
```

C++

```
__fastcall Boolean GetRequired();
```

Description

This function returns true or false to indicate whether a value must be entered by the end user before submitting a form. The value returned by this function can be accessed with server-side script using the Required property. Typically, this function is called while executing an adapter action that validates field values. The adapter action component will raise an exception if the value of the submitted field is empty. GetRequired calls ImplGetRequired (see page 5363).

See Also

ImplGetRequired (see page 5363)

54.1.28.2.14 TAdapterNamedField.GetValue Method

Gets the value of this adapter field as a Variant (see page 3421).

Pascal

```
function GetValue: Variant;
```

C++

```
__fastcall Variant GetValue();
```

Description

GetValue returns the result of ImplGetValue (see page 5363).

See Also

Value (see page 5369)

ImplGetValue (see page 5363)

54.1.28.2.15 TAdapterNamedField.GetVariableName Method

Gets the name used to reference this adapter field with server-side script.

Pascal

```
function GetVariableName: string;
```

C++

```
__fastcall UnicodeString GetVariableName();
```

Description

GetVariableName is called to retrieve the name used to access this adapter field with server-side script. GetVariableName calls ImplGetVariableName (see page 5364).

See Also

ImplGetVariableName (see page 5364)

54.1.28.2.16 TAdapterNamedField.GetVisible Method

Indicates whether the value of this adapter field should be displayed to the end-user.

Pascal

```
function GetVisible: Boolean;
```

C++

```
__fastcall Boolean GetVisible();
```

Description

The value returned by this function can be accessed with server-side script using the Visible property. GetVisible calls ImplGetVisible (see page 5364).

See Also

ImplGetVisible (see page 5364)

54.1.28.2.17 TAdapterNamedField.GetWebSnapObjClass Method

Returns the class type for this adapter field.

Pascal

```
function GetWebSnapObjClass: TObjectScripterClass; virtual;
```

C++

```
virtual __fastcall TObjectScripterClass GetWebSnapObjClass();
```

Description

This function returns the class type for this adapter field, which is used by the script engine to create a script object. GetWebSnapObjClass tells the script engine what type of object to create.

54.1.28.2.18 TAdapterNamedField.HasModifyAccess Method

Checks the end-user's right to modify this adapter field.

Pascal

```
function HasModifyAccess: Boolean;
```

C++

```
__fastcall Boolean HasModifyAccess();
```

Description

The value returned by this function can be accessed with server-side script using the CanModify property. HasModifyAccess calls ImplHasModifyAccess (see page 5365).

See Also

ImplHasModifyAccess (see page 5365)

54.1.28.2.19 TAdapterNamedField.HasViewAccess Method

Checks the end-user's right to view this adapter field.

Pascal

```
function HasViewAccess: Boolean;
```

C++

```
__fastcall Boolean HasViewAccess();
```

Description

The value returned by this function can be accessed with server-side script using the CanView property. HasViewAccess calls ImplHasViewAccess (see page 5365).

See Also

ImplHasViewAccess (see page 5365)

54.1.28.2.20 TAdapterNamedField.ImplAsFormatted Method

Returns text used to generate a representation of the adapter field value.

Pascal

```
function ImplAsFormatted: string; virtual;
```

C++

```
virtual __fastcall UnicodeString ImplAsFormatted();
```

Description

ImplAsFormatted is called by AsFormatted (see page 5355).

See Also

AsFormatted (see page 5355)

54.1.28.2.21 TAdapterNamedField.ImplGetDisplayLabel Method

Returns the suggested display label for this adapter field.

Pascal

```
function ImplGetDisplayLabel: string; virtual;
```

C++

```
virtual __fastcall UnicodeString ImplGetDisplayLabel();
```

Description

ImplGetDisplayLabel is called by GetDisplayLabel (see page 5357). ImplGetDisplayLabel returns the result of GetDefaultDisplayLabel (see page 5357). Descendants may override this function.

See Also

GetDisplayLabel (see page 5357)

GetDefaultDisplayLabel (see page 5357)

54.1.28.2.22 TAdapterNamedField.ImplGetDisplayWidth Method

Returns the suggested display width for this adapter field.

Pascal

```
function ImplGetDisplayWidth: Integer; virtual;
```

C++

```
virtual __fastcall int ImplGetDisplayWidth();
```

Description

This function is called by GetDisplayWidth (see page 5358) to retrieve the suggested display width for this adapter field. ImplGetDisplayWidth returns –1 to indicate an undefined display width. Descendants may override this function.

See Also

GetDisplayWidth (see page 5358)

54.1.28.2.23 TAdapterNamedField.ImplGetEchoActionFieldValue Method

Returns the value of the echo flag.

Pascal

```
function ImplGetEchoActionFieldValue: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplGetEchoActionFieldValue();
```

Description

This function is called by GetEchoActionFieldValue (see page 5358).

See Also

EchoActionFieldValue (see page 5368)

GetEchoActionFieldValue (see page 5358)

54.1.28.2.24 TAdapterNamedField.ImplGetInputName Method

Identifies the name to use when generating the HTML input for this adapter field.

Pascal

```
function ImplGetInputName: string; virtual;
```

C++

```
virtual __fastcall UnicodeString ImplGetInputName();
```

Description

When an action request is received, the name/value pairs in the HTTP are searched for adapter field values. For each adapter field value found, an IActionFieldValue (see page 5904) implementation is created. In order for the HTTP request to be interpreted properly, the HTML input fields must have names that correspond to the adapter fields they represent.

See Also

GetInputName (see page 5358)

IActionFieldValue

54.1.28.2.25 TAdapterNamedField.ImplGetMaxLength Method

Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.

Pascal

```
function ImplGetMaxLength: Integer; virtual;
```

C++

```
virtual __fastcall int ImplGetMaxLength();
```

Description

ImplGetMaxLength is called by GetMaxLength (see page 5359). ImplGetMaxLength returns –1 to indicate an undefined maximum length. Descendants may override this function.

See Also

GetMaxLength (see page 5359)

54.1.28.2.26 TAdapterNamedField.ImplGetRequired Method

Indicates whether the end-user must enter a value for this adapter field.

Pascal

```
function ImplGetRequired: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplGetRequired();
```

Description

ImplGetRequired returns False. Descendants may override this function.

See Also

GetRequired (see page 5359)

54.1.28.2.27 TAdapterNamedField.ImplGetValue Method

Gets the value of this adapter field as a Variant (see page 3421).

Pascal

```
function ImplGetValue: Variant; virtual;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

This function is called by GetValue (see page 5359). ImplGetValue returns Unassigned. Descendants override this function.

See Also

Value (see page 5369)

GetValue (see page 5359)

54.1.28.2.28 TAdapterNamedField.ImplGetVariableName Method

Gets the name used to reference this adapter field with server-side script.

Pascal

```
function ImplGetVariableName: string; virtual;
```

C++

```
virtual __fastcall UnicodeString ImplGetVariableName();
```

Description

This function is called by GetVariableName (see page 5360). GetVariableName (see page 5360) returns the field name set by ImplSetFieldName (see page 5366) unless this name is blank. If the field name is blank, the result of GetDefaultFieldName (see page 5357) is returned.

See Also

GetVariableName (see page 5360)

ImplSetFieldName (see page 5366)

GetDefaultFieldName (see page 5357)

54.1.28.2.29 TAdapterNamedField.ImplGetVisible Method

Indicates whether the value of this adapter field should be displayed to the end-user.

Pascal

```
function ImplGetVisible: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplGetVisible();
```

Description

This function returns true to indicate that the field should be displayed to the end user. Descendants may override this method.

See Also

GetVisible (see page 5360)

54.1.28.2.30 TAdapterNamedField.ImplHasModifyAccess Method

Checks the end-user's right to modify this adapter field.

Pascal

```
function ImplHasModifyAccess: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplHasModifyAccess();
```

Description

This function is called by HasModifyAccess (see page 5361) to check the end-user's right to modify the adapter field. If the ModifyAccess (see page 5369) property is not blank, this function calls the EndUserAdapter HasModifyRights function, passing the ModifyAccess (see page 5369) property value.

See Also

HasModifyAccess (see page 5552)

ModifyAccess (see page 5369)

HasModifyAccess (see page 5361)

54.1.28.2.31 TAdapterNamedField.ImplHasViewAccess Method

Checks the end-user's right to view this adapter field.

Pascal

```
function ImplHasViewAccess: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplHasViewAccess();
```

Description

This function is called by HasViewAccess (see page 5361) to check the end-user's right to view the adapter field. If the ViewAccess (see page 5370) property is not blank, this function calls the EndUserAdapter's HasViewRights function, passing the ViewAccess (see page 5370) property value.

See Also

HasViewAccess (see page 5553)

ViewAccess (see page 5370)

HasViewAccess (see page 5361)

54.1.28.2.32 TAdapterNamedField.ImplSetEchoActionFieldValue Method

Sets the echo flag for this adapter field.

Pascal

```
procedure ImplSetEchoActionFieldValue(AValue: Boolean); virtual;
```

C++

```
virtual __fastcall ImplSetEchoActionFieldValue(Boolean AValue);
```

Description

ImplEchoActionFieldValue is called by SetEchoActionFieldValue (see page 5366). ImplEchoActionFieldValue is a placeholder. Descendants may override this method.

See Also

EchoActionFieldValue (see page 5368)

SetEchoActionFieldValue (see page 5366)

54.1.28.2.33 TAdapterNamedField.ImplSetFieldName Method

Sets the name that is used to reference this adapter field with server-side script.

Pascal

```
procedure ImplSetFieldName(const Value: string); virtual;
```

C++

```
virtual __fastcall ImplSetFieldName(const UnicodeString Value);
```

Description

ImplSetFieldName is called by SetFieldName (see page 5367). ImplSetFieldName stores the name in an instance variable. This method may be overridden by descendants.

See Also

SetFieldName (see page 5367)

54.1.28.2.34 TAdapterNamedField.ParentChanged Method

Handles movement of the component to a different parent.

Pascal

```
procedure ParentChanged; override;
```

C++

```
virtual __fastcall ParentChanged();
```

Description

ParentChanged is called when the parent component is changed. TAdapterNamedField (see page 5351) clears its cached reference to the parent adapter.

54.1.28.2.35 TAdapterNamedField.SetEchoActionFieldValue Method

Sets the echo flag for this adapter field.

Pascal

```
procedure SetEchoActionFieldValue(AValue: Boolean);
```

C++

```
__fastcall SetEchoActionFieldValue(Boolean AValue);
```

Description

SetEchoActionFieldValue calls ImplSetActionFieldValue.

See Also

EchoActionFieldValue (see page 5368)

ImplSetEchoActionFieldValue (see page 5365)

54.1.28.2.36 TAdapterNamedField.SetFieldName Method

Sets the name that is used to reference this adapter field with server-side script.

Pascal

```
procedure SetFieldName(const AName: string);
```

C++

```
__fastcall SetFieldName(const UnicodeString AName);
```

Description

SetFieldName is typically called at design time to set the field name of a new adapter field. SetFieldName calls ImplSetFieldName (see page 5366).

See Also

ImplSetFieldName (see page 5366)

54.1.28.3 TAdapterNamedField Properties

The properties of the TAdapterNamedField class are listed here.

Protected Properties

	Name	Description
R	Adapter (see page 5368)	Returns the parent adapter component.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	FieldName (see page 5369)	Identifies the name of this field when using server-side script.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.

54.1.28.3.1 TAdapterNamedField.ActionOrigValue Property

Retrieve the original value of this adapter field.

Pascal

```
property ActionOrigValue: IActionFieldValue;
```

C++

```
__property IActionFieldValue ActionOrigValue;
```

Description

Some adapter fields will include their original value as a hidden field in an HTML form. The original value can be compared with

the current value to verify that the current value hasn't been changed by another user between the time that the HTML form was generated and the HTML form was submitted. Use this property when executing an adapter action to retrieve the original value for this adapter field at the time that the HTML form was generated.

See Also

FieldFlags

54.1.28.3.2 TAdapterNamedField.ActionValue Property

Retrieve the value for this adapter field entered by the end-user.

Pascal

```
property ActionValue: IActionFieldValue;
```

C++

```
__property IActionFieldValue ActionValue;
```

Description

The ActionValue property retrieves the value(s) entered by the end-user and passed in the HTTP request when an HTML form is submitted. When executing an adapter action, use this property to retrieve the value(s) entered by the end-user.

54.1.28.3.3 TAdapterNamedField.Adapter Property

Returns the parent adapter component.

Pascal

```
property Adapter: TCustomAdapter;
```

C++

```
__property TCustomAdapter Adapter;
```

Description

Use this property to access the parent adapter component. The type of this class is TComponent because adapter components are not required to descend from a common adapter base class. Typically the adapter component is accessed through interfaces.

54.1.28.3.4 TAdapterNamedField.EchoActionFieldValue Property

Used to echo the value(s) entered by the end-user when generating an HTML form.

Pascal

```
property EchoActionFieldValue: Boolean;
```

C++

```
__property Boolean EchoActionFieldValue;
```

Description

The EchoActionFieldValue property is used to alter the source of the adapter fields value. When this flag is set, the adapter field retrieves it's value from the HTTP request. When this flag is clear, the adapter field retrieves it's current value. Typically, this flag is set after an error occurs while processing an adapter action. Setting this flag results in generated HTML that displays values entered by the end-user. This allows the end-user to make corrections and resubmit the form.

See Also

SetEchoActionFieldValue (see page 5366)

54.1.28.3.5 TAdapterNamedField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.28.3.6 TAdapterNamedField.ModifyAccess Property

Identifies the rights required to update this field.

Pascal

```
property ModifyAccess: string;
```

C++

```
__property UnicodeString ModifyAccess;
```

Description

The ModifyAccess property defines the access rights required to modify this field. When server-side script accesses the CanModify property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to updates an adapter field that does not allow access.

See Also

TWebUserList (see page 6796)

HasModifyAccess (see page 5552)

54.1.28.3.7 TAdapterNamedField.Value Property

Provides the value of an adapter field as a variant.

Pascal

```
property Value: Variant;
```

C++

```
__property Variant Value;
```

Description

The Value property returns the value of an adapter field as a Variant (see page 3421). Server-side script can access this value using the Value property. Note that descendant adapter fields support multiple values per field, files and images. For these fields, the Value property will not correctly represent the value of the adapter field.

See Also

GetValueCount (see page 5427)

GetValues (see page 5427)

54.1.28.3.8 TAdapterNamedField.ViewAccess Property

Identifies the rights required to view this field.

Pascal

```
property ViewAccess: string;
```

C++

```
__property UnicodeString ViewAccess;
```

Description

The ViewAccess property identifies the access rights required to view this field. When server-side script accesses the CanView property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to view an adapter field that does not allow access.

See Also

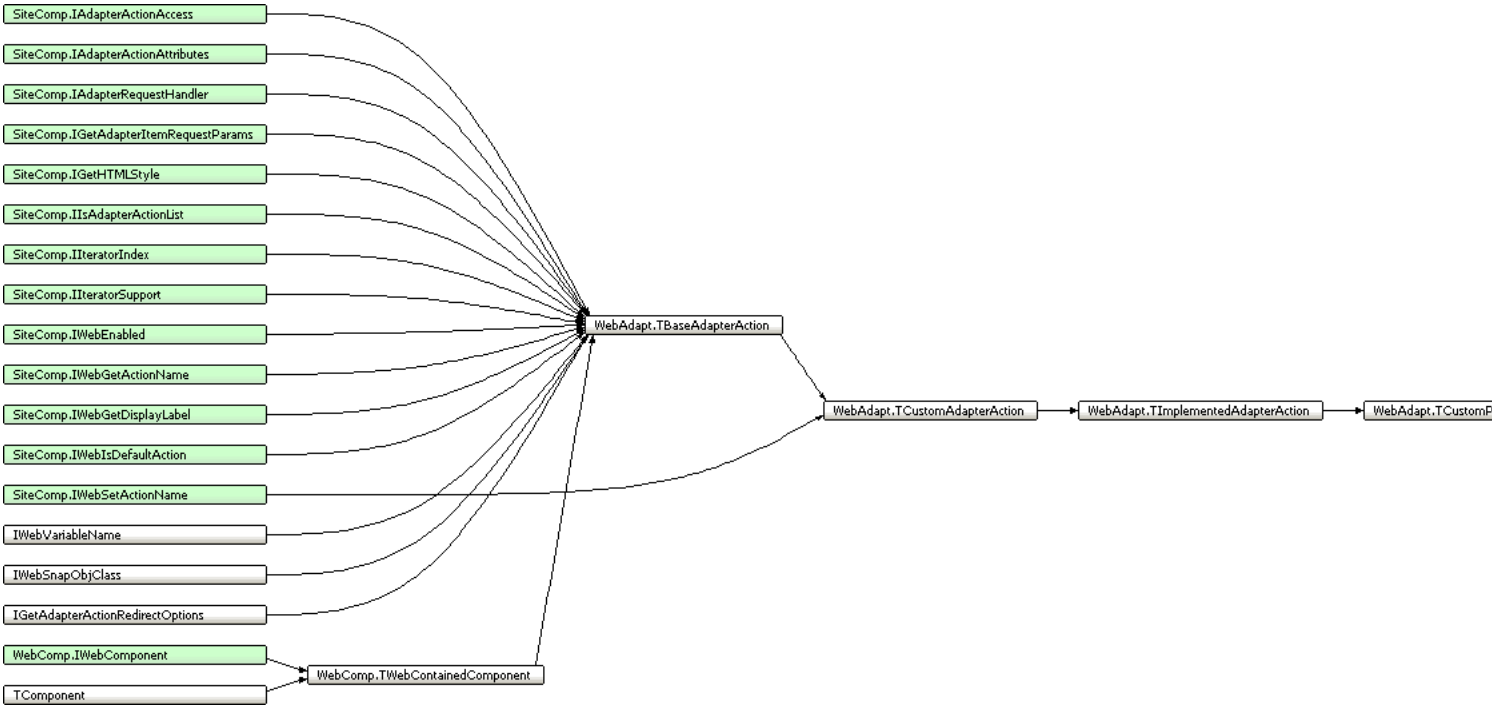
TWebUserList (see page 6796)

HasViewAccess (see page 5553)

54.1.29 TAdapterNextPageAction Class

TAdapterNextPageAction implements the next page command for TDefaultFieldsPagedAdapter (see page 5747).

Class Hierarchy



Pascal

```
TAdapterNextPageAction = class(TCustomAdapterPageAction);
```

C++

```
class TAdapterNextPageAction : public TCustomAdapterPageAction;
```

File

WebAdapt

Description

Add TAdapterNextPageAction to a descendant class of TDefaultFieldsPagedAdapter (see page 5747) such as TPagedAdapter (see page 5844).

See Also

TCustomAdapterPageAction (see page 5656)

TDefaultFieldsPagedAdapter (see page 5747)

TAdapterPrevPageAction (see page 5396)

TAdapterGotoPageAction (see page 5291)

TPagedAdapter (see page 5844)

54.1.29.1 TAdapterNextPageAction Members

The following tables list the members exposed by TAdapterNextPageAction.

Protected Methods

	Name	Description
	CheckExecuteAccess (see page 5452)	Checks end-user rights to execute this adapter action.
	CreateRequestContext (see page 5452)	Creates an object that describes the adapter action parameters and adapter field values.
V	DoAfterExecuteActionRequest (see page 5453)	Calls event handlers after the adapter action is executed.
V	DoAfterGetExecuteActionResponse (see page 5453)	Calls event handlers after the adapter action response is formulated.
V	DoBeforeExecuteActionRequest (see page 5453)	Calls event handlers before the adapter action is executed.
V	DoBeforeGetExecuteActionResponse (see page 5454)	Calls event handlers before the adapter action response is formulated.
	EndIterator (see page 5454)	Implements IIteratorSupport (see page 1054)'s EndIterator method.
	ExecuteActionRequest (see page 5455)	Executes the adapter action using parameters passed in the HTTP request.
	GetActionName (see page 5455)	Gets the name used to reference this adapter action with server-side script.
	GetAdapter (see page 5456)	GetAdapter returns the parent adapter component.
	GetAdapter (see page 5727)	Returns the parent adapter of this adapter action.
	GetAdapterItemRequestParams (see page 5456)	Provides the name/value pairs needed to execute this adapter action.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultActionName (see page 5374)	Gets the name used to reference this adapter action with server-side script.
V	GetDefaultDisplayLabel (see page 5375)	Provides the default display label for this adapter action.
	GetDisplayLabel (see page 5457)	Returns the suggested display label for this adapter action.
	GetDisplayStyle (see page 5457)	Returns a string value to suggest an HTML display style for this adapter action.
V	GetDisplayStyleType (see page 5458)	Suggests an HTML display type for this adapter action.
V	GetDisplayStyleType (see page 5661)	Suggests an HTML display type for this adapter action.
	GetErrors (see page 5458)	Returns the parent adapter's errors list.
	GetExecuteActionResponse (see page 5458)	Generates a response after the adapter action has been executed.
	GetFailureOptions (see page 5459)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	GetInputStyle (see page 5459)	Returns a string value to suggest an HTML display style for this adapter action.
	GetIsAdapterActionList (see page 5460)	Indicates whether this adapter action may have multiple commands.
V	GetItemCount (see page 5460)	Returns the number of commands defined by this adapter action.

	GetIteratorIndex (see page 5460)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method.
	GetNewPage (see page 5375)	Indicates the page to display when this action is executed.
	GetSuccessOptions (see page 5461)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	GetVariableName (see page 5461)	Gets the name used to reference this adapter action with server-side script.
	GetViewMode (see page 5462)	Returns a string value to suggest a view mode for this adapter action.
	GetViewModeType (see page 5462)	Suggests a view mode for this adapter action.
	GetVisible (see page 5462)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
	GetWebSnapObjClass (see page 5463)	Returns the class type for this adapter field.
	HandleRequest (see page 5463)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 5463)	Checks the end-user's right to execute this adapter action.
	ImplCreateRequestContext (see page 5464)	Creates an object that describes the action parameters and field values.
	ImplEndIterator (see page 5464)	Implements IIteratorSupport (see page 1054)'s EndIterator (see page 5454) method.
	ImplExecuteActionRequest (see page 5464)	Executes the adapter action using parameters passed in the HTTP request.
	ImplExecuteActionRequest (see page 5584)	Executes the adapter action using parameters passed in the HTTP request.
	ImplExecuteActionRequest (see page 5662)	Executes the adapter action using parameters passed in the HTTP request.
	ImplGetActionName (see page 5465)	Gets the name used to reference this adapter action with server-side script.
	ImplGetActionName (see page 5584)	Gets the name used to reference this adapter action with server-side script.
	ImplGetAdapterItemRequestParams (see page 5465)	Provides the name/value pairs needed to execute this adapter action.
	ImplGetAdapterItemRequestParams (see page 5584)	Provides the name/value pairs needed to execute this adapter action.
	ImplGetAdapterItemRequestParams (see page 5662)	Provides the name/value pairs needed to execute this adapter action.
	ImplGetDisplayLabel (see page 5465)	Returns the suggested display label for this adapter action.
	ImplGetExecuteActionResponse (see page 5466)	Generates a response after the adapter action has been executed.
	ImplGetFailureOptions (see page 5466)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	ImplGetIsAdapterActionList (see page 5466)	Indicates whether this adapter action may have multiple commands.
	ImplGetIteratorIndex (see page 5467)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5460) method.
	ImplGetSuccessOptions (see page 5467)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetSuccessOptions (see page 5585)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetVariableName (see page 5467)	Gets the name used to reference this adapter action with server-side script.
	ImplGetVisible (see page 5468)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
	ImplHandleRequest (see page 5468)	Executes the adapter action and generates a response.
	ImplHasExecuteAccess (see page 5468)	Checks the end-user's right to execute this adapter action.
	ImplInIterator (see page 5469)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5471) method.
	ImplIsDefaultAction (see page 5469)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplIsDefaultAction (see page 5663)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplNextIteration (see page 5470)	Implements IIteratorSupport (see page 1054)'s NextIteration (see page 5472) method.
	ImplSetActionName (see page 5585)	Sets the name that is used to reference this adapter action with server-side script.
	ImplStartIterator (see page 5470)	Implements IIteratorSupport (see page 1054)'s StartIterator (see page 5473) method.
	ImplWebEnabled (see page 5470)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	ImplWebEnabled (see page 5585)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	ImplWebEnabled (see page 5663)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	InIterator (see page 5471)	Implements IIteratorIndex (see page 1052)'s InIterator method.
	IsDefaultAction (see page 5471)	Indicates whether this adapter action should be added, by default, to the parent adapter.

	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	NextIteration (see page 5472)	Implements IIteratorSupport (see page 1054)'s NextIteration method.
	ParentChanged (see page 5472)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetActionName (see page 5586)	Sets the name that is used to reference this adapter action with server-side script.
	SetDisplayLabel (see page 5472)	Set the value of the DisplayLabel (see page 5474) property.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartIterator (see page 5473)	Implements IIteratorSupport (see page 1054)'s StartIterator method.
	WebEnabled (see page 5473)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Protected Properties

	Name	Description
	Adapter (see page 5474)	Provides access to the parent adapter component.
	Adapter (see page 5727)	Returns the parent adapter of this adapter action.
	Errors (see page 5475)	Returns the parent adapter's Errors list.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnExecute (see page 5588)	Called to execute this action using parameters passed in the HTTP request.
	OnGetEnabled (see page 5589)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Public Methods

	Name	Description
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	CreateRequestContext (see page 1013)	Creates an object that describes the adapter action parameters and adapter field values.
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.
	GetAdapterItemRequestParams (see page 1024)	This is GetAdapterItemRequestParams, a member of class IGetAdapterItemRequestParams.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetIsAdapterActionList (see page 1050)	This is GetIsAdapterActionList, a member of class IIsAdapterActionList.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 984)	This is GetVisible, a member of class IAdapterActionAttributes.
	HandleRequest (see page 1013)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 983)	This is HasExecuteAccess, a member of class IAdapterActionAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.

	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.
	NextIteration (see page 1056)	Advances to the objects next item.
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

Public Properties

	Name	Description
R	ActionName (see page 1087)	This is ActionName, a member of class IWebGetActionName.
R	ActionName (see page 5474)	Identifies the name of this action when using server-side script.
	ActionName (see page 5586)	Identifies the name of this action when using server-side script.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	IsAdapterActionList (see page 1050)	This is IsAdapterActionList, a member of class IIsAdapterActionList.
R	ItemCount (see page 5475)	Returns the number of items defined by an adapter action.
R	ItemIndex (see page 5476)	Returns the index of the current item of an adapter action.
R	IteratorIndex (see page 1054)	Indicates the index of the current item.
R	Visible (see page 984)	This is Visible, a member of class IAdapterActionAttributes.

Published Events

	Name	Description
	OnAfterExecute (see page 5377)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5378)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5378)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5378)	Called before the adapter action response is generated.
	OnGetParams (see page 5379)	Specifies name/value pairs needed to execute this adapter action.

Published Properties

	Name	Description
	DisplayLabel (see page 5376)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5376)	Defines the rights required to execute this action.
	RedirectOptions (see page 5377)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.29.2 TAdapterNextPageAction Methods

The methods of the TAdapterNextPageAction class are listed here.

Protected Methods

	Name	Description
V	GetDefaultActionName (see page 5374)	Gets the name used to reference this adapter action with server-side script.
V	GetDefaultDisplayLabel (see page 5375)	Provides the default display label for this adapter action.
V	GetNewPage (see page 5375)	Indicates the page to display when this action is executed.

54.1.29.2.1 TAdapterNextPageAction.GetDefaultActionName Method

Gets the name used to reference this adapter action with server-side script.

Pascal

```
function GetDefaultActionName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultActionName();
```

Description

GetDefaultActionName returns "NextPage".

See Also

GetActionName (see page 5455)

GetDefaultActionName (see page 5456)

54.1.29.2.2 TAdapterNextPageAction.GetDefaultDisplayLabel Method

Provides the default display label for this adapter action.

Pascal

```
function GetDefaultDisplayLabel: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultDisplayLabel();
```

Description

GetDefaultDisplayLabel returns ">>". This displays as '>>' in the browser.

See Also

DisplayLabel (see page 5474)

54.1.29.2.3 TAdapterNextPageAction.GetNewPage Method

Indicates the page to display when this action is executed.

Pascal

```
function GetNewPage(var AValue: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean GetNewPage(int AValue);
```

Description

GetNewPage determines whether the current page can be incremented. If so, the AValue parameter is modified and true is returned. Otherwise, false is returned.

See Also

GetNewPage (see page 5661)

RecordCount (see page 5761)

PageSize (see page 5761)

CurrentPage (see page 5760)

54.1.29.3 TAdapterNextPageAction Properties

The properties of the TAdapterNextPageAction class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5376)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5376)	Defines the rights required to execute this action.
	RedirectOptions (see page 5377)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.29.3.1 TAdapterNextPageAction.DisplayLabel Property

Suggests a display label for this adapter action.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the a button or hyperlink to execute this adapter action. Typically the adapter action is displayed using server-side script, either generated or custom written. Server-side script uses the DisplayLabel property to access this value.

See Also

ImplGetDisplayLabel (see page 5465)

SetDisplayLabel (see page 5472)

54.1.29.3.2 TAdapterNextPageAction.ExecuteAccess Property

Defines the rights required to execute this action.

Pascal

```
property ExecuteAccess: string;
```

C++

```
__property UnicodeString ExecuteAccess;
```

Description

The ExecuteAccess property defines the access rights required to execute this action. When server-side script accesses the CanExecute property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to execute an adapter action that does not allow access.

See Also

TWebUserList (see page 6796)

HasExecuteAccess (see page 5552)

54.1.29.3.3 TAdapterNextPageAction.RedirectOptions Property

Indicates whether to perform an HTTP redirect after successfully executing this action.

Pascal

```
property RedirectOptions: TAdapterActionRedirectOptions;
```

C++

```
__property TAdapterActionRedirectOptions RedirectOptions;
```

Description

Set RedirectOptions to indicate that HTTP redirect should be performed after executing this adapter action. An HTTP redirect causes the browser to "forget" about the parameters passed when executing the adapter action. Without a redirect, the browser's Refresh or Reload command cause the last HTTP request to be resent, resulting in re-execution of the adapter action.

See Also

SendRedirect

54.1.29.4 TAdapterNextPageAction Events

The events of the TAdapterNextPageAction class are listed here.

Published Events

	Name	Description
	OnAfterExecute (see page 5377)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5378)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5378)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5378)	Called before the adapter action response is generated.
	OnGetParams (see page 5379)	Specifies name/value pairs needed to execute this adapter action.

54.1.29.4.1 TAdapterNextPageAction.OnAfterExecute Event

Called after the adapter action has executed.

Pascal

```
property OnAfterExecute: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterExecute;
```

Description

Implement OnAfterExecute to do something after the action has executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterExecute is called by DoAfterExecuteActionRequest.

See Also

DoAfterExecuteActionRequest (see page 5453)

OnAfterExecuteAction (see page 5576)

OnBeforeExecute (see page 5478)

54.1.29.4.2 TAdapterNextPageAction.OnAfterGetResponse Event

Called after the adapter action response is generated.

Pascal

```
property OnAfterGetResponse: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterGetResponse;
```

Description

Implement OnAfterGetResponse to do something after the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterGetResponse is called by DoAfterGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnBeforeGetActionResponse (see page 5578)

54.1.29.4.3 TAdapterNextPageAction.OnBeforeExecute Event

Called before the adapter action is executed.

Pascal

```
property OnBeforeExecute: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeExecute;
```

Description

Implement OnBeforeExecute to do something before the action is executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to prevent the action from being executed. OnBeforeExecute is called by DoBeforeExecuteActionRequest.

See Also

DoBeforeExecuteActionRequest (see page 5453)

OnAfterExecute (see page 5477)

OnBeforeExecuteAction (see page 5577)

54.1.29.4.4 TAdapterNextPageAction.OnBeforeGetResponse Event

Called before the adapter action response is generated.

Pascal

```
property OnBeforeGetResponse: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeGetResponse;
```

Description

Implement OnBeforeGetResponse to do something before the action response is generated. The Params parameter contains

the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to indicate that the response has been generated and no further processing is needed. OnBeforeGetResponse is called by DoBeforeGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnAfterGetResponse (see page 5477)

OnBeforeGetActionResponse (see page 5578)

54.1.29.4.5 TAdapterNextPageAction.OnGetParams Event

Specifies name/value pairs needed to execute this adapter action.

Pascal

```
property OnGetParams: TActionGetParamsEvent;
```

C++

```
__property TActionGetParamsEvent OnGetParams;
```

Description

Implement this event handler to specify the name/value needed to execute this action. For example, an action that deletes a row in a table will need a name/value pair that identifies the row to be deleted such as "Key=123".

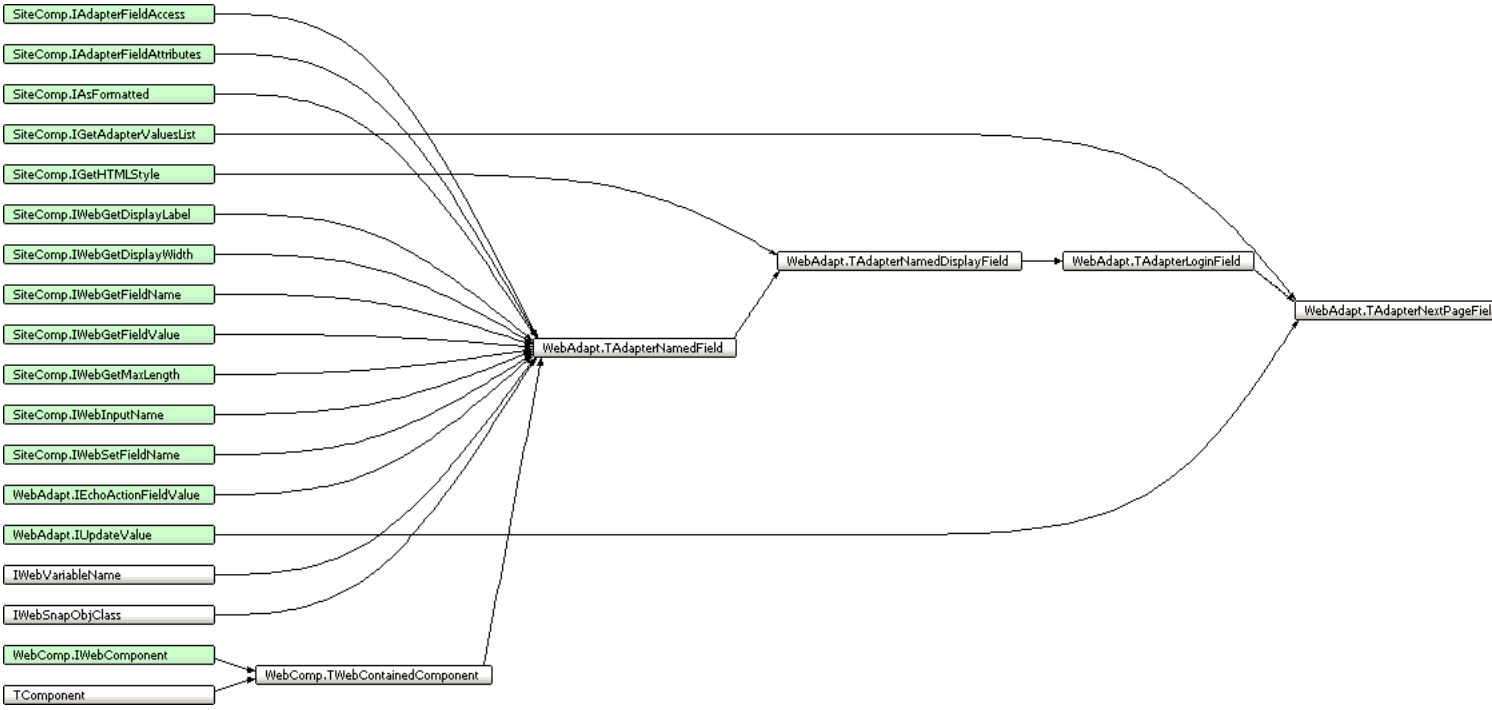
See Also

ImplGetAdapterItemRequestParams (see page 5465)

54.1.30 TAdapterNextPageField Class

The TAdapterNextPageField navigates to the next page of data.

Class Hierarchy



Pascal

```
TAdapterNextPageField = class(TAdapterLoginField, IGetAdapterValuesList, IUpdateValue);
```

C++

```
class TAdapterNextPageField : public TAdapterLoginField, public IGetAdapterValuesList, public
IUpdateValue;
```

File

WebAdapt

Description

TAdapterNextPageField is one of the components that is used by TPagedAdapter (see page 5844) along with the TAdapterNextPageAction (see page 5370) to navigate to the next page of data.

The TPagedAdapter (see page 5844) PageSize property indicates the number of rows displayed on a page. When the PageSize is not 0, the TPagedAdapter (see page 5844) component automatically adds built-in actions for moving between pages. These actions are TAdapterGotoPageAction (see page 5291), TAdapterPrevPageAction (see page 5396), and TAdapterNextPageAction (see page 5370). The TAdapterPageProducer can be used to generate HTML hyperlinks or buttons for these actions.

See Also

TPagedAdapter (see page 5844)

TAdapterPrevPageAction (see page 5396)

TAdapterGotoPageAction (see page 5291)

TCustomAdapterPageAction (see page 5656)

54.1.30.1 TAdapterNextPageField Members

The following tables list the members exposed by TAdapterNextPageField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetAdapterValuesList (see page 5384)	Returns a values list adapter containing the names of the published pages.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5384)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5384)	Returns the echo flag for this adapter field.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5385)	Returns the page name to be displayed after login.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5385)	Sets the echo flag for this adapter field.

	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	UpdateValue (see page 5386)	Updates the parent adapter's next page property with the value entered by the end-user.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 5383)	Frees an instance of TAdapterNextPageField (see page 5379).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
R	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
R	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.
R	Adapter (see page 5323)	Returns the parent adapter of this adapter field.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Properties

	Name	Description
	DisplayLabel (see page 5386)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5386)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5387)	Identifies the name of this field when using server-side script.

54.1.30.2 TAdapterNextPageField.Destroy Destructor

Frees an instance of TAdapterNextPageField (see page 5379).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAdapterNextPageField();
```

Description

Destroy removes this component from its parent's list of components that generate HTML before freeing the memory used by TAdapterNextPageField (see page 5379).

54.1.30.3 TAdapterNextPageField Methods

The methods of the TAdapterNextPageField class are listed here.

Protected Methods

	Name	Description
	GetAdapterValuesList (see page 5384)	Returns a values list adapter containing the names of the published pages.
V	GetInputStyleType (see page 5384)	Suggests an HTML input type for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5384)	Returns the echo flag for this adapter field.
V	ImplGetValue (see page 5385)	Returns the page name to be displayed after login.

	ImplSetEchoActionFieldValue (see page 5385)	Sets the echo flag for this adapter field.
	UpdateValue (see page 5386)	Updates the parent adapter's next page property with the value entered by the end-user.

54.1.30.3.1 TAdapterNextPageField.GetAdapterValuesList Method

Returns a values list adapter containing the names of the published pages.

Pascal

```
function GetAdapterValuesList: IValuesListAdapter;
```

C++

```
__fastcall IValuesListAdapter GetAdapterValuesList();
```

Description

GetAdapterValuesList returns a reference to TLogicalPageList (see page 5819). This function will be called when server-side script references the ValuesList property of this adapter field. Typically, server-side script uses the ValuesList property to populate an HTML select list with the names of published pages. The end-user may select one of these pages to go to after login.

See Also

IValuesListAdapter (see page 1072)

54.1.30.3.2 TAdapterNextPageField.GetInputStyleType Method

Suggests an HTML input type for this adapter field.

Pascal

```
function GetInputStyleType(const AAdapterMode: string): TAdapterInputHTMLElementType; override;
```

C++

```
virtual __fastcall TAdapterInputHTMLElementType GetInputStyleType(const UnicodeString
AAdapterMode);
```

Description

GetInputStyleType overrides TAdaperNamedDisplayField's GetInputStyleType. GetInputStyleType returns htmliSelect indicating that a single selection list HTML element should be used to input a value for this adapter field.

See Also

GetInputStyleType (see page 5347)

TAdapterInputHTMLElementType (see page 1124)

54.1.30.3.3 TAdapterNextPageField.ImplGetEchoActionFieldValue Method

Returns the echo flag for this adapter field.

Pascal

```
function ImplGetEchoActionFieldValue: Boolean; override;
```

C++

```
virtual __fastcall Boolean ImplGetEchoActionFieldValue();
```

Description

ImplGetEchoActionFieldValue returns the value of an instance variable.

See Also

ImplGetEchoActionFieldValue (see page 5362)

EchoActionFieldValue (see page 5368)

ImplGetValue (see page 5385)

ImplSetEchoActionFieldValue (see page 5385)

54.1.30.3.4 TAdapterNextPageField.ImplGetValue Method

Returns the page name to be displayed after login.

Pascal

```
function ImplGetValue: Variant; override;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

If the EchoActionFieldValue (see page 5368) property is true, then the page name selected or entered by end-user is returned. If the EchoActionFieldValue (see page 5368) property is false then the parent adapter's NextPage property is returned. The value returned by ImplGetValue is used when server-side script references the EditText property of this adapter field while generating the login form.

See Also

EchoActionFieldValue (see page 5368)

ActionValue (see page 5368)

NextPage (see page 5713)

54.1.30.3.5 TAdapterNextPageField.ImplSetEchoActionFieldValue Method

Sets the echo flag for this adapter field.

Pascal

```
procedure ImplSetEchoActionFieldValue(AValue: Boolean); override;
```

C++

```
virtual __fastcall ImplSetEchoActionFieldValue(Boolean AValue);
```

Description

ImplSetEchoActionFieldValue sets an internal variable to true. The echo flag is typically set by an adapter action when an error occurs while processing an HTTP request. The purpose of the echo flag is to preserve the value entered by the end-user. When the echo flag is true, ImplGetValue (see page 5385) returns the value entered by the end-user rather than the value of the adapter field.

See Also

ImplSetEchoActionFieldValue (see page 5365)

EchoActionFieldValue (see page 5368)

ImplGetValue (see page 5385)

ImplGetEchoActionFieldValue (see page 5384)

54.1.30.3.6 TAdapterNextPageField.UpdateValue Method

Updates the parent adapter's next page property with the value entered by the end-user.

Pascal

```
procedure UpdateValue(AActionRequest: IActionRequest; AFieldIndex: Integer); virtual;
```

C++

```
virtual __fastcall UpdateValue(IActionRequest AActionRequest, int AFieldIndex);
```

Description

Typically a single selection list HTML element is displayed on the login form. The list contains all of the published pages. The HTTP request will contain the page name selected by the end-user.

See Also

NextPage (see page 5713)

IActionRequest

54.1.30.4 TAdapterNextPageField Properties

The properties of the TAdapterNextPageField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5386)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5386)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5387)	Identifies the name of this field when using server-side script.

54.1.30.4.1 TAdapterNextPageField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.30.4.2 TAdapterNextPageField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.30.4.3 TAdapterNextPageField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

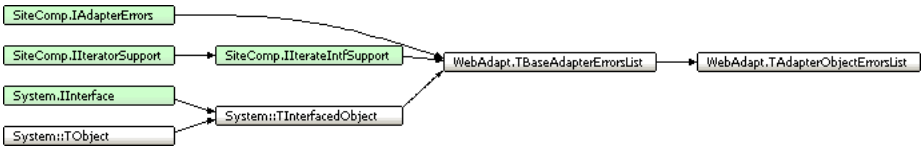
```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.31 TAdapterObjectErrorsList Class

Class Hierarchy



Pascal

```
TAdapterObjectErrorsList = class(TBaseAdapterErrorsList);
```

C++

```
class TAdapterObjectErrorsList : public TBaseAdapterErrorsList;
```

File

WebAdapt

Description

This is class WebAdapt.TAdapterObjectErrorsList.

54.1.31.1 TAdapterObjectErrorsList Members

The following tables list the members exposed by TAdapterObjectErrorsList.

Protected Data Members

	Name	Description
	FRefCount (see page 3344)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_AddRef method.
	_Release (see page 3345)	Implements the IInterface (see page 3502) System::TInterfacedObject::_Release method.
	EndIterator (see page 5483)	Signals the end of the iterating operation.
	GetCurrentIntf (see page 5483)	This is GetCurrentIntf, a member of class TBaseAdapterErrorsList.
	GetError (see page 5484)	Returns a particular error.
	GetErrorCount (see page 5484)	Return the number of errors in the errors list.
	GetObjectErrors (see page 5484)	Returns an object that is used to enumerate all errors associated with an adapter field.
	HasObjectErrors (see page 5484)	Indicates whether the errors list contains objects associated with a particular adapter field.
V	ImplClearErrors (see page 5485)	This is ImplClearErrors, a member of class TBaseAdapterErrorsList.
V	ImplDefineLabel (see page 5390)	This is ImplDefineLabel, a member of class TAdapterObjectErrorsList.
V	ImplGetError (see page 5390)	This is ImplGetError, a member of class TAdapterObjectErrorsList.
V	ImplGetErrorCount (see page 5390)	This is ImplGetErrorCount, a member of class TAdapterObjectErrorsList.
V	ImplGetObjectErrors (see page 5486)	This is ImplGetObjectErrors, a member of class TBaseAdapterErrorsList.
V	ImplHasObjectErrors (see page 5486)	This is ImplHasObjectErrors, a member of class TBaseAdapterErrorsList.
	NextIteration (see page 5486)	Advances to the objects next item.
	QueryInterface (see page 3347)	Implements the IInterface (see page 3502) System::TInterfacedObject::QueryInterface method.
	StartIterator (see page 5486)	Positions the object on its first item and starts the iteration process.

Public Methods

	Name	Description
	_AddRef (see page 3503)	Increments the reference count for this interface.
	_Release (see page 3503)	Decrements the reference count for this interface.
V	AddError (see page 5481)	This is the overview for the AddError method overload.
V	AfterConstruction (see page 3345)	Responds after the last constructor executes.
V	AfterConstruction (see page 3357)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 3346)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 3358)	Responds before the first destructor executes.
	ClassInfo (see page 3358)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 3359)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 3361)	Determines whether an object is of a specific type.
	ClassParent (see page 3361)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 3364)	Returns the class reference for the object's class.
	CleanupInstance (see page 3367)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearErrors (see page 996)	Clears the errors list.
	ClearErrors (see page 5482)	Clear error list.
	Create (see page 5389)	This is Create, a member of class TAdapterObjectErrorsList.
V	DefaultHandler (see page 3367)	Provides the interface for a method that processes message records.

	DefineLabel (see page 996)	Associates a label with all errors associated with a particular adapter field.
	DefineLabel (see page 5483)	Define error label for field.
V	Destroy (see page 3356)	Disposes of an object instance.
V	Dispatch (see page 3369)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndIterator (see page 1056)	Signals the end of the iterating operation.
V	Equals (see page 3371)	Checks if the current instance and the parameter are equal.
	FieldAddress (see page 3371)	This is the overview for the FieldAddress method overload.
	Free (see page 3372)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 3374)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 3379) method.
	GetCurrentIntf (see page 1051)	This is GetCurrentIntf, a member of class IIterateIntfSupport.
	GetError (see page 996)	Returns a particular error.
	GetErrorCount (see page 997)	Return the number of errors in the errors list.
V	GetHashCode (see page 3375)	Returns an integer containing the hash code.
	GetInterface (see page 3375)	Retrieves a specified interface.
	GetInterfaceEntry (see page 3376)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 3376)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetObjectErrors (see page 997)	Returns an object that is used to enumerate all errors associated with an adapter field.
	HasObjectErrors (see page 997)	Indicates whether the errors list contains objects associated with a particular adapter field.
	InheritsFrom (see page 3376)	Determines the relationship of two object types.
	InitInstance (see page 3377)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 3377)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 3378)	This is the overview for the MethodAddress method overload.
	MethodName (see page 3379)	Returns the name of a class method by address.
V	NewInstance (see page 3346)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 3379)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NextIteration (see page 1056)	Advances to the objects next item.
	QueryInterface (see page 3504)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 3380)	Handles exceptions in methods declared using the safecall calling convention.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
V	ToString (see page 3380)	Returns a string containing the class name.
	UnitName (see page 3380)	Returns a string containing the unit name.

Public Properties

	Name	Description
R	ErrorCount (see page 998)	Returns the number of errors in the errors list.
R	ErrorCount (see page 5487)	Number of error objects contained.
R	Errors (see page 998)	Returns an error from the list.
R	Errors (see page 5487)	Access to error objects.
R	RefCount (see page 3347)	Indicates the number of interface pointers currently dependent upon the object.

54.1.31.2 TAdapterObjectErrorsList.Create Constructor

Pascal

```
constructor Create(AErrors: TAdapterErrorsList; const AName: string);
```

C++

```
__fastcall TAdapterObjectErrorsList(TAdapterErrorsList AErrors, const UnicodeString AName);
```

Description

This is Create, a member of class TAdapterObjectErrorsList.

54.1.31.3 TAdapterObjectErrorsList Methods

The methods of the TAdapterObjectErrorsList class are listed here.

Protected Methods

	Name	Description
	ImplDefineLabel (see page 5390)	This is ImplDefineLabel, a member of class TAdapterObjectErrorsList.
	ImplGetError (see page 5390)	This is ImplGetError, a member of class TAdapterObjectErrorsList.
	ImplGetErrorCount (see page 5390)	This is ImplGetErrorCount, a member of class TAdapterObjectErrorsList.

54.1.31.3.1 TAdapterObjectErrorsList.ImplDefineLabel Method

Pascal

```
procedure ImplDefineLabel(const AName: string; const ALabel: string); override;
```

C++

```
virtual __fastcall ImplDefineLabel(const UnicodeString AName, const UnicodeString ALabel);
```

Description

This is ImplDefineLabel, a member of class TAdapterObjectErrorsList.

54.1.31.3.2 TAdapterObjectErrorsList.ImplGetError Method

Pascal

```
function ImplGetError(I: Integer): IAdapterError; override;
```

C++

```
virtual __fastcall IAdapterError ImplGetError(int I);
```

Description

This is ImplGetError, a member of class TAdapterObjectErrorsList.

54.1.31.3.3 TAdapterObjectErrorsList.ImplGetErrorCount Method

Pascal

```
function ImplGetErrorCount: Integer; override;
```

C++

```
virtual __fastcall int ImplGetErrorCount();
```

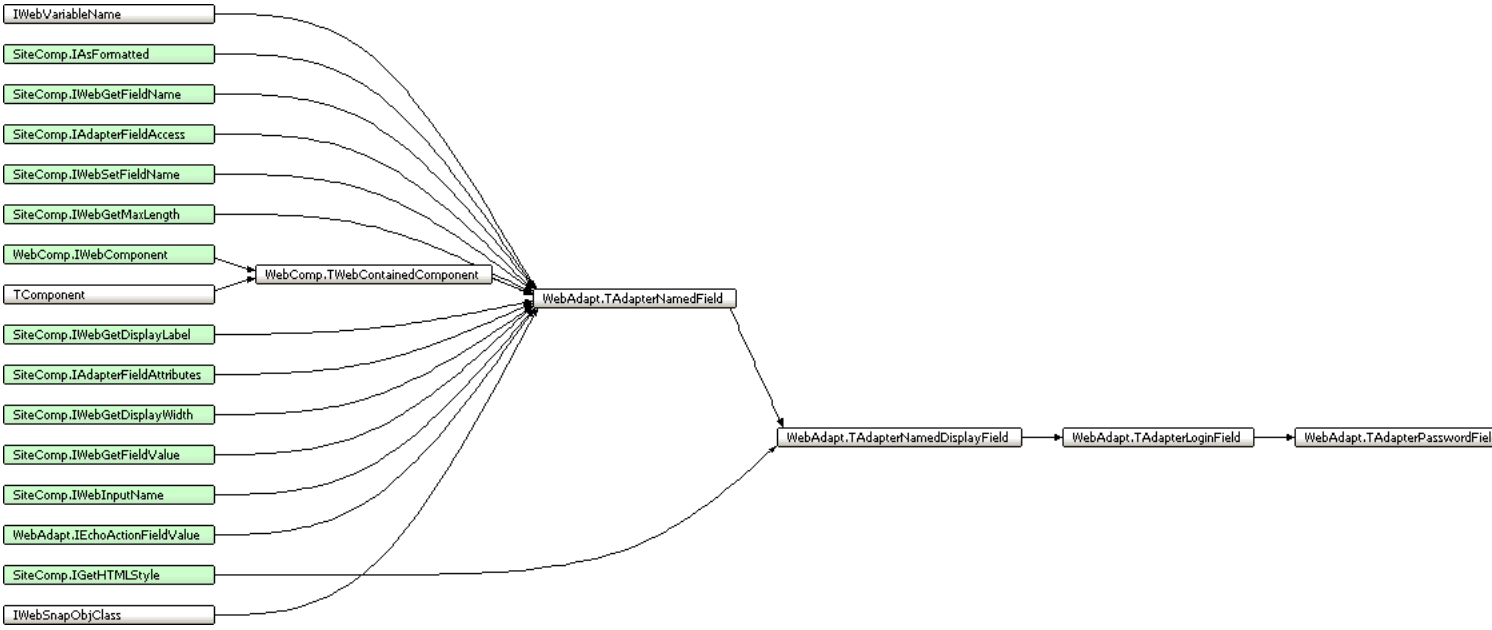
Description

This is ImplGetErrorCount, a member of class TAdapterObjectErrorsList.

54.1.32 TAdapterPasswordField Class

TAdapterPasswordField is an adapter field used to access the password entered by the end-user.

Class Hierarchy



Pascal

```
TAdapterPasswordField = class(TAdapterLoginField);
```

C++

```
class TAdapterPasswordField : public TAdapterLoginField;
```

File

WebAdapt

Description

TAdapterPasswordField is added to TLoginFormAdapter (see page 5824). TAdapterUserNameField (see page 5433), TAdapterPasswordField, TLoginFormAdapterLoginAction (see page 5835) and TAdapterNextPageField (see page 5379) are used with TLoginFormAdapter (see page 5824) to generate an HTML login form. When the HTML form is submitted, TAdapterPasswordField is used to extract the end user's password from the HTTP request.

See Also

TAdapterLoginField (see page 5320)

TLoginFormAdapter (see page 5824)

TAdapterUserNameField (see page 5433)

TAdapterNextPageField (see page 5379)

TLoginFormAdapterLoginAction (see page 5835)

54.1.32.1 TAdapterPasswordField Members

The following tables list the members exposed by TAdapterPasswordField.

Protected Methods

	Name	Description
	AsFormatted (see page 5355)	Returns text used to generate a representation of the adapter field value.
	CheckModifyAccess (see page 5355)	Checks end-user rights to modify the adapter field value.
	CheckViewAccess (see page 5356)	Checks end-user rights to view the adapter field value.
V	FullyQualifyInputName (see page 5356)	Indicates whether the HTML input names must be qualified with the name of the adapter.
	GetAdapter (see page 5356)	GetAdapter returns the parent adapter component.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultDisplayLabel (see page 5357)	Provides the default display label for this adapter field.
V	GetDefaultFieldName (see page 5357)	Gets the default name used to reference this adapter field with server-side script.
	GetDisplayLabel (see page 5357)	Returns the suggested display label for this adapter field.
	GetDisplayStyle (see page 5346)	Returns a string value to suggest an HTML display style for this adapter field.
V	GetDisplayStyleType (see page 5347)	Suggests an HTML display type for this adapter field.
	GetDisplayWidth (see page 5358)	Returns the suggested display width for this adapter field.
	GetEchoActionFieldValue (see page 5358)	Returns the value of the echo flag.
	GetInputName (see page 5358)	Identifies the name to use when generating an HTML input for this adapter field.
	GetInputStyle (see page 5347)	Returns a string value to suggest an HTML input style for this adapter field.
V	GetInputStyleType (see page 5394)	Suggests an HTML input type for this adapter field.
	GetMaxLength (see page 5359)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
	GetRequired (see page 5359)	Indicates whether the end-user must enter a value for this adapter field.
	GetValue (see page 5359)	Gets the value of this adapter field as a Variant (see page 3421).
	GetVariableName (see page 5360)	Gets the name used to reference this adapter field with server-side script.
	GetViewMode (see page 5348)	Returns a string value to suggest a view mode for this adapter field.
V	GetViewModeType (see page 5348)	Suggests a view mode for this adapter field.
	GetVisible (see page 5360)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	GetWebSnapObjClass (see page 5360)	Returns the class type for this adapter field.
	HasModifyAccess (see page 5361)	Checks the end-user's right to modify this adapter field.
	HasViewAccess (see page 5361)	Checks the end-user's right to view this adapter field.
V	ImplAsFormatted (see page 5361)	Returns text used to generate a representation of the adapter field value.
V	ImplGetDisplayLabel (see page 5348)	Implements interface access to the DisplayLabel (see page 5350) property.
V	ImplGetDisplayLabel (see page 5361)	Returns the suggested display label for this adapter field.
V	ImplGetDisplayWidth (see page 5349)	Implements interface access to the DisplayWidth (see page 5350) property.
V	ImplGetDisplayWidth (see page 5362)	Returns the suggested display width for this adapter field.
V	ImplGetEchoActionFieldValue (see page 5362)	Returns the value of the echo flag.
V	ImplGetInputName (see page 5362)	Identifies the name to use when generating the HTML input for this adapter field.
V	ImplGetMaxLength (see page 5363)	Returns the maximum length, in characters, that the user should be allowed to enter when entering a value for this adapter field.
V	ImplGetRequired (see page 5349)	Implements interface access to the Required (see page 5351) property.
V	ImplGetRequired (see page 5363)	Indicates whether the end-user must enter a value for this adapter field.
V	ImplGetValue (see page 5395)	Returns the value associated with this adapter field.
V	ImplGetVariableName (see page 5364)	Gets the name used to reference this adapter field with server-side script.
V	ImplGetVisible (see page 5364)	Indicates whether the value of this adapter field should be displayed to the end-user.
V	ImplHasModifyAccess (see page 5365)	Checks the end-user's right to modify this adapter field.
V	ImplHasViewAccess (see page 5365)	Checks the end-user's right to view this adapter field.
V	ImplSetEchoActionFieldValue (see page 5365)	Sets the echo flag for this adapter field.
V	ImplSetFieldName (see page 5366)	Sets the name that is used to reference this adapter field with server-side script.

	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	ParentChanged (see page 5366)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetDisplayLabel (see page 5349)	SetDisplayLabel sets the value of the DisplayLabel (see page 5350) property.
	SetEchoActionFieldValue (see page 5366)	Sets the echo flag for this adapter field.
	SetFieldName (see page 5367)	Sets the name that is used to reference this adapter field with server-side script.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.

Protected Properties

	Name	Description
	Adapter (see page 5368)	Returns the parent adapter component.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Methods

	Name	Description
	AsFormatted (see page 1014)	This is AsFormatted, a member of class IAsFormatted.
	Create (see page 5346)	Creates an instance of TAdapterNamedDisplayField (see page 5343).
	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetDisplayWidth (see page 1089)	This is GetDisplayWidth, a member of class IWebGetDisplayWidth.
	GetEchoActionFieldValue (see page 5881)	This is GetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	GetFieldName (see page 1090)	This is GetFieldName, a member of class IWebGetFieldName.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputName (see page 1099)	This is GetInputName, a member of class IWebInputName.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetMaxLength (see page 1096)	This is GetMaxLength, a member of class IWebGetMaxLength.
	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetRequired (see page 1000)	This is GetRequired, a member of class IAdapterFieldAttributes.
	GetValue (see page 1092)	This is GetValue, a member of class IWebGetFieldValue.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 1000)	This is GetVisible, a member of class IAdapterFieldAttributes.
	HasModifyAccess (see page 999)	This is HasModifyAccess, a member of class IAdapterFieldAccess.
	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	HasViewAccess (see page 999)	This is HasViewAccess, a member of class IAdapterFieldAccess.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetEchoActionFieldValue (see page 5881)	This is SetEchoActionFieldValue, a member of class IEchoActionFieldValue.
	SetFieldName (see page 1116)	This is SetFieldName, a member of class IWebSetFieldName.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.

Public Properties

	Name	Description
	ActionOrigValue (see page 5367)	Retrieve the original value of this adapter field.
	ActionValue (see page 5368)	Retrieve the value for this adapter field entered by the end-user.

R	Adapter (see page 5323)	Returns the parent adapter of this adapter field.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	EchoActionFieldValue (see page 5882)	This is EchoActionFieldValue, a member of class IEchoActionFieldValue.
	EchoActionFieldValue (see page 5368)	Used to echo the value(s) entered by the end-user when generating an HTML form.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	InputName (see page 1100)	This is InputName, a member of class IWebInputName.
	ModifyAccess (see page 5369)	Identifies the rights required to update this field.
	ReadOnly (see page 5351)	Indicates whether this adapter field is read-only.
R	Required (see page 1001)	This is Required, a member of class IAdapterFieldAttributes.
	Required (see page 5351)	Indicates whether the end-user must enter a value for this adapter field.
R	Value (see page 1092)	This is Value, a member of class IWebGetFieldValue.
R	Value (see page 5369)	Provides the value of an adapter field as a variant.
	ViewAccess (see page 5370)	Identifies the rights required to view this field.
R	Visible (see page 1001)	This is Visible, a member of class IAdapterFieldAttributes.

Published Properties

	Name	Description
	DisplayLabel (see page 5395)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5395)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5396)	Identifies the name of this field when using server-side script.

54.1.32.2 TAdapterPasswordField Methods

The methods of the TAdapterPasswordField class are listed here.

Protected Methods

	Name	Description
V	GetInputStyleType (see page 5394)	Suggests an HTML input type for this adapter field.
V	ImplGetValue (see page 5395)	Returns the value associated with this adapter field.

54.1.32.2.1 TAdapterPasswordField.GetInputStyleType Method

Suggests an HTML input type for this adapter field.

Pascal

```
function GetInputStyleType(const AAdapterMode: string): TAdapterInputHTMLElementType; override;
```

C++

```
virtual __fastcall TAdapterInputHTMLElementType GetInputStyleType(const UnicodeString
AAdapterMode);
```

Description

GetInputStyleType overrides TAdaperNamedDisplayField's GetInputStyleType method. GetInputStyleType returns htmliPassword indicating that a password input HTML element should be used to input a value for this adapter field.

See Also

GetInputStyleType (see page 5347)

TAdapterInputHTMLElementType (see page 1124)

54.1.32.2.2 TAdapterPasswordField.ImplGetValue Method

Returns the value associated with this adapter field.

Pascal

```
function ImplGetValue: Variant; override;
```

C++

```
virtual __fastcall Variant ImplGetValue();
```

Description

ImplGetValue returns an empty string. Server-side script accesses the result of this function using the EditText or Value (see page 5369) property of the adapter field. These server-side script properties may be used to generate the HTML login form. ImplGetValue returns an empty string so that the generated login form's password field will be blank. When the login form is submitted, the ActionValue (see page 5368) property can be used to access the password entered by the end-user.

See Also

ActionValue (see page 5368)

54.1.32.3 TAdapterPasswordField Properties

The properties of the TAdapterPasswordField class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5395)	Suggests a display label for this adapter field.
	DisplayWidth (see page 5395)	Suggests a display width, in characters, for this adapter field.
	FieldName (see page 5396)	Identifies the name of this field when using server-side script.

54.1.32.3.1 TAdapterPasswordField.DisplayLabel Property

Suggests a display label for this adapter field.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this label or not. Server-side script uses the DisplayLabel property to access this value.

See Also

GetDisplayLabel (see page 5357)

54.1.32.3.2 TAdapterPasswordField.DisplayWidth Property

Suggests a display width, in characters, for this adapter field.

Pascal

```
property DisplayWidth: integer;
```

C++

```
__property int DisplayWidth;
```

Description

Set this property to indicate the width, in characters, that is suggested when generating an HTML field to display the value of this adapter field. Typically the adapter field is displayed using server-side script, either generated or custom written. The server-side script may be written to use this width or not. Server-side script uses the DisplayWidth property to access this value.

See Also

GetDisplayWidth (see page 5358)

54.1.32.3.3 TAdapterPasswordField.FieldName Property

Identifies the name of this field when using server-side script.

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;__property UnicodeString FieldName;
```

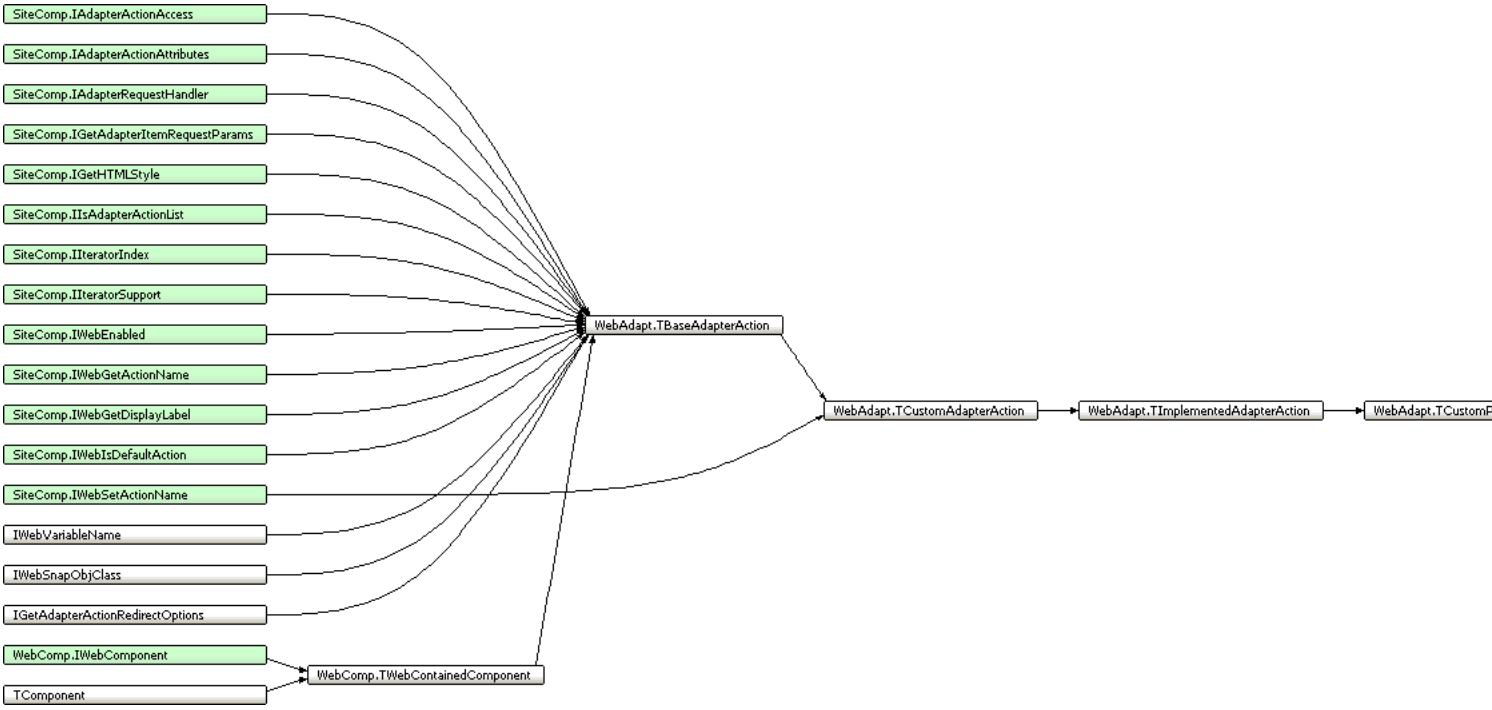
Description

The FieldName property defines the name used to access the adapter field with server-side script. Server-side script can access this value using the Name property.

54.1.33 TAdapterPrevPageAction Class

TAdapterPrevPageAction implements the previous page command for TDefaultFieldsPagedAdapter (see page 5747).

Class Hierarchy



Pascal

```
TAdapterPrevPageAction = class(TCustomAdapterPageAction);
```

C++

```
class TAdapterPrevPageAction : public TCustomAdapterPageAction;
```

File

WebAdapt

Description

Add TAdapterPrevPageAction to a descendant class of TDefaultFieldsPagedAdapter (see page 5747) such as TPagedAdapter (see page 5844).

See Also

TCustomAdapterPageAction (see page 5656)

TDefaultFieldsPagedAdapter (see page 5747)

TAdapterNextPageAction (see page 5370)

TAdapterGotoPageAction (see page 5291)

TPagedAdapter (see page 5844)

54.1.33.1 TAdapterPrevPageAction Members

The following tables list the members exposed by TAdapterPrevPageAction.

Protected Methods

	Name	Description
	CheckExecuteAccess (see page 5452)	Checks end-user rights to execute this adapter action.
	CreateRequestContext (see page 5452)	Creates an object that describes the adapter action parameters and adapter field values.
V	DoAfterExecuteActionRequest (see page 5453)	Calls event handlers after the adapter action is executed.
V	DoAfterGetExecuteActionResponse (see page 5453)	Calls event handlers after the adapter action response is formulated.
V	DoBeforeExecuteActionRequest (see page 5453)	Calls event handlers before the adapter action is executed.
V	DoBeforeGetExecuteActionResponse (see page 5454)	Calls event handlers before the adapter action response is formulated.
	EndIterator (see page 5454)	Implements IIteratorSupport (see page 1054)'s EndIterator method.
	ExecuteActionRequest (see page 5455)	Executes the adapter action using parameters passed in the HTTP request.
	GetActionName (see page 5455)	Gets the name used to reference this adapter action with server-side script.
	GetAdapter (see page 5456)	GetAdapter returns the parent adapter component.
	GetAdapter (see page 5727)	Returns the parent adapter of this adapter action.
	GetAdapterItemRequestParams (see page 5456)	Provides the name/value pairs needed to execute this adapter action.
	GetContainerList (see page 6041)	Returns the TWebComponentList (see page 6025) object that the Web parent uses to manage this and its other Web items.
V	GetDefaultActionName (see page 5401)	Gets the name used to reference this adapter action with server-side script.
V	GetDefaultDisplayLabel (see page 5401)	Provides the default display label for this adapter action.
	GetDisplayLabel (see page 5457)	Returns the suggested display label for this adapter action.
	GetDisplayStyle (see page 5457)	Returns a string value to suggest an HTML display style for this adapter action.
V	GetDisplayStyleType (see page 5458)	Suggests an HTML display type for this adapter action.
V	GetDisplayStyleType (see page 5661)	Suggests an HTML display type for this adapter action.
	GetErrors (see page 5458)	Returns the parent adapter's errors list.
	GetExecuteActionResponse (see page 5458)	Generates a response after the adapter action has been executed.
	GetFailureOptions (see page 5459)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	GetInputStyle (see page 5459)	Returns a string value to suggest an HTML display style for this adapter action.
	GetIsAdapterActionList (see page 5460)	Indicates whether this adapter action may have multiple commands.
V	GetItemCount (see page 5460)	Returns the number of commands defined by this adapter action.
	GetIteratorIndex (see page 5460)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex method.
V	GetNewPage (see page 5402)	Indicates the page to display when this action is executed.
	GetSuccessOptions (see page 5461)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	GetVariableName (see page 5461)	Gets the name used to reference this adapter action with server-side script.
	GetViewMode (see page 5462)	Returns a string value to suggest a view mode for this adapter action.
V	GetViewModeType (see page 5462)	Suggests a view mode for this adapter action.
	GetVisible (see page 5462)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
V	GetWebSnapObjClass (see page 5463)	Returns the class type for this adapter field.
	HandleRequest (see page 5463)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 5463)	Checks the end-user's right to execute this adapter action.
	ImplCreateRequestContext (see page 5464)	Creates an object that describes the action parameters and field values.
	ImplEndIterator (see page 5464)	Implements IIteratorSupport (see page 1054)'s EndIterator (see page 5454) method.
V	ImplExecuteActionRequest (see page 5464)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplExecuteActionRequest (see page 5584)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplExecuteActionRequest (see page 5662)	Executes the adapter action using parameters passed in the HTTP request.
V	ImplGetActionName (see page 5465)	Gets the name used to reference this adapter action with server-side script.
V	ImplGetActionName (see page 5584)	Gets the name used to reference this adapter action with server-side script.
V	ImplGetAdapterItemRequestParams (see page 5465)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetAdapterItemRequestParams (see page 5584)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetAdapterItemRequestParams (see page 5662)	Provides the name/value pairs needed to execute this adapter action.
V	ImplGetDisplayLabel (see page 5465)	Returns the suggested display label for this adapter action.
V	ImplGetExecuteActionResponse (see page 5466)	Generates a response after the adapter action has been executed.

	ImplGetFailureOptions (see page 5466)	Indicates whether to perform an HTTP redirect after execution of this adapter action fails.
	ImplGetIsAdapterActionList (see page 5466)	Indicates whether this adapter action may have multiple commands.
	ImplGetIteratorIndex (see page 5467)	Implements IIteratorIndex (see page 1052)'s GetIteratorIndex (see page 5460) method.
	ImplGetSuccessOptions (see page 5467)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetSuccessOptions (see page 5585)	Indicates whether to perform an HTTP redirect after successfully executing this action.
	ImplGetVariableName (see page 5467)	Gets the name used to reference this adapter action with server-side script.
	ImplGetVisible (see page 5468)	Indicates whether a button or hyperlink for this adapter action should be displayed on the HTML page.
	ImplHandleRequest (see page 5468)	Executes the adapter action and generates a response.
	ImplHasExecuteAccess (see page 5468)	Checks the end-user's right to execute this adapter action.
	ImplInIterator (see page 5469)	Implements IIteratorIndex (see page 1052)'s InIterator (see page 5471) method.
	ImplIsDefaultAction (see page 5469)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplIsDefaultAction (see page 5663)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	ImplNextIteration (see page 5470)	Implements IIteratorSupport (see page 1054)'s NextIteration (see page 5472) method.
	ImplSetActionName (see page 5585)	Sets the name that is used to reference this adapter action with server-side script.
	ImplStartIterator (see page 5470)	Implements IIteratorSupport (see page 1054)'s StartIterator (see page 5473) method.
	ImplWebEnabled (see page 5470)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	ImplWebEnabled (see page 5585)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	ImplWebEnabled (see page 5663)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.
	InIterator (see page 5471)	Implements IIteratorIndex (see page 1052)'s InIterator method.
	IsDefaultAction (see page 5471)	Indicates whether this adapter action should be added, by default, to the parent adapter.
	IsDefaultField (see page 6042)	Indicates whether this component represents a Web item that is used by default when the parent's set of Web items is not explicitly assigned.
	NextIteration (see page 5472)	Implements IIteratorSupport (see page 1054)'s NextIteration method.
	ParentChanged (see page 5472)	Handles movement of the component to a different parent.
	ParentChanged (see page 6042)	Responds when the WebParent (see page 6044) property changes.
	ReadState (see page 6043)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetActionName (see page 5586)	Sets the name that is used to reference this adapter action with server-side script.
	SetDisplayLabel (see page 5472)	Set the value of the DisplayLabel (see page 5474) property.
	SetParentComponent (see page 6043)	Sets the WebParent (see page 6044) property to be the same as this component's parent.
	SetWebParent (see page 6043)	Sets the value of the WebParent (see page 6044) property.
	StartIterator (see page 5473)	Implements IIteratorSupport (see page 1054)'s StartIterator method.
	WebEnabled (see page 5473)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Protected Properties

	Name	Description
	Adapter (see page 5474)	Provides access to the parent adapter component.
	Adapter (see page 5727)	Returns the parent adapter of this adapter action.
	Errors (see page 5475)	Returns the parent adapter's Errors list.
	WebContainedComponentHelper (see page 6044)	Provides access to the helper object that implements the IWebComponent (see page 6093) interface for this contained component.
	WebParent (see page 6044)	Indicates the component that uses this TWebContainedComponent (see page 6038) as one of its Web items.

Public Events

	Name	Description
	OnExecute (see page 5588)	Called to execute this action using parameters passed in the HTTP request.
	OnGetEnabled (see page 5589)	Indicates whether a button or hyperlink for this adapter action should be enabled on the HTML page.

Public Methods

	Name	Description
V	Create (see page 6039)	Creates and initializes an instance of TWebContainedComponent (see page 6038).
	CreateRequestContext (see page 1013)	Creates an object that describes the adapter action parameters and adapter field values.
V	Destroy (see page 6040)	Frees an instance of TWebContainedComponent (see page 6038).
	EndIterator (see page 1056)	Signals the end of the iterating operation.
	GetActionName (see page 1087)	This is GetActionName, a member of class IWebGetActionName.
	GetAdapterItemRequestParams (see page 1024)	This is GetAdapterItemRequestParams, a member of class IGetAdapterItemRequestParams.
	GetContainer (see page 6094)	Returns the value of the Container (see page 6096) property.
	GetDisplayLabel (see page 1088)	This is GetDisplayLabel, a member of class IWebGetDisplayLabel.
	GetDisplayStyle (see page 1032)	Returns the preferred display style for an adapter field or adapter action.
	GetIndex (see page 6094)	Returns the value of the Index (see page 6097) property.
	GetInputStyle (see page 1033)	Returns the preferred editing style for an adapter field.
	GetIsAdapterActionList (see page 1050)	This is GetIsAdapterActionList, a member of class IIsAdapterActionList.
	GetIteratorIndex (see page 1053)	Returns the value of the IteratorIndex (see page 1054) property.
V	GetParentComponent (see page 6041)	Returns the object that uses this component to generate HTML.
	GetViewMode (see page 1033)	Returns the preferred mode of an adapter field.
	GetVisible (see page 984)	This is GetVisible, a member of class IAdapterActionAttributes.
	HandleRequest (see page 1013)	Executes the adapter action and generates a response.
	HasExecuteAccess (see page 983)	This is HasExecuteAccess, a member of class IAdapterActionAccess.
V	HasParent (see page 6041)	Indicates whether this component appears in another component's list of Web items.
	InIterator (see page 1053)	Indicates whether the object is iterating over its items.
	IsDefaultAction (see page 1101)	This is IsDefaultAction, a member of class IWebIsDefaultAction.
	NextIteration (see page 1056)	Advances to the objects next item.
	SetActionName (see page 1115)	This is SetActionName, a member of class IWebSetActionName.
	SetComponentList (see page 6095)	Sets the value of the ComponentList (see page 6096) property.
	SetContainer (see page 6095)	Sets the value of the Container (see page 6096) property.
	SetIndex (see page 6095)	Sets the value of the Index (see page 6097) property.
	StartIterator (see page 1056)	Positions the object on its first item and starts the iteration process.
	WebEnabled (see page 1084)	This is WebEnabled, a member of class IWebEnabled.

Public Properties

	Name	Description
R	ActionName (see page 1087)	This is ActionName, a member of class IWebGetActionName.
R	ActionName (see page 5474)	Identifies the name of this action when using server-side script.
	ActionName (see page 5586)	Identifies the name of this action when using server-side script.
W	ComponentList (see page 6096)	Indicates the component list that contains the Web item.
	Container (see page 6096)	Specifies the component that uses content generated by this Web item.
	Index (see page 6097)	Indicates where the Web item appears in the Web component list's array of Web items.
R	IsAdapterActionList (see page 1050)	This is IsAdapterActionList, a member of class IIsAdapterActionList.
R	ItemCount (see page 5475)	Returns the number of items defined by an adapter action.
R	ItemIndex (see page 5476)	Returns the index of the current item of an adapter action.
R	IteratorIndex (see page 1054)	Indicates the index of the current item.
R	Visible (see page 984)	This is Visible, a member of class IAdapterActionAttributes.

Published Events

	Name	Description
	OnAfterExecute (see page 5404)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5404)	Called after the adapter action response is generated.
	OnBeforeExecute (see page 5404)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5405)	Called before the adapter action response is generated.
	OnGetParams (see page 5405)	Specifies name/value pairs needed to execute this adapter action.

Published Properties

	Name	Description
	DisplayLabel (see page 5402)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5403)	Defines the rights required to execute this action.
	RedirectOptions (see page 5403)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.33.2 TAdapterPrevPageAction Methods

The methods of the TAdapterPrevPageAction class are listed here.

Protected Methods

	Name	Description
	GetDefaultActionName (see page 5401)	Gets the name used to reference this adapter action with server-side script.
	GetDefaultDisplayLabel (see page 5401)	Provides the default display label for this adapter action.
	GetNewPage (see page 5402)	Indicates the page to display when this action is executed.

54.1.33.2.1 TAdapterPrevPageAction.GetDefaultActionName Method

Gets the name used to reference this adapter action with server-side script.

Pascal

```
function GetDefaultActionName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultActionName();
```

Description

GetDefaultActionName returns "PrevPage".

See Also

GetActionName (see page 5455)

GetDefaultActionName (see page 5456)

54.1.33.2.2 TAdapterPrevPageAction.GetDefaultDisplayLabel Method

Provides the default display label for this adapter action.

Pascal

```
function GetDefaultDisplayLabel: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDefaultDisplayLabel();
```

Description

GetDefaultDisplayLabel returns "<<". This displays as '<<' in the browser.

See Also

DisplayLabel (see page 5474)

54.1.33.2.3 TAdapterPrevPageAction.GetNewPage Method

Indicates the page to display when this action is executed.

Pascal

```
function GetNewPage(var AValue: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean GetNewPage(int AValue);
```

Description

GetNewPage determines whether the current page can be incremented. If so, the AValue parameter is modified and true is returned. Otherwise, false is returned.

See Also

GetNewPage (see page 5661)

RecordCount (see page 5761)

PageSize (see page 5761)

CurrentPage (see page 5760)

54.1.33.3 TAdapterPrevPageAction Properties

The properties of the TAdapterPrevPageAction class are listed here.

Published Properties

	Name	Description
	DisplayLabel (see page 5402)	Suggests a display label for this adapter action.
	ExecuteAccess (see page 5403)	Defines the rights required to execute this action.
	RedirectOptions (see page 5403)	Indicates whether to perform an HTTP redirect after successfully executing this action.

54.1.33.3.1 TAdapterPrevPageAction.DisplayLabel Property

Suggests a display label for this adapter action.

Pascal

```
property DisplayLabel: string;
```

C++

```
__property UnicodeString DisplayLabel;
```

Description

Use this property to suggest a display label to use when generating HTML to display the a button or hyperlink to execute this adapter action. Typically the adapter action is displayed using server-side script, either generated or custom written. Server-side

script uses the DisplayLabel property to access this value.

See Also

ImplGetDisplayLabel (see page 5465)

SetDisplayLabel (see page 5472)

54.1.33.3.2 TAdapterPrevPageAction.ExecuteAccess Property

Defines the rights required to execute this action.

Pascal

```
property ExecuteAccess: string;
```

C++

```
__property UnicodeString ExecuteAccess;
```

Description

The ExecuteAccess property defines the access rights required to execute this action. When server-side script accesses the CanExecute property, this value is checked against the end user's rights. Typically, an exception is raised when an end-user attempts to execute an adapter action that does not allow access.

See Also

TWebUserList (see page 6796)

HasExecuteAccess (see page 5552)

54.1.33.3.3 TAdapterPrevPageAction.RedirectOptions Property

Indicates whether to perform an HTTP redirect after successfully executing this action.

Pascal

```
property RedirectOptions: TAdapterActionRedirectOptions;
```

C++

```
__property TAdapterActionRedirectOptions RedirectOptions;
```

Description

Set RedirectOptions to indicate that HTTP redirect should be performed after executing this adapter action. An HTTP redirect causes the browser to "forget" about the parameters passed when executing the adapter action. Without a redirect, the browser's Refresh or Reload command cause the last HTTP request to be resent, resulting in re-execution of the adapter action.

See Also

SendRedirect

54.1.33.4 TAdapterPrevPageAction Events

The events of the TAdapterPrevPageAction class are listed here.

Published Events

	Name	Description
	OnAfterExecute (see page 5404)	Called after the adapter action has executed.
	OnAfterGetResponse (see page 5404)	Called after the adapter action response is generated.

	OnBeforeExecute (see page 5404)	Called before the adapter action is executed.
	OnBeforeGetResponse (see page 5405)	Called before the adapter action response is generated.
	OnGetParams (see page 5405)	Specifies name/value pairs needed to execute this adapter action.

54.1.33.4.1 TAdapterPrevPageAction.OnAfterExecute Event

Called after the adapter action has executed.

Pascal

```
property OnAfterExecute: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterExecute;
```

Description

Implement OnAfterExecute to do something after the action has executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterExecute is called by DoAfterExecuteActionRequest.

See Also

DoAfterExecuteActionRequest (see page 5453)

OnAfterExecuteAction (see page 5576)

OnBeforeExecute (see page 5478)

54.1.33.4.2 TAdapterPrevPageAction.OnAfterGetResponse Event

Called after the adapter action response is generated.

Pascal

```
property OnAfterGetResponse: TActionExecuteEvent;
```

C++

```
__property TActionExecuteEvent OnAfterGetResponse;
```

Description

Implement OnAfterGetResponse to do something after the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. OnAfterGetResponse is called by DoAfterGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnBeforeGetActionResponse (see page 5578)

54.1.33.4.3 TAdapterPrevPageAction.OnBeforeExecute Event

Called before the adapter action is executed.

Pascal

```
property OnBeforeExecute: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeExecute;
```

Description

Implement OnBeforeExecute to do something before the action is executed. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to prevent the action from being executed. OnBeforeExecute is called by DoBeforeExecuteActionRequest.

See Also

DoBeforeExecuteActionRequest (see page 5453)

OnAfterExecute (see page 5477)

OnBeforeExecuteAction (see page 5577)

54.1.33.4.4 TAdapterPrevPageAction.OnBeforeGetResponse Event

Called before the adapter action response is generated.

Pascal

```
property OnBeforeGetResponse: TActionExecuteHandledEvent;
```

C++

```
__property TActionExecuteHandledEvent OnBeforeGetResponse;
```

Description

Implement OnBeforeGetResponse to do something before the action response is generated. The Params parameter contains the adapter action parameters (name/value pairs) that were passed in the HTTP request. Set the Handled flag to indicate that the response has been generated and no further processing is needed. OnBeforeGetResponse is called by DoBeforeGetExecuteActionReponse.

See Also

DoBeforeGetExecuteActionResponse (see page 5454)

OnAfterGetResponse (see page 5477)

OnBeforeGetActionResponse (see page 5578)

54.1.33.4.5 TAdapterPrevPageAction.OnGetParams Event

Specifies name/value pairs needed to execute this adapter action.

Pascal

```
property OnGetParams: TActionGetParamsEvent;
```

C++

```
__property TActionGetParamsEvent OnGetParams;
```

Description

Implement this event handler to specify the name/value needed to execute this action. For example, an action that deletes a row in a table will need a name/value pair that identifies the row to be deleted such as "Key=123".

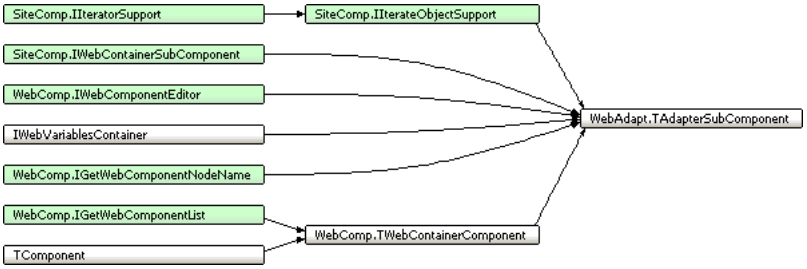
See Also

ImplGetAdapterItemRequestParams (see page 5465)

54.1.34 TAdapterSubComponent Class

TAdapterSubComponent is the base class for objects that represent a collection of actions or fields that belong to an adapter.

Class Hierarchy



Pascal

```
TAdapterSubComponent = class(TWebContainerComponent, IWebContainerSubComponent,
IWebComponentEditor, IWebVariablesContainer, IGetWebComponentNodeName, IIterateObjectSupport);
```

C++

```
class TAdapterSubComponent : public TWebContainerComponent, public IWebContainerSubComponent,
public IWebComponentEditor, public IWebVariablesContainer, public IGetWebComponentNodeName,
public IIterateObjectSupport;
```

File

WebAdapt

Description

Adapter (see page 5418) components use a TAdapterSubComponent descendant to represent the list of actions they can execute or the list of fields whose values they support. Each TAdapterSubComponent is specialized for a specific type of object (actions or fields), and represents either the set of explicitly assigned actions or fields, or the set that the adapter contains by default.

TAdapterSubComponent introduces support for:

Associating the collection with an adapter component.

Assigning variable names to the child items in the collection. These are the names of variables that server-side script can use to refer to the actions or fields.

Letting server-side script use an enumerator to iterate over all the child items in the collection.

Working with the WebSnap designers at design time.

TAdapterDefaultFields (see page 5237)

54.1.34.1 TAdapterSubComponent Members

The following tables list the members exposed by TAdapterSubComponent.

Protected Methods

	Name	Description
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
V	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.
	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
V	GetChildren (see page 6065)	Executes a callback for each child Web item.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
V	GetDefaultWebComponents (see page 5411)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
V	GetVariablesInUse (see page 5413)	Returns the value of the VariablesInUse (see page 5419) property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	GetWebComponents (see page 6065)	Returns the list of Web items that this item manages.
V	ImplCanAddClass (see page 5414)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
V	ImplGetDefaultComponentList (see page 6066)	Returns a list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	ImplGetWebComponentNodeName (see page 5415)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
V	SetChildOrder (see page 6066)	Positions a child component in the list of child Web items.
V	SetDefaultWebComponents (see page 5416)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
V	SetWebParent (see page 5417)	Introduces a method to associate this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Protected Properties

	Name	Description
R	Adapter (see page 5418)	Indicates the adapter that uses this object to manage its fields or actions.
R	VariablesInUse (see page 5419)	Lists those fields or actions in the collection for which variables are defined.
R	WebContainerComponentHelper (see page 6067)	Provides access to the helper object that allows this object to manage its Web items.

Public Methods

	Name	Description
V	Create (see page 6064)	Creates and initializes an instance of TWebContainerComponent (see page 6063).
V	Destroy (see page 6064)	Frees an instance of TWebContainerComponent (see page 6063).
	GetComponentList (see page 6082)	This is GetComponentList, a member of class IGetWebComponentList.
	GetDefaultComponentList (see page 6082)	This is GetDefaultComponentList, a member of class IGetWebComponentList.
V	GetParentComponent (see page 5412)	Returns the associated adapter.
V	HasParent (see page 5414)	Indicates whether this component has an associated adapter.
V	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.

	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.

54.1.34.2 TAdapterSubComponent Methods

The methods of the TAdapterSubComponent class are listed here.

Protected Methods

	Name	Description
	CanAddClass (see page 5408)	Indicates whether an object of a specified type can be added to this collection.
	EndIterator (see page 5409)	Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.
	FindNamedVariable (see page 5409)	Returns the item from this list with a specified variable name.
	FindVariable (see page 5410)	Returns the item from this list with a specified variable name.
	FindVariableContainer (see page 5410)	Returns the Web module that contains a specified item from this list.
	GetCurrentObject (see page 5411)	Returns the current field or action from the list when an enumerator is iterating over child items.
	GetDefaultWebComponents (see page 5411)	Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.
	GetVariable (see page 5412)	Returns a child item from this list, given its position in the list of child items with variable names.
	GetVariableCount (see page 5413)	Indicates the number of items in this list that can be accessed from server-side script.
	GetVariablesInUse (see page 5413)	Returns the value of the VariablesInUse (see page 5419) property.
	GetWebComponentNodeName (see page 5413)	Returns a string that indicates the type of items in this collection.
	ImplCanAddClass (see page 5414)	Provides the underlying implementation for the CanAddClass (see page 5408) method.
	ImplGetWebComponentNodeName (see page 5415)	Provides the underlying implementation for the GetWebComponentNodeName (see page 5413) method.
	NextIteration (see page 5415)	Changes the current object to the next item that has a variable name.
	NotifyAdapterChange (see page 5416)	Notifies the associated adapter when the list of items changes.
	SetDefaultWebComponents (see page 5416)	Sets the list of Web items that are used by default if an application does not explicitly assign child items to this object.
	SetWebParent (see page 5417)	Introduces a method to associate this component with an adapter.
	StartIterator (see page 5418)	Makes the first child item with a variable name the current object.

Public Methods

	Name	Description
	GetParentComponent (see page 5412)	Returns the associated adapter.
	HasParent (see page 5414)	Indicates whether this component has an associated adapter.
	ReadState (see page 5416)	Reads the component's published properties, stored data, and owned components from a reader object.
	SetParentComponent (see page 5417)	Sets the Adapter (see page 5418) property to be the same as this component's parent.

54.1.34.2.1 TAdapterSubComponent.CanAddClass Method

Indicates whether an object of a specified type can be added to this collection.

Pascal

```
function CanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean CanAddClass(TComponent * AParent, TClass AClass);
```

Description

The IDE calls CanAddClass to determine what Web items can be added to this list. This method allows the IDE to limit the

actions or fields in the collection to those that are appropriate for the associated adapter.

AParent is the TAdapterSubComponent (see page 5406) descendant to which the Web item will be added.

AClass is the class of the proposed child item.

CanAddClass returns true if the TAdapterSubComponent (see page 5406) descendant can include a child of type AClass, false otherwise.

CanAddClass calls the virtual ImplCanAddClass (see page 5414) method to determine whether a class of Web item is valid.

See Also

ImplCanAddClass (see page 5414)

Adapter (see page 5418)

54.1.34.2.2 TAdapterSubComponent.EndIterator Method

Stops the TAdapterSubComponent (see page 5406) object from iterating over the Web items it lists.

Pascal

```
procedure EndIterator(OwnerData: Pointer);
```

C++

```
__fastcall EndIterator(void * OwnerData);
```

Description

EndIterator is part of the support that allows server-side script to use an enumerator to iterate over all the child items in the collection. This method is called when the enumeration stops. In TAdapterSubComponent (see page 5406), EndIterator does nothing. This method exists only as a backstop for the standard call made from server-side script.

OwnerData is a pointer to object-specific information returned by the last call to the StartIterator (see page 5418) or NextIteration (see page 5415) method. TAdapterSubComponent (see page 5406) does not use the OwnerData parameter.

See Also

StartIterator (see page 5418)

NextIteration (see page 5415)

GetCurrentObject (see page 5411)

54.1.34.2.3 TAdapterSubComponent.FindNamedVariable Method

Returns the item from this list with a specified variable name.

Pascal

```
function FindNamedVariable(const AName: string): TComponent; virtual;
```

C++

```
virtual __fastcall TComponent * FindNamedVariable(const UnicodeString AName);
```

Description

FindNamedVariable searches the list of child items that have variable names (the VariablesInUse (see page 5419) property) to find one with the specified name. The associated adapter component calls this method from its FindNamedField or FindNamedAction method to look up a field or action with a specified name.

AName is a variable name. Typically, this comes from server-side script that is looking for a child of an adapter with this name.

FindNamedVariable returns the item from the list with the specified variable name. If none of the items in the list have the name AName, FindNamedVariable returns nil (Delphi) or NULL (C++).

See Also

VariablesInUse (see page 5419)

FindVariable (see page 5410)

GetVariable (see page 5412)

GetVariableCount (see page 5413)

FindVariableContainer (see page 5410)

FindNamedField (see page 5544)

FindNamedAction (see page 5544)

54.1.34.2.4 TAdapterSubComponent.FindVariable Method

Returns the item from this list with a specified variable name.

Pascal

```
function FindVariable(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindVariable(const UnicodeString AName);
```

Description

FindVariable method is called from server-side script to locate a field or action with a specified name. This method is identical to the FindNamedVariable (see page 5409) method, except that it is not virtual. Instead, FindVariable calls the virtual FindNamedVariable (see page 5409) method.

AName is a variable name.

FindNamedVariable (see page 5409) returns the item from the list with the specified variable name. If none of the items in the list have the name AName, FindNamedVariable (see page 5409) returns nil (Delphi) or NULL (C++).

See Also

VariablesInUse (see page 5419)

FindNamedVariable (see page 5409)

GetVariable (see page 5412)

GetVariableCount (see page 5413)

FindVariableContainer (see page 5410)

54.1.34.2.5 TAdapterSubComponent.FindVariableContainer Method

Returns the Web module that contains a specified item from this list.

Pascal

```
function FindVariableContainer(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindVariableContainer(const UnicodeString AName);
```

Description

FindVariableContainer searches the list of child items that have variable names (the VariablesInUse (see page 5419) property) to find one with the specified name. It then returns the Web module that contains the component it located.

AName is the name of the action or field to locate.

FindVariableContainer returns the Web module that containse the specified item. If there is no item in the list with the name AName, FindVariableContainer returns nil (Delphi) or NULL (C++). If FindVariableContainer includes an item with the specified name, but is unable to determine what Web module contains that item, FindVariableContainer raises an EAdapterException (see page 5177) exception.

See Also

VariablesInUse (see page 5419)

FindNamedVariable (see page 5409)

GetVariable (see page 5412)

GetVariableCount (see page 5413)

EAdapterException (see page 5177)

54.1.34.2.6 TAdapterSubComponent.GetCurrentObject Method

Returns the current field or action from the list when an enumerator is iterating over child items.

Pascal

```
function GetCurrentObject(OwnerData: Pointer): TObject;
```

C++

```
__fastcall TObject * GetCurrentObject(void * OwnerData);
```

Description

GetCurrentObject is part of the support that allows server-side script to use an enumerator to iterate over all the child items in the collection. This method returns the current child item.

OwnerData is a pointer to object-specific information returned by the last call to the StartIterator (see page 5418) or NextIteration (see page 5415) method. TAdapterSubComponent (see page 5406) does not use the OwnerData parameter.

See Also

StartIterator (see page 5418)

NextIteration (see page 5415)

EndIterator (see page 5409)

54.1.34.2.7 TAdapterSubComponent.GetDefaultWebComponents Method

Returns a list of actions or fields that are used by default if an application does not explicitly assign child items to this object.

Pascal

```
function GetDefaultWebComponents: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetDefaultWebComponents();
```

Description

GetDefaultWebComponents supplies the default set of child items for this component. As implemented in TAdapterSubComponent (see page 5406), GetDefaultWebComponents always returns nil (Delphi) or NULL (C++) because this class represents only a single list of items. Descendants that represent the default fields or actions of the associated adapter (TAdapterDefaultActions (see page 5231) and TAdapterDefaultFields (see page 5237)) override this method to return the list of default fields or actions.

See Also

GetWebComponents (see page 6065)

TAdapterDefaultActions (see page 5231)

TAdapterDefaultFields (see page 5237)

54.1.34.2.8 TAdapterSubComponent.GetParentComponent Method

Returns the associated adapter.

Pascal

```
function GetParentComponent: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetParentComponent();
```

Description

TAdapterSubComponent (see page 5406) overrides the GetParentComponent method that is introduced in TComponent for the streaming system that loads and saves components. It returns the value of the Adapter (see page 5418) property (the adapter that uses this component to represent the set of its fields or actions).
